DIOSCORIDÉA'CEÆ, a natural order of plants, of which the genus *Dioscorea* (see YAM) is the type. They are twining shrubs, with large tubers, either above or below ground. They are generally classed with endogenous plants; they are among the *Dictyogens* of Lindley. There are about 120 known species. The most important plants of the order are the different species of *Dioscorea* or YAM (q. v.). Black BRYONY (q. v.) is its only representative in the British flora. *Testudinaria elephantipes*, a South African species, sometimes called *Elephants' Foot*, and *Hottentots' Bread*, has a large fleshy rhizome, with a rough cracked bark, which is used as food by the Hottentots in times of scarcity.

DIOSCORIDÉS, PEDANIUS, or PEDACIUS, a Greek physician, was a native of Anazarba, or Anazarbus, in Cilicia, and flourished in the 1st or 2d c. of our era. He accompanied the Roman armies as physician through many countries, and collected a great store of information and personal observation on plants. In his great work, *De Materia Medica*, he treats of all the then known medicinal substances and their properties, real or reputed, on the principles of the so-called 'humoral pathology.' Two other works bear the name of D., but their genuineness is very

questionable. During 15 centuries, D. maintained undisputed authority in botany and in materia medica, an authority which he still holds among the Turks and Moors. The best editions of D. are by Saraceus (Frankf. 1598), and Sprengel (2 vols., Leip. 1829). The *De Materia Medica* has been translated into the Italian, German, French, and Spanish languages. There is also an Arabic translation in MS. in various libraries of Europe.

DIO'SMA. See BUCKU.

DIO'SPYROS. See DATE PLUM and EBONY.

DIP, in Geology, is the inclination of strata downwards into the earth. The amount or angle of dip is the degree of deviation from a level line, or the plane of the horizon. The point of dip is the point of the compass to which the dip is inclined.

DIPHThERIA, or DIPHThERITIS (Fr. *diphtherite*, from Gr. *diphthera*, a pellicle), a name first applied by M. Bretonneau of Tours, a distinguished French physician, to a form of very fatal sore throat occurring epidemically, chiefly in children, and apt to be confounded both with Croup (q. v.) and with malignant sore throat (*Angina maligna*), as it is found in connection with Scarlet Fever (q. v.). Diphtheria is distinct from both these diseases, not only in its symptoms, but in the character and position of the morbid changes on the mucous membrane. In croup, there is a pellicular membrane, indeed, but it is almost confined to the air-passages, and centres in the Larynx (q. v.); in diphtheria, it usually begins in the pharynx or back of the throat, and often extends down the œsophagus, or gullet. Croup is also a much more decidedly inflammatory disease than diphtheria. Malignant or ulcerative sore throat has even less in common with diphtheria; for in the latter there is no ulceration in the majority of cases, the mucous membrane being merely covered over with a more or less thick veil of false membrane; in both affections, however, there is enlargement of the glands behind the ear and in the neck, generally in the neighbourhood of the parts internally affected. The throat affection in diphtheria is often accompanied by a very low and dangerous form of fever, with great and rapid loss of the patient's strength, which is still further reduced of course by the inability to take food; in other cases, the disease is fatal by suffocation, and tracheotomy has been performed (in some few instances successfully) to relieve the patient from impending death. After the acute disease is over, the recovery may be delayed by paralytic symptoms of various kinds; or simply by extreme debility, with exhaustion and loss of appetite. Diphtheria was supposed by Bretonneau to be contagious, but it is doubted by many whether the evidence of contagion is sufficient. There is no good evidence of any specific cure. The use of the tincture of muriate of iron in large doses (fifteen to twenty drops frequently repeated) has been recommended; also various disinfectants and caustics applied to the throat, as nitrate of silver, hydrochloric acid mixed with honey, and latterly Condy's disinfecting fluid; but all of these have also frequently failed in the hands of experienced physicians. Diphtheria does not appear to be so much under the influence of known sanitary conditions as other epidemics; at least its mode of origin and diffusion are still extremely uncertain.

DIPHTHONG (Gr. having a double sound) means two vowel sounds following one another so closely as to form but one syllable, as in *out*. In this combination the sound is really composed of an *a* as heard in *father*, and a *u* as heard in *put*. Many double vowels in English are not real diphthongs, there being only one sound heard. The

spelling of the English language has little or no relation to the pronunciation in this matter. In many syllables written with two vowels, only one sound is heard, as in *bread*. The single vowel letters, again, often have a diphthongal sound; thus the long sound, as it is called, of *i* is really composed of the sound of *a*, as heard in *father*, and that of *e*, in *me*; and *une* is pronounced as if written *teun* or rather *tyun*. Such words as *bread*, *field*, which are now monophthongs, were doubtless at one time real diphthongs, and are still so pronounced in many parts of England.

DIPLACA'NTHUS, a genus of fossil ganoid fishes, peculiar to the old red sandstone, in which six species have been found. The body was covered with very small scales, and the tail was heterocercal. There were two dorsal fins, which with each of the other fins were furnished with a strong spine in front, the base of which was simply imbedded in the flesh, as in the dog-fish, and not articulated, as in the siluroids. The head was large, and the mouth wide, and opening obliquely.

DIPLOGRAP'SUS, a genus of fossil zoophytes, differing from the Graptolite (q. v.) in having a double series of cells. They are found in great abundance in the anthracitic shales of the Silurian measures.

DIPLO'MA (Gr. *diploō*, I double, or fold). This term originated in the ancient custom of writing solemn documents on two tablets of wax, which were doubled, or laid one upon the other (see DIPRYCH), or on writing material which was folded. The Roman emperors were in the habit of giving diplomas to public servants, and to couriers, to enable them to procure the use of the public servants and horses; hence diploma came to signify a royal charter or prince's letters-patent. The term is now mostly applied to instruments given by universities and other learned societies, in proof of the holder having attained a certain degree; or to the licences held by professional persons to practise their art.

DIPLOMACY, the art of managing the intercourse and adjusting the relations of foreign states, by means of ambassadors, envoys extraordinary, consuls, &c. The principles and rules of diplomacy are embodied partly in those international customs and usages which constitute what may be called common, and in those treaties which may be regarded as statute international law. The diplomatic relations of this country are practically under the superintendence of the Secretary of State for Foreign Affairs, but the power of sending ambassadors to, and receiving ambassadors from, foreign states, is an inalienable privilege of the crown. It was doubted whether an exception had not been made in the case of Rome, by the statutes passed against papal encroachments; and it was thought expedient to remove such doubt by 11 and 12 Viet. c. 108, which authorises her Majesty to enter into diplomatic relations, provided that no person in holy orders in the Church of Rome, or Jesuit, or member of any other religious order, community, or society of that church, bound by monastic or religious vows, shall be received as ambassador at the court of London. Ambassadors are not subject to the municipal laws of the states in which they reside, the theory being that they represent the persons of their respective masters, who cannot be subject to any other laws than those of their own country. If an ambassador offends against the municipal law, or abuses his character, he may be sent home, and accused before his master. Though there was much doubt on the point, this rule seems to extend to crimes against

natural law, e. g., to murder, or *mala in se*, as well as to crimes artificially created by the policy of the particular state, *mala prohibita*; and it is now said that the case of Don Pantaleon Sa, the brother and secretary of the Portuguese ambassador, who was executed for an atrocious murder during the protectorate of Cromwell in 1654, was no exception, as he was not 'joined with his brother in the same commission.' See AMBASSADOR, EMBASSY. The arrangement of international ceremonies belongs to the subject of diplomaey. To treat it in detail would lead us far beyond our limits, and we must content ourselves with remarking a few of the customary and conventional modifications which affect the general principle of international law by which all independent states are held to be equal.

*Royal honours* are enjoyed by the empires and kingdoms of Europe, including the Swiss Confederation, the grand duchies of Germany, and, amongst Catholic states, by the pope; and the same right extends to the United States of America. These, along with other rights of greater importance, include the right of taking precedence of the others in all international ceremonials. Amongst those who enjoy royal honours, the order of precedence, after much discussion, was left by the Congress of Vienna on the ancient footing of custom merely. The rule thus fixed is said to be the following: Monarchs enjoying royal honours, but not crowned heads, yield precedence to those who are, whilst they enjoy it over all other monarchs, demi-sovereigns, and rulers of dependent states. This rule leaves the relative rank of the crowned heads and other classes amongst themselves undetermined, and a curious expedient has been found for obviating the necessity of a minuter classification. By what is called the *alternat*, the rank and places of the various powers are changed from time to time in a certain order determined by lot. If there are several parties to a treaty, for example, a corresponding number of copies is made of it, the name of each state being named first in the copy which it preserves, and the others in the order determined by the *alternat*. But the right to alternation has sometimes been a subject of contention. In 1742, it was refused to Prussia by Great Britain; and Hungary and Sardinia had great difficulty in obtaining it at the peace of Aix-la-Chapelle.

The subject of maritime ceremonies will be treated under its respective heads. They consist of salutes either with cannon, or with the flag or pendant, by furling it, lowering it, or pulling it down. There is also a salute with sails, which generally consists in lowering the foretopsail. Maritime ceremonies are usually made the subject of express compact, but, as a general rule, on the open seas, a ship carrying a pendant salutes a ship of a friendly power carrying an admiral, and detached ships generally salute fleets. It is provided by 22 and 23 Vict. c. 5, repealing in so far 6 Anne, c. 7, that pensions granted for diplomatic services, according to the provisions of 2 and 3 Will. IV. c. 116, shall not disqualify the holder from being elected, or sitting, or voting as a member of the House of Commons.

**DIPLOMATICS**, the science of ancient writings. The term can scarcely be said to have been at any time in general use in this country, and even on the continent it has latterly given way to the more convenient and descriptive term, **PALEOGRAPHY** (q. v.).

**DIPLOPTERUS**, a genus of fossil ganoid fishes, four species of which have been discovered in the old red sandstone, and two in the carboniferous series. They have heterocercal tails, with double

anal and dorsal fins, opposite each other, but having the dorsal pair a little apart. The head is large and flattened, and the teeth are fewer and larger than in the allied genera. The scales are perforated with small foramina.

**DIPPEL'S ANIMAL OIL**, called also Empyrenumatic Animal Oil, or Rectified Oil of Hartshorn, is prepared by the destructive distillation of bones in close vessels, when **BONE-BLACK** (q. v.) is left in the retort or vessel, and the crude oil distils over into a suitable receiver. When obtained in this manner, it is a thick viscid oil of a brown colour, and a very disagreeable odour, but on redistillation it may be obtained limpid and colourless. Air and light affect the pure or rectified oil, and render it coloured and somewhat viscid. Its elementary constituents are carbon, hydrogen, nitrogen, and oxygen, and it contains a number of volatile organic bases, such as aniline, picoline, &c. Dippe's animal oil is a powerful medicinal agent, and when swallowed in doses of a few drops, it is antispasmodic, and stimulates the vascular and nervous systems. In large doses, it is a powerful irritant poison.

**DIPPER** (*Cinclus*), a genus of birds of the Thrush family (*Merulidae*), distinguished from the other birds of that family by an almost straight, compressed, sharp-pointed bill, and still more by their manners and habits. They frequent clear pebbly streams and lakes, feeding chiefly on molluscs and on aquatic insects and their larvæ, which they seek even under water, diving with great facility, and moving about for a short time at the bottom of the water. They carry their rather short tail elevated after the manner of wrens, which they also resemble in their 'frequent becks' or dipping of the head, accompanied with an upward jerking of the tail. One species is found

Water Ousel (*Cinclus aquaticus*).

in Britain, the **COMMON D.**, or **WATER OUSEL** (*C. aquaticus*), a bird rather smaller than any of the British thrushes, of a generally dark-brown colour, with throat and upper part of the breast pure white. It is found throughout the whole of Europe and the north of Asia, but chiefly in hilly or mountainous districts. It is not gregarious. The D. never fails to attract notice, as it sits upon some stone in the midst of or beside the stream, its white breast rendering it conspicuous as it repeats the movement from which it derives its name. It builds a very curious nest of interwoven moss, domed and with the entrance in the side, usually in some mossy bank close by a stream, and often near or under a cascade. The assertion which has been made, that the D. walks without apparent muscular effort at the bottom of the water, is

incorrect; its feet are not well formed for walking, and it moves under water by means of its wings—which are short—not without much muscular effort. The statement also often made, that it eats the spawn of salmon and other fishes, in the belief of which it is much persecuted in Scotland, although not improbable, is not sufficiently authenticated. Other species of *D.* are found in Asia and North America.

**DIPPING-NEEDLE.** If a magnetic needle be supported so as to be free to move vertically, it does not at most places on the earth's surface rest in a horizontal position, but inclines more or less from it. If the vertical plane in which the needle moves is the magnetic meridian of the place, the angle between the needle and the horizontal line is called the dip or inclination of the needle. Thus, if the needle, NS,

be supported at its centre, C, so as to be free to move vertically, the plane of the paper being supposed to be that of the magnetic meridian, the angle NCa is the dip. The dip of the magnetic needle at any place can be ascertained with very great exactness by means of the dipping-needle, fig. 2. It consists of a graduated circle, AA, fixed vertically in the frame FF, and moving with it and the vernier V, on the horizontal

Fig. 1.

force of the earth's magnetism exerted upon the poles of the needle in any vertical plane in which it may happen to be, as resolved into two forces, one acting at right angles to the plane, and the other acting in the plane. There being a corresponding but opposite force at each pole, we have thus two statical couples acting on the needle—one tending to turn it at right angles to the plane in which it moves, and the other tending to bring it round to a position in the plane such that the needle and the forces of the couple may be in a line. In the dipping-needle, the mode of support completely neutralises the first of the couples; and the position that the needle takes in any plane is due wholly to the second. When the plane of the needle is at right angles to the magnetic meridian, the forces of this latter couple act vertically, and bring the needle to the same position. This, then, gives us the means of determining the magnetic meridian, for we have only to bring the vertical circle round till the needle stands at 90° to put it in a plane at right angles to that meridian; and then by moving the vernier on the horizontal circle over 90°, we place the upper circle and needle in the plane of the magnetic meridian. The dipping-needle thus serves the purpose of a Declination Needle (q. v.). In bringing the needle round from the plane at right angles to the magnetic meridian, the dip is less and less, till it becomes least in the plane of that meridian. We might thus also find the magnetic meridian, for it is that plane in which the dip of the needle is least. When the needle is in the plane of the magnetic meridian, the couple which acts in other vertical planes at right angles to them disappears, and the whole force of the terrestrial magnetism acts at each pole of the needle, forming a couple which swings the needle round till it stands in a line with itself. The degree on the circle then pointed to by the needle is the dip at the place of observation. Two readings are necessary, for the reason stated in the DECLINATION NEEDLE. One reading is taken, the needle is then reversed so as to change its supports, and then a second reading is noted, and the mean of the two gives the correct reading. The position of the needle when the dip is read off is manifestly the same that a needle suspended in air, if that were possible, and free to move in any way, would finally assume. In resolving, therefore, the total directive force of the earth as we have done above, we must keep in mind that it always acts parallel to the direction of the dipping-needle.

**DIPSACEÆ AND DIPSACUS.** See TEASEL.

**DIPSAS** (Gr. a kind of serpent), a genus of non-venomous serpents of the family *Colebridae*, of very elongated form, and with a thick, broad, and obtuse head. They are tree-snakes, inhabitants chiefly of the warm parts of Asia and America. One species only, *D. fallax*, somewhat doubtfully referred to this genus, occurs in the south of Europe. Some of the species are of great size. The figure represents a large and beautiful species found in Java and Sumatra. The form is more attenuated than in others of the genus.

Fig. 2.

graduated circle HH. This last is supported by a tripod furnished with levelling screws. At the centre of the circle, C, there are two knife-edges of agate, supported by the frame, and parallel to the plane of the circle. The needle, NS, rests on these knife-edges by means of two fine polished cylinders of steel, which are placed accurately at the centre of the needle, and project at right angles from it: so adjusted, the needle moves with little or no friction. It is so made, moreover, that before being magnetised it remains indifferently in any position; after magnetisation, therefore, the dip which it shews is wholly due to the magnetic influence of the earth.

In order to understand how an observation is made with the dipping-needle, we must regard the directing

*Dipsas cyanodon.*

**DIPSOMA'NIA**, or **OINOMA'NIA**, from the Greek words *dipsa*, thirst, or *oinos*, wine, and *mania*—terms of modern invention, to denote an irresistible or insane craving for alcoholic stimulants, when occurring in a habitual or confirmed form, and requiring confinement or restraint of the person for its cure. Much discussion has taken place in regard to this and other forms of what is often called Moral Insanity; the most recent views of physicians, however, tend to shew that the drinking insanity, or *furor bibendi*, as it was called by an early writer on the subject, is often associated with other forms of mental derangement, and is very apt to be, in connection with one or more of these forms, hereditarily transmitted, even through several generations; so that the really physical or insane character of the craving for stimulants, at least in some cases, may be regarded as a well-established fact in medicine. The legal and general questions in connection with this subject will be discussed under the heads of **INSANITY** and **INTEMPERANCE**.

**DIPTERA** (Gr. two-winged), an order of insects, which received from Aristotle the name it still bears. Its distinguishing characters are so obvious that it has been acknowledged, with little change of its limits, by almost all naturalists. **FLY** is a popular name very generally applied to dipterous insects, and often with some distinguishing prefix (as House-fly, Flesh-fly, Blow-fly, Bot-fly, Crane-fly, &c.), although it is sometimes used with such prefix to designate insects not belonging to this order (Dragon-fly, Day-fly, May-fly, &c.). Midges, gnats, and mosquitoes are also dipterous insects. In the number of species which it contains, this is one of the most extensive orders of insects: some of the species are also remarkable for the immense multitudes in which they appear; and although most of them are of small size, and few attract us by brilliant hues, not a few are important on account of the annoyance or mischief which they cause, either in their perfect or in their larva state; whilst many of their larvæ (maggots) are also very useful in consuming putrescent animal matter, which might otherwise prove a source of pestilence.

The *D.* have only two wings, which are membranous and simply veined. A little behind the wings are two small slender organs called *Halteres*, poisers, or balancers, the use of which is not well known. They are usually present even in those exceptional insects of this order in which the wings are not developed. The head of the *D.* is generally in great part occupied by the large compound eyes, which often contain thousands of facettes; and besides these, three simple or stemmatic eyes (ocelli) are often also present, placed upon the crown of the head. The mouth is formed exclusively for suction, and is usually furnished with a short membranous suctorial proboscis, composed of parts which represent, although so differently modified, the portions of the mouth in coleopterous and other masticating insects, some of the parts, however, often disappearing. The proboscis of many is capable of piercing the skins of animals on the juices of which they feed; others are quite destitute of this power of piercing. Many feed chiefly on saccharine and other vegetable juices. In some genera, the perfect insect seems destitute of a mouth; and the term of life, after the perfect state has been attained, very brief in some, appears to be brief in all. The power which many dipterous insects possess of walking even on very smooth surfaces, in any position, even with the back downwards, familiar to every one in the example of the common house-fly, has not yet received a sufficient explanation. The opinion that their feet are furnished with discs for the formation of a vacuum, has been

called in question, but nothing satisfactory has been substituted for it. The terminal rings of the abdomen in the females of many species, form an ovipositor capable of piercing the substances in which the eggs are to be laid, and composed of pieces which may be exerted or retracted into one another like those of a telescope. The eggs are very generally deposited in putrescent animal substances, but those of some kinds in the bodies of living animals, some in vegetable substances; the larvæ of some live in water; the eggs of a few are hatched within their own bodies, and the larvæ of some even remain there till they pass into the pupa state. All the *D.* undergo a complete metamorphosis. Their larvæ are destitute of true feet, although some of them have organs which serve for the same purpose; some have a distinct head; but others have the head soft and changeable in form, capable of being retracted into the body, and distinguishable only by its position, and by the organs of the mouth. Those which dwell in water or in fluid putrescent matters, have a retractile tail-like prolongation of the body, terminated by a radiated expansion, which communicates with air-tubes, and constitutes part of a very remarkable respiratory system. The larvæ of some *D.* spin cocoons when about to pass into the pupa state; but in others, the skin of the larva hardens and encases the pupa; the perfect insect finally making its escape by forcing off with its head the end of its pupa case.

**DIPTERA'CEÆ**, or **DIPTEROCARPA'CEÆ**, a natural order of exogenous plants, consisting of beautiful and majestic trees, natives of the East Indies. Some trees of this order, of which about fifty species are known, are highly valuable as timber-trees. Among them is the **SAL** (*q. v.*), the most esteemed timber-tree of India. They abound also in balsamic resin, and their resinous products are used for a variety of purposes. See **ANIME**, **CAMPION**, **COPAL**, **DAMMER**, **PINY VARNISH**, and **SAL**.—*Dipterocarpus*, the genus from which the above order has received its name, contains several species of the noblest trees of India. They abound in the warm parts of the east coast of the Bay of Bengal and the Eastern Peninsula. The wood is used for house-building, ship-building, &c. *D. turbinatus*, the **GURJUN** or **GOORJUN TREE**, the species by which the genus first became known, often attains a height of upwards of 200 feet, and a girth of 15 feet. It has a pale-gray trunk, rising without a branch till it forms at its summit a small symmetrical crown. The leaves are broad, glossy, and beautiful; the flowers in white racemes, but not conspicuous. The wood is hard, close-grained, and durable. A fragrant oil exudes from the trunk, which is extremely valuable for pitch and varnish, and is also used medicinally. It is procured by cutting transverse holes in the trunk, pointing downwards, and lighting fires in them, which causes the oil to flow. The tree is sometimes called the **WOOD-OIL TREE**. This oil or balsam is also procured from other species of *Dipterocarpus*. *D. trinervis* yields a resin which is valuable for plasters, and acts on the mucous membranes like Balsam of Copaiva. The Javanese smear banana leaves with this resin, which then burn as torches, with a pleasant odour and white light.

**DIPTERUS**, a genus of fossil ganoid fishes, peculiar to the old red sandstone, in which two species have been found. They derive their name from their most striking characteristic—the double anal and dorsal fins, which are opposite to each other. The head is large and flattened, the teeth subequal, the scales perforated by small foramina, and the tail heterocercal.

**DIPTYCH** (Gr. *diptucha*), a double writing-tablet, or two writing-tablets, which could be folded together. Herodotus speaks of such a tablet, made of wood and covered with wax. It was in the later Roman time, however, that they were most used, and those which have been preserved belong chiefly to the period when classical was merging into mediæval life. The beautiful carving with which they are often covered on the outside, consequently represents not unfrequently a combination of classical and of Christian subjects. Ivory and metal were sometimes employed in place of wood; but the construction was always the same, the wax with the writing being in the inside. Under the emperors, diptychs were distinguished into consular and ecclesiastical. The former, which were presented by the consuls and other magistrates to their friends, and those officially connected with them, on their entrance on office, were inscribed with their names, and bore their portraits. The ecclesiastical diptychs, on the other hand, are decorated with scenes from sacred history, and were preserved in the churches as part of the sacred ornaments. Those that exist are of various sizes, rarely exceeding eight inches by four.

**DIPUS.** See **JERBOA**.

**DIRECT.** See **COLLATERAL**.

**DIRECT AND RETROGRADE.** In Astronomy, the motion of a planet is said to be direct when the planet goes forward by its proper motion in the zodiac according to the succession or order of the signs (i. e., from west to east), or when it appears to do so to an observer. On the other hand, it is said to be retrograde when it appears to go the contrary way.

**DIRECTOR**, one of a number of persons appointed to conduct the affairs of joint-stock undertakings, such as banks, railways, water and gas companies, fire and life assurance companies, and various kinds of manufacturing and trading concerns. The office of a director is in all cases one of less or more responsibility, sometimes of considerable risk, and according to commercial maxim, ought not to be accepted lightly or for the mere honour which is supposed to be incidental to the position. On this point, unfortunately, there is not a little loose morality and want of due consideration. Men are seen to enter on the office with scarcely a thought of attending to their duty, or of the injury they may inflict by allowing their names to be attached to undertakings in the management of which they cannot be said to take any particular interest. Latterly, so many instances have occurred of the perfunctory performance of the duties of directors, greatly to the damage of those who confided in them, that, perhaps, new and more wholesome views may arise on the subject. As a member of a body incorporated by the legislature, a railway director is bound to administer the affairs of the company only with the means legitimately put at his disposal, nor can he be expected to incur any personal liability to sustain the general operations. Usually, however, when there is any temporary or peculiar shortcoming in the finances, the directors overdraw to a certain extent the company's bank account on their personal responsibility; in all such cases, and where the outlay has been justifiable, the shareholders rarely decline to authorize measures which will relieve the directors of their obligations. In the case of banks, there are usually two kinds of directors—the ordinary and the extraordinary. The ordinary directors are practically the conductors of the undertaking, while the extraordinary attend only on particular occasions, and are, in fact, little else than ornamental appendages, whose names impart a

degree of distinction to the concern. As regards bank as well as railway directors, it is the rule that they must respectively possess a certain amount of stock. It is an understanding that the directors of railways, banks, and assurance companies, should be paid in some way for their services. Being mostly men in business, they cannot be expected to give away their time and take trouble for nothing. Their payment, however, in the shape of an *honorarium*, is generally trifling in comparison to the amount of labour which is to be encountered. At meetings of shareholders, small sums are voted to be set aside for the directors, which sums are for the most part appropriated in the ratio of attendance. The fee of a bank director is not unusually half a guinea at each meeting; though it is as customary for those present to divide amongst them the sum set apart for the occasion, wherefore the regular attenders get most. The insignificance of these fees, even where no stinginess prevails, is employed as an argument why anything like a scrupulous examination into affairs is not reasonably to be expected—an argument seemingly of no great moral or legal force; for it is clear there can be no valid excuse for neglecting a trust which has been voluntarily accepted.

The difficult questions as to the cases in which directors incur liability for the losses sustained by the shareholders whose affairs they have undertaken to manage, which are now (1861) occupying so much of the attention of the courts and the public, will be discussed under the head of **LIABILITY**. Of the statutory provisions as to directors contained in the Joint-stock Companies Acts (the principal act is 19 and 20 Vict. c. 47), the chief are these—1. That the first directors shall be selected, and their number determined, by the subscribers of the original memorandum of association, who shall themselves be deemed directors until other directors are appointed. 2. That his office of director shall be vacated by the acceptance of any other office or place of profit under the company, by bankruptcy or insolvency, or by being concerned in any contract with the company. 3. At the first ordinary meeting after the incorporation of the company, the whole of the directors shall retire from office; and at the first ordinary meeting in every subsequent year, one-third of the directors for the time being, or if their number is not a multiple of three, then the number nearest to one-third, shall retire from office. In every subsequent year, one-third, or other nearest number, who have been longest in office, shall retire. A retiring director shall be re-eligible. 4. The company in a general meeting may increase or diminish the number of directors. 5. Any casual vacancy occurring in the board of directors may be filled up by the directors; but any person so chosen shall retain his office so long only as the vacating director would have retained the same if no vacancy had occurred. The company, in general meeting, may remove any director, and appoint another in his stead. 6. The directors may meet together for the dispatch of business, adjourn, and otherwise regulate their meetings as they think fit, and determine the quorum necessary for the transaction of business. 7. Questions arising are determined by a majority of votes, the chairman having a casting vote in case of equality. 8. A director may at any time summon a meeting of directors. 9. The directors elect their own chairman, and determine the period of his office. In case no chairman has been appointed, or he is absent, the directors shall appoint one of their number to preside for that time only. 10. Directors may delegate their powers to committees of such number as they may judge expedient. 11. The directors must cause minutes to be made in books

provided for the purpose. These minutes shall set forth all appointments of officers made by the directors, the names of the directors present at each meeting of directors or of committee, all orders made by meetings or committees, and all resolutions and other proceedings of these bodies. These minutes shall be signed by the chairman, and shall be receivable in evidence of what took place without any further proof. 12. The directors, with the sanction of the company in a general meeting, may declare that a dividend shall be paid to the shareholders in proportion to their shares. No dividend shall be payable except out of the profits arising from the business of the company. 13. If the directors shall declare any dividend when the company is known by them to be insolvent, or any dividend the payment of which would, to their knowledge, render it insolvent, they shall be jointly and severally liable for the debts of the company then existing, and for all that shall be thereafter contracted, so long as they shall respectively remain in office. It is provided that the amount for which they shall be so liable shall not exceed the amount of the dividend declared, and that if any of the directors were absent at the time of making the dividend, or protested in writing, they shall be exempted from liability. Before recommending a dividend, the directors may set aside a reserved fund out of the profits of the company. In companies incorporated for carrying on undertakings of a public nature, such as railways, the appointment, rotation, and powers of directors, are regulated by the statute commonly called 'The Companies Clauses Act,' 8 Vict. c. 16 (for Scotland, c. 17). Two directors are sufficient to sign a contract. The directors have the management and superintendence of the affairs of the company, and may lawfully exercise all the powers of the company, except such matters as are specially directed to be transacted by a general meeting of the company. See LIABILITY (LIMITED) ACTS, JOINT-STOCK COMPANIES.

**DIRECTORY.** On the death of Robespierre, in 1794, a reaction commenced in the Convention itself, as well as throughout all France, against the sanguinary excesses of the Terrorists. Ultimately a new constitution—that of the year 3 (1795)—gave birth to a new government, composed of a legislative body divided into two councils—the Council of Five Hundred, whose function was to propose laws; and the Council of the Ancients, whose function was to pass them. The actual executive power was intrusted to five members chosen from both sections, and who sat at the Luxembourg. Their names were L<sup>é</sup>peaux, Letourneur, Rewbel, Barras, and Carnot. These five constituted the famous *Directory*. They assumed authority in a moment of immense peril. France was environed with gigantic adversaries, while distrust, discontent, and the malice of rival factions made her internal administration almost hopeless. The frantic heroism of her soldiers saved her from spoliation by the foreigner; and had all the members of the Directory been patriotic and honest, she might have been saved also from spoliation by her own children. But, on the contrary, the home-policy of the Directory was deplorable. The demoralisation which had begun to characterise officials even in Danton's time, now seized almost every class. Barras, a representative of all the turpitude of the hour, set the example. The majority of the two Councils were equally corrupt; and although there were some both in the Councils and Directory whose virtues and talents were unimpeachable, yet they were too weak to counteract the knavery of their associates. It soon became clear that France

could not be reconstituted by the fag-ends of the Revolution. The power and skill requisite for such a herculean work must be sought for elsewhere, among men who had received a nobler discipline than could be obtained in the political squabbles of the metropolis. Such was the thought of the Abbé Sièyes. He turned his eyes to the army, where a host of new and brilliant names had appeared—Hoche, Joubert, Brune, Kleber, Desaix, Massena, Moreau, Bernadotte, Augereau, Bonaparte. Sièyes propounded his plan for the overthrow of the Directory, and the establishment of a consulate, that should be, in reality, a monarchy under republican forms, first of all to Moreau, who was frightened by its audacity; then to Bernadotte, whose excessive caution hindered him from approving of it; then to Augereau, who could not understand it; and finally to Bonaparte, on his return from Egypt. The last admired the project; a conspiracy was rapidly formed; all those functionaries who had been promised places by the Directory, but had not received them, offered their aid; and by the *coup d'état* of the 18th Brumaire (q. v.), an end was put to a government of weakness, immorality, and intrigue. It was succeeded by the Consulate (q. v.).

**DIRECTORY FOR THE PUBLIC WORSHIP OF GOD,** a code of regulations concerning the different parts of public worship, drawn up by the Westminster Assembly in 1644, ratified by the English parliament in the same year, and adopted by the General Assembly of the Church of Scotland and by the Scottish parliament in 1645. It was on express order from both Houses of the English parliament, that the Westminster Assembly addressed itself to the work of preparing this Directory, to supply the place of the Book of Common Prayer, which had been abolished. In Scotland, it was hailed as conducive to 'a happy unity and uniformity in religion among the kirks of Christ in these three kingdoms, united under one sovereign,' and to 'the corroboration of peace and love between the kingdoms.' Many of the regulations of the Directory are still complied with in all branches of the Presbyterian Church in Scotland, but in many things it has been generally departed from; and a disposition prevails in almost all quarters to allow greater freedom and variety in the forms and unessential circumstances of worship; whilst many esteem a departure from the requirement of unnecessary *uniformity* in these things, as tending not a little towards the healing as well as the prevention of divisions, and the establishment of a real *unity*, and even as more consistent with the first principles of Presbyterianism.

**DIRECTRIX** is a right line perpendicular to the axis of a conic section, in reference to which its nature may be defined. Assuming the indefinite line AB in the figure as the directrix, and F a point without it as a focus, then, if the line FD revolve about F as a centre, while a point D moves in it in such a manner that its distance from F shall always be to CD, its perpendicular distance from the line AB, in a constant ratio, then the curve VD, described by the point D, is a conic section, and is an ellipse, a parabola, or an hyperbola, according as FD is less than, equal to, or greater than CD, or FV than VA. The constant ratio referred to is called the determining ratio of the conic.

**DIRK** is a short dagger which at various times and in various countries has been much used as a

weapon of offence. In the royal navy, at the present day, it is worn by officers rather for ornament than for use, belted and buckled to the left side.

**DIRK-HARTOG ISLAND**, measuring 45 miles by 10, lies off the west coast of Australia, in lat. 26° S., and long. 113° E. Along with two smaller islands to the north, all the three having their lengths parallel with the mainland, it forms the breast-work of Shark's Bay, one of the most commodious inlets on that coast.

**DIRT-BEDS**, the quarrymen's name, introduced into geology, of several layers which occur in the Lower Purbeck Beds (q. v.), having the appearance of black dirt. They rest on the fresh-water beds of the Lower Purbeck, and consist of one principal

Dirt-bed (Isle of Portland) :

a, fresh-water calcareous slate; b, dirt-bed with stools of trees; c, lowest fresh-water beds of the lower Purbeck; d, Portland stone, marine.

layer, from 12 to 18 inches thick, and from two to four thinner layers. The substance is, to a large extent, a dark-brown or blackish earthy lignite, being the remains of an ancient vegetable soil. Through it are dispersed, in considerable abundance, rounded fragments of stones from three to nine inches in diameter. Fossil Cycads and Zamias are the predominant vegetable remains; they occupy their original upright position, having become fossil on the spots where they grew. The stumps stand erect for a height of from one to three, or even more feet, and at distances from each other similar to what may be observed in a recent forest. Besides these, the dirt-bed contains the silicified stems of coniferous trees, laid prostrate in fragments three or four feet in length. From the accompanying diagram, it will be seen that the marine oolitic limestone, called Portland stone, was overspread with fluvial mud, which became the soil on which a forest of Cycads and Zamias grew, and that this was afterwards submerged without any violent agitation, since the layer of black earth has not been abraded, and then was covered with standing fresh water, from which the beds of calcareous mud, now converted into slate, were deposited.

**DISABILITY**, LEGAL, is either absolute, which wholly disables the person from doing any legal act—e. g., outlawry, excommunication, attainder, alienage—or partial, such as infancy, coverture, lunacy, drunkenness, and the like. It may arise from the act of God, of the law, of the individual himself, or of his ancestor, or the person from whom he inherits.

**DISBANDING**, in Military Matters, is the breaking up of a regiment or corps. When peace is proclaimed after a war, and a reduction of the army becomes necessary, this is effected by disbanding or disembodiment; the men are discharged, and the officers are mostly placed on half-pay.

**DISBAR**, the degradation from the rank of barrister-at-law. This power is in England reposed in the benchers of the four Inns of Court. As the courts of law require that every barrister, before he is allowed to practise, must have been admitted to that office by one of the Inns of Court, so they will refuse

to hear any one who has been deprived of his rank by the same authority. The power has rarely been exercised, and only when the conduct of the offending party has been grossly irregular. There can be no doubt that the high position held by the bar has been in great measure sustained by the code of honour administered by the Societies of the Inns of Court—a code by which those who are by nature devoid of the feelings of gentlemen are obliged, outwardly at least, to recognise and to observe the demeanour of gentlemen. For some time this wholesome censorship had been exercised with less vigilance than formerly, but a case of disbarring has recently occurred.

In Scotland, the power to disbar rests in the Faculty of Advocates (q. v.).

**DISC**, in Botany, a part intervening in some flowers between the stamens and the pistil. It seems in most cases to represent an inner whorl of stamens variously modified. It is often a mere ring; sometimes it exhibits a whorl of scales or of rudimentary stamens, or even of petal-like appendages; sometimes it rises into a sort of cup around the pistil; sometimes, as in the rose, it assumes the form of a waxy lining of the tube of the calyx. It is often glandular, and secretes a honey-like fluid. It is one of the parts included under the vague comprehensive term *nectary* by the older botanists.

**DISC AND DISCOBOLUS**. See QUOIR.

**DISCHARGE**, from the Military Service, is obtainable occasionally by non-commissioned officers, and rank and file, with the sanction of their commanding officer. Every soldier is engaged for a term of years; and if he quits before the expiration of that time, it cannot legally be without permission asked and obtained. On obtaining his discharge, the soldier pays a sum of money computed with reference to the unexpired period of service. If a soldier has many years still to serve, the discharge-purchase may amount to as much as £20. In the sappers and miners, where the men are all artisans, more or less skilled in mechanical employments, it may even amount to £35; and among this corps, such discharges are very frequent, on account of the value placed on the services of these intelligent men by private employers.

Earl Grey, when Colonial Secretary, introduced the plan of enabling discharged soldiers to settle on a piece of land in the colonies, instead of returning home.

Sometimes this mode of leaving the army is not voluntary. Soldiers are occasionally 'discharged with ignominy' for some offence that brings dishonour on the corps. In such case, the regiment is assembled, the crime recapitulated, and the sentence read. The buttons, facings, chevrons, medals, and all decorations, are cut from the man's uniform, and he is 'drummed out' of the regiment, if a foot-soldier, or by sound of trumpet, if it be a cavalry regiment. Notice of his degradation is afterwards sent in writing from the War-office to his parents or relations.

**DISCHARGING**, in the Royal Navy, is the process of placing a ship 'out of commission.' A regiment of soldiers is permanently in pay, whether engaged in active service or not; but the crew of a ship are paid wages only so long as their names are on the books of a ship 'in commission.' Naval officers, too, are on full pay only so long as they belong to a particular ship in commission.

**DISCIPLINE**, FIRST BOOK OF, or OF POLICY, in Scottish Ecclesiastical History, an important document, drawn up by John Knox and four other ministers, in 1560. Along with the Confession of Faith of the same year, it must be held as exhibiting

the principles on which the Reformed Church of Scotland was originally founded. It lays down rules for the election of 'pastors or ministers' by the congregation, their examination by 'the ministers and elders, &c., also for the election of elders and of deacons; it recognises the office of Superintendent (q. v.) as then established; but it is most largely occupied with things pertaining to ecclesiastical discipline, strictly so called, and the mode of dealing with persons guilty of offences. The First Book of Discipline never received the sanction of an act of parliament, but was subscribed by many of the nobles and barons.

**DISCIPLINE**, SECOND BOOK OF, or 'Heads and Conclusions of the Policy of the Kirk,' a document of great importance in the ecclesiastical history of Scotland, adopted by the General Assembly in 1578; and, although never ratified by act of parliament, still frequently appealed to as the most perfect and authoritative exhibition of Scottish Presbyterianism. The separations which have taken place from the Established Church in Scotland, have not been on the professed ground of dislike to the constitution exhibited in the Second Book of Discipline, but of anxiety for its perfect maintenance; and this document has recently been adopted as one of the articles of union among Scottish Presbyterian churches in Australia. It was prepared with great care by a committee of the General Assembly, in which Andrew Melville took a leading part; and in a time of much conflict between the court and the church, concerning the power of the civil government in things ecclesiastical, church government, and Patronage (q. v.). It begins by asserting strongly the powers regarded as essentially inherent in the church, sets forth the distinctions between civil and ecclesiastical government and their mutual relations, and lays down a thoroughly Presbyterian platform of church-government.

**DISCIPLINE**, in Naval and Military matters, is a general name for the rules laid down for the proper behaviour of the persons employed. The Mutiny Act, the Articles of War, and general orders issued by the Admiralty and the War Office, form collectively the code by which the discipline is regulated. See ARTICLES OF WAR, MUTINY ACT.

In the army, regimental discipline is chiefly maintained by the adjutant. He sees the regimental orders carried out; superintends the drill and field movements; inspects and tells-off all guards, escorts, and parties; regulates all duty rosters, or rollsters; receives garrison orders; keeps regimental books. The adjutant-general is to the whole army what the adjutant is to a regiment, in reference to discipline. In the navy, the discipline is necessarily very strict.

**DISCOBOLI**, according to Cuvier, a family of

Discoboli (*Liparis Montagu*):  
a, sucker, on a larger scale.

malacopterous fishes, remarkable for having the ventral fins united to form a sucking disc on the under

surface of the body. To this family, also called *Cyclopteridae*, belong the Lump-sucker (*Cyclopterus lumpus*), the unctuous sucker or sea-owl or cock-paddle *smail*, and one or two other British fishes. To this family Cuvier also referred the Remora (q. v.), adverting, however, to the different position of the sucking disc, and other important distinctions, on account of which a very different place in the system is now assigned to it. The use of the sucking disc, however, is much the same—that of attaching the animal to fixed substances, so that it may remain and obtain its food, where otherwise it would be swept away by the current. The adhesive power of the sucker, in the larger specimens of the lumpfish, remains after death.

**DISCORD**, sounds which have no harmonical relation whatever; differing from Dissonance (q. v.), which in musical language is applied to sounds that are in grammatically correct relation to each other, though not consonant.

**DISCOUNT**, the difference between a sum of money due at a future period and its present value; or the deduction made from the amount of a debt that is paid before it is due. It is usually ascertained—in the case of bills of exchange, promissory-notes, and the like—by subtracting from the principal amount its interest, calculated from the date of payment until the date when the amount is due; but this, although sanctioned by usage, leads to an excess of charge, the interest being thus advanced to the lender before it has actually accrued. True discount is computed as follows: Suppose that £100 is advanced for one year at, say 5 per cent., the sum repayable at the end of the year in respect of this advance will be £105; therefore, £100 is the present value of £105 due a year hence; and from this conclusion it is easily deduced by proportion, that the value of £100 due a year hence is £95, 4s. 9½d. Hence the true discount on £100 due in a year at 5 per cent., is £4, 15s. 2¾d. The usual formulas are—

for the present value,  $\frac{100 A}{100 + nr}$ ; for the discount,  $\frac{Anr}{100 + nr}$ ; where 'A' is the principal sum due; 'n' the time, in years or fractions of a year; and 'r' the rate per cent., simple interest being assumed. For example, let it be required to find the discount on £97, 7s. 6d., due seven months hence, at 4½ per cent. Here  $A = £97, 7s. 6d. = 97.375$ ,  $n = \frac{7}{12}$ ,  $r = 4\frac{1}{2}$ ;  $nr = \frac{7}{12} \times \frac{9}{2} = \frac{63}{8} = 7\frac{7}{8}$ .  $Anr = 97.375 \times 7\frac{7}{8}$ .

$100 + nr = 100 + 7\frac{7}{8} = 107\frac{7}{8}$ .  
Hence the discount is  $\frac{97.375 \times 7\frac{7}{8}}{107\frac{7}{8}} = \frac{97.375 \times 21}{821}$   
 $= \frac{2044875}{821} = 2491 = £2, 9s. 10d.$

But it is easier first to determine the present value, and hence, by subtraction from the amount due, the discount.

An extension of the above formulas is necessary in computations connected with leases, reversions, &c., to be valued on the stricter principle of compound interest, for which, see INTEREST.

By discount is likewise understood the depreciation in value of a fixed investment; as when a railway share, on which say £100 has been paid, can be sold for £90 only, the 'discount' being thus 10 per cent.

The allowance made to a trader, under the name of discount, for prepayment of a debt, is usually greater than the current rate of interest, as the creditor receiving the money before it becomes due, secures himself against the insolvency of the debtor.

The rates of discount vary according to the demand for money and the nature of the security.

## DISCOVERY—DISHONOUR OF A BILL.

The range in Britain is from 3 to 10 per cent., except in the case of doubtful bills or post-obit bonds, when a much higher rate is exacted. Bills at and under three months' currency are usually charged a per cent. less than those of a long date. In the colonies higher rates are allowed.

**DISCOVERY, BILL OF**, a bill in Chancery (q. v.) which prays the disclosure by the defendant of some matter pertinent to the cause of the plaintiff. By means of bills of discovery, the equity courts formerly possessed an advantage over the courts of common law in extracting evidence from the parties to a suit, who could not be examined as witnesses in an action at law. But by 14 and 15 Vict. c. 99, 16 and 17 Vict. c. 83, and 17 and 18 Vict. c. 125, parties to an action are now competent witnesses, and compellable to give evidence.

**DISCUSSION**, in Scotch Law. By the law of Scotland, all cautioners, unless bound jointly and severally with the principal debtor, were formerly, and cautioners bound prior to the passing of the Mercantile Law Amendment Act (21st July 1856) are still, entitled to insist that the creditor shall call on the principal debtor in the first place; or *discuss* him, as it is technically said. Where the principal debtor fails to satisfy the obligation in full, the creditor was bound to give the cautioner the benefit of such portion of it as he did discharge. Discussion was not merely a demand for payment, but enforcement of it, in so far as the means of the principal debtor admitted of. Cautioners bound subsequently to the date of the Mercantile Law Amendment Act (19 and 20 Vict. c. 60, s. 6), can enjoy the right of discussion only by express stipulation.

**DISEASE**, according to its literal construction, a state of *dis-ease*, or absence of the condition of health, in which all the faculties and organs of the body and mind work together harmoniously and without sensible disturbance. In a strictly scientific sense, there may be disease without pain or uneasiness in the ordinary meaning of these words, but hardly without functional disturbance or incapacity of some kind. It is, therefore, only necessary to include in the definition of disease the diminution of functional power, whether attended or not by suffering, and the scientific and practical ideas of the word will closely correspond. It must be admitted that slight structural and functional deviations from the state of health are sometimes unnoticed; but only because they are slight, and because the functions to which they extend are not habitually in use to the full extent. A great deal of unnecessary obscurity is found, especially in continental writers, in discussing the abstract idea of disease, which has been connected with all the most intangible subtleties of the most abstruse and metaphysical philosophy, by regarding it as dependent upon the idea of life and of the vital force. Many authorities have thus generalised disease into a separate active principle, opposed to, and everywhere seeking to destroy, the principle of health; and Paracelsus was hardly more open to objection on the ground of absurdity than many others of his countrymen, when, in his picturesque and at the same time mystical manner, he endowed the vital principle with a kind of personality, and spoke of disease as due to the whims and caprices of a displeased and resentful Archæus, an idea which was still further developed by Van Helmont. It is common to treat of disease as being *functional* or *organic*, i. e., evidenced by changes of function or of structure; but function and structure are so closely allied in fact and in nature, that the more this distinction is examined, the more vague and impalpable

it becomes, and it can therefore only be kept up as a provisional and conventional arrangement. The classification and arrangement of diseases according to their external characters has been termed Nosology (q. v.); while the observation of their more intimate and less superficial relations in connection with their causes and results, is called Pathology (q. v.); both of these sciences, of course, being kept in view in the healing art or Medicine (q. v.), of the more practical portion of which they form the pillars.

**DISEASES OF PLANTS** form a subject of study interesting equally in its scientific and its economic or practical relations, but in regard to the most important parts of which much obscurity and uncertainty still exist. Enough, indeed, is known to shew that, as might have been expected, an analogy subsists between the kinds of disease to which plants are subject and those of animals, both in their nature and their causes, yet with wide differences, according to the difference between vegetable and animal life. Plants, like animals, are liable to suffer from unsuitable external circumstances, as of temperature, drought, or moisture, &c.: they are liable, like animals, to suffer from deficiency of food, from excess of it, or from being compelled to subsist on improper kinds of it, or too exclusively on some particular kind. They often suffer much from vegetable parasites, chiefly fungi, and from multitudes of minute animals, which, without eating them up, destroy organs essential to their health, or prey upon their juices. The constitutions of plants are accommodated to particular temperatures, and they neither flourish when the temperature is for any considerable time much above or much below certain limits, very different, however, for different species. Light is of the greatest importance to vegetable life, and a want or deficiency of it speedily produces an unhealthy condition, the proper chemical changes not taking place in the juices of the plant; and this unhealthy condition, sometimes very extensively produced in gloomy seasons, when the deficiency of light is accompanied with excess of moisture both in the air and in the soil, renders plants very liable to the attacks both of vegetable parasites and of minute animal tribes.

Excess of nutriment, causing an extreme rapidity of growth, sometimes produces an unhealthy condition in particular parts of plants, in which a greater amount of tissue is developed in a single season than can be thoroughly matured.—Manures, injudiciously and unsuitably applied, are often productive of disease. Putrescent matter coming in contact with the roots of many plants, is very injurious to them, and causes *canker*.—Contagion, as a cause of disease in plants, if not fully demonstrated, is rendered highly probable by such facts as the memorable prevalence of the potato disease, and the rapid spread of the vine disease (*oïdium*); nor does the existence of particular fungi in the diseased plants materially affect this probability.

With regard to the diseases of plants generally, little has been hitherto found practicable in the way of cure, and prevention is the object chiefly aimed at in all investigations of their nature and causes.

Some of the most important diseases of plants are noticed under particular heads; and some of the most destructive parasitic fungi are described in their proper places in this work.

**DISHONOUR OF A BILL**. When the drawee, or person on whom a bill is drawn, declines to accept it or to pay it, he is said to dishonour it. The act of drawing or of indorsing a bill implies an obligation to pay it in the last instance, and the

person in whose favour it is drawn has thus recourse against the drawer and indorsers, should the drawee fail to accept or to pay. In order to preserve this recourse, however, it is indispensable that notice of dishonour shall be given to the drawer and indorsers. No particular form of notice is requisite. The notice must be such as to identify the bill, and to inform the party to whom it is given of the protest, a copy of which ought to accompany it. If the notice is put into the post-office, and properly addressed, it is sufficient; and even verbal notice, if clear, will suffice. In the case of foreign bills, the period within which notice must be given is regulated by the usages and customs of merchants. Any delay which can fairly be ascribed to neglect or omission, and is not justified by the circumstances of the case, will be fatal to the bill-holder's claim for recourse. In inland bills and notes, the rule till lately in Scotland was, that fourteen days after the protest was taken should be allowed. This has been altered by the Mercantile Law Amendment Act (19 and 20 Vict. c. 60), which provides (s. 14) that notice of dishonour of inland bills and promissory-notes, in order to entitle the holder to recourse, shall be given 'in the same manner and within the same time as is required in the case of foreign bills by the law of Scotland.' To both classes of bills, then, the English rule is now applicable, which is, that notice must, in the general case, be sent the next day, where the parties reside in the same place, and by the next post, if they reside at a distance.

**DISINFECTANTS** are a class of substances which have the power of absorbing or destroying the effluvia or fetid odours evolved from putrescent matter, and the miasmatic matter generated in low, marshy, and ill-drained localities. The principal substances capable of being used for this purpose are chlorine, bleaching-powder, animal charcoal, vegetable (wood) charcoal, chloride of zinc, sesquichloride of iron, nitrate of lead, acetate of lead, and nitrous acid. Chlorine (q. v.), either when used by itself, or in combination with lime, as bleaching-powder, is probably the most powerful disinfecting agent. When liberated into an apartment, it immediately causes the destruction of infections or other deleterious matters. The mode of its action appears to be principally due to the great affinity of chlorine for the hydrogen of the gaseous compounds evolved from putrefying matter, and in abstracting the hydrogen, the chlorine destroys the organic substance. A simple way of employing chlorine as a disinfecting agent in sick-rooms, and adjacent lobbies and apartments, is to place a thin layer of bleaching-powder upon a plate, from which the carbonic acid of the air will liberate chlorine rapidly enough to be of essential service in keeping down infection, and without causing any inconvenience to the inmates. If a more plentiful supply of chlorine be desired, a little vinegar added to the bleaching-powder will liberate the gas freely. Charcoal is also of great service in removing fetid effluvia. Clothes possessing a disagreeable odour may be deprived of it by being rolled up or placed in a box with charcoal; and a thin layer of the latter strewn over putrefying matter, such as the decomposing carcass of an animal, immediately absorbs the effluvia, and the air above becomes quite sweet. The charcoal acts first by absorbing the odoriferous gases, such as ammonia, hydro-sulphuric acid (sulphuretted hydrogen), &c., and thereafter aids in the oxidation of these into nitric acid, sulphuric acid, and water. As agents capable of being employed in the deodorisation and purification of offensive liquids, such as bilge-water and sewerage-water, there are chloride of zinc—Burnett's disinfecting liquid (q. v.)—chloride of manganese,

perchloride of iron (Ellerman's deodorising fluid), and nitrate of lead (Ledoyen's disinfecting fluid); but these liquids are not true disinfectants, and are merely serviceable in deodorising by fixation. The employment of fumigating pastilles, burning brown paper, and fumigations with camphor, benzoin, mastic, amber, lavender, and other odoriferous substances, is merely serviceable in cloaking over the offensive, fetid, and hurtful gases, and should never be resorted to unless in conjunction with the use of other agents possessing the properties of true disinfectants, and especially with the means of effective ventilation. See MANGANESE.

**DISLOCATION** consists in the displacement of one bone from another with which it forms a joint (*put out of joint* being the popular expression). Dislocations are generally the result of sudden accident, but may be the result of disease, or may be congenital. The displacement may be *partial* or *complete*; and surgeons classify their cases into *simple* dislocations, when the skin remains unbroken, and compound, when there is a wound by which the external air may communicate with the joint. Occasionally, in addition to the dislocation, there are fractures of the bones, or lacerations of important blood-vessels in the neighbourhood; it is then termed a complicated dislocation. Dislocation is a rare accident in infancy and old age, because in the former the joint-ends of the bones are very flexible, and yield to violence; while the aged skeleton is so rigid that the brittle bones fracture under force that would drive younger and firmer ones out of their sockets. Dislocations are most frequent between the ages of thirty and sixty. Persons with weak muscles, and lax, long ligaments, or those in whom the latter have been softened by inflammation of the joint, are predisposed to dislocation. The joints most frequently displaced are the shoulder and the elbow.

*General symptoms of a dislocation.*—After a blow, fall, or violent muscular exertion, a limb is found to be immovable at the injured joint, there is great pain, and the shape of the part is changed; but soon swelling ensues, and every distinctive mark about it is obscured. If left alone, or merely treated as an inflamed joint, the swelling gradually subsides; but the immobility continues, the limb is crippled for months or years, when at last nature forms a new socket for the end of the bone, and some amount of useful motion is restored. The proper shape of the part is never restored, but remains an eyesore to the patient, and a disgrace to the surgeon.

*The general treatment of dislocations* consists in their reduction, or pulling the displaced bone back into its place. Its return is opposed by the muscles attached to it, which are stimulated to contraction by the

Reduction of Dislocation of Shoulder-joint.

pain of the operation, which requires, of course, a good deal of force to be employed. It is desirable to remove this spasm of the muscles, which is the

great obstacle to the reduction of a dislocation; and in former days, bleeding from the arm, emetics, the warm bath, &c., were generally made use of; now-a-days, chloroform or ether attains the same ends, and renders the treatment of dislocations much more simple and humane than before the introduction of anaesthetics.

When the surgeon is about to reduce a dislocation requiring any degree of force, he fastens the part of the limb above the displaced bone or the trunk, so as to afford him *counter-extension*; he then pulls on the limb either with his hands, or with a bandage or handkerchief attached to it. The best way of

Clove-hitch.

fastening this is to roll a bandage, wetted, to prevent slipping, round the limb, and then taking the thing with which he wishes to extend in both hands, he casts it into two loops, forming what is called a *clove-hitch*, and then slips the double noose up the limb till it rests on the wet bandage previously applied. In old-standing cases, the hands grow weary before the extension has been kept up sufficiently long, so it is well to adapt pulleys to draw upon the clove-hitch, as with them the traction can be regulated as the surgeon desires. Sudden, forcible pulling is useless and hurtful, the object being merely to tire out the muscles which resist the attempts at reduction; when they are exhausted, the bone will generally slip back into its place with an audible snap.

A class of shrewd individuals, called '*bone-setters*,' frequently derive profit from some conditions of joints which resemble dislocations. Chronic rheumatic inflammation is occasionally known to fix itself by an accident on some particular joint, especially the shoulder or hip, and may so change the surfaces of the bone-ends that they are spontaneously dislocated; the empiric, naturally antagonistic to the regular practitioner, tells the patient that when he met with the accident the dislocation occurred, but that his doctor overlooked it. Again, many persons who have injured their joints do not submit to having them moved about, after the first inflammation has subsided. The bone-setter gives a forcible bend to the limb, which breaks up the adhesions; and because he has done roughly what the doctor would have done equally well gently, the patient praises him, while he blames the one who guided his joint in safety through the first effects of the accident.

Whenever a dislocation occurs, the nearest medical man should be summoned, even should the mere displacement be rectified at once, because no such accident can occur without some tearing of the soft parts, and it will depend on the after-treatment whether the joint will ever become useful again or not. It must also be remembered, that the sooner a dislocation is reduced, the easier is the reduction. Since the introduction of anaesthesia, however, and the subcutaneous division of tissues, many ancient cases may be improved, and many crippled limbs restored to usefulness.

**DISLOCATION, or FAULT,** a term used in Geology to characterise certain displacements common among stratified rocks. The agency that raised these rocks above the waters of the sea, produced in the elevation numerous rents. In their simplest form, the rents are mere cracks, the parts, though separated, remaining contiguous; sometimes a greater or less fissure intervenes between the

disunited portions, and this is filled with materials pressed in from above, or with igneous rocks intruded from below. The beds, however, are not always found at the same level—a displacement as well as a severance often takes place, so that the beds on one side of the fissure or crack are many feet, or many hundreds of feet, above or below the beds on the other side with which they were once continuous. One of the best known faults is that called the '*Ninety Fathom Dike*' in the Newcastle coal-field. The same beds are 90 fathoms lower on the northern than they are on the southern side. The fissure varies in width from a few feet in some places to more than 20 yards in others: it is filled with sandstone. In the Edinburgh coal-field, the greatest fault is the one known as the '*Sheriffall Slip*.' It has produced a dislocation of the strata to the extent of 400 or 500 feet, so that the coal which is worked on the south side of the slip, near the surface, is on the north side 500 feet below it. Mr. Milne Home enumerates 120 faults in the Mid-Lothian and East-Lothian coal-fields. He has himself examined 78 of these, and has found that 35 dip to the south, and 43 to the north; and that while the sum of the down-throws by the faults dipping to the south is 385 fathoms, those dipping to the north have depressed the strata 754 fathoms.

Faults in coal-fields are well known, because of their serious interference with the progress of the miner. But though they often cause considerable labour and expense in searching for the continuation of a valuable seam of coal, they have corresponding advantages, since they disclose on the surface the value of the buried minerals, and when filled with solid materials, they form embankments which confine water, and thus save considerable expense in draining the mine.

The amount of dislocation is the measure of a line drawn from one part of the bed, at right angles to its plane, to a line produced from the other separated part of the bed representing its plane. Thus, in the diagram, AB shews the

Diagram of Dislocated Strata.

extent of the down-throw, say 10 feet. Although no notion can be formed, in meeting with a fault, of the extent of dislocation, yet the direction in which the lost strata are to be sought can be certainly determined, for it has been found to be an invariable law, that the strata are lowest on the overlapping side of the slip, so that in the diagram the beds *a, b, c* are 10 feet deeper in the overlying side than the same beds on the other. Faults have local names from the miners, all of which have been used by geologists. They are called hitches, dikes, troubles, slips, slides, heaves, and throws.

**DISMAL SWAMP,** measuring 30 miles from north to south by 10 in breadth, lies chiefly in Virginia, but partly in North Carolina. In the centre is Lake Drummond, covering about six square miles. Elsewhere the surface is divided between tangled reeds and heavy timber, with a thick undergrowth. This extensive morass has been, at a vast cost, traversed lengthwise by a canal, which

connects New Lebanon, in North Carolina, with Norfolk, in Virginia.

**DISMANTLE** is the operation which a ship undergoes when to be laid up in ordinary, or placed out of service. She is unrigged; the yards and most of the ropes are removed; and the upper masts taken down.

**DISMAS**, Sr, the name which Catholic tradition has attached to the 'good thief.' He is represented with a cross beside him.

**DISORDERLY HOUSE.** See **NUISANCE**, **MORAL**.

**DISPART**, in Gunnery, is a mark set upon the muzzle of a gun, to aid the gunner in obtaining a line of sight truly parallel with the axis of the bore. The dispart, in strictness, is not the mark itself, but a distance or quantity denoted by the mark; and 'to dispart' a gun is to determine this distance. It depends mainly on the relation between the diameter of the breech and that of the muzzle.

**DISPENSATION**, a licence granted by the pope for that which is ordinarily prohibited. The nature and limits of the dispensing power have been the subject of much discussion not only in controversy with Protestants, but among Roman Catholics themselves. It is held by the extreme advocates of papal power, that the pope may dispense in any divine law, except the articles of faith; by others, that his dispensing power does not extend to express precepts of the New Testament; some say that his dispensation is valid only when it proceeds upon just cause; some, that it is not properly a relaxation of the law's obligation, but merely a declaration that in the particular case the law is not applicable. The usage of the Church of Rome, however, agrees with the opinions of her theologians in making the pope supreme in releasing from oaths and vows; and a decree of the Council of Trent anathematizes all who deny the power of the church to grant dispensations for marriages within the prohibited degrees of the Mosaic law; whilst the multiplied prohibited degrees of the canon law give much occasion for the more frequent exercise of the same power.—Nothing really of the nature of a dispensation is known in any Protestant church. The only kind of dispensations now in use in England, are those granted by a bishop to a clergyman, to enable him to hold more benefices than one, or to absent himself from his parish. Formerly, the pope's dispensations in England, as elsewhere, prevailed against the law of the land, not in ecclesiastical matters only, but in all that large department of civil affairs which, by an interested fiction, was brought within the scope of ecclesiastical government. This abuse was swept away at the Reformation, by 25 Henry VII. c. 21. The power of the pope was then conferred on the Archbishop of Canterbury, in so far as it was not contrary to the law of God. The granting of special licences of marriage, and the like, is the only form in which it is ever exercised.

In former times, the crown claimed a dispensing power in civil, similar to that which belonged to the pope in ecclesiastical matters. The power was grossly abused by James II., and was consequently expressly abolished by the Bill of Rights. The privilege of granting pardons in capital cases is the only form in which the dispensing power of the crown still exists.

**DISPERSION.** Ordinary white light is heterogeneous in its character, being composed of rays of different refrangibility, and the term dispersion is used in optics to denote the separation of these

rays by refraction. Transparent media of various kinds possess different dispersive powers, or, in other words, different powers of widening the angle between the red and violet rays, when a ray of white light suffers refraction through a prism of given angle at a given angle of incidence. The circumstance called the 'irrationality of dispersion,' consists in the fact, that when a spectrum is measured after Fraunhofer's manner, it is found that the distance between any of the same two fixed lines of the spectrum has not a constant ratio to the distance between the extreme fixed lines, where different media are used. See **SPECTRUM**. It may be noticed that the word dispersion is also sometimes used to denote in Optics irregular reflection or the scattering of light on imperfectly polished surfaces. See **CATOPTRICS**. The amount of light not reflected according to the regular law varies with the nature of the reflecting surface. In the case of light incident at right angles upon a surface of common glass,  $\frac{1}{3}$  only is properly reflected. In perpendicular reflection at an ordinary silvered looking-glass, about  $\frac{1}{2}$  is lost by this sort of dispersion. A little less than  $\frac{1}{2}$  is lost in perpendicular reflection from highly polished speculum metal.

**DISPLAYED**, in heraldic usage, means *expanded*; as an eagle displayed, or what is vulgarly known as a spread eagle. See **EAGLE**.

**DISPOSITION**, in Art, differs from *composition*, inasmuch as the former has reference to the arrangement of the parts, the latter to the effect of the whole.

**DISPOSITION**, in Music, a term now used in organ-building, adopted from the German, meaning the arrangement and combination of the stops on the different rows of keys and pedals, with the pitch of each stop, or length of the lowest CC pipe.

**DISPOSITION**, in the Law of Scotland, is a deed of conveyance, applicable either to heritable or movable property, but most frequently used for the purpose of transferring the former from the seller to the buyer. There is another well-known form of the deed, the object of which is to settle a whole succession, both heritable and movable, a will or testament, in Scotland, being applicable only to movable property. This latter deed is commonly known as a disposition and settlement. The following are the clauses usually contained in a disposition for the purpose of conveying heritable property: 1. The *narrative* or *inductive* clause, in which the names of the disponent and disponentee are set forth, the cause of granting the deed is stated, and the receipt of the price or consideration is acknowledged, if the conveyance has been for an onerous cause. 2. The *dispositive* clause, in which the maker of the deed 'sells and disposes,' or 'gives, grants, and disposes,' if there has been no price paid or consideration given. 3. A clause obliging the disponent to infest. See **INFESTMENT**. 4. A procuratory of Resignation (q. v.). 5. A clause of Warrantice (q. v.). 6. An *assignment* to the title-deeds and rents of the subject. 7. An obligation to free the disponentee from public burdens due before his term of entry. 8. A clause to the effect that the title-deeds have been delivered to the disponentee. 9. A clause of registration. 10. A precept of Sasine (q. v.). And lastly, a Testing Clause (q. v.), in which the deed is authenticated in the usual manner. Though it is still optional to make use of these clauses, they have been greatly shortened by the Act 10 and 11 Vict. c. 48 (1847), and some are entirely dispensed with by the Titles to Lands Act, 21 and 22 Vict. c. 76 (1858). A disposition for the conveyance of movables is a much simpler document. It often bears reference to an inventory containing a more particular

enumeration of the effects conveyed. It grants power to the donee to take possession of the subjects, and it also contains clauses of warrant and registration, and a testing clause. The disposition and settlement, again, varies in form according to the nature of the property conveyed, and the arrangements which are made with reference to it. Sometimes it is a direct conveyance; in other cases it conveys the property to trustees, to be held and administered by them for the benefit of other parties. In this latter case, it is known by the name of a trust-disposition and settlement. Where contingencies which cannot be foreseen with certainty are anticipated, where the management is complicated by details, or where the operations under the deed are likely to be protracted, the appointment of trustees (see TRUST) is usually resorted to. In either case, the grantor's life-interest in the property is reserved by a special clause, and there is also a clause dispensing with delivery. An excellent form, for the guidance of the practitioner in the preparation of this deed, will be found in the *Juridical Styles* (vol. ii. p. 442, 2d ed.). A disposition in security which corresponds to the English mortgage, will be explained under HERITABLE SECURITIES.

DISRAELI, ISAAC, D.C.L., a well-known English author, was the descendant of a Hebrew family which flourished first in Spain, and afterwards in Italy. His father, Benjamin D'Israeli, came to England in 1748, entered into business in London, amassed a fortune while yet in middle life, and retiring to Enfield, there died in 1817, aged 90. His son Isaac, born at Enfield in 1766, was educated at Amsterdam and Leyden. He commenced his career as a poet and novelist; but, after the publication of the first volume of his *Curiosities of Literature* (1791), he discovered that his forte lay not in creative literature, but in the illustration of history and literary character, and to this he devoted himself. His style is elegant and pleasing, presenting the fruits of antiquarian research and study without their dryness and general want of connection. No writer is more instructively amusing or amusingly instructive than he. Lord Byron speaks of him as 'that most entertaining and searching writer.' D. died in 1848.

D.'s principal works are the *Curiosities of Literature* (1791—1823; new edition, with Life, Lond. 1851); *A Dissertation on Anecdotes* (1793); *Essay on the Manners and Genius of the Literary Character* (1795, 14th ed., 1850); *Inquiry into the Literary and Political Character of King James I.* (1816); *Commentaries on the Life and Reign of Charles I.* (1828—1831); *Eliot, Hampden, and Pym* (1832); *Amenities of Literature* (1841)—for which he received from the university of Oxford the honour of D.C.L.

DISRAELI, BENJAMIN, THE RIGHT HON., author and statesman, eldest son of the preceding, was born in London 1805; he received a private education, which was carefully superintended by his father. At the age when most other young men who rise to political distinction are sent to a university, he was articled to a solicitor, with a view of qualifying him for a situation in a government office which had been obtained for him by his father. The drudgery of a lawyer's office being distasteful to him, he contributed to a Tory journal, the *Representative*, which came to an untimely end. In 1827, he published his novel *Finian Grey*, which was succeeded at intervals by other brilliant works of fiction, including *The Young Duke*, *Contarini Fleming*, *The Wondrous Tale of Aloy*, and *Henrietta Temple*. He also wrote the *Rise of Iskander*, a *Vindication of the British*

*Constitution*, and the *Revolutionary Epic*, an epic ridiculing revolutions, and which was universally considered a failure. After visiting Italy and Greece, and extending his travels to Turkey and Syria, he returned to England, to find the country involved in the Reform Bill agitation. His sympathies appear now to have inclined to Radicalism in politics; and having obtained recommendations from Mr Hume and Mr O'Connell, he presented himself in 1832 to the electors of Wycombe, but was defeated. At the general election in 1835, he met with no better success; and leaving Wycombe, he, in April in the same year, contested Taunton on Conservative principles, which he declared to be 'exactly the same principles that he had always professed.' It is, perhaps, needless to state, that the nation at large has failed to observe the consistency of principle which D. claims to have exhibited. He failed to carry his election against Mr Labouchere; and an unfriendly allusion, in one of his election speeches, to Mr O'Connell, brought down upon him a maliciously humorous allusion to his Hebrew extraction, and involved him in a hostile and belligerent correspondence with a son of the Irish Liberator. He again returned to his pen; but in 1837, his desire for a political career being unabated, he was gratified by an invitation to contest Maidstone in the Conservative interest along with Mr Wyndham Lewis. He was elected, and at the age of 32 took his seat in the House of Commons. Claiming the attention of the House with undue precipitation, before he had sufficiently studied its temper, and exciting much laughter by an *outré* manner and extravagant gestures, he was so disconcerted, that he sat down abruptly, but not without uttering the remarkable prophecy: 'I have begun many things several times, and have often succeeded at last. I shall sit down now, but the time will come when you will hear me.' In 1838, Mr W. Lewis died, and in the following year D. married the relict of his late colleague. At the general election in 1841, he did not seek the suffrages of his former constituents, but obtained a seat for Shrewsbury. As the leader of the 'Young England party,' he had now gained the ear of the House, and he became at length the organ of the dissatisfaction with which the landed aristocracy and country gentry regarded Sir Robert Peel's relaxations of the system of protection to native industry. His brilliant invective and polished sarcasm inspired the Protectionist party with fallacious hope and confidence. He denounced the great Conservative minister as the head of an 'organised hypocrisy'—as 'a great middleman who bamboozled one party, and plundered the other'—and as a politician who 'had found the Whigs bathing, and stolen their clothes.' Fortunately, however, such word-mongering could not prevent the triumph of a wise, salutary, and even imperatively required measure. In 1846, when Peel moved the abolition of the corn-laws, D., now M.P. for Bucks, in vain attempted to overthrow the measure. By his energy and eloquence, however, he saved the defeat from becoming a rout, and formed the nucleus of a powerful opposition. On the death of Lord George Bentinck in 1848, D. succeeded to the leadership of the Protectionist party in the Commons, and in the following year called the attention of parliament to the burdens on land and the depression of the agricultural interest. He bore generous testimony to the political consistency and private worth of his predecessor in his *Lord George Bentinck, a Biography*, which had an extended circulation. In 1852, the Earl of Derby, having undertaken the construction of a cabinet, offered him the post of Chancellor of the Exchequer. It was the first

time a brilliant novelist had ever figured as the finance minister of a great commercial state, and it argues well for the versatility of his genius that he emerged with honour and credit from the ordeal. His second budget, in 1853, failed, however, to find acceptance with the House of Commons, and the government being outvoted upon it, the Derby cabinet ceased to exist. D. resumed the undisputed leadership of the opposition in the Lower House, from which he was again summoned in 1858, to fill the post of Chancellor of the Exchequer in the second administration of the Earl of Derby. In 1859, he introduced, on the part of the government, a measure of Parliamentary Reform, which, being thrown out, was followed by the resignation of the government. As a debater, he excels in personal invective and sarcasm. Since he has been in parliament, he has written *Coningsby*, *Sybil*, and *Tancred*—novels in which politics and fiction are curiously but not unsuccessfully mingled.

**DISRUPTION**, the name generally given in Scotland to the famous act of 1843, by which upwards of 400 ministers of the Church of Scotland (nearly two-fifths of the whole) left their churches and manse to vindicate principles which they conceived to be essential to the purity of that church, and in harmony with its earlier history. The word Disruption was probably chosen to indicate that these ministers did not look on their act as a *secession* or *dissent* from the Church of Scotland, but as a *split* or *division* within it, and the body immediately after formed by them assumed the name of the Free Church of Scotland. See **FREE CHURCH**.

**DISSECTION**. See **ANATOMY ACT**.

**DISSEISIN**. See **SEISIN**.

**DISSENTERS**, the common appellation of those who dissent or differ from the established church of their country in any of its doctrines, or in any part of its constitution, and therefore separate themselves from it. Although sometimes employed as a sufficiently appropriate designation of the sects which separated themselves from the general body of the church during the early and middle ages, the term dissenters belongs to modern times and Protestant countries; the claims of the Roman Catholic Church, where dominant, having always been asserted in a manner incompatible with the existence of recognised religious dissent. The measure in which the rights of dissenters are conceded by law, may be esteemed a fair test of the religious liberty enjoyed in a country, and of the general enlightenment of a people. The term dissenters is of English origin and growth, although its almost exact equivalent may be said to have existed in Poland in the name *Dissidents*, a term which first appears in the acts of the Warsaw Confederation of 1573, and there denotes the Polish Protestants, in contradistinction to the members of the established Catholic religion. After 1632, the term Dissidents was applied in Poland to all who were not Roman Catholics, such as Lutherans, Calvinists, Greeks, Armenians, &c.

In England, the term dissenters appears to have come into use in the 17th c., as synonymous with *Nonconformists*; and from England its use was transferred to Scotland in the 18th c., after the Secession (q. v.) Church had been founded in that country. It is usually applied to those who agree with the established church in the most essential doctrines, but differ from it on some minor point, or on questions of church-government, relation to the state, rites, &c.; as in England to Presbyterians, Independents, and Baptists. The claim of the Church of Rome to be regarded as the *Catholic*

Church prevents its members from accepting the name dissenters, and others seldom seek to apply it to them. On somewhat similar grounds, it is rejected by *Episcopalians* in Scotland; and for very different reasons, to be found in the peculiar circumstances which attended their growth, the *Methodist* (q. v.) churches are seldom included in it, as ordinarily used. See **ESTABLISHED CHURCH**, **NONCONFORMISTS**, **PURITANS**, **SECESSION CHURCH**, **TOLERATION**, &c.

The term Dissenters is not strictly legal or ecclesiastical, those to whom it applies being usually described in legal language by a periphrasis. It may be said to be a convenient term to designate those Protestant denominations which have dissented from the doctrine and practice of the church as by law established. Immediately after the Reformation, dissenters, or nonconformists, as they were then called, were subjected to severe restrictions and penalties. 'During the Rebellion, the laws against Protestant sectaries were repealed; but they revived at the Restoration; and the parliament of Charles II. proceeded to enforce systematically, by new measures of vigour, the principle of universal conformity to the established church.'—Stephen's *Com.* iii. 53. By I Will. and Mary, c. 18, the restrictions on dissenters were first relaxed, and certain denominations were suffered to exercise their own religious observances. From that period, various statutes have been passed, each extending in some degree the free exercise of religious opinion. At the present time, dissenters of all denominations are allowed to practise without restraint their own system of religious worship and discipline. They are entitled to their own places of worship, and to maintain schools for instruction in their own opinions. They are also permitted, in their character as householders, to sit and vote in the parish vestries. A dissenter, if a patron of a church, may also exercise his own judgment in appointing a clergyman of the Church of England to a vacant living. See on this subject, Stephen's *Eccles. Lav.*

A similar amount of religious liberty is enjoyed in Scotland, not so much derived from or guarded by special statute; fully recognised, however, by decisions of courts, as belonging to the law of the country.

Since the beginning of the 18th c., the Presbyterian, Independent or Congregationalist, and Baptist denominations in England, have been associated under the name of the *Three Denominations*. This association was fully organised in 1727, and enjoys—like the Established clergy of London and the two great universities—the remarkable privilege of approaching the Sovereign on the throne. Notwithstanding much weakness, arising from doctrinal and other differences, this association has contributed much to promote toleration and religious liberty in England.

**DISSEPIMENT** (Lat. *dissepio*, I separate), in Botany, the partition between two Carpels (q. v.) in an ovary or fruit composed of a number of carpels. A dissepiment is formed by the union of the sides of two carpels. Sometimes dissepiments meet in the centre or axis, completely dividing the ovary or fruit into cells; sometimes they are partial, appearing as mere projections from the outer walls of the ovary or fruit, and leaving it one-celled. Many ovaries and fruits exhibit partitions not formed by the union of the sides of carpels: these are sometimes called *spurious dissepiments*.

**DISSOLUTION OF MARRIAGE**. See **DIVORCE**.

**DISSOLVING VIEWS** are pictures painted upon glass, and made to appear of great size and

with great distinctness upon a wall by means of a magic lantern with strong lenses and an intense oxyhydrogen light, and then—by removal of the glass from the focus, and gradual increase of its distance—apparently dissolved into a haze, through which a second picture is made to appear by means of a second slide, at first with a feeble, and afterwards with a strong light. Subjects are chosen to which such an optical illusion is adapted, such as representations of the same object or landscape at different periods. Dissolving views were invented and first exhibited as a popular entertainment in England.

**DISSONANCE** is the opposite of consonance, and is applied to those intervals in music whose relative proportions are to a certain extent unsatisfactory to the ear, and produce a degree of disquietude. In a special sense, the term dissonance is applied to the interval causing the unpleasant effect; which sound is not always, as some think, the upper note, but may be the middle or the lowest note. Many believe that the feeling of dissatisfaction produced by the dissonances of music, arises from the mind not being able without difficulty to comprehend at once the arithmetical proportions of the vibrations. The foundation of dissonance, however, is generally allowed to be more æsthetical than intellectual, as through the vibrations of a sounding body the air is put into a similar state of vibration, which is communicated to our ear, and so to our whole nervous system, through which we obtain the inward feeling representing the sound. In music, dissonance may be called a necessary æsthetical evil, which is used in the finest musical works for the purpose of producing pleasing contrasts, with their resolutions. In modern music, dissonance is divided into *essential* and *accidental*; the former arising fundamentally, the latter arising from passing notes, anticipations, suspensions, &c. See HARMONY.

**DISTAFF**, the staff on which the flax or wool is fastened, and from which the thread is drawn in spinning. A distaff of a very elegant construction is represented in art, and was no doubt generally used in antiquity. It is made of a cane-stick, the top of which is slit in such a manner as that the portions, when bent downwards, form a receptacle for the flax or wool. A ring was put over the top, for the purpose of keeping the divided ends of the cane together. The accompanying illustration is from Fairhol's *Dictionary of Terms in Art*. The distaff was dedicated to Pallas; and the Fates are always represented with it, and engaged in spinning the thread of life. It has ever been considered as the peculiar emblem of feminine as opposed to male occupations, and has come to be used figuratively for a woman.

Distaff.

**DISTANCE**. The limit of view in a picture, or *point of distance*, as it is called in perspective, is that portion of the picture where the visual rays meet; the *middle distance* being the central portion between the extreme distance and the foreground. The art of producing on the eye the effect of real distance, in so far as it is not accomplished by mere mechanical rules, is one of the most subtle branches of landscape-painting, and cannot be acquired otherwise than by long experience, and a careful study of the effects of light and shade.

**DISTEMPER** (Fr. *détrempe*), a coarse mode of painting, in which the colours—of a commoner kind than those usually employed for artistic purposes—are mixed in a watery glue, such as size

and whiting. The chief purposes for which distemper is now used are scene-painting and staining-papers for walls. But it is known that the old masters frequently executed pictures and portions of pictures in distemper, and then oiled them, by which means they acquired the character of being painted originally in oil. It is said that Paul Veronese sometimes began his pictures in distemper, and finished them in oil, and that he frequently painted his skies in distemper. Distemper is often ignorantly supposed to be identical with Fresco (q. v.). The difference is, that whilst in the former the colours are laid on a dry surface, in the latter they are put on wet mortar or plaster. See SIZE.

**DISTEMPER** is a typhoid inflammation affecting the upper air-passages of young dogs, and resembling in many respects the strangles of young horses, and the scarlatina and other such complaints of children. Like these, it is generally contagious, occurs only once in a lifetime, runs a definite course, is accompanied by low fever and debility, and is most successfully treated by good nursing and attention to diet and regimen. The eyes are red, weak, and watery; the nose dry and hot; draughts of air or movements of the animal readily excite sneezing or cough; there is dulness, fever, and loss of appetite. The thickened slimy mucus which the inflamed membrane, after some days, secretes, accumulates about the eyes and nostrils, and lodging in the bronchial tubes, prevents the free access of air, and the proper purification of the blood. Hence ensue distressed breathing, increasing weakness, and symptoms of nervous disturbance, such as staggering gait, Chorea (q. v.), and fits. All dogs are liable to distemper, but the delicate, highly bred, and artificially treated varieties suffer most severely, and amongst them the mortality is very great. Bleeding, physicking, and all irritating and reducing remedies, must be carefully avoided, and a good dry bed in a comfortable airy place provided. The stomach, which is generally overloaded, should be relieved of its contents by an emetic, which, for an ordinary sized English terrier, may consist of two grains each of tartar emetic and ipecacuanha, with eight or ten grains of common salt, given in a wine-glassful of tepid water. If no effect is produced, the dose must be repeated in twenty minutes. Constipation, if present, should be corrected by half an ounce each of castor and olive oil, to which, in large dogs, a few grains of gray powder is a useful addition. The febrile symptoms, if acute, may be alleviated by giving four times daily, in cold water, two drops of tincture of aconite, and five grains each of nitre and extract of belladonna. Distressed breathing will be relieved by applying to the chest and sides, for an hour or two continuously, a thick flannel cloth, wrung at short intervals out of hot water. The throat may also be rubbed with hartshorn and oil, and the nostrils sponged and steamed occasionally. Give frequently, and in small quantities at a time, milk and bread, or any other such simple and digestible food; and when recovery is tardy, and weakness ensues, endeavour by nursing, Tonics (q. v.), and Stimulants (q. v.) to support the strength.

The term distemper is sometimes applied to influenza (q. v.) in horses, and epizootic pleuropneumonia (q. v.) in cattle.

**DISTICH** (Gr. *distichos*, consisting of two rows or ranks) is the classical name given to any two lines, but especially to a hexameter and pentameter, making complete sense. It was much used by the Greeks and Romans as a vehicle for the expression of single thoughts and sentiments; and hence

became almost exclusively employed for the classical epigram. The great poets of modern Germany, Goethe, Schiller, &c., have also shewn a fondness for the distich, and remarkable skill in the use of it. A collection of moral maxims in Latin, ascribed to a certain Cato, Dionysius (q. v.), are called *Disticha*, and were highly popular during the middle ages.

**DISTILLATION** is an important process in the arts. It consists essentially in converting a liquid into vapour in a close vessel, by means of heat, and then conveying the vapour into another cool vessel, where it is condensed again into a liquid. When applied to a solid, the process is called *Sublimation*. The object of distillation is to separate one substance from others with which it may be mixed. In distillation proper, no chemical decomposition takes place; when any of the substances are decomposed, it is called **DESTRUCTIVE DISTILLATION** (q. v.). The possibility of separating substances by vaporising them depends upon the fact, that very few substances are volatile at the same temperature. Thus, water boils or becomes rapidly converted into vapour at 212°, alcohol at 173°, sulphuric ether at 94.8, while oil of turpentine must be raised to 318°, and mercury to 662°; and some substances, again, are altogether *fixed*. By applying the proper degree of heat, then, and *no more*, the more volatile of two substances may be expelled from the less volatile; and supposing the vapours of the two to rise mixed, as they are gradually cooled, that of the less volatile will be condensed before the other, thus affording another opportunity of separation.

It is often, however, not so easy to obtain a perfectly pure product by distillation as might at first appear, owing to another fact in chemistry—namely, that many bodies which, when pure, require a high temperature to vaporise them, become more easily vaporised when mixed with substances more volatile than themselves. Owing to this, it is impossible to obtain, by distillation alone, alcohol perfectly free from water. The circumstance, on the other hand, is sometimes turned to good account in another way. By distilling, for instance, parts of plants with water, the essential oils pass over with the steam, and are then separated from the condensed water by other processes.

The applications of distillation are numerous both in chemistry and in the practical arts. Pure water is obtained by distillation, the most of the substances dissolved in natural waters being fixed. Sea-water may thus be rendered drinkable, and there are apparatus for the special purpose. But wherever there are cooking-utensils, a distilling apparatus might be improvised. The pure water that descends from the clouds is produced in a way which is just the process we are speaking of on a large scale. See **EVAPORATION**. It is no figure of speech to say that the dews are 'distilled.'

The extraction of zinc from the ore is a distillation; the metal, when reduced, passes over in vapour, and is condensed in a separate vessel. When the zinc ore contains cadmium, this metal, being more volatile, comes over in the first portions, and may be removed. When mercury is used to extract particles of gold from sand, the mercury is distilled off from the amalgam, leaving the gold, which is fixed. The mercury being condensed, is again ready for use.

The most extensive application of distillation is in the manufacture of intoxicating spirits, and in ordinary language this is the most common use of the word. Strictly speaking, indeed, the spirits are not produced by the act of distillation; that is done by the previous step of Fermentation (q. v.); and distillation merely separates the spirits from the

mixture in which they already exist. But it may be as well to give some account of the whole process under this head.

All the intoxicating drinks used in ancient times seem to have been the products of fermentation merely. The art, as it has been called, of evoking the fiery demon of drunkenness from his attempered state in wine and beer, is a discovery of modern times. It is first mentioned by an Arabian physician of the 11th c., Abulkasem, though the invention is attributed by some to the northern nations. The name *aqua vita*, given to distilled spirits by early physicians and alchemists, shews what an estimate they made of the discovery. Raymond Lully declares this admirable essence to be an emanation of the Divinity, an element newly revealed to man, but hid from antiquity, because the human race were then too young to need this beverage, destined to revive the energies of modern decrepitude. Sadly have these anticipations been belied!

Spirits were first distilled from wine, and hence called spirits of wine. An endless variety of substances are now used in this extensive manufacture. Alcohol (q. v.) is the essential ingredient of all spirits, and it results from the decomposition of sugar, which, by the process of fermentation, is resolved into carbonic acid and alcohol. Sugar, then, is the direct source of alcohol, and accordingly all vegetable products containing sugar, such as grapes, the sugar-cane, sweet fruits, beet-root, &c., may be used in the manufacture of spirits. But there is another more abundant vegetable substance—namely, *starch*—which is easily convertible into sugar, and thus becomes indirectly a source of alcohol. In malt, and in germinating seeds generally, there is found a substance called *diastase* (q. v.). If a small quantity of this, or of an infusion of malt, be added to a paste of starch, it will in a short time become thin and sweet, the whole of the starch being transformed into sugar. See **BEER**. It is thus that grain of all kinds, potatoes, and other substances which contain little or no free sugar, are yet capable of yielding alcoholic spirits.

All substances, then, containing either sugar or starch, or both, will yield spirits. With sugar, the manufacture consists of two processes—fermentation and distillation. When starch is the original source, as is more commonly the case in the distilleries of this country, the first step is to convert it into sugar, or to *saccharify* it. This is the object of what is technically called *mashing*, which consists in mixing the materials in a triturated state with water at the temperature of about 160°. It is mostly from barley, oats, and rye that spirits are manufactured; wheat is less used, owing to its cost. Raw grain is ground to meal; malt is only bruised. A certain proportion of malt is always used, even in distilling from raw grain or potatoes, as the diastase of the malt is necessary to set agoing the saccharine fermentation. After being agitated for two or three hours, the saccharine infusion, called *wort*, is drawn off from the grains, and cooled. To this wort is now added a certain quantity of yeast or barm, which induces the vinous fermentation, and resolves the saccharine matter into alcohol and carbonic acid, accompanied by a rise of temperature. The alcoholic mixture which results is called the *wash*, and is now ready for distillation. This takes place in an apparatus called a still, or Alembic (q. v.). In its older and simpler form, the still consists of a copper vessel, into which the wash is put. This vessel is provided with a close head, terminating in a bent tube, which passes, in a spiral form (the worm), through the refrigerator, filled with cold water. See **STILL**. When heat is applied to the still, the spirit begins to rise in vapour at 176°,

along with more or less steam; these vapours pass through the worm, become condensed by the cold, and drop or trickle in the form of liquid into a receiver. The product of this first distillation in a simple still is called *low wines*. This is then redistilled at a lower temperature, in order to deprive it of part of the water and of the fetid oils that had passed over with the alcohol. To obtain great purity and strength, repeated distillation is used.

A great improvement in distilling was invented in 1801 by a workman of Montpellier, of the name of Adam. By making the vapours arising from the still pass through a series of winding passages, maintained at a determinate degree of heat, and deposit part of their water and other impurities, he was able to obtain from wine a spirit of any required cleanness and strength *at one operation*. This principle has been adapted, by Pistorius of Berlin (1817), to the distillation of the coarser washes of grain and other materials.

Absolute or anhydrous Alcohol (q. v.) cannot be obtained by distillation alone. Rectified spirit, or spirit of wine, for burning in a lamp, still contains, when of ordinary strength, about 25 per cent. of water. Alcohol is considerably lighter than water, its specific gravity being 793 (water, 1000). The stronger any spirit is, then, the less will be its specific gravity; and thus the strength of spirits may be ascertained by an instrument which measures their specific gravity, the *Aërometer* (q. v.) or *hydrometer*. The excise of Great Britain has established one degree of strength as the legal standard, and this is called *proof*. The specific gravity of proof-spirit is 918.6, and it contains nearly equal weights of water and alcohol.

If only alcohol and water passed over in distillation, all spirits, from whatever extracted, would be the same; but this is not the case. Brandy, which is distilled from wine, has a peculiar essential oil derived from the grape, and also some acid; rum is impregnated with an essential oil from the sugar-cane, and with other impurities; malt liquor has the essential oil of barley, &c. It is these essential oils that give to the various spirits their distinguishing flavours. Some of the oils and other impurities are disagreeable and positively noxious; and it is one of the objects of *rectifying* to remove these. The mellowing effect of age upon spirits is owing to the evaporation or spontaneous decomposition of the essential oils. Newly distilled spirits are in general fiery, and specially unwholesome.

Sugar, when fermented, resolves itself into nearly equal weights of carbonic acid and alcohol; a pound of sugar, therefore, should yield upwards of half a pound of proof-spirit. The quantity of spirit afforded by different grains depends upon the proportion of starch they contain: 100 pounds of starch is calculated to yield 35 pounds of alcohol, equal to nearly 8 gallons of proof-spirits. Of the various grains, wheat is the most productive. Taking the average of wheat, barley, rye, oats, and maize, 100 pounds of corn yield 40 pounds of spirit of specific gravity 942 = 3.47 gallons proof. A distiller of malt whisky, says Dr Ure, calculates on obtaining two gallons of proof-spirits from one bushel of malt in ordinary years. The highest yield is 20 gallons per quarter of 8 bushels.

The principal intoxicating beverages produced by distillation are: 1. Brandy (q. v.), which name is applied properly only to spirits distilled from wine. 2. Rum is manufactured from molasses and other uncrystallisable products of the sugar-cane. 3. Corn or malt spirit, under the various names of British spirits, gin, whisky, &c. The Dutch distillers give a peculiar flavour to their spirits (Hollands) by

adding a portion of juniper-berries to the other ingredients. From the French name of the juniper, *genièvre*, come *geneva* and *gin*. 4. Spirits from various vegetable substances. In Germany, a great quantity of spirit is distilled from potatoes, which contain about five per cent. of starch. Beet-root and carrots are also used in the same way. The Swedes make a kind of spirit from the sap of the birch, and the maple and other trees are turned to a similar account. We have, besides, cherry-brandy, peach-brandy, cider-spirit, &c. 5. Arrack (q. v.) is the East Indian name for all ardent spirits. See SPIRITS.

**DISTILLATION, DESTRUCTIVE**, is the term applied to the process of heating vegetable and animal substances in retorts or similarly closed vessels, at a temperature sufficient to decompose the original substance, and obtain therefrom products possessing different properties from the material which yielded them. Examples of this process are, the heating of coal in gas-works at a red heat, when it resolves itself into coke, which is left in the retort, and coal-gas, naphtha, tar, &c., which distil over into suitable receivers; the treatment of coal at and below a low red heat, when it yields much paraffine oil; the distillation of wood in close vessels, at a red heat, when charcoal is left in the vessel, and wood-vinegar, wood-spirit, tar, &c., pass over in vapour, and are condensed; and the heating of bones in similar retorts, when animal charcoal is left in the retort, and Dippel's animal oil distils over.

**DISTILLED WATER** is the condensed product obtained by the distillation of water. All natural waters, even rain-water, contain certain saline matters (common salt, &c.) in a state of solution, from which they can only be completely freed by the process of distillation. The characters of distilled water are, that it possesses a mawkish, insipid taste, without odour or colour, and when evaporated to dryness in a vessel, it ought to leave no residue. The other properties of distilled water will be noticed under WATER.

**DISTILLED WATERS** are obtained by distilling water along with the parts of plants containing essential oils. Rose-water and lavender-water are familiar examples.

**DISTORTION**. The rules of perspective impose certain conditions in the delineation of natural objects, and when the image formed by a lens on the focusing screen of a camera obscura does not fulfil those conditions, it is said to be distorted. The effect of distortion is to render all straight lines, which do not pass through the centre of the lens, curvilinear, and also so to alter the relative proportions of objects in the picture as to be opposed to the principles of true perspective. Distortion, in the camera obscura, is generally produced by the eccentric incidence of the oblique pencils.

**DISTREIN**. See DISTRESS.

**DISTRESS**, in English law, is the common-law remedy by which a man may remunerate himself for non-payment of rent or other duties, or may impound another's cattle trespassing upon his land. Distress is defined to be 'the taking of a personal chattel out of the possession of the wrong-doer into the custody of the party injured, to procure a satisfaction for the wrong committed.'—Stephen's *Com.* iii. 342. Distress is a remedy of the feudal law. It was an Incident (q. v.) inseparable from the fealty to the lord; so that, as Lord Coke lays down, a lord granting the rent to another, and retaining the fealty, the grantee of the rent could not distress.—*Co. Litt.* 150 a. Distress was incident to every service;

hence it might be put in force for failure to do suit in the lord's court, or for not payment of the duties awarded in a court leet. In modern days, distress is practically enforced chiefly for non-payment of rent, for non-payment of certain public rates, and upon cattle straying upon land not belonging to their master. Cattle so straying may be impounded and retained as security till their owner make satisfaction. Distress for public rates is allowed by the statutes imposing the rates. In this species of distress, and distress for non-payment of rent, the articles are not merely kept as security, but may be sold to pay the amount due. Whatever goods the landlord finds on the premises, even goods belonging to a stranger, may be distrained; but animals *ferre nature*, and goods delivered to the tenant by way of trade, may not be taken. A landlord may, by special statute, 11 Geo. II. c. 19, distress goods fraudulently carried off the premises; and by the same statute he may, with the assistance of the peace-officer of the parish, break open doors to obtain the goods so removed.—See Stephen's *Com.* iii. 341—350.

**DISTRIBUTION OF SPECIES.** See SPECIES.

**DISTRIBUTIONS, STATUTE OF,** the statute 22 and 23 Car. II. c. 10, explained by 29 Car. II. c. 3. This statute regulates the division of the estate, according to the law of England, of a person dying intestate. A widow is by this act entitled to one-third of the estate in case there are children, the remainder being divided between the children in equal portions. If there be no children, the widow has half, and the other half is divided among the nearest of kin, or their representatives. If no widow, the children take all. If neither widow nor children, the estate is divided amongst the next of kin. In this case, the father (or, if he be dead, the mother) excludes brothers and sisters of the deceased; but by 1 Jac. II. c. 17, the mother of an intestate must take equally with the brothers and sisters of the deceased.

**DISTRICTS, MILITARY,** are certain regions into which the United Kingdom is divided for military purposes, to facilitate command and organisation. Each has its head-quarters at a particular town. Without defining the districts particularly, they may be denoted as follow. The northern district has its head-quarters at Rotherham; the south-western, at Portsmouth; the western, at Plymouth; all the rest of England forms a district, of which London is the head-quarters. Scotland forms a district, with head-quarters at Edinburgh; while Ireland is in no less than five districts, with head-quarters at Dublin, Armagh, Athlone, Cork, and Limerick.

**DISVELOPED, or DEVELOPED,** is applied to the colours of a regiment or army, which are said, herakdically, to be disvelloped when they are flying.

**DITCH,** in Agriculture, is a trench usually made along the sides of fields, so that all the drains may be led into it. A hedge is often planted along the side, and the two form a better fence for cattle. In cold undrained lands, the earth thrown out of the trench forms a mound of dry earth, which is particularly serviceable for the growth of thorn-hedges. Accordingly, this is the common mode adopted in planting hedges in such districts, where the subsoil is often close, tenacious, and not well suited for their growth. Various forms of ditches are made, sometimes a double ditch is adopted, and the hedge planted between. In arable lands, however, since the general use of small and large pipes, ditches have been converted into underground drains, which has effected a great

saving of land, as well as giving to the fields a tidy appearance.

**DITCH** is one of the most important of the defence-works of a fortified place. It is a broad and deep trench, that may either be kept dry or filled with water; in practice, it is generally dry.

In permanent works, such as the regular fortifications of a town, the *rampart* and the *ditch* are the most important; the former being inside the latter, and formed mainly of the earth excavated from it. The ditch is often 120 feet wide, 12 feet deep below the natural level of the ground, and 24 feet beneath the parapet of the rampart. See COVERT WAY.

**DITHYRAMBUS,** originally a surname of Bacchus, of uncertain derivation and meaning, was subsequently applied to a species of lyric poetry cultivated more particularly at Athens, and characterised by loftiness and vehemence of style, which, however, at a later period, degenerated into bombast and extravagance. The D. was originally a passionate hymn, sung by one or more revellers to the music of a flute; but Arion (q. v.) invented for it a regular choral or antistrophic form. It is this form which is generally spoken of as the dithyramb. It subsequently received various alterations, but no specimens of it have survived.

**DITTMARSH, NORTH and SOUTH** (Danish, *Norder* and *Süder Ditmarchen*), the name given to the western district of the German duchy of Holstein, lying between the Eider and the Elbe. The entire area is 500 square miles. Pop. 75,000. In old German times, D. formed a part of Saxony beyond the Elbe, and is worthy of special notice, because the inhabitants have preserved to the present day the peculiarities of antiquity. It has its own collection of laws, known as the *Ditmarsh Land-book*, which originated in 1321 from 48 judges; was altered in 1447, first printed in 1497, amended in 1567, and finally enjoined anew in 1711. Whatever authentic notices, traditional and otherwise, we possess of D., we owe to Joh. Adolphi (b. 1559, d. 1629), whose *Chronik des Landes D.* (Ditmarsh Chronicle), written in the Lower Saxon dialect, was published in the original text, with 23 dissertations by Dahlmann (Kiel, 1827).

**DITTANY** (*Dic-tamnus*), a genus of plants of the natural order *Rutaceæ*, having a short 5-partite calyx, five somewhat unequal petals, ten stamens, and five 1—3-seeded follicular capsules cohering at the base. The COMMON D., also called BASTARD D., or FRAXINELLA (*D. albus*), a native of sunny mountains and rocks and dry mountain-forests of the south of Europe, especially in calcareous soils, is very generally cultivated as a garden-flower.

It is a perennial, with stem  $1\frac{1}{2}$ —3 feet high, perfectly unbranched, bearing a few pinnated leaves, which have 3—5 pair of leaflets and an odd one,

Dittany:  
a, top of stem, with leaves and flowers; b, fruit.

and terminating in a beautiful erect raceme of 10–20 flowers. The flowers are of a fine rose colour, with darker veins, more rarely white. The plant diffuses a powerful fragrance from its numerous oil-glands when in flower, and during dry hot weather exhales such a quantity of volatile oil, that its sudden combustion makes a slight flash when a candle is brought near it on a warm summer evening. The root is thick, white, and very bitter, and was formerly in high repute in medicine as a tonic stimulant, but is now neglected.—D. of Crete, used as a febrifuge, is a very different plant (*Origanum Dictamnus*) a kind of Marjoram (q. v.).

**DITTAY**, a technical term in the criminal law of Scotland, now little used, signifying the ground of indictment or substance of the charge. By *taking up dittay* was understood the collecting of information in order to trial, which is now effected by what is called a precognition.

**DĪŪ**, a seaport, situated at the eastern extremity of an island of the same name off the south coast of Guzerat, in Hindustan; is well fortified, having a tolerably safe harbour, with a general depth of three or four fathoms. The anchorage, however, is said to be gradually becoming shallower. Pop. of town about 11,000. The place has been in possession of the Portuguese ever since 1515; but, from its detached and isolated position, its trade is of little consequence.

**DIURETICS**, medicines having the property of increasing the secretion or excretion of urine, and on this account much employed in dropsies, as well as in a variety of other diseases. The principal diuretics are the salts of potash, especially the nitrate, acetate, and bitartrate (cream of tartar); squill, in powder, vinegar, or syrup; digitalis or foxglove, in powder or infusion; the decoction or infusion of broom-tops (*scoparium*); the decoction of the American winter-green or pyrola; the alcohols and ethers, with most of the volatile oils, especially that of juniper, as in gin; the berries of the common elder; the tincture of cantharides or Spanish flies; turpentine, &c. The last named (from the alcohols onwards in the above enumeration) are more or less irritating in their effects on the urinary organs, and should not be used without due consideration as to the requirements of the particular case. Cream of tartar and the broom-decoction form one of the safest and best diuretic mixtures which can be employed for domestic purposes; or cream of tartar may be given alone, either dissolved in hot water, and allowed to cool, or in substance along with syrup.

**DIVAN** is a Persian word, having various significations. It is used in the sense of a muster-roll, a register of payments or account; it is also applied to a collection of poems or songs by one and the same author. Goethe uses it in this sense in his *Westöstliche Divan*. Divan means next an administrative board; the highest council of state at Constantinople is called *Divāni humājān*, most illustrious divan. Finally, Divan is the name for the state or reception room in palaces and the private houses of the richer citizens. Along the walls of the room are ranged low sofas, covered with rich carpets, and provided with many cushions. Hence the name divan has been transferred in the west of Europe to a kind of sofa.

**DIVEL ON THE NECK**, an instrument of torture used against the Lollards. It is thus described by Fox, in his *Acts and Monuments*: 'Certain strait irons called the divel on his neck being after an horrible sort devised, straitening and winching the neck of a man with his legs together, in such sort as the more he stirreth in it, the straiter it presseth

him, so that within three or four hours, it breaketh and crusheth a man's back and body in pieces.'—Cowel's *Interpreter*.

**DIVER**, or **LOON** (*Colymbus*), a genus of birds of the family *Colymbidae* (q. v.), having a strong, straight, rather compressed pointed bill, about as long as the head; a short and rounded tail; short wings, thin compressed legs placed very far back, and the toes

Head and Foot of Great Northern Diver.

completely webbed. They fly well, but are particularly expert in diving. They prey upon fish, which they pursue under water, making use partly of their wings, but chiefly of their legs and webbed feet in their subaqueous progression. They are scarcely capable, however, of walking on land, and the name *Loon* is supposed to refer to this incapacity, and to be from the same root with *lame*. The **GREAT NORTHERN D.**, or **LOON**, also called the **EMMER** or **EMMER GOOSE** (*C. glacialis*), is a bird about two feet and three-quarters long, exhibiting no little beauty of plumage; the upper parts black, spotted with

Great Northern Diver (*Colymbus glacialis*).

white; the head black, with tints of green and blue; the belly white. It is a winter visitant of the British coasts, even to the furthest south, and is occasionally seen in inland districts; is found in like manner in most parts of Europe, the north of Asia, and North America, as far south as Texas, but it breeds chiefly in the more northern regions, as Labrador, Iceland, and Spitzbergen. It is not exclusively marine, being often seen on large rivers, and making its nest on the shores of fresh-water lakes. Its cry is very peculiar and wild, has been likened to the howl of a wolf, and is in some countries superstitiously regarded as ominous of evil. It is easily tamed, and becomes very familiar.—The **BLACK-THROATED D.** (*C. arcticus*) is another northern bird, of similarly wide geographic distribution, but much smaller size, being only about twenty-six inches in length. It is

found at intervals distributed round the coasts of Britain, and it occasionally breeds in the freshwater lochs of the north of Scotland. The RED-THROATED D. (*C. septentrionalis*) is also found in all the northern parts of the world, is more common in Britain than either of the other species, and is the bird generally called Loon on the British coasts. In size it scarcely equals the Black-throated Diver. Its back is brownish-black, the belly white, the throat red. The flesh of all the Divers is dark, tough, and unpalatable.—The name D. is sometimes extended to all the *Colymbida* (q. v.), sometimes to all the *Brachyptera* (q. v.).

**DIVERGENT.** See CONVERGENT.

**DIVERTIMENTO, or DIVERTISSEMENT,** a species of musical composition consisting of different movements, arranged in an easy style for one or more instruments, but not so elaborately wrought out as the sonata, or other more regular compositions. The divertimento has generally no fixed character, being merely a musical picture without any attempt at artistic effect, or other aim than to please the ear, and may be said to take its place between the *Etude* and the *Capriccioso*. The divertimento was greatly in vogue during the last half of the 18th century; until then, the word had never been used to denote a musical composition. In France, divertimento is the name given to certain dances and songs introduced between the acts of an opera, or play, for the amusement of the public during the pause, and as such it was used there much earlier than in Italy or Germany.

**DIVIDEND,** the sum apportioned to creditors from the realised assets of a bankrupt estate, and which is at the rate of so much per pound of the claims. The half-yearly interest on the public funds, and periodical profits on shares in joint-stock undertakings, are also called the dividends, the latter being usually declared half-yearly, by order of the directors. Occasionally the dividends do not exhaust the profits, and the surplus is allowed to accumulate, until it is paid to the shareholders as an extra dividend called a bonus.

**DIVIDING ENGINE.** See GRADUATION.

**DIVIDIVI, or LIBIDI'BI,** the curved pods of *Cesalpinia coriaria* (see CESALPINIA), a tree which grows on the coasts of Curaçoa, Carthageua, and other parts of tropical America. They have been long used there for tanning, but have recently acquired importance as an article of commerce. A considerable quantity is now annually brought to Britain. Dividivi is one of the most astringent substances known.

**DIVINATION** (Lat. *divinatio*), is the act of discovering the hidden, but more particularly the future, in a supernatural way. Men have at all times set their own imaginations above the causes of nature, and by a curious subjective process, have endeavoured to draw out of themselves what could in reality be only derived from a study of the laws of nature. Thus, there have been instituted systems of superstition among almost all nations of the world at one period of their history, which the march of scientific discovery and the beneficent influences of a rational religion have failed to wholly eradicate, so that, even among comparatively enlightened peoples, there lurks a deep substratum of this old-world feeling. A more special use of the term is to denote fortune-telling or sorcery (middle-age Latin *sortarius*, one who reads the future by means of lots or *sortes*). It was a maxim with the nations of antiquity, that if there are gods, they care for men; and if they care for men, they will send them signs of their will. This, with

some variations, has been a universal sentiment in all ages and countries. But it was the first step in this journey which presented the whole difficulty. How was man to know the will of the gods? The variety of answers which this question has drawn forth constitutes the history of divination. Thus, among the Greeks, the word for divination was *mantikē*, which signified more than the Latin *divinatio*; inasmuch as it was applied to any means by which the Deity discloses himself to man, while the Latin word denoted more the power which man is supposed to possess of discovering the future. With the Greeks, the seer was passive; with the Romans, he was active. See SEER and ORACLE. Astrology was a favourite method of divination among the ancient Chaldeans, as well as in the middle ages. *Auguries* and *auspices*—both words derived from *avis*, a bird—were systems brought to perfection by the Romans as means of knowing the will of the gods. See AUGURIES and AUSPICES. The sacrifice of beasts, besides, the casting of the horoscope, and the observing of the constellations, were all favourite modes of guessing at the future practised by the Romans. But the belief was not confined to the Old World. The Araucanians, a warlike nation of South America, seem to have placed as implicit faith in the divination of birds as did the Romans, and they practised this art in a way not very dissimilar. Even among ourselves, the merry-thought bone of fowls is known to possess a curious virtue, and boys need not be told the omens connected with the magpie.

An extensive set of omens have been taken from observing what first happens to one, or what animal or person one meets first in the morning, or at the commencement of an undertaking—the *first-foot*, as it is called. To stumble, has been universally held to presage misfortune. Some semblance of a reason might be found for this belief, inasmuch as stumbling may be supposed to indicate that that self-possession and conscious courage, which are in themselves half a victory over circumstances, are lacking—the want of them, therefore, being half a defeat; but in most cases the interpretation seems altogether arbitrary. The dread of a hare crossing the path seems to be widely prevalent; while to see a wolf is a good omen. This feeling is probably a remnant of warlike times, when the timid hare suggested thoughts of cowardice and flight; while the bold wolf, sacred to Odin, was emblematic of victory. The character of the hare for being unlucky is also connected with the deep-rooted belief, that witches are in the habit of transforming themselves into hares. That to meet an old woman is unlucky, is another very general belief; arising, without doubt, from the same causes that lead to their being considered witches. In some places, women in general are unlucky as first-foot, with the singular exception of women of bad reputation. This belief prevailed as far back as the age of Chrysostom. Priests, too, are ominous of evil. If hunters of old met a priest or friar, they coupled up their hounds, and went home in despair of any further sport that day. This superstition seems to have died out, except in the case of sailors, who still consider the clergy a 'kittle cargo,' as a Scotch skipper expressed it, and anticipate a storm or mischance when they have a black-coat on board. This seems as old as the days of the prophet Jonah.

The observation of *lucky* and *unlucky* days was once an important matter, and was often the turning-point of great events. It is now confined to the one subject of marriage. In fixing the wedding-day, May among months, and Friday among days, are shunned by many people both in the higher and lower orders; for in this matter, which is the

exclusive province of women, and in which sentiment and fancy are in every way so much more active than reason, the educated and uneducated are reduced to a level. Perhaps half the superstitious beliefs that yet survive among civilised and Christian communities, group themselves round the subject of love and marriage—of such intense interest to all, yet so mysterious in its origin, and problematical in its issue. The liking or passion for one individual rather than any other, is so unaccountable, that the god of Love has been fabled blind; it is of the nature of fascination, magic, spell. And then, whether happiness or the reverse shall be the result, seems beyond the reach of ordinary calculation. All is apparently given over to mystery, chance, fortune, and any circumstances may, for what we know, influence or indicate what fortune's wheel shall bring round. Hence the innumerable ways of prognosticating which of two or more persons shall be first married, who or what manner of person shall be the future husband or wife, the number of children, &c. It is generally at particular seasons, as at the Eve of St Agnes and Hallowe'en, that the veil of the future may thus be lifted.

Sneezing, likewise, has long been looked upon as supernatural, for this reason, that it is sudden, unaccountable, uncontrollable, and therefore ominous. The person is considered as possessed for the time, and a form of exorcism is used. A nurse would not think she had done her duty if, when her charge sneezes, she did not say: 'Bless the child,' just as the Greeks, more than two thousand years ago, said: 'Zeus protect thee.'

One general remark, however, it is important to make in regard to omens. An *omen* is not conceived to be a mere sign of what is destined to be, it is conceived as causing in some mysterious way the event it forebodes; and the consequence, it is thought, may be prevented by some counter-acting charm. Thus the spilling of salt not only forebodes strife, but strife is conceived as the consequence of the spilling of the salt, and may be hindered by taking up the spilled salt and throwing it over the left shoulder.

An important exercise of the diviner's art is to determine the innocence or guilt of parties. This will be treated under ORDEAL. But it would be impossible to enumerate the endless modes of divination for which learned names have been found. Some of the principal are—*Axinomancy* (q. v.), *Belomancy* (q. v.), *Bibliomancy* (q. v.), *Botanomancy*, or divination by means of plants and flowers (it was practised by the ancients, who were wont to bruise poppy-flowers betwixt their hands, under the conviction that they could thereby discover their loves. Hence Theocritus calls the poppy *Teliphilos*, quasi *Deliphilos*; i. e., a *tell-love*. Goethe has made a beautiful use of another form of this superstition, which existed among the Teutonic races no less than among the old Greeks. The child-like Marguerite, in *Faust*, seeks to discover whether or not Faust loves her by plucking the leaves from a star-flower, murmuring alternately, 'He loves me,' 'He loves me not,' and finds to her joy that the *last* leaf comes away while she is saying, 'He loves me'); *Capnomancy* (q. v.), *Cheirromancy* (q. v.), *Coscinomancy* (q. v.), *Crystallomancy* (q. v.), *Cup*, *Divination by* (q. v.); *Geomancy* (this was anciently practised by casting pebbles on the ground, from which conjectures were formed; but the Arabian geomancy was more recondite, being founded on the effects of motion under the crust of the earth, the chinks thus produced, and the noises or thunderings heard); *Hydromancy*, divination by water or by a mirror, in which the diviner shews

the image of an absent person, what he is doing, &c. (this mode of divination plays an important part in the Arabian romances); *Lithomancy*, a species of divination performed by stones, but in what manner it is difficult to ascertain; *Onciromancy* (see DREAMS); *Pyromancy*, or divination by flame (it was common among the Greeks and Romans: if the flame of the sacrifice was vigorous and quickly consumed the victim, if it was clear of all smoke, and did not crackle, but burn silently in a pyramidal form, the omen was favourable; otherwise, it was not); *Rabdomancy* (see DIVINING-ROD); and *Terophim* (q. v.).

**DIVINE RIGHT.** A term applied to describe the source of the power claimed for the monarch, by the royalist party, in the great controversies between the monarchical and the parliamentary or commonwealth parties in England in the 17th century. The monarch was held to be the immediate representative of the Deity, to whom alone he was responsible for all his actions—a principle which, of course, relieved him from all human responsibility. The idea was little known in this country until the quiet transfer of the crown from the Tudor to the Stewart dynasty shewed that the hereditary principle was firmly established. It was found by some ecclesiastics in the doctrines of the civil law, which, in imitation of the practice of oriental nations, flattered the Roman emperors by attributing to them a power founded on divine institutions. Throughout a long and miserable contention, divine right was on the one side maintained to be the source of political power, while on the other it was maintained that that power emanated from the will of the people, expressed in what was called 'the social contract.' The chief writers on the side of divine right were Salmasius and Sir Robert Filmer; on the other, Milten, Algernon Sydney, and Harrington. The controversy revived in the discussions which caused the French revolution, long after the settlement of the crown on William and Mary and the Hanover dynasty had settled it in Britain.

**DIVINE SERVICE**, a tenure by which the tenant was bound to do some special divine service, as to sing so many masses, to distribute a certain sum in alms, or the like. It differed from Frankalmoign (q. v.) in this, that the lord could distrain for the former, not for the latter, which, being an indefinite service, could be enforced only by a complaint to the ordinary or visitor.

**DIVING.** The 'treasures of the deep' have at all times been the subject of much visionary exaggeration, and the accounts of the exploits of divers equally extravagant. We could name a popular school-book, still in extensive use, where children are seriously informed that the pearl-divers of the East acquire by practice the power of remaining under water from 15 to 20 minutes. Such statements are common enough in narratives of ancient date, in some of which the time is extended to two hours. It need scarcely be said that these accounts are absurd, no such endurance being possible. The more skilful divers may remain under water for two, or even three minutes; some modern accounts say four, and even six, but this is very doubtful. In a swimming and diving contest between some North American Indians and Englishmen in a London swimming-bath, one of the Indians, a renowned swimmer and diver, remained under water just one minute and a half, but a London artisan beat him by a few seconds.

In the *Encyclopædia Britannica*, Professor Faraday describes an interesting fact to which his attention was directed by a gentleman connected with the

Asiatic Society, who, according to Professor Faraday, was the first to make the observation. It was observed that by breathing hard for a short time, as a person does after violent exercise, the breath could then be held much longer than otherwise. Professor Faraday found that he could only hold breath for three-quarters of a minute, if he attempted it without preparation, but that after eight or ten of such forced inspirations, he could hold breath for two minutes. This he explained on the supposition that, ordinarily, a considerable quantity of carbonic acid remains in the involved passages of the lungs, but that it becomes completely expelled by the forced breathing, and its place supplied by atmospheric air. As regards the novelty of the observation, Professor Faraday is mistaken, as the writer of this can testify, for when a boy, he and his companion bathers in the Serpentine, in Hyde Park, commonly practised it. The Red Indian and the artisan above referred to also did the same; it is, in fact, a sort of preparation that a practised diver would make almost instinctively. After a few deep inspirations of this kind, a sense of giddiness is felt, and it is not prudent to carry the experiment far beyond this stage, as a fit of insensibility not unlike apoplexy is apt to result.

This giddiness, which is always produced, and the possible insensibility, indicate a different explanation from that of Faraday. The mere removal of residual carbonic acid from the lungs is not sufficient to explain these; we should rather suggest that all the phenomena result from an excessive oxygenation of the blood, and a consequently accelerated circulation similar to that produced by breathing nitrous oxide. It will be easily understood, that if the blood be forced to take an excess of oxygen, a longer time should elapse before a fresh supply would become necessary—that is, before suffocation would take place; and the giddiness, flushing of the face, and the insensibility, are results to be expected from such an excess.

Most divers suffer severely from the continual efforts in holding the breath; bloodshot eyes and spitting of blood are common among them. This rude mode of diving is now but little used except for pearl and sponge fishing; and even for these purposes, only an uncivilised people, with very little capital and knowledge, would continue to use it, as the modern applications of science afford such immense advantages for all kinds of subaqueous operations, as will be seen by the next article.

**DIVING-BELL.** From what has been stated in the preceding article **DIVING**, it will be at once understood that for all such purposes as subaqueous works upon the foundations of piers, bridges, &c., or the exploration and raising of sunken vessels, the efforts of the unaided diver would be almost valueless, and accordingly various contrivances for supplying air to the diver have been made. The *cacabus aquaticus*, or aquatic kettle, described by Taisnier as having been used by two Greeks in Spain, at Toledo, in 1533, in the presence of the Emperor Charles V. and a multitude of spectators, is one of the earliest reliable accounts of a diving-bell. From his description, this must have been similar in principle and construction to the modern diving-bell, but of clumsy dimensions, and wanting in efficient means of renewing the supply of air. Dr Halley's diving-bell, about 1720, was a wooden chamber of about sixty feet internal capacity, open at the bottom, where it was loaded with lead, to keep it perpendicular in its descent. Strong pieces of glass were set in the upper part, to admit light. Casks filled with air, and loaded with lead, were let down with the bung-hole downwards; and from these a supply of air was drawn by means of a

bosc. The form of diving-bell now in use was first constructed by Smeaton for the works at Ramsgate harbour, 1788. It was of cast iron, and weighed 50 cwt.; its height, 4½ feet; length,

the same; and width, 3 feet. It sunk by its own weight, and was lighted by stout pieces of bull's-eye glass, firmly cemented in brass rings near the top. The principle of the diving-bell will be easily understood by floating a piece of lighted candle or a wax-match on a cork, and then covering it with an inverted tumbler, and pressing it downwards; the candle will descend below the level of the surrounding water, and continue burning for a short time, although the tumbler be entirely immersed. The reason is obvious enough: the air in the tumbler having no vent, remains in it, and prevents the water from occupying its place, so that the cork and candle, though apparently under water, are still floating, and surrounded by the air in the tumbler; the candle continues burning until the oxygen of the air is exhausted, and then it goes out, as would the life of a man under similar circumstances. If vessels full of air, like the barrels of Dr Halley, were submerged, and their contents poured into the tumbler, the light might be maintained; but this could be better done if a tube passed through the tumbler, and air were pumped from above through the tube into the tumbler.

The modern diving-bell, which is made of cast iron like Smeaton's, is supplied with air in this manner. It must be remembered that air is compressible, and diminishes in bulk in proportion to the pressure, so that at a depth of about 33 feet in water, it would occupy half the space it filled at the surface; if the inverted tumbler were carried to this depth, it would be half-filled with water. A considerable quantity of air has, therefore, to be pumped into the diving-bell, merely to keep it full as it descends; the air thus compressed exerts a corresponding pressure, and would rush up with great force if the tube were open and free. This is prevented by a valve opening downwards only.

When the diving-bell has reached its full depth, the pumping is continued to supply air for respiration; and the redundant air overflows, or rather underflows, by the open mouth, and ascends to the surface in great bubbles. The diving-bell is provided with a platform or seat for the workmen, and suspended from a suitable crane or beams projecting from a barge or pier; men above are stationed to work the pumps, and attend to the signals of the bellman. These signals are simply made by striking the sides of the iron diving-bell with a hammer, and as sound is so freely communicated through water, they are easily heard above. One blow signifies 'more air;' two blows, 'stand fast;' three, 'leave up;' four, 'lower down;' five, 'to eastward;' six, 'to westward;' &c. These, of course, may be modified as agreed upon. Messages are also sent up, written on a label attached to a cord.

Diving-bell:  
a, section showing inside;  
b, top.

The sensations produced in descending are rather curious. Immediately on the mouth of the diving-bell striking the water, a feeling like a slight blow on the internal ear is produced; a dull ringing in the ears and a sense of deafness follows.

The workmen accustomed to subaqueous existence do not suffer these inconveniences; novices feel pains in the head and ears, but these pass away after a short initiation. It is stated that one man who had suffered from difficulty of breathing was completely cured by 'belling,' and that deafness is not produced by it, but, on the contrary, is in some cases relieved.

**DIVING-DRESS.** In Schott's *Technica Curiosa*, published in 1664, is described a *lorica aquatica*, or aquatic armour, which consisted of a leathern dress, to protect the diver from the water, and a helmet. In 1721, Halley describes a contrivance of his own of nearly the same kind; its object was to enable the diver to go out from the bell and walk about, he was to be provided with a waterproof-dress, and a small diving-bell, with glass front, as a helmet over his head, which was to be supplied with air by means of a tube from the diving-bell.

The modern diving-dress is made of Indian-rubber cloth; a strong metal helmet, with round pieces of plate-glass in front, rests upon a pad on the shoulders; the air is supplied to this helmet from above, in the same manner as for the diving-bell, but instead of the waste air passing out below, a second tube carries it up. Leaden weights are attached to the side of the diver, and thus he may descend a ladder and walk about below. He carries with him one end of a cord communicating with the assistants above, and by pulling this, as agreed upon, makes a series of signals.

**DIVING-ROD**—often called the *Virgula Divina*, the *Baculus Divinatorius*, the Caduceus or wand of Mercury, the Rod of Aaron, &c.—is a forked branch, usually of hazel, and sometimes of iron, and even of brass and copper, by which it has been pretended that minerals and water have been discovered beneath the surface of the earth. The rod, when suspended by the two prongs, sometimes between the balls of the thumbs, will distinctly indicate, by a decided inclination, it is alleged, the spot over which the concealed mine or spring is situated. Other powers are ascribed to the divining-rod, but this is the chief. Many men, even of some pretensions to scientific knowledge, have been believers in the occult power ascribed to this magic wand. Agricola, Sperlingius, and Kirchnmayer, all believed in its supernatural influence. So did Richelet, the author of the Dictionary. The learned Morhoff remained in suspense, while Thouvenot and Pryce, in the latter part of the 18th c., gave ample records of its supposed power. Bayle, in his Dictionary, under the word *Abaris*, gives some ingenious arguments both for and against the divining-rod. In a work published by Dr Herbert Mayo in 1847 and 1851, entitled, *On the Truth contained in Popular Superstitions*, he gave some curious illustrations of the art, supposed to be possessed by one in forty of the Cornish miners. At Weilbach, in Nassau, he likewise met with one Edward Seebold, who, he says, possessed the power, but afterwards lost it. Arthur Phippen, in 1853, published a pamphlet containing an account of two professional diviners or dowzers. One of them, named Adams, gave remarkable indications of being able to detect water underground. He not only was able to discover the particular spot where water might be found, he could even perceive a whole line of water running underground.

Scientific men, who have bestowed any care on

the examination of nature, regard this alleged power of the divining-rod as an unconscious delusion, ascribing the whole phenomenon to the effect of a strong impression on the mind acting through the agency of the nerves and muscles. See ANIMAL MAGNETISM.

**DIVISIBILITY** is that property of quantity, matter, or extension, through which it is either actually or potentially separable into parts. Whether matter is or is not indefinitely divisible, is a question which has occupied the minds of philosophers since very early times. See ATOM. There is no doubt that, abstractly speaking, it is indefinitely divisible. We cannot conceive any body or space so small but that we can subdivide it in imagination, and thus figure to ourselves bodies and spaces still smaller; and practically, we know that the subdivision of matter is carried in nature far beyond appreciation either by our senses or by calculation. The diffusion of odours through the air for long periods from odoriferous bodies without their suffering any sensible change of weight, and the tinging of great quantities of fluid by very minute portions of colouring matter, are cases commonly appealed to in proof of the extreme fineness of certain material particles; while, by experiment, it is shewn that there is no practical limit to the divisibility of even the most solid substances. Thus, an ounce-weight of silver, gilt over with eight grains of gold, has been drawn out into a wire 13,000 feet long, which was all its length covered with the gold; and a tube of glass presented to the blow-pipe has been drawn out till it became as fine as a silk fibre, or  $\frac{1}{25000}$ th of an inch thick, still retaining its character as a tube with a distinct interior and exterior surface. In fact, in theory, great and small are mere terms of relation; under the microscope, objects invisible to the eye appear of considerable bulk; and as Sir John Herschel, in his celebrated *Introduction to the Study of the Physical Sciences*, has put it, there is no reason why a mote in a sunbeam should not be in itself a world. With regard to the indefinite divisibility of space, it may be demonstrated geometrically; and perhaps, after all, it is the feeling that space is infinitely divisible, which compels our minds most strongly to resist the notion of ultimate atoms with definite forms, as conceived in the corpuscular theory.

**DIVISIBILITY**, in the Theory of Numbers, means the capability of any number of being divided by another without remainder. To find the condition of divisibility of one number, N, by another, D. Let  $N = b_m r^m + b_{m-1} r^{m-1} + \dots + b_1 r + b_0$ . See NOTATION. Then  $N = b_m (D + (r - D))^m + b_{m-1} (D + (r - D))^{m-1} + \dots + b_1 (D + (r - D)) + b_0$ . Expanding the different terms of the right-hand side of this equation, it will appear that  $\frac{N}{D}$  will be a whole number, if  $b_0 + b_1 (r - D) + \dots + b_m (r - D)^m$  be divisible by D. Hence, if  $r = 10$ , or the number be in the denary scale, and  $D = 9$ , and therefore  $(r - D) = 1$ , any number will be divisible by 9, if  $b_0 + b_1 + b_2 + \dots + b_m$  is so, or if the sum of its digits is divisible by 9.

**DIVISION**, one of the four principal rules of arithmetic, is that by which we find how often one quantity is contained in another. It is a compendious method of subtraction, by which we can at once take one number from another as often as it is contained in it. There are three numbers concerned in division: the dividend, or number to be divided; the divisor, or that by which the dividend is to be divided; and the quotient, or the number expressing how often the divisor is contained in the dividend.

The symbols of division are  $b) a$ ,  $\frac{a}{b}$ , or  $a \div b$ , where  $a$  is the dividend, and  $b$  the divisor.

There are various methods of division, such as the English, Flemish, Italian, Spanish, German, and Indian methods, which differ merely in the manner of arranging and disposing the numbers. The English method will be found explained in all the ordinary text-books of arithmetic. There are also rules of division for the division of integers, fractions, and algebraical quantities. The general rule for the division of vulgar fractions is, to multiply the one by the reciprocal of the other. The division of decimal fractions is performed in the same way as the division of integers. And, in algebra, division is practically performed as in arithmetic, either by making a fraction of the dividend and divisor, and reducing the numerator and denominator by the parts common to both, or else by dividing the former by the latter, after the manner of long division. See any text-book on Algebra. For division by logarithms, see LOGARITHMS.

**DIVISION, BENEFIT OF.** By the law of Scotland, co-cautioners are each ultimately liable for the whole debt which they have guaranteed. Each, however, is liable only for his own proportion, so long as the others are solvent, provided he has not expressly renounced that privilege, or is not bound conjunctly and severally with the principal debtor, and the debt must thus be divided amongst them. The law of division is not affected by the Mercantile Law Amendment Act; and it is therefore necessary, where there are more cautioners than one, that all should be proceeded against.

**DIVISION**, in Military matters, is one section of an army, indefinite in point of numbers, but established as a matter of convenience. It often comprises infantry, cavalry, and artillery, and is in effect a small army in itself, commanded by a general officer. In the Crimean war, for instance, a British division comprised two brigades, each of three or four battalions.

**DIVISION, NAVAL**, was a secondary group of ships in a large fleet, generally three to a squadron. In a very large and complete fleet, there might be as many as nine admirals or flag-officers commanding nine divisions, in three squadrons of three divisions each. The distinction of squadron has now been abolished, and individual ships are too gigantic to allow of large numbers being manœuvred in one fleet.

**DIVISION OF LABOUR**, or **DIVISION OF EMPLOYMENT**, a term often used by political economists to express a means by which labour is economised, or, as another method of stating the same result, by which production is increased. The problem in division of labour is so to adjust matters in any given community that each member of it shall work, or be able if he pleases to work, with the greatest possible results. In practice it is, like most other arrangements, apt to be too broad or too narrow. The old term, 'jack of all trades and master of none,' expresses the truth, that people who try too many things are not likely to be adepts in any. On the other hand, few people can do any sort of work to great perfection, unless it is part, as it were, of a group of functions for which they are more or less prepared. A good dentist will be in some measure a surgeon; a conveyancer or a special pleader will know something of the other departments of legal practice; a shipwright will be able, on occasion, to do other kinds of carpentry, and he will be the better of a general knowledge of the mechanical powers. That division of labour, in fact, which is really productive, is where a man who can do several things selects one as that which he can

do best, or has most opportunity of doing. By constant practice at that one thing, and the withdrawal of his attention from other matters, he achieves perfection and rapidity of execution. There is an important difference between this selection of a special pursuit, and the inability to do anything more than one thing, which is often confounded with it. In the former case, the worker, whether with head or hand, has great resources, for his adopted pursuit is the best, out of several others, on which he can fall back. The man who can do only one thing is in a precarious condition, because that one thing may be superseded. Indeed, as the one thing which can be so done is generally a very simple thing, it is almost a law in political economy that it will come to be superseded by machinery. Such was the fate of the hand-loom weavers, whose function, especially in the plainer and lighter fabrics, was too easy to last. Of the division of unskilled and easy labour, there is an excellent illustration in Adam Smith's description of pin-making: 'One man draws out the wire, another straightens it, a third cuts it, a fourth points it, a fifth grinds it at the top for receiving the head; to make the head requires two or three distinct operations; to put it on is a peculiar business; to whiten the pin is another; it is even a trade by itself to put them into a paper; and the important business of making a pin is in this manner divided into above eighteen distinct operations, which in some manufactories are all performed by distinct hands.' This division was doubtless useful, so long as pins were made entirely by human hands. It prompted serious inquiries, however, how far such functions were of an improving or a deteriorating character, and essays were written to prove that in manufacturing countries human beings were deteriorating, as no one of them had the faculty of self-support in separation from his fellows, and none could even make one single article by himself, all being dependent for their bread on a complex co-operation, which might break down any day. The answer to such fears may be found in the pin-making of the present day, where one man tends a machine, feeding it with wire at one end, while the pins drop out at the other. This, too, is the fruit of division of labour, for many skilful heads and hands have been occupied in bringing to perfection the different parts of the machinery. It is of the highest importance to the working-classes of a country, to keep in view that though the division of labour does sometimes create functions which, while they are extremely simple and easy, are of value as helping other functions to go on, yet this kind of easy and uniform work has no stability in it, and the possession of the facility for doing it acquired by practice is no permanent industrial endowment, since it is pretty sure some day to be superseded by machinery.

**DIVISOR.** See **DIVISION**. See also **PRIME NUMBERS**.

**DIVORCE**, is defined by a Scottish writer to be 'the disruption, by the act of the law, of the conjugal tie, made by a competent court on due cause shewn.'—Fraser, *Pers. and Domestic Relations*, i. 645. This definition correctly expresses the law of divorce as it now stands in the United Kingdom. There are some differences of detail in the working of the law in England and Scotland, which will be noticed below.

The desire to obtain a release from the matrimonial bond has existed at all times and under all legal systems. In heathen nations, this release was often granted on the slightest grounds. Even among the Romans, marriage was regarded as little more than a conventional union, to be observed so long

only as it suited the mutual convenience of the spouses. Christian nations, on the other hand, adopting as the basis of their systems the Scriptural law, as declared Matt. xix. 9, Mark x. 9-11, Luke xvi. 18, and 1st Cor. vii. 10, 11, are agreed in considering marriage a sacred tie, not to be dissolved except on the ground of unfaithfulness to the marriage vow. Even this limited ground for dissolution of marriage is denied by a large portion of the Christian world. By the civil law, as it existed for some centuries after Christianity, a greater laxity was allowed in regard to divorce. The Emperor Constantine was the first to prohibit dissolution of marriage by simple consent of the parties. This practice was again revived under the Emperors Theodosius and Valentinian; and though these emperors subsequently rescinded this edict, yet the rule as to the grounds on which marriage might be dissolved continued to fluctuate. By the canon law, marriage was regarded as a sacrament; and though marriages contracted in disobedience to certain rules might be declared null *ab initio*, a marriage validly contracted would not be dissolved except by papal dispensation. But the rule of the canon law was not uniformly adopted by the states of Europe, and it was not till the famous Council of Trent issued a decree, in its 24th session, in 1562, declaring marriage indissoluble even after the adultery of one or both of the parties, that a uniform rule on the subject was established. But before this decree was issued, the reformation had made progress throughout Europe, and thus a change again took place in regard to the law of divorce. It should be observed, that though by the canon law divorce *a vinculo matrimonii* was unattainable, parties might obtain a separation *a mensâ et thoro*. The nature of this remedy will be explained below.

Roman Catholic countries adopted the principle laid down by the Council of Trent, and this rule continues to be in force in most countries which are in the Roman Catholic communion. But by the Code Civile of France, divorce is allowable on the ground of adultery and certain other causes. Countries which adopted the reformed religion, have varied greatly in the rules established in regard to the question of divorce. In Holland, divorce is permitted on the ground of adultery and desertion. In America, the practice varies in different states. 'In several of them no divorce is granted but by special act of the legislature, according to the English practice; and in others, the legislature itself is restricted from granting them, but it may confer the power on courts of justice. So strict and scrupulous has been the policy of South Carolina, that there is no instance in that state since the revolution of a divorce of any kind, either by sentence of a court of justice or by act of the legislature. In all other states, divorce *a vinculo* may be granted by courts of justice for adultery. In New York, the jurisdiction of the courts as to absolute divorce for causes subsequent to marriage is confined to the single cause of adultery; but in most of the other states, in addition to adultery, intolerable ill-usage, or wilful desertion, or unheard-of absence, or habitual drunkenness, or some of them, will authorise a decree for divorce *a vinculo* under different modifications and restrictions.'—Kent, *Comm.* iv. 105. In England, previous to the passing of the late Divorce and Matrimonial Act, marriage was by the common law indissoluble. It was, indeed, competent to obtain a declaration of nullity of marriage on the ground of relationship, previous marriage of one of the parties, mental or physical incapacity, or coercion. But the judgment so obtained was not a

decree of divorce, but a declaration that the marriage tie between the parties had never really been contracted. A wife may now obtain a divorce on the ground of the husband's incestuous adultery; or of his bigamy with adultery; or of rape; or of sodomy; or of adultery coupled with gross cruelty; or of adultery coupled with desertion without reasonable excuse for two years. The husband may obtain a divorce on the ground of the wife's adultery. But neither party can obtain a divorce on the ground of mere desertion alone, however long continued. The court may order the husband to pay a divorced wife a certain sum for her maintenance during their joint lives. A decree of divorce does not come into full force until six months after it is pronounced. The bars to a divorce are condonation, connivance, or collusion. When divorced, the parties are at liberty to marry with third parties. When the divorce is on the ground of adultery, both parties may be examined as witnesses, 32 and 33 Vict. c. 68.

In Scotland, divorce may be obtained on the ground of adultery or wilful desertion. Immediately after the reformation, the courts in Scotland recognised the right of either spouse to obtain a divorce on the ground of adultery. And in the year 1573, a statute was passed declaring that, in case either husband or wife should desert without due cause for four years, the injured party might raise an action of adherence, and, in case redress was not obtained, a decree of divorce might be pronounced. In Scotland, it is not permitted that a marriage should take place between the offending parties. The effect of a decree of divorce on the pecuniary interests of the parties, is to cause the offender to forfeit all benefit which might accrue to him or her from the marriage. Separation *a mensâ et thoro* may also be obtained in Scotland on the ground of ill-usage, and perhaps desertion (q. v.). Condonation and collusion, but not recrimination, are, in Scotland, a bar to obtaining a dissolution of marriage on the ground of adultery.

**DIVORCE AND MATRIMONIAL COURT.** Vic. c. 103, 23 and 24 Vic. 144, and amending acts, changed the law of England on the subject of divorce. By the first of these acts, the jurisdiction in divorce causes is transferred from the ecclesiastical courts to a new court constituted for the purpose. The court is composed of a judge ordinary, the three chiefs in the courts of common law, and three puisné judges. It is provided that either spouse may obtain a divorce on the ground of adultery, but in case the wife is petitioner, the adultery must be accompanied by cruelty or desertion. By 23 and 24 Vic. c. 144, the power to pronounce a decree of divorce, which was at first reposed in the whole court, is given to the judge ordinary sitting alone; but in this case the decree so pronounced is a decree *visi*, and cannot become final for at least six months. After decree of divorce, the offending party is free to marry again even with the paramour. But it is enacted, 20 and 21 Vic. c. 85, sec. 57-58, that no clergyman shall be compelled to solemnise the marriage of any person who has been divorced. He must, however, allow another clergyman, if willing to do so, to perform the marriage. A party applying for a divorce will not be allowed to obtain judgment, should it appear that he or she has been guilty of recrimination by committing the same offence, or that there is collusion between the parties in order to procure the divorce. Parties also who have condoned the offence—that is, who after it has been discovered have consented again to live as husband and wife—will not be allowed to obtain a divorce. In order to guard against fraud by parties conniving to procure

a divorce, power is given to the Queen's proctor, by 23 and 24 Vic. c. 144, to interpose, in case he have reasonable ground to suspect collusion or recrimination, in order to oppose a petition for divorce. By these acts, parties are also entitled to obtain a judicial separation on the ground of adultery, cruelty, or desertion. Judicial separation is declared to be in place of a separation *a mensa et thoro*. A married woman, having obtained decree of judicial separation, is declared to be in all respects as a *feme sole* in regard to any property that she has or may acquire. Even before obtaining a separation, a woman deserted by her husband may obtain from the court a protection for any property which she may acquire by her own industry.

From the conflict of laws in various countries on the subject of divorce, questions have frequently arisen as to the competency of a sentence of divorce by a tribunal having power according to the *lex loci* to pronounce such sentence, to annul a marriage contracted in a country where such divorce is not allowed. It appears now to be the generally received opinion, that wherever parties are domiciled they will be allowed to avail themselves of the laws of this domicile. But the courts will not recognise a transient visit to a foreign country as sufficient ground to sustain a divorce. On the subject of this article, see Paterson's *Compendium of English and Scotch Law*, Fraser's *Personal and Domestic Relations*, and Swabey *On the Divorce and Matrimonial Act*.

DIXON, WILLIAM HEPWORTH, an English author, was born in the West Riding of Yorkshire in 1821, and settled in London in 1846, where he soon acquired a considerable reputation by his writings. A series of papers, published in the *Daily News*, 'On the Literature of the Lower Orders,' and another on 'London Prisons,' attracted considerable attention. The latter reappeared in a volume published in 1850. Before this, but in the same year, he published *John Howard, and the Prison World of Europe*. It was with difficulty he could induce a publisher to accept it, yet when published, it went through three editions in one year. D. now devoted himself principally to historical biography. In 1851, appeared the first edition of his *William Penn*, a work called into existence by the onslaught made by Macaulay on the eminent Quaker, in which D. undertook to disprove Macaulay's charges. In 1852 was published his *Life of Blake*; and in the same year an anonymous pamphlet, entitled *The French in England*, the design of which was to allay the fear of a French invasion which at that time was pretty general. In 1853, D. was appointed editor of the *Athenæum*—a chair he vacated in 1869. In 1860 he published his *Life of Lord Bacon*. In 1863 he published the *Holy Land*. He gave the public *New America* in 1867; and in 1868, *Spiritual Wines*. *Free Russia* appeared in 1870, and *The Switzers* in 1872.

DIXON'S ENTRANCE, a strait of 100 miles in length from east to west, on the north-west coast of America, divides Queen Charlotte Island on the south from the Prince of Wales Archipelago on the north. It is, therefore, of some political importance, as separating the British possessions in this quarter from those of the United States. Lat. 54° 30' N., and long. 132° W.

DIZFUL, a town of Persia, on the river Dizful, in lat. 32° 10' N., and long. 48° 34' E. It is the capital and principal mart of its province (Khuzistan). A handsome bridge of twenty arches crosses the river here. The foundation is of stone and of ancient date, the upper portions are of brick and are modern. Pop. estimated at 15,000.

DIZIER, Sr, a town of France, in the department of Haute-Marne, 10 miles north of Vassy, is situated on the Marne, which here begins to be navigable. It is a very long and narrow, but well-built town, the streets being wide, clean, and regular. In 1544, D. resisted for a month the assaults of a Spanish army under Ferdinand de Gonzaga; a resistance of the greatest consequence to the French ruler, Francis I., the delay enabling him to collect his forces to oppose the march of the Spaniards upon Paris. In 1814, the French twice defeated here the invading army of the allies. The chief industrial features of the place are iron forges and foundries, boat-building yards, in which a great number of river and canal boats, generally of about 100 tons, are constructed, and cotton factories. There is also a considerable trade in wood, iron, and grain. Pop. (1872) 8167.

DJEZZAR, i. e., *Butcher*, the name given, on account of his cruelty, to Achmed Pasha, famous for his obstinate defence of Acre against Napoleon I. He was born in Bosnia about 1735, and rose, through murder and treason, from the condition of a slave to the pashalic of Acre. In the beginning of 1799, the French entered Syria from Egypt, and advanced from victory to victory till they reached Acre, which was laid siege to on the 20th March. By the advice of Colonel Philippeaux, a French emigré, and of Sir Sydney Smith, the commander of the British fleet in the Levant, D. was induced to hold out; and such was the savage doggedness of his resolution, that Bonaparte was obliged to retire on the 21st of May. It is said that during the siege he sat on the floor of his palace surrounded by a heap of gory skulls, distributing money to all who brought in the heads of Frenchmen. He died at Acre in 1804. D. was at times maniacal in his cruelties. He whipped off the heads of his wives without the slightest ceremony—seven at a time! But he had also moments of remorseful tenderness, in which he helped the poor and provided for those he had injured. He is said to have possessed the sharpest discernment, and was a very vigorous ruler.

DMITROV, an ancient town of Russia, on the Jakhrama, an affluent to the Volga, 40 miles north of Moscow. It covers a large area, a considerable part of which is occupied by gardens, but as a whole is poorly built. It contains a college and seven churches, and has manufactures of silk and cotton goods, tanneries, &c. Pop. (1867) 8042.

DNIEPER, one of the large rivers of Europe, has its source in certain swampy forest-lands in the north of the Russian government of Smolensk. Its general direction, till it reaches Kiev, is south. From Kiev, its course is south-east to Ekaterinoslav, where it turns directly south past Alexandrovsk, below which town it sweeps round to the south-west, and pursues that direction until it debouches in the Black Sea, between the governments of Kherson and Taurida, its embouchure forming a gulf of about 50 miles in length, with a breadth of from 1 to 6 miles. Its principal affluents are the Desna and Soj from the east, and the Pripet, the Beresina, and the Druz from the west. The total length of the D. is upwards of 1000 miles, and it is navigable almost from its source, its breadth at Dorogobush, about 50 miles below its source, being 210 feet. Some of the finest governments of the Russian empire lie within its basin, with all of which its navigable branches and canals enable it to hold communication. In its upper part, it flows through a marshy forest territory; its middle and lower course is rocky. Below Ekaterinoslav, indeed, there are no less than 13 rapids in

the course of about 40 miles; but these impediments to navigation have been overcome in part by blasting, and by splendid hydraulic-works erected by the Russian government. The produce of the provinces, consisting for the most part of corn, timber, iron, salt, hemp, and linen, are usually conveyed down the river to ports on the Black Sea, but many vessels pass annually from the D. to the Baltic by the Beresina and the Dwina. At Smolensk, the waters of the D. are frozen from November to April; at Kiev, they are ice-bound only from January to March. Sturgeon, carp, and pike abound in the river. As the *Borysthenes* the river was known in the 7th c. before Christ to the Greeks, who regarded it as the most valuable river on earth next to the Nile.

DNIESTER, a river of Europe, flowing chiefly through Russia, but having its rise in the Carpathian Mountains, in the Austrian crown-land of Galicia, about lat. 49° 10' N., long. 23° E. Its general course, until it reaches the Russian territory, is south-east; it then runs east for a short distance, and thence south-south-east, forming the boundary between Bessarabia and Kherson, past Mohilev, Dubossari, and Bender, to the Black Sea, which it enters by a shallow shore lake, 19 miles in length and 5 in breadth, between Akerman and Ovidiopol. The total length of the D. is between 500 and 600 miles, its current throughout being very rapid. Until it reaches the Russian frontier, its right bank is skirted by offsets from the Carpathians; but at that point, the country, which above has been level on only one side, opens into a broad flat plain, through which the river, broken at intervals by masses of rock, rushes muddy and turbid. The downward navigation is interrupted by a series of falls and whirlpools. Wood and grain are the chief products conveyed down the river.

DŌĀ'B, a word of Sanscrit origin, signifying primarily 'two rivers,' but applied, like the Gr. *Mesopotamia*, and the Lat. *Intervallum*, to the country between two rivers. The two roots of the word are common to all the Aryan languages: the first appears in Lat. *duo*, Eng. *two*; the second in Celt. *avon*, a river, and in Danube or *Donau*. Punjab ('five rivers') is a term of the same kind; but while Punjab exists merely as a proper name of one particular region, Dŏāb is used as the common appellation of any region in general that fulfils the conditions. When introduced, however, without local reference of any kind, the Dŏāb means the space enclosed by the Jumna on the south-west and the Ganges on the north-east—a space extending from Allahabad to the base of the Himalayas, a distance of upwards of 500, with an average breadth of 55 miles. The fertility of this region has been much increased by the Ganges Canal (q. v.).

DŌ'BCHICK. See GREBE.

DOBELL, SYDNEY, a living English poet, was born in London in 1824. His father, who was a wine-merchant, removed to Cheltenham in 1835. Here D., whose education was entirely private, lived till 1850, when the *Roman* was published, and received with favour by the literary world. After the publication of this poem, D. resided for some time in Switzerland. Shortly after his return, the delicate state of his wife's health brought him to Edinburgh, where he remained till 1857. He now resides on the Cotswold Hills, near Gloucester. Besides the *Roman*, D. has published *Baldur* (1854), *Sonnets on the War*, in conjunction with Mr A. Smith (1855), and *England in time of War* (1856). His poems exhibit a singular mixture of the philosophical and the poetical spirit. Many of his

passages are as spiritual in conception and lavish in imagery as the finest portions of Shelley; others, again, are as obscure, intricate, and involved as the rhymed enigmas of Cowley or Donne. In 1865, D. published a pamphlet on parliamentary reform, in which he advocated a graduated suffrage and plurality of votes; and in 1871, *England's Day*—one of the best of his lyrics—a defiance thrown at Bismark, President Grant, and Gortschakoff.

DŌBELN, a town of Saxony, 36 miles south-east of Leipzig, is pleasantly situated on an island formed by the Mulde. It is well built, and contains a richly endowed hospital. Its chief manufactures are linen, woollen, and cotton cloth, brass-ware, and hats. D. has also several bleach-fields and worsted-mills. Pop. (1871) 10,078.

DOBROW'SKI, JOSEPH, the founder of Slavic philology, was born August 17, 1753, at Gyermet, near Raab in Hungary, where his father, a Bohemian by birth, was stationed in garrison. He studied at the gymnasium of Deutschbrot, and subsequently at Klattan and Prague. In 1772 he entered the order of the Jesuits at Brünn, but on its dissolution ten months after, he returned to Prague, to continue his theological studies, and in 1776 became tutor in the family of the Count von Nostitz. During the years 1780–1787, he edited a critical journal of Bohemian and Moravian literature. This soon involved him in various strifes, and ultimately the review was 'stopped' by the authorities, but not before it had added largely to D.'s reputation. In 1792, at the expense of the Royal Bohemian Scientific Society, he made a journey to Denmark, Sweden, and Russia, to search after the fate of those Bohemian books and MSS. which the Swedes had carried off from Prague during the Thirty Years' War. Two years after, he travelled through Germany, Italy, and Switzerland. On his return, he manifested symptoms of a disordered mind, and in 1801 had to be confined for some time. He speedily recovered, but was subject to intermittent fits of insanity until his death, which happened January 6, 1829. D. is reckoned one of the highest, if not the very highest, authority on all matters connected with Bohemian history and literature. His principal productions are—*Scriptores rerum Bohemicarum* (Prag. 2 vols., 1783–1784); *Geschichte der Böhm., Sprache und ältere Literatur* (Prag. 1792); *Die Bildsamkeit der Slaw. Sprache* (Prag. 1799); *Deutsch-Böhm., Wörterbuch* (2 vols., Prag. 1802–1821), in which he was largely assisted by other eminent Bohemian scholars; *Lehrgebäude der Böhm.-Sprache* (Prag. 1809); and *Institutiones Lingue Slavonicæ Dialecti Veteris* (Vienna, 1822), probably his most important work. D. wrote only in German or Latin, being of opinion that the Bohemian language was not a suitable vehicle for the expression of learned inquiry.

DOBRU'DSCHIA (anciently, *Scythia Minor*), a name used to denote the north-eastern portion of Bulgaria (q. v.). It is separated by the Danube from Wallachia on the west, and from Moldavia on the north; is bounded on the east by the Black Sea, into which its northern extremity stretches; while towards the south its limits are not clearly defined. The D. has long been a famous battle-ground. Some of the earliest incidents of the Russian war of 1854–1856 took place here.

DOCETÆ (from the Gr. *dokēō*, to appear or seem) was the name given in the early church to those heretics who held that the human nature of Jesus Christ was a semblance and not a reality. The philosophers of polytheism, as well as of Judaism, had explained the appearances of divinities

and of angels by holding that the assumption of bodies was only momentary, or in appearance. And when the Gnostic Christians found it impossible to conceive the essential union of the divine nature with a body composed of matter, which they held to be the seat of all evil, they had recourse to the same expedient. The difficulty was got over in one of three ways: the body of Christ was either considered a real earthly body, but not belonging essentially to his nature, and only assumed for a time; or it was declared to be a mere appearance or illusion; or, finally, it was believed to be a heavenly body, composed of ethereal substance, though having the appearance of being material. All the Gnostic heretics held Docetism in one or other of these three forms, with the exception of those who were led by the same difficulty to deny the divine nature of Jesus Christ, and reduce him to a mere human sage. While the first of these alternative forms of heresy seems to have completely died out, the last, under various names, has continued to the present time. For a clear and learned account of Docetism, consult Neander's *Dogmengeschichte* (History of Doctrine). English by J. E. Ryland; published by H. G. Bohn, in 2 vols., 1858.

**DOCK** (*Lapathum*), a sub-genus of the genus *Rumex*, the other species of which are generally called **SORREL** (q. v.), containing those which are not acid, and of which the flowers are hermaphrodite. They are large perennial herbaceous plants, natives chiefly of temperate climates, with large generally lanceolate or ovate leaves, and panicles of small greenish flowers. They have great tap-roots, and are with difficulty eradicated from pastures. They also multiply rapidly by seed. The best mode of dealing with them, is generally found to be repeated cutting away of their leaves and shoots, by which the plants are killed. Many of the species prefer watery places. A number are natives of Britain, and several of the European ones have found their way to North America, where they have become troublesome weeds, a number of really indigenous species being also found there. Useless and even troublesome as the D. is generally esteemed, yet the large astringent roots are capable of being beneficially employed in medicine; and those of the great Water D. (*R. hydro-lapathum*) in particular—for which the Druids entertained a superstitious veneration—are administered as an antiscorbutic. They are also employed in rheumatism, and sometimes as a styptic, sometimes to form an astringent gargle, and sometimes as a dentifrice. *R. alpinus* is called **MONK'S RHUBARB**, and its root was formerly employed instead of rhubarb, but is less powerful. It is a native of the Alps, and has been found in several places in Britain.—The roots of docks have been sometimes used in dyeing, and give a great variety of shades, from straw-colour to a pretty fine olive, and a fine deep-green to cloths which have been previously blued.

**DOCK**, an enclosure for the accommodation of shipping, and of which there are three kinds—viz., wet or floating; tidal, which may with more propriety be called harbours or basins; and dry or graving. Wet Docks are for the purpose of maintaining a level nearly uniform with that of high-water, so as to keep vessels always afloat, and to save them from rubbing up and down the quays with the rise and fall of the tide, and being sometimes too high and at other times too low for convenience in shipping or discharging cargoes.

Wet docks are generally surrounded by quay or wharf walls of masonry or brickwork, but where

they are wanted chiefly for laying up vessels in, and not for loading or unloading, their margin is sometimes only a natural sloping beach. They are of most importance in places where there is a great rise and fall of tide, such as at Bristol or Liverpool, where they are almost indispensable; while, again, in the Clyde, where the tides are small, they have not yet been used, though they have been projected at Glasgow for many years past. Wet docks are generally entered by means of what is called a lock (see Lock), having two gates, in one leaf, or more frequently in two folding-leaves each, which enables vessels to enter or depart for a considerable time before and after high-water; but frequently, for the sake of economy both in space and in cost, they have only one gate, so that vessels can only enter or depart at or very near high-water, unless the water in the dock be run down considerably below that level.

The water in wet docks is sometimes kept, by means of pumping, permanently at as high a level as that of the highest tides, when a supply of pure water can be procured, to prevent the silting caused by the admission of any considerable body of turbid water by the gates, but that involves the necessity of locking up or down always except at the highest tides. The tendency to silt up by deposits of fine mud is of common occurrence, and dredging, or some other plan, must be resorted to for the purpose of keeping the dock reasonably clear. In almost all cases, wet docks require to be occasionally emptied for the purpose of cleaning.

Dock-gates are generally opened and shut by means of chains worked by hand, either by winches or capstans; but of late years they have in some cases been moved by hydraulic machinery, as at Great Grimsby, the Victoria Docks in the Thames, and Albert Dock, Leith.

Tidal docks require no particular description; they are merely basins surrounded by quay walls, and having open entrances permitting the free flow and ebb of the tide, as at Greenock and Troon, and they have the advantage of requiring no opening or shutting of gates. With small tides, they answer very well, and they are sometimes made deep enough to keep vessels afloat at low-water; but with tides of considerable range they are attended with the disadvantage of large vessels grounding at low-water, and from the large volume of water, generally more or less turbid, which enters at every tide, they are much more liable to silt up than wet docks are. For ridding them of muddy deposits, the plan is sometimes resorted to of letting out a reserve of water with a sudden gush from an enclosure at the inner end, at the time the tide has receded. This is called scouring. Such is the process pursued at Boulogne and elsewhere.

The quays of wet and of tidal docks must have mooring-ports or rings for making vessels fast to.

Plan of Dry Dock.

## DOCK WARRANTS—DOCK-YARD BATTALIONS.

They are generally provided with sheds to keep goods dry, with cranes (see *HYDRAULIC CRANE* in *SUPP.*) for shipping or unloading heavy articles, and with staiths or drops in the case of coal-shipping ports, and now they very frequently have rails laid along them.

Dry docks are used for the purpose of laying vessels dry for examination or repairs. They may have their entrance either from a wet dock or from a tidal harbour; but the former is by much the better arrangement, as it admits of vessels being docked or taken out at any time of tide, and it keeps a more equal pressure on the gates, thereby making them less liable to leak. They require to be built of good water-tight masonry. The entrance has generally a pair of folding-gates pointing outwards, to exclude the water; but sometimes it is closed by means of a caisson—viz., a vessel shaped something like the hull of a small ship, and having a keel and two stems, which fit into a groove in the masonry. The caisson is sunk into the groove by admitting water into its interior, and is floated out again by pumping out the water. When the tides are very large, the bottom of the dock may sometimes be placed above low-water, so that it may be run dry without pumping; but generally the bottom of a dry dock for the reception of any but very small vessels is below that level, in which case a steam-engine and pumps, with a well and water-channels leading to it, are required for emptying the dock.

Section of Dry Dock.

The floor is nearly level, and the keel of the vessel to be docked rests on wooden blocks fastened down to prevent them floating, and of such a height as to admit of the shipwrights getting under the vessel's bottom. Side-shores are put in, to keep the vessel in an upright position, and blocks are fitted in under the bilges as soon as possible after the water has been got out of the dock. The sides generally consist of stone steps called altars, for the purpose of fixing the lower ends of the shores, and also for the convenience of supporting the workmen's scaffolds. Dry docks are frequently made long enough to hold three or four vessels of considerable size at one time, in which case they are placed, not in the centre line of the dock, but obliquely across, so as to give more available length.

The use of the graving dock is frequently superseded by that of Morton's patent-ship. See *SLIP*. Graving-docks of large dimensions are very expensive works, and the difficulty of making them water-tight is very great. In many cases, therefore, recourse is had to a pontoon or floating-dock, sometimes termed a 'camel.' See *FLOATING-DOCK* in *SUPP.* The use of the floating-dock, together with the application of hydraulic pressure for the raising of ships, is to be seen at the 'Thames Graving-Docks,' where there are two rows of cast-iron columns, five

feet diameter, and 16 in each row. The rows are 60 feet apart, and the practical working length is 350 feet. Each column encloses a hydraulic press of 10 inches diameter, with a length of stroke of 25 feet. There are cross-heads on the top of each ram, from the ends of which cross-girders extend across the dock to the corresponding column on the opposite side, which girders form a large wrought-iron gridiron or platform, which is raised or lowered at pleasure with the vessel upon it. When a vessel is to be repaired, an open pontoon is selected to suit its dimensions, which is sunk in position to the bottom of the dock, and resting on the iron gridiron. After the vessel is floated over the pontoon, the whole is raised by the hydraulic presses, and the pontoon being emptied of water, sustains the weight of the vessel to be repaired, and is then floated away into some convenient part of the dockyard.

Liverpool has twenty graving-docks, many of them being 600 feet, and some even 750 feet in length. No docks in the world are on so splendid a scale as those of London, Liverpool, and Birkenhead, which are of immense area, covering hundreds of acres. Surrounded with substantial stone quays, provided with gates, placed under a proper police, and otherwise managed in a costly manner, these, as well as nearly all other docks in Great Britain, require to be supported by rates levied from the vessels resorting to them; and for levying these rates, powers are taken in the acts of parliament authorising the construction of the respective docks. Sometimes the dock dues or rates are imposed on vessels in bulk according to tonnage, and in other instances, the rates are so much per ton, according to the nature or value of the goods. See *McCulloch's Commercial Dictionary*. Generally, the dues are complained of as being a heavy burden on commerce; but so enormous is the cost of constructing docks, that the joint-stock companies by which they are for the most part owned, do not often realise good returns for their investments. The most remarkable circumstance connected with English docks, is the rapid extension of the dock-system on the Mersey at Liverpool. The original old dock contained an area of 3 acres 1200 yards, and 557 lineal yards of quay space. The total quay space of 1873 was 16 miles 1489 yards.

**DOCK WARRANTS** are orders or authorities for the removal of goods and merchandise warehoused in the various docks. The orders are granted by the proper officer at the docks, on application of the importer, in favour of any one whom the latter shall name. Careful rules as to obtaining warrants are laid down by the East and West India Dock and the London Dock Companies. These rules are, in a great measure, followed by the other dock companies in the kingdom. Unless the rules are complied with, goods will not be delivered from the docks. Warrants may be obtained for either the whole or a part of a cargo consigned. A warrant may be assigned by the holder. A single warrant may also, at the desire of the holder, be divided into smaller warrants, and these also may be assigned. In case a warrant is lost, a new warrant will not be issued till the loss has been advertised, and the holder furnish the company with an engagement to indemnify them for any loss which may arise.

**DOCK-YARD BATTALIONS**, prior to the establishment of volunteer corps, formed a special element in the British military service, intended chiefly for the defence of the royal dock-yards. It was in 1847 that an item first appeared in the estimates of £20,000 for training and exercising about 9000 men in these battalions. Clerks, artisans, and

labourers formed the body. The colonel was a naval officer, and commissions were given to the other officers. The men received remuneration for the time lost in drilling. A few hours per week in summer were set apart for drilling under the management of sergeants and corporals of marines. At first, the enlistment was voluntary; afterwards, compulsory. These battalions were abolished in 1861.

**DOCK-YARDS, ROYAL.** Under the names of the several towns where the royal dock-yards are situated, will be found brief notices of those establishments. Under the present heading, a few remarks may be useful concerning the whole of them collectively.

Most of the royal ships are built by the government, at one or other of the dock-yards at Portsmouth, Plymouth, Sheerness, Chatham, or Pembroke. Each of these establishments comprises covered slips on which the ships are built, docks in which they are kept, and all the appliances for rigging them out for sea. Boat-building and mast-making are also carried on; and in some, though not all of the yards, rope-making, sail-making, anchor-forging, block-making, and other manufacturing operations connected with the finishing and furnishing of ships. There are also arrangements connected with the storing of guns and other munitions of war. The yards at Plymouth, Gosport, and Deptford are limited to large establishments for victualling the navy; while, of the dock-yards proper, some have appliances for supplying seamen's clothing and necessaries; some for repairing steam-machinery for war-steamer; one (at Chatham) for making most of the articles in copper and brass required by the navy. Since the creation of a steam-navy, and the large substitution of iron for wood in ship-building, an increasing proportion of the royal ships are built in private yards. All the dock-yards are under the Admiralty, and each is governed by a distinct set of officers responsible only to that department. The chief officer, called the superintendent, is generally an admiral, but sometimes only a captain; and the office is deemed an honourable recognition of past services. The superintendent controls all the other officers, and all the artificers and labourers employed; examines the accounts, authorises the payments, and is responsible for the stores. When a new ship is to be built, or other work executed, the superintendent receives general instructions from the Admiralty, while special instructions are conveyed to other officers more immediately concerned with the actual working. In those yards where steam-machinery is repaired and fitted, engineers form an important part of the establishment. The artisans of the dock-yards comprise shipwrights, calkers, joiners, sawyers, smiths, millwrights, blockmakers, riggers, sailmakers, ropemakers, &c.; while under these is a large body of labourers.

Without entering into detailed items, mention may be made of the following provision for the dock-yards, for the year 1873—1874: £133,502 for salaries to superintendents, clerks, &c.; wages of artificers and labourers, £885,691; sundry charges, £95,887. These charges are exclusive of all materials, and are for the dock-yards only, as distinguished from the victualling yards. The materials for ship-building and steam-machinery were set down at £1,072,350.

The management of the royal dock-yards is considered to be very defective. Several committees and commissions have been appointed, in recent years, to investigate the causes of the defects, and to suggest remedies; and the reports issued on the subject are engaging the attention of the government and the legislature.

**DOCTOR** (Lat. *docēre*, to teach), a teacher. Originally, the word doctor was used, in accordance with its etymological derivation, to signify a teacher in general, and it was not till the 12th c. that it became a title of honour for the learned, irrespective of the function of communicating knowledge. It had frequently appended to it, in those early days, some additional expression intended to characterise the peculiar gift of its possessor. Thus, Thomas Aquinas was called the Doctor Angelicus; Bonaventura, the Doctor Seraphicus; Alexander de Hales, the Doctor Irrefragabilis; Duns Scotus, the Doctor Subtilis; Roger Bacon, the Doctor Mirabilis; William Occam, the Doctor Singularis; Gregory of Rimini, the Doctor Authenticus; Joseph Gerson, the Doctor Christianissimus; Thomas Bradwardine, the Doctor Profundus; and the like. The word had long been used, even in the universities, as a general expression for a teacher before it came to designate a degree or rank in the learned hierarchy to which only the united body of the teachers could advance or promote the candidate. These formal promotions commenced at Bologna in the 12th c., and the learned Irnerius, the regenerator of the Roman law at that period, is said to have introduced the ceremonial which was afterwards universally adopted. Irnerius, however, is a sort of mythical hero in university history, and such statements with regard to him must be received with caution. See **PROMOTION**. The university of Paris almost immediately followed in the footsteps of Bologna, the first reception of doctors having taken place in the year 1145, in favour of Peter Lombard and Gilbert de la Porrée, the greatest theologians of the day. Subsequently to this period, the emperors were in use expressly to confer upon the universities the right of appointing doctors of laws by their authority and in their name. The example of the emperors was speedily followed by the popes, who conferred corresponding rights with reference to the canon law. From the 11th to the 13th c., there seems reason to believe that, both in Italy and France, the terms master and doctor were pretty nearly synonymous. In the German universities, the professors of theology were more commonly known as masters; and in the beginning of the 15th c., in accordance with the practice of the university of Prague, the distinction was pretty consistently made between doctors of law and medicine, and masters of theology and philosophy. In modern times, the title of Doctor has been applied almost everywhere to the three faculties of Theology, Law, and Medicine. In Germany, it extends to that of philosophy, in which, in this country, the older title of Master is still retained. The doctor's degree is, in general, conferred at the instance of the dean of the faculty to which it appertains. It is granted either on examination, and after the ancient form, at least, of publicly defending a learned thesis in Latin has been observed, or else it is an honorary degree, conferred in consideration of the general reputation of the recipient for eminence in some particular branch of learning, philosophy, or science. See **DEGREE**. In Germany, the doctor ranks before the untitled nobility and next to the knight; and amongst themselves, doctors take the rank of the faculties to which they respectively belong, the first being theology, the second law, and the third medicine. In Oxford and Cambridge, and recently also in the German universities, doctors of music have been created. In the latter country, also, learned ladies have occasionally shared the honours of the doctorate. Dorothea Schlözer received the degree of doctor of philosophy from the university of Göttingen in 1787; Mariano Charlotte von Siebold, that of medicine from Giessen in 1817; and Johanna Wittenbach, in philosophy,

from Marburg in 1827. Of the four ancient degrees of Bachelor (q. v.), Master of Arts (q. v.), Licentiate (q. v.), and Doctor, the modern university of France has retained only those of bachelor, licentiate, and doctor. Up to the period of the revolution, the highest consideration attached to the title of Doctor of the Sorbonne (q. v.)—that famous theological faculty, which was called 'the perpetual council of the Gallican church,' and of which the present faculty of theology of the Academy of Paris is but a feeble and lifeless reproduction. But though the degrees of the Sorbonne continued to enjoy, and apparently to merit, some degree of respect, such was by no means the case with those of the other schools of learning in France. Furettièrre, in his Dictionary, defines a bachelor as a man who learns, and a doctor as a man who forgets. The ridicule of Voltaire, La Fontaine, Le Sage with his Doctor Sangrado, and Molière in the *Malade Imaginaire*, will readily occur to our readers as illustrating the position which was then held very generally by French doctors.

In England, the doctor's degree was not introduced into the universities till the reign of John or of Henry III. At first it was a very rare and highly prized honour, and the ceremony of conferring it was attended by scenes of feasting and revelry, of which curious accounts will be found in Antony à Wood's *History and Antiquities of the University of Oxford*. Coloured engravings of the dresses worn by doctors of the several faculties at Oxford and Cambridge are given in Ackermann's Histories of these Universities. As to professional uses of the degree of Doctor of Civil Law, see DOCTORS COMMONS.

**DOCTORS COMMONS**, formerly the college of the doctors of civil law in London, wherein the Court of Admiralty and the principal ecclesiastical courts were held. It was founded by Dr Henry Harvey, Dean of the Arches, previous to which time the doctors had lived in Paternoster Row. The original building was burned in the great fire in 1666, when the doctors removed for a time to Exeter House. After some time the Commons was rebuilt, and the doctors returned to their former quarters. The courts which have been wont to hold their sittings at Doctors Commons are—the Court of Arches, the Archdeacon's Court, the Prerogative Court, the Faculty Court, the Court of Delegates, and the Court of Admiralty. The Prerogative Court is now amalgamated in the Probate Court (q. v.), and the Court of Delegates (q. v.) is transferred to the Judicial Committee of the Privy Council. At the time when these courts were all in full operation, their times of session were regulated by terms, as in the courts of equity and common law, a certain day in the week being assigned to each court for hearing its causes. The Court of Arches, the Archdeacon's Court, the Faculty Court, and the Court of Admiralty, are now the only courts which continue to exercise their functions in this once famous spot. The Court of Arches (so called from having sat in *Archebus*, or under the arches or bows of Bow Church, Cheapside) is the court of appeal belonging to the Archbishop of Canterbury. The judge in this court is styled Dean of the Arches, and he has jurisdiction, as the archbishop's principal official, in all ecclesiastical causes within the province of Canterbury. He has original jurisdiction, also, in certain causes by *Letters of Request* (q. v.). It was by virtue of letters of request that matrimonial causes were tried in the Court of Arches; but this branch of its jurisdiction is now removed to the Divorce Court (q. v.). The Archdeacon's Court is an inferior court for the consideration of ecclesiastical questions occurring within the archdeaconry. For an account of the other courts mentioned in

this article, see the several heads to which they refer. The practitioners in the several courts to which we have alluded were the doctors of civil law, called in the ecclesiastical courts advocates and proctors, who performed similar duties to those of attorneys or solicitors in the courts of law and equity. Both classes of practitioners required, in order to their admission to practice, to obtain the fiat of the Archbishop, and afterwards to be duly admitted by the Dean of the Arches. The form of admission was in both cases attended with much ceremony. The doctor elect was introduced to the presiding judge by two doctors habited in their scarlet robes. The candidate then made a short Latin speech, and was admitted to practise in the courts. The habit of the doctors is a scarlet robe with a hood, which, in case the doctor be a graduate of Oxford, is bound round with taffeta. If he belongs to the University of Cambridge, it is trimmed with white miniver. The proctors were, in like manner, introduced by two senior proctors. Their dress is a black robe with a hood lined with fur. A proctor could not take a clerk till he had been a numerary for five years, and he was not entitled to take a second till the first had performed five years of service. The number of doctors and proctors has varied much at different periods. In the year 1694, the number of the former was limited to forty-four, and of the latter to forty-three. For a full account of Doctors Commons, see Stowe's *London*.

**DOCTRINAIRE** (a French term derived from doctrine) signifies, properly, the scientific talking up and exposition of a subject, as opposed to a treatment which is merely external, and which rests on accidental characteristics. In general, however, it is used as a term of reproach, to characterise views which are pedantic, schoolmasterly, and unpractical. In this sense it was applied in France, during the Restoration, by the reactionary court-party to the fraction of the parliamentary opposition, who supported scientific doctrines of constitutional liberty against the arbitrary will of the monarch. This party, which had its rallying-point in the salons of the Duc de Broglie, was led in the chamber by Royer Collard, and supported in the press and before the public by Guizot, and the younger members of what afterwards became the Orleans party. The development of the constitution on the basis of the *charte* of Louis XVIII., was the watchword of those men; but their real inspiration was derived from England. When the revolution of 1830 occurred, they became the advisers and ministers of the king of the French, and were more deeply imbued with the principles of constitutional monarchy than any other political party that has ever existed in France. The true fathers of the *doctrinaires* were Mounier, Lally Tollendal, Clermont Tonnerre, Talleyrand, and the Abbé Montesquieu; and the cradle of the party was the original *comité* of the constitution, which, about twenty-five years before, elaborated the *charte* of 1814. Its present representatives still find a centre in the court of the exiled Queen Marie Amalie at Claremont, and a vigorous supporter in her gifted son, the Duc d'Aumale.

**DOCTRINE**. See DOGMA.

**DODD, THE REV. WILLIAM, LL.D.**, was born in 1729 at Bourne, in Lincolnshire; was educated, in the first place, at a private school; and was admitted, in 1745, as a sizar to Clare College, Cambridge, where, after five years of study, he took his degree of B.A. Shortly after, he removed to London, received orders from the bishop of that city, and soon afterwards gained a reputation as a popular

preacher and as a successful littérateur. Through his celebrity as a divine and man of letters, and by means of flattering the great, he succeeded well in London, and in 1763 was appointed tutor to Philip Stanhope, the fifth Earl of Chesterfield. His habits, however, were very expensive, and an income of £800 per annum, even when augmented by the produce of his literary labours, was not sufficient to supply his wants. This extravagance proved his ruin, as it tempted him to forge the signature of his former pupil, the Earl of Chesterfield, to a bond for £4200. For this crime he was arrested in February 1777, and though he refunded the money, he was tried, convicted, and executed on the 27th of July. His writings are numerous and varied. His *Beauties of Shakespeare* (2 vols., Lond. 1753) is well known, as are also his *Reflections on Death* (1763), and *Thoughts on Death*, a poem composed during the time that intervened between his conviction and execution.

**DODDER** (*Cuscuta*), a genus of plants referred by some botanists to the natural order *Convolvulaceæ*, and regarded by others as the type of a small distinct natural order, *Cuscutaceæ*; which differs from *Convolvulaceæ* in the habit of the plants, leafless climbing parasites, with flowers in dense clusters; in having scales on the tube of the corolla alternate with its segments; and in having a spiral thread-like embryo, lying in a mass of fleshy albumen, whilst the cotyledons are so small that the embryo has been described as destitute of them. There are about fifty known species of *Cuscutaceæ*,

Dodder (*Cuscutaceæ*).

chiefly found in the warmer temperate parts of the globe. The name *D.* is often extended to all of them. One or two species of *Cuscuta* are natives of Britain, parasitic on leguminous plants, heath, thyme, hops, nettles, &c. A species of *D.* is very injurious to crops of flax in Germany, and leguminous crops often suffer from this cause in the south of Europe. The seed of *D.* germinates in the ground, but the stem soon seeks to attach itself to plants by little rootlets which it sends out, and the original root dies. The appearance of *D.* has been described as resembling 'fine, closely tangled, wet catgut.'

**DODDRIDGE, PHILIP, D.D.**, an eminent dissenting preacher and author, was born in London in the year 1702, and educated for the ministry at a theological academy at Kibworth, in Leicestershire,

presided over by a Mr John Jennings. In 1722, he became pastor of the dissenting congregation at Kibworth, and in 1729 received a call to Northampton, where he also became president of the theological academy now removed from Kibworth to that town. Here he continued to preach and train young students for the ministry till within a short period of his death, which occurred at Lisbon, October 26, 1751, whither he had gone for the benefit of his health. *D.* was a man of the most amiable character, deep piety, and extensive accomplishments. His principal work is *The Rise and Progress of Religion in the Soul* (1750). It has been translated into Dutch, German, Danish, and French. Besides this, may be mentioned *The Family Expositor* (6 vols., 1760—1762); his *Course of Lectures*, delivered to the students under his charge, and published by the Rev. Samuel Clarke (1763); and a great variety of sermons on miscellaneous religious topics. *D.* also wrote a considerable number of hymns, which hold a high rank among those used by English and Scotch dissenters.

**DODECAGON.** A regular polygon of twelve equal sides and angles. See **REGULAR FIGURE**.

**DODECAHEDRON,** one of the five regular solids, is bounded by twelve equal and regular pentagons. See **REGULAR BODY**.

**DÖDERLEIN, LUDWIG**, a German philologist, was born at Jena, 19th December 1791; studied at Munich, Heidelberg, Erlangen, and Berlin; and in 1815 was appointed professor of philology at the academy of Berne. About the year 1820, he went to Erlangen as second professor of philology, and in 1827 became first professor and also director of the philological seminary. His principal works are *Latéinischen Synonymen und Etymologien* (6 vols., Leip. 1826—1833); *Latéinischen Wortbildung* (Leip. 1833); *Handbuch der Lat. Etymologie* (Leip. 1841); *Homerische Glossarium* (1 vol., Leip. 1850). *D.* has also edited several classical works such as the *Oedipus Colonneus* of Sophocles, and the *Opera* of Tacitus.

**D'ODO** (*Didus*), a genus of birds commonly ranked among the *Brevipennes* (q. v.) or *Struthious* birds (Ostrich, Cassowary, &c.), although exhibiting very anomalous peculiarities; but still more interesting because, whilst it appears to be now completely extinct, its extinction has taken place very recently, and through the agency of man; at least one species (*D. ineptus*) being known to have existed less than two hundred years since. It is described by several voyagers of the 16th and 17th centuries, and seems even to have been brought alive to Europe. It inhabited the islands of Bourbon and Mauritius. That any species of *D.* was ever seen by European voyagers in Madagascar, is not so certain; and the Solitaire (q. v.) of the island of Rodriguez, now also extinct, was a very different bird. The *D.*, according to the descriptions given of it by those who saw it, and which are confirmed by pictorial representations, apparently not unworthy of confidence, was a bird larger than a swan; of a very heavy, clumsy form and corresponding gait, with short thick scale-covered legs; three rather short toes before and one behind; large head; very large bill, the upper mandible longer than the under, and much hooked at the point; the wings so short as to be of no use for flight, and furnished only with a few black feathers; the general plumage a kind of grayish-down; the tail merely a tuft or bunch of curiously curled feathers. The *D.* was so abundant when some of the first voyagers visited Mauritius, that they became satiated with its flesh, although they describe it, particularly the breast, as good for food. The birds were easily killed, being wholly

unable to fly, and running slowly. Their speedy extinction after the islands began to be visited and settled, is thus easily accounted for. The D. seems to have been adapted for living in tropical woods, where the luxuriant vegetation afforded it a ready supply of food, and its powerful hooked bill, which

Dodo.

has led some naturalists to assign it a place among birds of prey, was probably intended for tearing vegetable and not animal substances. However singular this bill is in a struthious bird, it has been well remarked that it is not more so than the very different bill of the *apteryx*.

There are rude figures of the D. in several works of the 17th c., and in particular one, evidently superior to the rest, in Bontius (edited by Piso, 1658)—who calls the bird *Dronte* or *Dodaers*—which perfectly corresponds with the descriptions given of it, with a painting preserved in the British Museum, said to have been drawn in Holland from the living bird, and with a representation of it discovered by Professor Owen in 1838 in Savery's picture of Orpheus and the Beasts at the Hague, which he thinks 'must have been copied from a study of the living bird.'

A foot of the D. is amongst the valued treasures of the British Museum; a head and a foot are preserved in the Ashmolean Museum at Oxford. It must ever be cause of regret, that a stuffed specimen which once existed in the Ashmolean Museum was allowed to decay, and finally destroyed in 1755 by order of the curators, who little imagined that portions of it escaping their sentence were to become objects of the highest interest to the whole scientific world.

DODONA, a city of Epirus, the seat of the oldest Grecian oracle there, is situated in one of the wildest districts south-west of the Lake of Janina. The Greek and Egyptian accounts of its origin differ. The priests of Jupiter in Egyptian Thebes related that two holy women were carried off from that city by a party of Phœnicians, one of whom was sold in Lybia, the other to the Greeks, and that these women founded the oracles at D. and Ammon. The inhabitants of D. related that two black doves took their flight from the city of Thebes, in Egypt, one of which flew to Lybia, the other to D.; that the latter perched upon an oak, and with a human voice commanded that an oracle should be founded on the spot. Herodotus is of opinion, that if the Phœnicians did actually carry off the two women already alluded to, one of them was probably sold into Greece; that the strange language and dark complexion had caused them to be likened to birds; and that when they became acquainted with the Greek tongue, they were said to have spoken with a human voice. Later authors ascribe the founding of the city to Deucalion. The sanctuary itself was

dedicated to Jupiter, who manifested himself from the boughs of an oak, probably by the noise of the wind through the tree. This was explained by the priests, who were termed Selloi or Helloi. The goddess Dione, by some said to be Aphrodite, by others Hera, afterwards appeared by the side of Jupiter, and the place of the priests was occupied by priestesses, who announced the will of the deity. D., though not equal in renown to Delphi, was yet frequently consulted on occasions of importance both by the Spartans and Athenians. Though the city of D. was destroyed in 219 B.C. by the Ætoliens, it recovered at a later period, was visited by the Emperor Julian on his march to Persia, and was in existence in the 6th c. A. D.

DO'SLEY, ROBERT, author and publisher, was born in 1703 near Mansfield, in Nottingham. His father, who is said to have been a schoolmaster, apprenticed him to a stocking-weaver; but finding this employment unsuitable, D. ran away, and was afterwards engaged as footman. While thus employed, he devoted his leisure moments to reading and the cultivation of letters, and eventually published, in 1732, a volume of poems, entitled *The Muse in Livery, or the Footman's Miscellany*. His next production, *The Toy Shop*, a dramatic piece, was submitted in manuscript to Pope, who undertook to recommend it to Rich, the manager of Covent Garden Theatre. It was acted under Rich's management in 1735 with great success. The proceeds resulting from the publication of these his first two works enabled D. to commence business as a bookseller, in which trade he was very successful. In 1737, his *King and the Miller of Mansfield* was brought out at Drury Lane, and met with an enthusiastic reception. This was followed by *Sir John Cockle at Court*, *The Blind Beggar of Bethnal Green*, and *Rez et Pontifer*, which were republished in a collected edition of his dramatic works with the title of *Trifles* (1748). Meantime, he was conducting his business with such ability and spirit, that in the course of three years after commencement he was in a position to buy copyrights. In 1738, he bought Johnson's *London*, giving for it no more than ten guineas. His most successful work was a tragedy called *Cleone*, which was acted at Covent Garden with extraordinary success. On its publication, 2000 copies were sold the first day, and within the year the work ran through four editions. With *Cleone* he closed his career of dramatic authorship. D. was connected either as contributor or publisher, and occasionally as both, with several magazines. He is, however, chiefly remembered now on account of his *Select Collection of Old Plays* (12 vols. 8vo, 1780); and his *Collection of Poems by Several Hands* (4 vols. 12mo, 1748). Besides the volume entitled *Trifles*, another volume of his collected works was published in 1772 under the title of *Miscellanies*. He died at Durham while visiting a friend, on the 25th September 1764.

DOE, JOHN, the fictitious plaintiff in ejection, whose services are dispensed with since the abolition of the fiction.—Wharton's *Law Lexicon*.

DO'FFER is that part of a carding-machine which takes the cotton from the cylinder when carded. See CARDING.

DOG (*Canis*), a genus of digitigrade (q. v.) carnivorous (q. v.) quadrupeds, which, as defined by Linnæus, included all that now form the family *Canidæ* (q. v.), and also hyænas. In the genus as now restricted, wolves and jackals are generally included by naturalists, along with those animals to which alone the name Dog is popularly applied, and a distinctive character of principal importance is found in the pupil of the eye, which is always

round—contracting circularly, whilst in foxes it assumes the form of a section of a lens when contracted. The present article is limited to dogs in the common acceptation of the term, wolves and jackals being the subjects of separate articles; and only remarks relative to dogs in general will here find a place, many of the particular kinds being sufficiently important to be separately noticed.

At the very outset we encounter one of the most perplexing and difficult questions in natural history, as to the number of *species* of dog, and the origin of the domestic dog; two questions in appearance but rather one in reality, and one on which the opinions of the most eminent naturalists are very much divided. According to some, all domestic dogs are to be regarded as of one species; and as in the case of some other valuable domestic animals, that species is not certainly known to exist in a truly wild state, all the wild dogs which must be admitted to belong to the same species being viewed as the offspring of domestic dogs which have returned to a wild state, and in which, however, it is supposed that the original type or characteristics of the species, modified by domestication, have in a great measure reappeared. According to others, there are numerous species of dog, originally distinct, which have been domesticated by the inhabitants of different countries, but which, however, are very nearly related not only in their physical characters but in their dispositions and in some of their principal instincts, and which were capable of intermixing, not perhaps indiscriminately, but within certain limits, and so as to produce new races. By some who hold the first of these opinions, it is further maintained that the wolf and the dog are one species, and that all domestic dogs are derived from the wolf; whilst others advocate the claims of the jackal to be regarded as their original parent and type. By some of those who hold the species to be numerous, it is supposed not improbable that the blood of wolves and of jackals may be mixed in some of the domestic races with that of the original dogs.—It is impossible for us to do more than state these different views, and a few of the principal arguments by which they are supported.

It is admitted on all hands, that there is great diversity among the different kinds of domestic dogs, many distinct races having long existed, which differ not only in size and other physical characters, but to a notable extent also in dispositions and instincts; it is further admitted that there appear to be no definite limits to the possible intermixture of these races with each other. So great is the diversity of physical characters, that naturalists of the greatest eminence almost acknowledge themselves incapable of pointing out any that are common to all dogs, and yet distinguish them all from the different species of wolves and jackals; and in fact, the *recurred tail*, not apparently a character of the first importance, is named by Cuvier himself as the most certain and unvarying specific distinction. The obliquity of the eyes of wolves is also contrasted with the more forward direction of those of dogs, which is accounted for—in favour of the theory of wolfish origin—by the supposition that it results from ‘the constant habit, for many successive generations, of looking forwards to their master, and obeying his voice.’—Bell’s *British Quadrupeds*. This, on the other side, is treated with ridicule; it is certainly a transition from the region of observation and ascertained fact to that of mere theory and conjecture. In size, dogs differ so widely that one is not as large as the head of another; the difference in form of body, head, or limbs, is almost equally great between the Newfoundland Dog or the Mastiff and the

Greyhound. The gradations, however, from one form or character to another, render it impossible to draw a fixed limit. In some races of dog, the hind-feet as well as the fore-feet have five toes, instead of four, which is more common; but this has not been much insisted on as a ground of specific distinction. Greater value ought perhaps to be attached to the want in some, as the Dholes (q. v.) of India, of the second tubercular tooth in the lower jaw; the hairiness of the soles of the feet of some is perhaps also not unimportant; and in favour of the opinion that domestic dogs have originated from an intermixture of several species, it has been urged that the number of teats in the female varies, and that there is sometimes even a difference between the number on one side and on the other, which has never been observed to be the case in wild dogs, and in them the number in the same kind is always uniform. Some of these points, however, have not received the investigation necessary to a confident determination of the measure of importance which ought to be assigned to them.

It seems to have been too hastily taken for granted, in favour of the opinion that there is only one species of dog, that all the wild races, even the dholes and the dingo, have sprung from domestic progenitors. There is certainly no evidence of this; and the fact that wild races exist, exhibiting marked diversities of character, in countries widely remote and of very different climates, is referred to with confidence on the other side, as affording at least a strong presumption in favour of the supposition that man has, in different countries, domesticated the species which he found there. We do not yet know enough of the amount and limits of the changes which circumstances and climate may produce, to warrant any confident conclusions on that ground. And if we were to adopt the views of those who ascribe least to such causes, we might yet demand them to shew why, although from certain original types no mixed race can originate, there may not yet be other original types capable of such combination, or why the limits must be held equally impassable between all that were framed by an original act of creation. That there was only one original pair of the human race, may be held, without our of necessity holding that there was only one original pair of dogs. But to this consideration due place has, perhaps, scarcely been given.

That the common fox—or any species of fox—is a parent of any race of dogs, is not the opinion of any naturalist. There are indeed some dogs, particularly of the Scottish shepherd-dog or *colly* race, which have a somewhat fox-like appearance; and a shepherd may sometimes be heard to speak of his dog as in part of fox-blood, but there is no well-authenticated instance of commixture between the fox and the dog. It is otherwise with regard to the wolf. Instances of commixture have certainly occurred, and without the compulsion of confinement; but such instances have apparently been very rare. Nor is it ascertained that the progeny is permanently fertile.

In favour of the specific identity of the dog and wolf, one of the strongest arguments is drawn from the equality of the period of gestation—63 days. But it may be remarked that an inequality of the period would have afforded a much stronger argument on the other side.

Against the identity of the dog and wolf, the difference of disposition has been strongly urged. In reply, it is shewn by well-authenticated instances that the wolf is very capable of that attachment to man which so remarkably characterises the dog. There is greater value, perhaps, in the argument of Colonel Hamilton Smith, that ‘if domestic dogs were

merely wolves modified by the influence of man's wants, surely the curs of Mohammedan states, refused domestic care, and only tolerated in Asiatic cities in the capacity of scavengers, would long since have resumed some of the characters of the wolf.

Buffon's notion, that the shepherd-dog is the original type of the whole species, from which all dogs are derived, is merely fanciful, and his endeavour to support it by a comparative view of the different kinds, only exhibits a certain amount of ingenuity.

The shepherd's dog is one of the kinds of dog having greatest development of brain, but it is still greater in the spaniel. The skulls of dogs, however, neither exhibit very marked distinctions when compared with each other, nor when compared with those of wolves and jackals.

It is universally believed that the diversity of colour exhibited by many dogs is a result of domestication, as it is neither found in those which may be supposed to exist in a state of original wildness, nor in those wild races which are certainly known to be the progeny of domestic dogs, a return to uniformity of colouring being apparently one of the most speedy consequences of a return to wildness. Black, reddish-brown, and white, the uniform colours observed in wild dogs, are, however, the colours which chiefly appear mixed in domestic races.

Pendulous ears are generally regarded as another result of domestication in dogs, as in rabbits; and it is certain that the wild races known have erect and pointed ears; but no wild race has been discovered at all corresponding to the mastiff in some of its other most notable characters, particularly the shortness of the muzzle, and depth of the chops, and it has therefore been conjectured that this and kindred races may have derived their origin from some wild dog of the interior of Asia, which has not yet come under the notice of any scientific observer.

The dog has been a domestic animal from a very early period. The earliest allusions to it are in the books of Moses, but they indeed correspond with the dislike and contempt still commonly entertained for it by many of the nations of Southern Asia. By Homer, however, it is very differently mentioned; and 'there is not a modern story of the kind which can surpass the affecting simplicity with which the poor dog's dying recognition of his long-lost master is related by one who wrote, probably, not less than 2700 years ago.' The sculptures of Nineveh, and the hieroglyphics of Egypt, attest the very early domestication of the dog, and the existence of races similar to some of those which exist at the present day; and the high value attached to it by many nations is further attested by the place assigned to it, or its image, as emblematic of the attributes which they ascribed to their gods. We do not now set so high a value on the dog, in consideration of mere usefulness to man, as on some of the other domestic animals; yet to the savage it is perhaps the most important of all, and some have supposed that by its aid the subjugation of other animals may have been first accomplished. Cuvier makes the strong assertion, that the dog 'is the most complete, the most singular, and the most useful conquest ever made by man.' The dog, far more than any other animal, becomes a humble friend and companion of man, often seeming actually to know and sympathise with the joys and sorrows of his master; and on this account it is, that he is alike 'the pampered minion of royalty and the half-starved partaker of the beggar's crust.'

The uses to which the dog is applied are numerous, and correspond, in some measure, not only with distinct physical characters, but with remarkably

distinct instincts of different breeds. Thus, whilst in some countries dogs are chiefly employed as beasts of draught, particularly for drawing sledges in the frozen regions of the north; and in other countries chiefly for the chase, the exquisite scent of some kinds, and the remarkable fleetness of others, variously recommending them for this use; we find them also rendering important services in the care of sheep and other cattle, and endowed with hereditary instincts wonderfully fitted for this purpose, and we find them, with like adaptation of instinct, highly valuable in watching and protecting the abodes and properties of their masters. Not the least interesting of the employments to which the dog has been devoted by man, is that of leading about the blind, which is often done with an intelligent and affectionate solicitude highly worthy of admiration.

Anecdotes illustrating not only the instincts, but the intelligence and affection of dogs, are familiar to every one, and form one of the most pleasing parts of many a book of natural history. Attractive to children, they are worthy of all the consideration which they can receive from the most philosophic mind. Volumes have been filled, and more volumes might easily be filled, with anecdotes well authenticated, and well worthy of preservation.

The dog produces usually from six to ten young ones at a birth. They are born blind, open their eyes about the tenth or twelfth day, attain their full growth in about two years, seldom live more than twelve or fifteen years, and almost never more than twenty.

No satisfactory classification of the different kinds of dog has ever been made. What some naturalists regard as types of species, others pronounce to be mere mongrel races. Nor can any principle of arrangement be found in form, roughness or smoothness of fur, or other such character, which will not associate kinds that are in other respects widely dissimilar, and separate some that are nearly allied.

Colonel Hamilton Smith arranges domestic dogs in six groups or sections: 1. 'The Wolf Dogs,' including the Siberian Dog, Esquimaux Dog, Iceland Dog, Newfoundland Dog, Nootka Dog, Sheep Dog, Great Wolf Dog, Great St Bernard Dog, Pomeranian Dog, &c. 2. 'The Watch and Cattle Dogs,' including the German Boar-Hound, Danish Dog, Matin, Dog of the North American Indians, &c. 3. 'The Greyhounds,' including the Brinjaree Dog, different kinds of Greyhound, Irish Hound, Lurcher, Egyptian Street Dog, &c. 4. 'The Hounds,' including the Bloodhound, Old Southern Hound, Staghound, Foxhound, Harrier, Beagle, Pointer, Setter, Spaniel, Springer, Cocker, Blenheim Dog, Water Dog or Poodle, &c. 5. 'The Cur Dogs,' including the Terrier and its allies. 6. 'The Mastiffs,' including different kinds of Mastiff, the Bull Dog, Pug Dog, &c. Colonel H. Smith does not include in any of these groups the dholes, dingoes, &c., which he even separates from the genus *Canis*.—Mr Richardson arranges dogs in three great groups, 'indicated by the least variable part of their osteological structure, cranial development.' 1. Including the Irish Wolf Dog, Highland Deerhound, all kinds of Greyhounds, and the Tiger Hound, characterised by *convergent* parietal bones, an elongated muzzle, and high and slender form. 2. Including the Great Dane, the French Matin, the Pariah of India, the Bloodhound, Staghound, Foxhound, Harrier, Beagle, Pointers, Terriers, Turnspit, Newfoundland Dog, Labrador Dog, Pomeranian Dog, Esquimaux Dog, Siberian Dog, Iceland Dog, Shepherd's Dog, &c., characterised by *parallel* parietal bones, and generally by much acuteness of smell. 3. Including Mastiffs, the Great St Bernard Dog, Bull Dog, Pug Dog, &c., characterised

by sensibly *divergent* parietal bones, bulk of body, robust structure, and combative propensities.

**DOG** (in Law). The keeping of vicious or destructive dogs, or other animals, except under proper precautions, is illegal; and the proprietor is liable for the damage which they occasion in all cases in which it cannot be clearly shewn that the fault lay with the party injured. Even before the injury occurs, it is competent to enforce measures of precaution. If a man have a dog which he knows to be of a savage nature, and addicted to bite, and he allow it to go in a frequented place without being muzzled or otherwise guarded so as to prevent it from committing injury, he may be indicted in England as for a common nuisance. If the dog be of a ferocious kind, as a mastiff, it has been held that he must be muzzled (1 Russ. 303); and it will be no defence in an action of damages against the master, that the person injured trod on the dog's toes, for he would not have trodden on them if they had not been there (3 Car. and P. 138). The harbouring of a dog about one's premises, or allowing him to resort there, will warrant indictment (M'Hone and Wood, 5 C. and P. 2). If a dog known to his proprietor to have previously bitten a sheep, be retained by him, the proprietor will be liable to all subsequent injuries even to other animals, as, e. g., a horse. (Burn's *Justice of the Peace*, vol. ii. p. 333.) In Scotland, a warrant may be obtained, on proof of vicious practices and danger to the public, either from the sheriff or the justices, on a summary complaint, to have a dog secured or slain, and the owner found liable in expenses. The complaint may be at the instance either of the fiscal or of a private party, with or without the fiscal's concurrence. An interdict may be granted against the dog going loose pending the discussion of the question as to whether or not he ought to be killed. Many local police acts contain provisions as to shutting up or muzzling dogs during the prevalence of weather likely to produce hydrophobia; and where such do not exist, the subject may be dealt with by the magistrate at common law. Formerly, the common law of England held that it was not larceny to steal any of the baser animals, in which class all dogs, except those of value, were included. But by 7 and 8 Geo. IV. c. 29, dog-stealing was declared to be an offence punishable by fine. This act was repealed, and new regulations of a more stringent kind made by 8 and 9 Vict. c. 47. By that enactment dog-stealing is a misdemeanour, punishable, on summary conviction, for the first offence, by six months' imprisonment and hard labour, or fine not exceeding £20 beyond the value of the dog. The second offence is an indictable one, punishable by fine or imprisonment and hard labour not exceeding eighteen months, or both. Similar punishment is provided for persons found in possession of dogs or dogs-skins, knowing them to have been stolen. A dog going into a neighbour's field does not afford ground for an action of trespass unless he does mischief; and even then the person who kills him in certain circumstances, may be liable in damages (2 Marsh. 584). The use of dogs for purposes of draught was prohibited under a penalty by 2 and 3 Vict. c. 47, which is explained by 17 and 18 Vict. c. 60, § 2. See **CRUELTY TO ANIMALS**.

**Tax on Dogs**.—The duty charged on every dog is 12s. The maximum charge for any number of hounds, £39, 12s., and for any number of greyhounds, £9. Any dog kept wholly for the care of sheep or cattle, if not a greyhound, hound, pointer, setting-dog, spaniel, lurcher, or terrier, and all dogs under six months' old, are exempt. (The duty is now 5s., and shepherds' dogs are not exempt.)

**DOG'BANE** (*Apocynum*), a genus of plants of the natural order *Apocynaceæ*, having bell-shaped

Dogbane:

a, end of branch, with leaves and flowers; b, a flower cut open; c, fruit.

**CANADIAN HEMP** (*A. cannabinum*), a plant noticed on another account in the article *Apocynaceæ*, possesses similar properties, and is frequently used in the United States.

**DOG-DAYS**. See **CANTICULAR DAYS**.

**DOG-DRAW**. An apparent depression of an offender against venison in the forest. Dog-draw is where any man hath stricken or wounded a wild beast by shooting with a cross-bow, long-bow, or otherwise, and is found with a hound or other dog drawing after him to receive the same.—Cowel's *Interpreter*.

**DOGE** (equivalent to *duke*) was the name of the chief magistrate, possessing princely rank, in the republics of Venice and Genoa. Dogate or dogado, both from the Latin *ducatu*, duchy, is used to indicate the dignity of doge. We find doges of Venice elected by the people, but enjoying almost the rights of absolute monarchs, as early as the beginning of the 8th century. Their power, however, was considerably reduced towards the end of the 12th c., through the creation of a Great Council, composed of 470 members, chosen from nobles as well as citizens, and invested with legislative power. These afterwards appointed six of their own number to superintend the doge in the exercise of his executive power. Further, the *pregadi*, or nobles, who formerly were admitted by the doge to a share in the public affairs, were organised into a regular board of administration, numbering 60 members. By the new constitution, the people, too, lost the most essential of their rights—viz., the right of electing the doge. This right was now changed into a privilege belonging exclusively to the Great Council, whose members elected 24 from among themselves, and these latter again elected, by ballot, 12 of their own number, upon whom devolved the right of appointing a doge. Sebastiano Ziani was the first doge thus elected, 1177; and on the occasion of his elevation to office, he scattered money among the people, to console them for the loss of their rights—an act which was imitated by his successors, and soon became a recognised custom, as was also the case regarding the manner in which he went through the ceremony of wedding the Adriatic Sea. The Pope Alexander III., whom, during his quarrels with the Emperor

Frederic I., the doge had faithfully supported, sent him, together with other privileges, a ring, as the symbol of domination the republic had acquired over the Adriatic. Accordingly, a marriage-ceremony took place on Ascension Day—a ring being thrown from the ship *Bucentaur* into the sea, to shew that as the wife is subject to her husband, so is the Adriatic Sea to the republic of Venice.' The practical bearing of the ceremony soon appeared in the shape of stringent measures, regulating the navigation of the Adriatic, and imposing tribute upon all foreign ships. The power of the doge underwent, in 1179, a signal modification; the *Treble Quarantia*—a high court of justice, composed originally of 40 members—having been erected, as also the board of *Advogadori*, for the settlement of fiscal questions instituted. During the reign of Jacopo Tiepolo (1229—1249), a new restriction arose from the creation of an independent police, and a still greater one from the formation of a tribunal consisting of three inquisitors and five correctors, who, on the demise of a doge, had to examine his conduct, sifting the minutest particulars of his private life. All these changes were effected by the Great Council, to the thorough exclusion of the people. In 1268, the Great Council, in order to cut short all family influence upon the affairs of the state, devised a curious and extremely complicated mode of election; but notwithstanding the limitations new and old, the power of a doge continued great, if he was only wise enough to profit by the contentions between nobles and citizens, the disputes of the different authorities, and especially by his own position as commander-in-chief of the forces and high-admiral of the navy. This last prerogative of the doge remained in vigour up to 1628, when, by a formal enactment, the doge was prohibited the exercise of such command, unless he were authorised by the Council of Forty. Other privileges, however, belonging originally to the dogate, were abrogated or circumscribed long before this, and especially during the period 1289—1311. Thus, at the instigation of the doge, Gradenigo, who was actuated by jealousy towards the mighty family Tiepolo, the famous law of 'closing the Great Council' was passed, and by it the whole legislative and judicial power made the heirloom of those families whose names were inscribed in the Golden Book, or *Libro d'Oro*. About that time (1309), ecclesiastics of any degree were declared unfit for political or judicial functions. To counterbalance the influence of discontented nobles, a public feast was instituted—to come off yearly—at which the doge gave a dinner to the fishermen, fraternising with them in testimony of equality. Shortly before Gradenigo's death, that terrible tribunal, the Council of the Ten, was erected, which was to be the highest in the state, irresponsible, and entitled to pass judgment upon the doge himself. In the meanwhile, the Great Council managed to get the functions, public as well as private, of the doge circumscribed in the minutest way. It was ordered that the doge should not announce his accession, except to the princes of Italy; neither was he permitted the opening of dispatches emanating from the popes or from princes; the kissing of his hands, or kneeling down in his presence, was strictly interdicted. He could not leave town, he possessed of real property abroad, or allow his children to contract matrimonial connections with foreign houses, accept denations, &c. He had to submit to the continued presence of two *advogadori*, to be fined for the least mistake, and bear the expenses of the ducal dignity from his own purse. To all these restrictions and burdens the doge declared himself liable on the occasion of his coronation, by signing a document

headed 'Promissione.' The state costume and retinue of the doge were minutely defined, and a trifle fixed as his salary. As a symbol of princely dignity, the doge wore a horned cap, and had the title of Serenity. The credentials of ambassadors were written in his name, but signed by a secretary of state, and sealed with the arms of the republic. The money was struck in his name, but not with his stamp or arms. All the magistrates rose and saluted the doge when he came into council, and the doge rose to none but to foreign ambassadors. His family was exempt from the jurisdiction of the Master of the Ceremonies; and his children, though excluded from public offices, were allowed to have staff-officers, and gondoliers in livery. After the death of And. Dandolo, 1354, on a motion from the correctors, the three presidents of the quarantia, and later six ministers, were joined to the six privy-councillors of the doge, who, together with the above-named, has formed henceforward the so-called *Signoria Serenissima*. At that stage the rank of doge could no longer be an object of ambition, and as early as 1339 a law was necessary to prohibit the doge elected from resigning his place. And. Contarini, 1367, accepted the proffered dignity only upon the threat of being declared a traitor to the country. In 1413, by a law emanating from the Great Council, the doge was even denied the title of Signoria, that of Messere being substituted instead; at the same time he was deprived of the right of convening an *arengo* or meeting of the people. With the fall of the Venetian republic, 1797, the dignity of doge also disappeared. There were in all 73 doges at Venice, the first of whom, Anafeste (Paoluccio), was elected 697; the last, Manin (Lodovico), 1788. In the Palazzo Ducale, the celebrated frieze of the doges is to be seen round the Sala del Maggior Consiglio, exhibiting 72 portraits, and one space covered with a black veil, with an inscription, indicating that Fabiero (Marino) was beheaded for high treason.

The republic of Genoa elected, after a victory gained by the party of the people (1339), Simon Beccanera for its first doge. He was elected for life, and with absolute power, of which, however, he allowed a share to 12 aldermen (*anziani*), the one half being chosen from the *cittadini* (citizens), the other among the *nobili* (nobles). In the long run of centuries, the power, duration, and splendour of the ducal seat underwent frequent changes, arising from the vicissitudes of the state and the hostilities between the popular and aristocratic parties. A constitution for defining the functions and prerogatives of the doge was framed in 1528, after the great victory of And. Doria over the French. According to this constitution, which, with slight modifications, remained till the end of the Republic, the dignity of doge was of two years' duration, under restrictions similar to those at Venice. The candidate was to be a noble, and at least 50 years of age. The doge presided, with the right of veto, in the sittings of the Great Council, composed of 300 members, as also in those of a smaller one, consisting of 100. These two councils exercised the legislative power, whereas the executive was vested in the doge, together with 12 *governadori* and 8 *procuratori*, among these latter being always the doge retiring. During the time of his government, the doge resided in the state palace, where he was liable to the same restrictions and ceremonies which were in use at Venice. When, in 1797, Genoa was occupied by the French, the dogate ceased to exist; in 1802, the Genoese Republic being, conjointly with the Ligurian, re-established, the ducal dignity was once more resuscitated; but in 1804, it

disappeared for ever, the Republic itself having been dissolved.

**DOG-FISH**, the popular name of some of the smaller species of shark; apparently owing its origin—like the names Porbeagle, Hound, &c., bestowed on others of the same family—to their habit of following their prey like dogs hunting in packs. Of the species to which the name D. is given on the British coasts, one of the most abundant is that sometimes called the COMMON D. (*Acanthias vulgaris*), also known as the PICKED (i.e., piked or spined) DOGFISH. It belongs to the family *Spinacidae*, of which one characteristic is the presence of a spine before each of the two dorsal fins; and which is further characterised by having spiracles or spout-holes; by having five gill-openings on each side all before the pectoral fins; and by having no anal fin, and no nictitating membrane of the eye. The body is long and tapering; the head flat; the snout conical; the teeth in both jaws sharp-edged, and formed for cutting. The tail-fin is longer than it is broad. The upper parts are slate-gray, the under parts yellowish-white; the skin very rough when rubbed from tail to head, but seeming quite smooth when rubbed in the contrary direction. This fish uses its spines in a remarkable manner, bending itself into the form of a bow, and unbending with a powerful spring; and ‘if a finger

Dogfish.

be placed on its head, it will strike it without piercing its own skin.’ It attains a length of three or four feet. It is very widely distributed, being found in the Atlantic, the Mediterranean, and the South Seas. It causes great annoyance to fishermen, by cutting the hooks from their lines, and still more by frightening away the shoals of herring, in which other kinds of D. share the blame with it. It sometimes appears in prodigious numbers; 20,000 have been taken in a net at one time on the coast of Cornwall; and the fishermen of the Orkneys and Hebrides sometimes load their boats to the water’s edge with them. The flesh, although coarse, is dried and eaten; the livers yield oil, and the refuse parts are used as manure.—The other British dogfishes belong to the genus *Scyllium*, of the family *Scylliidae*, which have an anal fin, and two dorsal fins placed far back. They resemble in general form the species just described, and like it, they have the tail-fin longer than it is broad—they have five gill-openings on each side—the last of which, however, is over the base of the pectoral fin. They have spout-holes, and no nictitating membrane; but their teeth are very different, having a long central point, with shorter points on each side. The SPOTTED D. of two species (*S. canicula* and *S. cutulus*), both of a generally reddish-brown colour, and marked with dark spots, is often taken with bait on all parts of the British coasts; and although almost never brought to market, is much used for

food in the Orkney Islands. It has been suggested that the fins of these and other sharks might be used for making gelatine soup, as in China.

**DOG-FOX**, a name sometimes given to certain small animals of the family *Caniide*, allied to the *Corsac* (q. v.), and, like it, referred to the genus *Cynalopex*. They have a sharp muzzle, not unlike that of a greyhound, rather large, erect, pointed ears, the pupil of the eye contracting circularly as in the dog, the tail bushy like that of a fox. They inhabit warm parts of Asia and Africa; and some, if not all of them, burrow.

**DOGGER** is a vessel something like a galliot or a ketch, used by the Dutch as a fishing-boat in the German Ocean. It is not certain whether these were named after the Doggerbank, or *vice versa*.

**DOGGERBANK**, an extensive flat sand-bank in the middle of the German Ocean, between England and Denmark, in lat 54° 10’—57° 24’ N., and long. 1°—6° 7’ E. It stretches 320 miles east-north-east, from 12 leagues east of Flamborough Head to within 20 leagues of Jutland. A prolongation runs east towards Horn Point, Denmark. The bank is in some parts 60 miles broad, but the average breadth is 40. Towards the English coast, it is only 9 fathoms deep, in some parts it is 30, but the average depth is 15 to 20. The surrounding sea is in many parts 24 to 60 fathoms deep. The surface of the bank consists chiefly of fine sand and ooze. It is the seat of important English and Dutch cod-fisheries. At the south end of D., in 1781, occurred the indecisive naval fight between the Dutch and English fleets, under Admirals Zoutman and Parker respectively.

**DOGGET’S COAT AND BADGE.** These form a prize at a rowing-match on the Thames every year on the 1st of August. The prize is a bequest of Thomas Dogget, an actor of Drury Lane Theatre, who desired to signalise the accession of George I. to the throne (August 1, 1715) by a prize of a waterman’s coat and badge. Such is the account usually given; it would appear, however, from the following notice in the *Times* newspaper (August 2, 1861), that there are several prizes rowed for on this occasion. ‘The first prize is a livery and badge given by Mr Thomas Dogget, deceased, to which the Fishmongers’ Company add a guinea. The second and third prizes are respectively five-eighths and three-eighths of the interest on £260, 17s. 3d., formerly £200 South Sea Stock, left in the will of Sir William Jolliffe, the amounts respectively being £4, 17s. 9d. and £2, 18s. 9d. The prize for the fourth man is £1, 11s. 6d., and for the fifth and sixth men each £1, 1s., the last three given by the Company.’ Besides these prizes, additional sums are occasionally given by private individuals to the winner, or to the first, second, and third in the race. The competition is by six young watermen whose apprenticeships have expired the previous year; each being in a boat by himself, with short oars or sculls. The large-master of the Fishmongers’ Company is ordinarily the umpire. The competition takes place when the current of the Thames, by recession of the tide, is strongest against the rowers; and the race, which is from London Bridge to the Old Swan at Chelsea, always excites much local interest, being one of those many sports in which the English take much pleasure.

**DOG-GRASS.** See **COUCH-GRASS.**

**DOGLIANI**, a town of Piedmont, Northern Italy, is situated in a mountainous district on the left bank of the Rea, 12 miles north-east of Mondovì. D. has the remains of an old castle, but no other buildings worthy of note. Here five annual fairs

are held, at which cattle, hemp, and victuals are chiefly sold. Pop. 5000.

**DOGMA** (Gr.), meant originally an opinion or proposition, put in the form of a positive assertion, its truth being supposed to have been previously shewn. In theology, it was understood to signify a doctrine founded on Scripture, and advanced not for discussion but for belief. But as this method of stating truth easily degenerates into the assertion of opinions without ground, and without regard to the aspect they may present to others, *dogma* and *dogmatism* have come in English to be almost synonymous with assertion without proof.

In continental theology, however, the word is still used without implying any censure, *Dogmas* (Ger. *dogmen*) meaning simply doctrines; and this is the case in our own expression, *Dogmatic Theology*, or *Dogmatic*, which is that branch of theology that treats of the systematic arrangement of the doctrines of Christianity. Older names for the same thing were *Locī Theologici* and *Theologia Positiva*.—The first attempt to give a connected view of Christian doctrine was made in the 3d c. by Origen in his work *De Principiis*. He was followed in the 4th c. by Augustine, who in his book *De Doctrina Christiana*, and others, treated of the whole body of doctrine held by the church, though without any very scientific arrangement. The contributions to *Dogmatic*, made in the 5th, 6th, and 7th centuries, were mere collections of 'sentences.' In the East, in the 8th c., the doctrines of the Greek Church were treated by John of Damascus in a form already Aristotelian, and his work may be considered the first systematically arranged treatise on *Dogmatic*. He makes no mention of purgatory. His book was as influential in the Greek Church as the writings of Augustine in the Latin. The regular systematising of doctrines began with the *Scholastics* in the 11th c., but degenerated often into hair-splitting. The first cultivators of *Dogmatic* theology among the *Scholastics* were Hildebert of Tours and Abelard, who were followed by Petrus Lombardus, Alexander de Hales, Thomas Aquinas, Duns Scotus, &c.

The era of the Reformation awoke *Dogmatic* to a new life, leading it back from Aristotle to biblical theology. But the controversies between the different churches in the 17th c., and the too great importance attached to Confessions of Faith, cramped anew its freedom, and gave it again a Scholastic turn. Many of our still standard treatises on systematic divinity wear traces of these fetters, and contrast strikingly with the independence and vigour of inquiry displayed in the similar works of Melancthon, Calvin, and other reformers. A fresh revival followed in Germany the spread of the critical philosophy of Kant, when biblical theology rose up in contradistinction to the theology of confessions, and *dogmatic* was grounded on the critical interpretation of Scripture rather than on traditional formulas. Hence, however, have sprung widely diverging views. One party still held fast by the existing confessions; another looked chiefly to the contents of Scripture; while a third subjected confessions and Scripture alike to the test of reason. Besides these, there arose in more recent times, a school of *dogmatic* theologians, formed on the philosophical systems of Jacobi and Schelling, who looked for the essence of religion in the human soul itself, and considered Christianity as the historical revelation of it. Of this school, Schleiermacher, and in some respects Neander and Rothe also, may be considered the representatives; and of all the German schools, it is that which seems to be exercising the greatest influence on the speculative theology of Britain. The most recent important work in this department of theology is Peter Lange's

*Philosophische Dogmatik* (2 vols., Heidelb. 1849—1851). The *Dogmatic* of D. F. Strauss is constructed from the Hegelian point of view, and in its leading results comes back to the system of Spinoza.

It deserves remark that Christian *dogmatic* and morality, which it had been the custom to discuss separately since the 17th c., have recently been treated in combination by Nitsch and Beck. The scientific investigation of Christian doctrine in Germany has not been confined to the Protestant churches. A number of Catholic theologians have occupied themselves with this branch of sacred science; some, as G. Hermes of Bonn, inclining to freedom of investigation, and others, as Liebermann, to the defence of the usual formulas.

The *HISTORY OF DOGMAS OR DOCTRINES* has been raised in Germany to the rank of a distinct branch of sacred science. In this country, the facts with which it deals have received only passing notice in treatises on systematic theology, and in ecclesiastical history have been considered as the 'internal history of the church.' The pursuit of this branch of inquiry is characteristic of Protestantism; in the Catholic Church, it is considered as endangering the unity of the faith. Many Protestants even dislike the idea of a 'development' of Christian doctrine, which seems to be involved in its having a history. It is not necessary, however, to believe that doctrines hitherto absolutely unknown or denied, came from time to time to be embodied in the orthodox creed of Christendom. See *DEVELOPMENT*. Though this may be denied, it remains an indisputable fact that the several doctrines came one after the other into prominence in the consciousness of the church; and that in each period of her history there is some one leading doctrine which assumed an importance, as if it were the mainstay of Christianity. To depict this succession or evolution of views with their struggles and modifications, and trace the different ways in which the several doctrines were at different periods formulated and embodied in the creeds, is the object of a *History of Doctrines* (Ger. *Dogmengeschichte*). There is, of course, room for great variety in the method of treating such a subject. One of the most important works on this subject is Neander's *Dogmengeschichte*, edited by J. L. Jacobi, Halle, 1856; a translation of which into English was published by Bohn, 2 vols., 1858.

**DOGS, ISLE OF, or Poplar Marshes**, a small peninsula in the county of Middlesex, England, formed by a circuitous winding of the Thames, is situated in the vicinity of London, distant three and a half miles east-south-east from St Paul's Cathedral. It is about a mile long, and three-quarters of a mile broad. In what may be called the isthmus of the peninsula are situated the West India Docks. It is said that the Isle of Dogs derives its name from the circumstance that the king's hounds were formerly kept here. This tradition, however, is not well authenticated.

**DOG-SHORE.** See *LAUNCHING*.

**DOG'S-TAIL GRASS** (*Cynosurus*), a genus of grasses having a pretty close spike or ear, each spikelet with two equal glumes and 3-5 florets, and beneath each spikelet a comb-like bract or involucre. The species, which are not very numerous, are chiefly natives of Europe and Asia. Two are found in Britain, but one only is common and valuable, the *CRESTED D. G.* (*C. cristatus*), which forms an important part of almost all good pastures, and is particularly esteemed for sheep-pastures and lawns, for the improvement of which it is often sown. Its herbage is fine and close, and its deep roots secure it against droughts, which cause

many other grasses to wither; but the herbage is not sufficient in quantity to make it desirable for hay.—The comb-shaped bract connected with each spikelet of this common grass is a very interesting and beautiful object. The seeds are small, shining, and yellow, whence the name *Gold-seed* sometimes given to this grass by farmers.

**DO'GWOOD**, or **DO'GBERRY**, the name usually given to some of the arboreous and shrubby species of the genus *Cornus*. See CORNEL. The common D. of Europe (*C. sanguinea*), a native of Britain and many parts of the continent, and also of the north of Africa, is a shrub of 4—15 feet in height, with ovate leaves, and terminal cymes of greenish-white flowers, which have an unpleasant odour. The leaves become of an intense dark-red colour before they drop off in autumn. The wood makes the very best charcoal for gunpowder. It is very hard, and is made into skewers for butchers and cooks, and into cogs for wheels. The young wood was, in former times, in request for the making of arrows. The fruit, which is small, dark purple, and very bitter,

Common Dogwood:  
a, branchlet, with leaves and flowers; b, fruit.

yields an oil said to be equal to that of the olive, and to the amount of 34 per cent. of its weight. This oil is used in France for lamps, and for the manufacture of soap.—The D. of North America (*C. florida*) is a small tree, found in the United States, from lat. 43° to Florida, with oval leaves, and small yellowish flowers, which are surrounded by large white roundish bracts. The berries are red, and remain on the tree most of the winter. The flowers appear before the leaves, and their large white bracts are amongst the ornaments of the American woods in spring. The tree attains a height of 20—30 feet, with a trunk 8 or 10 inches in diameter. The wood is white, hard, fine-grained, much esteemed and used for inlaying and ornamental work. The bark is very successfully employed in the cure of intermittent fevers. It is also a valuable tonic. It is one of the most valuable medicinal products of North America. The barks of several other North American species of *Cornus* possess similar properties.—**JAMAICA D.** is *Piscidia erythrina*, of the natural order *Leguminosae*, sub-order *Papilionaceae*, a good timber-tree, with hard and resinous wood, which lasts well either in or out of water; the bark of the root powerfully narcotic, used for stupefying fish, and also for relieving toothache, being applied to the tooth in the form

of a saturated tincture, or taken into the stomach as a powerful sudorific.

**DO'ILEY**, or **DO'ILY**, a small napkin used at table for putting glasses upon during dessert. Some are highly ornamented. The name is said to be derived from the original maker; but more probably it is a modification of the Dutch *dwale*, a towel, and was introduced along with the article from Holland.

**DOIT**, a small copper coin current in Scotland during the reigns of the Stuarts. It was a Dutch coin (*duit*), and in value the 160th part of a guilder, which, estimated at 20*d.* sterling, would make the doit equal to the eighth of an English penny, or half a farthing. By some authorities it is said to have been worth only the twelfth of a penny; in reality, it is difficult to say what was its worth, for being imported, like many other coins of the period, from Holland, it would rise and fall in value according to the scarcity of money. The doit must have been common in the early part of the reign of James VI. The kirk-session of Perth (16th April 1582) 'ordains James Sym to give the witch in the tollbooth 8 doits in the day' for subsistence.

**DOLA'BRA**, a rude ancient hatchet. They are represented on the columns of Trajan and Antoninus, and abound in all museums. When made of flint, which was their earliest and rudest form, they are usually called *celts* (q. v.).

**DO'LCÉ**, an Italian term in music, meaning softly and with tenderness.

**DO'LCI**, **CARLO** or **CARLINO**, a celebrated painter of the Florentine school, was born at Florence in 1616. He received his first instructions in art from Jacopo Vignali, a pupil of Roselli, and a remarkably skilful teacher. After an uneventful life spent entirely in his native city, D. died January 17, 1686. His works, which consist chiefly of madonnas and saints, exhibit the character attributed to him. The faces are full of a pleasing and tender softness, which, however, is often carried so far as to rob them of all character. D.'s drawing is generally correct, his colouring exquisitely delicate and transparent, and in the nicety and laborious care of his finish he approaches the most characteristic examples of the Dutch school. His works are numerous, and scattered over all Europe. Besides his madonnas, the most famous are his 'St Cecilia,' 'Christ Blessing the Bread and Wine,' 'Herodias with the Head of John the Baptist,' and 'Christ on the Mount of Olives.'

**DOLE** (Lat. *dolus*, guile), in Scotland, the amount of conscious guilt or evil intention which is necessary to make a legal crime. A person incapable of consent is also incapable of *dole*—*doli incapax*, as it is technically called. The corresponding phrase in England is *felonious intent*.

**DÔLE**, a well-built town of France, in the department of Jura, 28 mdes south-east of Dijon. It is delightfully situated on a vineyard slope rising from the right bank of the river Doubs, and the environs are tastefully laid out in gardens and promenades. The principal building is an immense cathedral, named, in honour of the Virgin, *Nôtre Dame*. The chief manufactures of D. are hosiery, tiles, pottery, chemical products, and beer; there are also iron-smelting furnaces, flour-mills, and some trade in corn, wine, wood, marble, and iron. Pop. 7759. D. is the *Dola Segunorum* of the Romans, of whose presence the ruins of two aqueducts, an amphitheatre, several temples, and the 'street' or road which passed from Lyon through D. to the Rhine, still give indications. There are also the

remains of a castle built by Frederick Barbarossa in the 12th century. D. is likewise memorable for having sustained several sieges.

DOLE-FISH seems to be that fish which fishermen employed in the north seas do of custom receive for their allowance, 35 Hen. VIII. c. 7.

DOLES AT FUNERALS; these are of great antiquity. St Chrysostom speaks of them as being given to procure rest to the soul of the deceased. On this ground, as well as on the score of general benevolence, the practice of making gifts to the poor at funerals was common until comparatively recent times; for it was continued, sometimes on a munificent scale, long after the custom of praying for the dead had been abandoned on the introduction of reformed doctrines. Nichols, in his *History of Leicestershire*, speaking of Strathern in Framland Hundred, observes of this usage: 'In 1790, there were 432 inhabitants, the number taken by the last person who carried about bread, which was given for *dole* at a funeral; a custom formerly common throughout this part of England, though now fallen much into disuse. The practice was sometimes to bequeath it by will; but, whether so specified or not, the ceremony was seldom omitted. On such occasions, a small loaf was sent to every person, without any distinction of age or circumstances, and not to receive it was a mark of particular disrespect.' These doles, whether in money or in articles of food and ale, were at one time common not only in England, but in Wales, Ireland, and Scotland; and the custom may be said to have represented, in a simple state of society, that form of benevolence which, in the present day, consists of bequests to hospitals and other public charities. By some writers, the custom of making doles at funerals is traced to the sin-offering of the Hebrews. See Brand's *Popular Antiquities*, edited by Ellis.

DOLGELLEY ('dale of hazels'), the capital of Merioneth, North Wales, near the centre of the county, and the largest town in it, is situated on the banks of the Union, 208 miles north-west by west of London. It lies in a rich and picturesque valley, at the foot of Cader Idris, and during the summer months is much frequented by English and foreign tourists. It has manufactures of coarse woollens and flannels; its Welsh Tweed is in great repute and demand throughout the kingdom; lamb and kid skins are tanned and dressed; and in the vicinity there are fulling-mills and bleach-greens. Pop. (1861) 2050. Here, in 1404, Owen Glendwr held a parliament, and signed a treaty of alliance with Charles king of France.

DOLICHOS, a genus of plants of the natural order *Leguminosæ*, sub-order *Papilionacea*, closely allied to *Phaseolus* (see KIDNEY BEAN), and chiefly distinguished by the extension of the base of the standard so as to embrace the wings of the corolla at their base. The genus includes a considerable number of species, some of them shrubby, some annual, and some perennial herbaceous plants. Some of them have beautiful flowers, and some of the herbaceous species are cultivated on account of their seeds, which afford a kind of pulse; or of their young pods, which, like those of the Kidney Bean, are boiled for the table. Among these are *D. Lablab*, a native of India and Egypt (which has been made the type of a separate genus, *Lablab*); *D. Nankinicus* (or *Lablab Nankinicus*), a Chinese species; *D. Lubia*, a native of Egypt; *D. sesquipedalis*, a native of America; *D. Soja* or *Soja hispida* (the Soy Bean), *D. Catiang*, and *D. uniflorus* (Horse Gram), natives of India; *D. sphaerospermus* (Calavana or Black-eyed Pea), a native of the West Indies. In the climate of Britain, even the most

hardy kinds require the aid of a little artificial heat, and they are reckoned inferior to other kinds of pulse or garden vegetables of easier cultivation. The well-known Chinese sauce or ketchup called Soy (q. v.) is made from the Soy Bean. Allied to D. is the genus *Canavalia*, to which belong the SWORD BEANS of India. *C. gladiata*, the commonly cultivated species, has pods two feet long. Another allied genus is *Psophocarpus*. The seeds of *P. tetragonolobus*, formerly *D. tetragonolobus*, are used in the Mauritius as peas are in Britain; and its pods and tuberous roots are common Indian esculents. Some species of *Pachyrhizus*, also an allied genus, are remarkable for their tuberous roots, as *P. angulatus* (formerly *D. bulbosus*), a native of India, now cultivated in South America and other warm countries, which produces pleasant turnip-like tubers; and *P. trilobus*, which has tubers two feet long and nearly cylindrical, much used as a boiled vegetable in China and Cochinchina.

DOLL, an imitative baby used as a toy by girls. The word doll is of doubtful derivation; possibly from *idol*, in French, the name is *poupée*; in German, *puppe*, from Lat. *pupa*, a girl, a doll. The use of dolls dates from the most remote times, and is common in all countries, barbarous as well as civilised, because it springs from that love of nursing and fondling infants which is implanted by nature in the female character. Precisely as a child in a princely mansion in England fondles a finely dressed doll worth a guinea, so does the child of an African or Esquimaux take delight in a piece of wood or bone carved rudely in the form of a baby—in fact, girls in the humbler ranks may sometimes be seen hugging and talking to a bit of stick decorated with a few rags, as if it were a live child. This is not the place to discuss this curious psychological phenomenon; it is enough to say that the love of dolls is a perfectly legitimate feeling, and its exercise helps to cultivate not only tender affections, but taste as regards the making and management of children's dresses. Accordingly, the keeping of a doll becomes a part of the home-education of girls; and is recognised to be so by the universality of the practice.

As in the case of most other Toys (q. v.), dolls were at one time imported into Great Britain chiefly from the Netherlands; and hence not an unusual name for a doll was a Flanders baby. These old Flemish or Dutch dolls were made of wood, with neatly formed faces and flashy dresses, the cheaper kinds having slender wooden legs. Latterly, there have been great improvements in the making of dolls, and in England it has assumed the character of a manufacture; but there are still large importations from the countries on the Rhine, France, and Switzerland. In these continental countries, women and children are mostly engaged in the manufacture. Some carve the heads and bodies, others paint the faces and necks, others prepare legs and arms, and a different class cut out, sew, and put on the dresses. These operations are seldom executed in one manufactory. Usually, dealers buy the fragments so far prepared by villagers, and get them put together in a wholesale way. As the time employed in the preparatory processes is scarcely of any marketable value, the prices of fragments are most insignificant. Hence, as regards all the cheap kinds, with painted faces and ringlets, dolls can be imported at a cost below that at which they could be executed by hand-labour in England. When, however, we come to dolls of a superior kind, with moulded wax or composition faces, arms, and feet, glass-eyes, stuffed bodies, flaxen ringlets, and gauze dresses, the English, by their machinery and capital, carry off the

trade. In London, in 1861, there were twenty-three doll-makers, of whom one made them from gutta-percha. In this as in other trades, there is an economic division of labour; for example, there are dolls' head-makers, dolls' leg and arm makers, doll sewers, doll stuffers, dolls' wig-makers, dolls' eye-makers, and doll dressers. For some dresses, remnants of calico, gauze, silk, and other materials are procured from shops; but for fashionably dressed dolls, much in demand, it is necessary to buy goods on a large scale. The extent to which dolls' glass-eyes are manufactured appears surprising. Some years ago, in evidence before a committee of the House of Commons, a glass-manufacturer at Birmingham stated that he had received, at one time, an order for £500 worth of dolls' eyes. The cheaper dolls' eyes are simply small hollow glass-beads, made of white enamel, and coloured with black or blue, but without any attempt at variety or effect; while those eyes of a higher quality have a ring of colour to represent the iris. The introduction of wires and mechanism to make the eyes move or wink at pleasure, and also to cause the doll to utter the sounds 'papa' and 'mamma,' have been highly appreciated steps in advance, with a corresponding rise in prices. It is stated in the experience of the trade, that since Victoria came to the throne, blue eyes for dolls have been in the ascendant in England; but that black eyes find the best market on the continent, especially for Spanish dolls. Black dolls are made for export to America, where they are in request by girls of negro parentage, and the introduction of gutta-percha is favourable for this branch of the trade. Composition-heads are usually made of *papier-mâché*, cast in a mould, and waxed and painted to represent the features.

One of the most attractive stalls at the Great Exhibition in 1851, was that which contained the dolls of Madame Montanari, a London manufacturer. Referring to this stall, the Jury Report said: 'It consists of a series of dolls, representing all ages, from infancy to womanhood, arranged in several family groups, with suitable and elegant model furniture. These dolls have the hair, eyelashes, and eyelids separately inserted in the wax, and are, in other respects, modelled with lifelike truthfulness. Much skill is also evinced in the variety of expression which is given to these figures, in regard to the ages and stations which they are intended to represent.' Some of those dolls were sold at five guineas undressed; and at a greatly increased price when richly attired. The same exhibition shewed how much skill is now exercised in making rag-dolls, in which almost every part is formed of textile materials.

DOLLAR is the name of a coin, and the unit in the monetary system, of the United States. The origin of the name deserves notice. *Dollar* is a variety of the Ger. *thaler*, Low Ger. *dahler*, Dan. *daler*; and the word came to signify a coin thus: About the end of the 15th c., the Counts of Schlick coined the silver extracted from their mines at Joachims-thal (Joachim's Valley) into ounce-pieces, which received the name of Joachims-thaler—the Ger. adjective from the name of the place ('Joachims-dalers,' as it were). These coins gained such a reputation, that they became a kind of pattern; and others of the same kind, though made in other places, took the name, only dropping the first part of the word for shortness. The American dollar is taken from the old Spanish dollar or piastre, and is only slightly less. It was formerly only of silver; but since the influx of Californian gold (1849), a great issue of gold dollar-pieces has taken place. The basis of the monetary system of the United States is silver, and since

1837 the silver dollar is required to contain 412½ troy grains, or 26.4246 Fr. grammes, the fineness of which is fixed at  $\frac{1}{100}$ , i. e.,  $\frac{1}{100}$  of it is alloy. In the standard silver of Great Britain  $\frac{1}{2}$  is alloy. The United States dollar is generally estimated in exchange at 4s. 2d. sterling. Besides dollars, there are coined in silver, *half-dollars*, *quarter-dollars*, *dimes* ( $\frac{1}{10}$  dol.), *half-dimes* ( $\frac{1}{20}$  dol.), and three-cent pieces. With regard to these, it was enacted in 1853 that the weight of the half-dollar shall be 192 grains, and that of the others proportional to this; and that such silver coins shall be legal tenders for all sums not exceeding five dollars. Accounts are kept in dollars and cents, or hundredths of a dollar, which are written thus: \$13.78—thirteen dollars and seventy-eight cents. The standard gold of the United States is of the same fineness as the silver—namely,  $\frac{9}{10}$ ; and of this are coined double eagles, eagles, half-eagles, and quarter-eagles, of 20, 10, 5, and 2½ dollars, besides three-dollar and one-dollar pieces. The dollar or thaler in Germany has various values. That of Prussia, which is most current, is equivalent to 3s. sterling.

DO'LLAR, a village in Clackmannanshire, on the right bank of the Devon, ten miles east-north-east of Stirling. It lies in a plain under the Ochills (q. v.). Coal and iron occur in the vicinity. D. is noted for its academy, founded in 1818 under the will of Captain M'Nab, a native of the parish, who bequeathed £80,000 for the purpose. The academy was incorporated by act of parliament in 1847, and has a Principal and 14 teachers in the classics, arts, modern languages, &c. The minister and kirk-session of D. were the original patrons and governors, but in 1847 the trust was extended so as to include the Lord-lieutenant, Vice-lieutenant, Convener and Sheriff of the county, the Principal of the University of Edinburgh, county gentlemen, two members of the Presbytery of Stirling, and two representatives appointed by the parliamentary electors of Dollar. Pop. (1861) 1776. The principal industrial feature of D. are its many famous bleacheries on the banks of the Devon. A mile north of D. are the fine ruins of Castle Campbell, in a wild romantic situation, on the top of a high almost insulated rock, in a hollow in the bosom of the Ochills, amid mountain rivulets and thick bosky woods. It long belonged to the Argyll family. John Knox is said to have resided in the castle under the protection of Archibald, fourth Earl of Argyll, who was the first Scotch noble to embrace Protestantism publicly. (1871—pop. 2123.)

DO'LLART, THE, a gulf of the German Ocean, at the mouth of the river Ems, between Hanover and Holland. It is about 10 miles in length by 7 in breadth, and was formed by inundations of the sea, the first of which took place in the latter half of the 13th c., and the last in the 16th century. By these watery invasions a large number of villages were submerged, and thousands of persons perished.

DOLLOND, JOHN, a distinguished optician, inventor of the achromatic telescope, was descended from a French refugee family, and born in London, June 10, 1706. His father was an operative silk-weaver, in humble circumstances, and D. was also brought up to that occupation. Engaged at the loom all day, he devoted great part of the night to his favourite studies of mathematics, optics, and astronomy. Not content with these, he turned his attention to the most varied subjects, made himself acquainted with anatomy, and even theology, and went so far in the study of the classical languages as to translate the Greek Testament into Latin. French, German, and Italian also, he knew well. He apprenticed his eldest son, Peter, to

an optician; and after the latter had established himself in business on his own account, he was joined by his father in 1752. John D. now devoted himself to the improvement of the dioptric telescope, in which he was encouraged by the most distinguished scientific men of the time. After a series of well-contrived experiments and researches, carried on for several years, he succeeded in constructing lenses that produced images without any coloured fringe. See ACHROMATIC. This was undoubtedly the greatest improvement that the telescope had received since its first invention. The Memoir (published in the *Philosophical Transactions* for 1758) in which he gave an account of his investigations, was rewarded by the council of the Royal Society with the Copley medal. In 1761, D. was elected a Fellow of the Royal Society; his death took place on the 30th of November of the same year. His two sons continued to carry on the business with great reputation and success.

**DOLLY SHOP**, the name popularly given in London to a shop where rags and other kinds of old articles are bought, and over the door of which a black doll is usually suspended. It is understood that dolly shops are in many instances a kind of unlicensed pawnbroking concerns. For small articles, a few pence are given, on the understanding that the seller can buy them back at an advance some days after. In Edinburgh and Glasgow, shops of this kind are known as *wee pawn*s, and give some concern to magistrates and police.

**DOLMEN**, the name given in France to what British archaeologists call a **CROMLECH** (q. v.). The dolmen, properly so called, consists of *one* large unhewn stone resting on two or more unhewn stones placed erect in the earth. But the name is sometimes applied to structures where several blocks are raised upon pillars, so as to form a sort of gallery. One of the most remarkable monuments of this kind is the *Pierre Couvert*, about a mile and a half from Saumur. It is 64 feet long, about 15 feet wide, and about 6 feet high. It has four stones on each side, four on the top, and one at each end. The stone at the east end has fallen down; all the others appear to be as they were originally placed. Some of them are of great size, one on the roof measuring 24 feet in length, and more than 2 feet in thickness. All are of the sandstone of the neighbourhood. The floor is unruined. Dolmen is believed to be a Celtic word, signifying a stone table. The monuments to which the name is given are supposed to be the sepulchres of the ancient Celts or Gauls.

**DOLomite, BITTER SPAR, or MAGNESIAN LIMESTONE**, a mineral consisting of Carbonate of Lime and Carbonate of Magnesia in somewhat variable proportions, sometimes nearly equal, the carbonate of lime often greatly preponderating; and usually containing also a little—sometimes nearly 20 per cent.—of carbonate of iron. It is softer than limestone; usually white; sometimes gray, yellow, or brown; and occurs compact, cellular, or porous, granular, foliated, and crystallised. Its crystals are usually rhomboidal, and its cleavage is rhomboidal. It is readily distinguished from limestone by its feeble effervescence in acids. It occasionally occurs in veins accompanied with quartz, calcareous spar, &c., but also as a rock, and forms mountain masses. It is often used as a building stone; the new Houses of Parliament are built of it. It is also burned and made into mortar, but the lime obtained from it remains much longer caustic than lime from common limestone; and if spread on land in the same quantity, impairs rather than increases the fertility of the soil, seeming to burn up the vegetation. The magnesia which such

'lime' contains, does not enter rapidly into combination with carbonic acid as lime does, and to the magnesia this injurious influence on vegetation is ascribed.—*Brown Spar* (q. v.) or *Pearl Spar* is a variety of dolomite.

**DOLPHIN** (*Delphinus*), a genus of *Cetacea*, the type of a family, *Delphinidae*, which is characterised by a moderate size of head—differing in this from the *Catodontidae* or *Physeteridae* (see **CACHOLOT**)—and usually by having numerous simple and conical or nearly conical teeth in both jaws, although some of the species lose those of the upper jaw at an early age. The blow-hole is single. The family *Delphinidae* includes, along with the dolphins, porpoises, grampus, &c., many animals, which on account of their larger size are very commonly called *whales*, as the Beluga or White Whale, the Caating Whale, the Bottlehead, &c. It contains also a few species, which inhabit, not the ocean, but tropical and sub-tropical rivers, as the Soosoo of the Ganges and the *Inia* of the Amazon. The true Dolphins have the snout prolonged into a rather slender beak, which is not only abruptly separated from the convex forehead, but even by a marked furrow. Both jaws are furnished with numerous equal teeth. The species are numerous, most of them recently discovered, and none of them apparently having the very wide geographical range formerly ascribed to

Common Dolphin (*Delphinus delphis*).

the common D. (*D. delphis*), with which they were confounded. They are very voracious animals, and are said to prey not only on fishes, medusæ, cephalopods, &c., but even on the wounded and feeble of their own species. They live, however, in herds, which often delight the voyager in the ocean solitude by the gambols which they perform around his ship. They may be discerned at a great distance; as they are continually leaping from the surface of the sea, an action which, as it seems to have no obvious object, is probably the mere exuberance of animal mirth. When a shoal is seen thus frolicking at the distance of a mile or two, in a few moments, having caught sight of the ship, down they come trooping with the velocity of the wind. When arrived, they display their agility in a thousand graceful motions, now leaping with curved bodies many feet into the air, then darting through a wave with incredible velocity, leaving a slender wake of whitening foam under the water; now the thin back-fin only is exposed, cutting the surface like a knife; then the broad and muscular tail is elevated as the animal plunges perpendicularly down into the depth, or dives beneath the keel to explore the opposite side.

The Common D. is found in the Mediterranean and in the Northern Atlantic Ocean. It is usually not more than 6 or 8 feet long, but individuals have

been seen of 10 feet. The body tapers towards the tail. The tail is crescent-shaped, and about a foot in breadth. The beak is about 6 inches long. The blow-hole is crescent-shaped, with the horns directed backwards. The colour is blackish on the back, grayish on the sides, and a satiny glistening white beneath. The female D. brings forth a single young one at a time, which she suckles and nurses with great care. Although an inhabitant of the ocean, the D. emits a peculiar murmuring or suppressed lowing cry. The flesh of the D. was formerly considered a delicacy, and sailors still regard the capture of one as a happy event.

From the form of its beak, the D. receives from the French the names of *Bec d'Oie* (Goose-beak) and *Oie de Mer* (Goose of the Sea). It was very differently regarded and designated by the ancient Greeks: it was their *Hieros Ichthys* (sacred fish), was invested with many fabulous attributes, and was the subject of many mythological legends. It was supposed to be peculiarly friendly to men. It

Dolphin.

was sacred to Apolle, who was worshipped at Delphi with dolphins for his symbols. The figure of the D. (see accompanying illustration) appears on many ancient coins and medals: it is said to have been borne on the shield of Ulysses; it early appeared on the shield of some of the princes of France, and gave its name to one of the fairest of the French provinces, from which the heir-apparent of the French throne came to be styled the Dauphin. It is not easy to account for the high regard in which the D. was anciently held; nor is it altogether easy to explain the very general transference of its name in modern times to the coryphene, a very different creature, remarkable for those changes of colour in its dying moments which poets have delighted to celebrate.

Of the other species of D. one only occurs, and that but rarely, in the British seas, the Bottle-nosed D. (*D. Tursio*), which is said sometimes to attain a length of 24 feet. It appears to belong to the northern parts of the world.

Dolphins not unfrequently enter the mouths of rivers. A dolphin of the Arctic Ocean (*D. leucas*) ascends into the fresh water of the Obi, to prey upon the ascending fishes of various kinds.

**DOLPHIN, BLACK** (*Aphis Fabae*), a species of *Aphis* (q. v.), or plant-louse, which infests the

Black Dolphin:

a, a colony; b, a winged insect, magnified; c, a wingless female, magnified.

bean, and often does considerable injury to crops, sucking the juices of the plants and preventing the

development of flower-buds. It is of a dull, black, or dark-green colour, the young spotted with silvery white. The first that appear are all wingless, but by and by winged individuals are produced, and the pest spreads with great rapidity. It is in the succulent tops of the plants that the aphides first appear, and a common practice of gardeners is to remove the tops in which they are observed.

**DOM, or DON** (from Lat. *dominus*, lord). This title was originally assumed by the popes, from whom it descended, in France at least, to bishops and other dignitaries, and finally to monks. In Portugal, the title *dom* is confined to the sovereign and his family. The Spanish *don* was originally confined to the nobility, but is now bestowed by courtesy as indiscriminately as the English *Mr* or *gentleman*. The feminine *doña* is, in like manner, given to ladies.

**DO'M-BOC, or DOO'M-BOOK** (book of dooms or sentences, *liber judicialis*), the code of laws compiled by King Alfred, chiefly from the West-Saxon collection of his own ancestor Ina, but comprising also many portions of the Kentish collection of Ethelbert, with the supplements of his successors, and of the Mercian laws of Offa. 'Ina's collection,' says Dr Pauli, 'was the only one received entire into the Codex, which was chiefly applicable to the condition of the West Saxons. A few articles were admitted here and there from the Kentish and Mercian laws, but research into this matter is not possible, as Offa's book is lost.' Alfred made few if any original laws, but contented himself with restoring, renovating, and improving those which he found already in existence. The West-Saxon dialect had become a written language earlier than any of the Teutonic dialects of the continent; and as the power of the clergy in Saxon England was of a more limited kind than elsewhere, the laws of England, up to the period of the Norman Conquest, were administered in the vernacular speech of the people. Alfred's peculiarly Christian character is strongly impressed on his code, which begins with extracts from the Bible, 'The Lord spake all these words, saying, I am the Lord thy God.' Then follow the ten commandments, the part of the Mosaic law relating to criminal offences, and passages from the New Testament, including the golden rule. Yet it should be observed, that these extracts prove not the *ecclesiastical*, but only the *scriptural* character of the *Dom-boc*. The code was ratified by the Witan, as Alfred expressly informs us. In addition to Dr Pauli's life of Alfred, now published in two English translations, the reader is referred, for information on this subject, to Thorpe's *Introduction to Alfred's Laws, in the Ancient Laws and Institutes of England*, i. p. 58.

**DOMBROWSKI** (properly **DARBROWSKI**), JAN HENRYK, a distinguished Polish general, was born 29th August 1755, at Pierszowice, in the district of Cracow. He entered the service of the Elector of Saxony in 1770; but in 1792, on the first symptoms of the insurrection in Poland, proceeded to Warsaw. He took part in the Polish campaigns against Russia and Prussia, and exhibited such remarkable military talent, that on the termination of hostilities, Suwarow offered him employment in the Russian service, and Prussia made him a similar offer. Both were refused, and D. went to France, where, in 1796, he was commissioned by the Directory to form a Polish Legion among his exiled countrymen, of which he was appointed commander. The legion brilliantly distinguished itself in the Italian campaign. While in Rome, the admirable discipline which D. preserved among his troops, raised him so high in the

estimation of the Senate, that it presented him with the standards which his great countryman Sobieski had taken from the Turks, when he compelled them to raise the siege of Vienna, and which he had sent to the church of San Loretto. In the campaign of 1799—1800, D. gave splendid proofs of his courage. After the peace of Amiens, D. became a general of division in the service of the Cisalpine Republic; and after the battle of Jena, along with Wybicki, he was ordered by Napoleon (1806) to summon his countrymen to arms. His entrance into Warsaw, at the head of twelve Polish divisions, resembled a classical 'triumph.' At Dirschau and Friedland, he won fresh laurels. In the fatal Russian campaign of 1812, he commanded one of the three divisions of the fifth *corps d'armée*, and at the passage of the Beresina, saved from destruction the relics of Poniatowski's corps. In 1813, at the head of his Poles, he took an honourable part in the battles of Teltow, Grossbeeren, Jüterbogk, and Leipsic. After the fall of Napoleon, D. returned to Poland, and in 1815 was appointed by the Emperor Alexander a general of cavalry and Polish senator; but in the following year he withdrew from public employment to his estate in the duchy of Posen. He died 6th June 1818.

**DOME** (Ital. *duomo*). Though often used synonymously with *Cupola* (q. v.), a dome, in the stricter sense which it has obtained in the languages of Northern Europe, signifies the external part of the spherical or polygonal roof, of which the *cupola* (*cupo*, or *cup*) is the internal part. In Italian usage, however, it has a wider signification than even the first, being used to denote the cathedral or chief church of a town, *the house* (*domus*) *par excellence*, or house of God. The cause of the name of the building being thus applied to the form of the roof which covered it, arose from the fact, that the chief churches of Italy were at one period almost universally so roofed. In tracing the historical origin of the dome, we are usually in the habit of regarding it as originating with the architecture of the Eastern Empire, because it was at Constantinople and in the Byzantine provinces that it was first employed in ecclesiastical structures. But it was the Romans who, in reality, were the inventors of the dome, as of all the other applications of the semicircular arch. Of their success in applying it to large buildings, we have abundant proof in the ancient domes still to be seen in Rome and its neighbourhood. The dome of the Pantheon is still probably the most magnificent dome in existence, and others of smaller size are to be seen in the temples of Bacchus, Vesta, Romulus, Hercules, &c. 'From Rome it went to Constantinople, and from the same source, also, came the few insignificant attempts at domes in the Western Empire.'—Fergusson's *Handbook of Architecture*, ii. 943. The external form of the dome of the church of St Sophia at Constantinople, which became the typical Christian structure of the kind, will be seen in the illustration appended to **BYZANTINE ARCHITECTURE**. See **PANTHEON**. The dome of San Vitale, at Ravenna (q. v.), is said to be still more ancient than that of San Sophia, and is a very remarkable structure of the same class. On the church of St Marco, at Venice, there are no less than five domes, the centre one, as is usual, being much larger than the others. The interior of these domes is covered with Mosaic (q. v.). So far from being peculiar to the few churches we have mentioned, domes occur in the churches of almost every town along the western shore of the Adriatic, and form, in fact, the chief architectural feature of this side of Italy. The construction of domes in modern times was revived in Rome, by the building of that of Our Lady of

Loretto in 1507. But the three most celebrated modern domes are those of St Peter's (q. v.) at Rome, of St Paul's (q. v.) in London, and of the Pantheon (q. v.) in Paris. A very complete article on domes, which has been condensed in the *Penny Cyclopædia*, will be found in the *Encyclopédie Méthodique*, under 'Architecture.'

**DOMENICHI'NO**, or **DOMENICO**, **ZAMPIERI**, a celebrated painter of the Bolognese school, was born in Bologna, 1581. He began his studies under D. Calvaert, and completed them under the Caracci. During the whole of his career, D. had much to suffer from the jealousy of rivals, who are not free from the suspicion of having caused his death by poison, 1641. His frescoes are distinguished by correctness of design, soft delicacy, and freshness of colour; the heads of his figures, in particular, are remarkable for expressive force. The master-piece of D., the 'Communion of St Jerome' (in the Vatican), though suggested by Ag. Caracci's, is a sublime production. The 'Life of the Blessed Virgin,' and the 'Cure of the Demoniac Boy,' are of exquisite beauty. Out of Italy, the Museum of the Louvre possesses the largest number of D.'s works.

**DOMESDAY BOOK**, or **DOO' MSDAY BOOK**, the name of one of the oldest and most valuable records of England, containing the results of a statistical survey of that country made by William the Conqueror, and completed in the year 1086. The origin of the name—which seems to have been given to other records of the same kind—is somewhat uncertain; but it has obvious reference to the supreme authority of the book in doom or judgment on the matters contained in it. It was anciently known by several other names, such as the *Liber de Wintonia*, or Book of Winchester; and the *Rotulus Wintonia*, or Roll of Winchester, because it was at one time preserved in the royal treasury in that city; the *Liber Regis*, or the King's Book; the *Scriptura Thesauri Regis*, or Record of the King's Treasury (where it was long kept, together with the king's seal, under three locks and keys); the *Liber Censualis Angliæ*, or Rate-book of England.

The way in which the survey was made will be best described in the words of the contemporary writer in the Anglo-Saxon Chronicle. After relating how, in the year 1085, England was threatened with invasion from Denmark and Flanders, and how King William prepared for its defence by laying waste the sea-shores, and by raising the largest army that had ever been seen in the island, 'billeting the soldiers upon his subjects, every man according to the land which he possessed,' the annalist goes on to say that at midwinter, when the king was at Gloucester, 'he had a great consultation, and spoke very deeply with his witan [i. e., great council or parliament] concerning this land, how it was held, and what were its tenantry. He then sent his men all over England, into every shire, and caused them to ascertain how many hundred hydes of land it contained, and what lands the king had in it, what cattle there were in the several counties, and how much revenue he ought to get yearly from each. He also caused them to write down how much land belonged to his archbishops, to his bishops, his abbots, and his earls, and—that I may be brief—what property every inhabitant of all England possessed in land or in cattle, and how much money this was worth. So very straitly did he cause the survey to be made, that there was not a single hyde, nor a yardland of ground, nor—it is shameful to say what he thought no shame to do—was there an ox, or a

cow, or a pig passed by, and that was not set down in the accounts, and then all these writings were brought to him.

The survey was made by commissioners called the King's Justiciaries, who seem to have had the help of the chief men of every shire. By a sworn assize or jury of the sheriffs, lords of manors, presbyters of churches, reeves [i. e., grievous or overseers] of hundreds, bailiffs, and six villeins [i. e., tenants at will] of every village, they made inquest as to the name of the place; who held it in the time of King Edward (1041—1066); who was its present possessor; how many hydes there were in the manor; how many ploughgates in demesne [i. e., reserved in the lord's own hand]; how many homagers or vassals; how many villeins; how many cottars; how many serfs; what freemen; how many tenants in socage [i. e., tenants by hereditary right]; how much wood;

how much meadow and pasture; what mills and fish-ponds; how much had been added or taken away; what was the gross value in King Edward's time; what was the present value; and how much each free-man or soc-man has or had. Of all this there was to be a threefold return or valuation: 1. As the land was held in King Edward's days; 2. As it had been given by King William; 3. As it stood at the time when the survey was made; and the jurors were to say further whether the value could now be raised.

The returns thus gathered in the several shires, and their hundreds and other subdivisions, were arranged and digested in the record which is now called the Great or Exchequer Domesday. The enumeration of the cattle and swine, which so moved the indignation of the Anglo-Saxon chronicler, was omitted from the record, doubtless because the

## Specimen of Domesday Book :

The reading is as follows :

Rex tenet in Dominio Stocche. De firma Regis Edwardi fuit. Tunc se defendebat pro 17 Hidis. Nichil geldaverunt. Terra est 16 Carucate. In Dominio sunt 24 Carucate & 24 Villani et 10 Bordari cum 20 Carucis. Ibi Ecclesia quam Willelmus tenet de Rege cum dimidia Hida in Elemosina. Ibi 5 Servi & 2 Molini de 25 sol. & 16 Acres Prati. Silva 40 Porcurni & ipsa est in parco Regis.

Tempore Regis Edwardi & post valebat 12 lib. Modo 15 lib. Tamen qui tenet reddit 15 lib. ad pensum. Vicecomes habet 25 solid.

live-stock was altering every month and year, so that an account of its numbers in any one year could not be of permanent importance; but that the enumeration was made, is proved by the records called Little Domesday and the Exon Domesday. These are believed to be transcripts of the original rolls or returns made by the Conqueror's commissioners for the counties of Essex, Norfolk, Suffolk, Wilts, Dorset, Somerset, Devon, and Cornwall; and they set forth the number of horses, oxen, sheep, goats, and pigs, together with some other details left out in the compilation of the Great Domesday.

The mere statement which has been made of its contents, is enough to shew the immense value of Domesday Book for all purposes of inquiry into the ancient condition of England. 'It will ever,' says Dr Lappenberg, 'be found an inexhaustible source of information respecting the Anglo-Saxon and Norman constitutions, particularly the rights and revenues of the kings and their vassals, the relations of cities and towns, statistic accounts of various kinds, families and their landed members, together with innumerable matters highly interesting to inquiring posterity, but unnoticed by the chroniclers of those times, either as too well known or as worthless. An intimate acquaintance with Domesday should supply the basis of every historical account of England, particularly of its special history during the middle age.' No other country of Europe can shew such a work. It was fit, therefore, that it should have been the first great English record published at the

national cost. It appeared in 1783 in two folios, being printed with types cast for the purpose, so as to represent the contractions of the original manuscript, and having been ten years in passing through the press. In 1816, two supplementary volumes were published, the one containing an excellent general introduction, by Sir Henry Ellis of the British Museum, with indices of the names of places and of the tenants in chief mentioned in the work; the other containing four other records of the same nature: 1. The Exon Domesday, already mentioned; 2. The Inquisitio Eliensis, a record closely resembling the Exeter Domesday, containing the survey of the lands of the monastery of Ely, in the counties of Cambridge, Hertford, Essex, Norfolk, Suffolk, and Huntingdon; 3. The Winton Domesday, containing two surveys of the city of Winchester, one made between 1107 and 1128, the other in 1148; and, 4. The Boldon Book, a survey of the possessions of the see of Durham, made in 1183. This last work is especially valuable, as partially supplying a deficiency in the survey for Domesday Book, which did not extend to the counties of Durham, Northumberland, Westmoreland, and Cumberland, either, it would seem, because they had been lately laid waste by the Conqueror, or because his dominion was not fully established in them. A new and better edition of the Boldon Book was issued in 1852 by the Surtees Society, which, in 1857, printed *Bishop Hatfield's Survey*, another record of the possessions of the see of Durham, compiled between 1315 and 1381. A new and enlarged edition of

Sir Henry Ellis's *General Introduction to Domesday Book*, was published in 1833, in 2 vols. 8vo. In 1861, a fac-simile copy of that part of Domesday Book which relates to Cornwall, was published by the Ordnance Survey, as an example of what can be done by the new process of engraving called photozincography. 'The process,' says Sir Henry James, in his report of the Topographical Department of the War Office, presented to parliament in 1861, 'is so extremely simple and inexpensive, that the sale of a few copies of the fac-simile at 4s. 6d. a copy, will cover the entire expense of the publication.' Should this experiment succeed, it is the intention of the government to publish the whole of Domesday Book, county by county, in the same way.

DOMESTIC ANIMALS are those which, in order to turn them to his use, man has tamed or reduced in a greater or less measure from their natural wildness, and which he makes the objects of his care, and in a living state his property. Many animals are useful to man, which he has never thus appropriated. Such are the deer and other game which the hunter pursues, and fishes generally, whether of the sea, lake, or river. Man has not yet found it possible to domesticate them, or has not found it necessary or desirable to do so. Individuals, indeed, of some species may have been domesticated, and become very tame, but these are exceptional instances. In general, those only are called domestic animals which have existed from one generation to another in a state of domestication. Of almost all of them, domesticated races exist, considerably different from any that are now found in a state of nature; the peculiar circumstances in which they are placed by domestication exercising a modifying influence, like that of cultivation in plants. Domestic animals mostly belong to the classes of Mammals and Birds. Of mammals, those which have been domesticated are exclusively of the common quadruped form, and mostly herbivorous. The greatest number, and these among the most important, belong to the order of Ruminants; some of them being valuable for their flesh, their milk, their hair or wool, their hide, &c., or as beasts of burden and of draught, some even on all these accounts. To this order belong the ox, buffalo, and yak, the sheep, the goat, the reindeer, the camel, and the llama and alpaca. Of other herbivorous quadrupeds, the most important are the horse and ass, the elephant and the hog. Of the elephant, however, although for many ages it has been much employed for various purposes in India, no domesticated race exists; the individuals which man reduces to his service, being still taken as at first from among the wild denizens of the forest. Domesticated races exist of two comparatively unimportant quadrupeds of the order of Rodents, the rabbit and the cavy or Guinea-pig.—Of carnivorous quadrupeds, there are only two which have been generally and thoroughly domesticated, the dog and the cat. The uses to which these animals are destined are very different from those in order to which herbivorous quadrupeds are kept in a domestic state. Analogous to one of the uses of the dog is that to which the cheetah or hunting-leopard is applied by some of the princes of India, but like the elephant, it is only individually domesticated. The same remark may be made concerning some other animals—the otter, the civet, &c.—which in different countries are tamed or kept in confinement to meet certain purposes for which man finds it convenient to employ them. The domestication of the ferret is rather more complete.—Of birds, the most important domestic species belong to the gallinaceous order, and to the family *Anatidæ* among web-footed birds. To the former belong the common domestic fowl, the turkey,

the peacock, the Guinea-fowl, &c.; to the latter, the goose, duck, &c. Of other birds, none can be said to be truly domesticated, except, perhaps, one or two species of song-birds, particularly the canary. The birds used in falconry are domesticated only in the same sense as the cheetah; but it is not uninteresting to observe that man has been able to make both birds and beasts of prey his servants.—Reptiles are quite capable of being tamed, and in some countries some of them are occasionally kept in houses for killing flies, or even for killing mice and rats; but none of them can be enumerated among domestic animals. Nor, perhaps, can any species of fish be so regarded, although artificial ponds have long been in use, and some species of fresh-water fish are to a certain extent the objects of care and of a kind of culture on the part of man.—In the lower divisions of the animal kingdom, only a few species ever receive such culture, or in their living state are claimed by man as his property. All these belong to the class of insects—viz., two or three species of bee, two or three species of silk-worm moth, and two or three species of cochineal insect. These may perhaps more fitly be described as *cultivated* than as *domesticated*.

Many animals not yet domesticated, might probably be added with advantage to the number of domestic animals. Adaptation to particular climates and situations might probably be found to recommend species allied to those in which great part of the wealth of mankind has long consisted, and from which still more of it has been derived. It is not impossible, also, that as the waste places of the world become peopled, animals already becoming scarce, may be advantageously domesticated on account of their fur or other products for which they are now pursued by the hunter.—The principal domestic animals, however, of the present day, have been domestic animals, and highly valued as such, from time immemorial. We have no record of the domestication of the ox, the horse, the camel, the dog, &c. Even the llama and alpaca, although known only to the inhabitants of the Andes and adjacent regions, were found in a state of domestication there when South America was first visited by Europeans, and their subjection to man is probably to be referred to the earliest periods of Peruvian civilisation. The limitation of some domestic animals to particular countries and climates—of which we have notable instances in the camel of the Asiatic deserts, the reindeer of the arctic regions, the yak of the steep and snow-clad Himalaya, the buffalo of tropical marshes, and the South American quadrupeds just mentioned—forbid us to suppose that all the important domestic animals were domesticated by the same people and at the same period, or that they have all spread in a state of domestication from a common centre or source. Yet there are many circumstances which point to the same Asiatic region as that in which the greater number of them were first domesticated, which is commonly regarded as the cradle of the arts and sciences, and even of the human race.

DOMESTIC ARCHITECTURE. The external forms and internal arrangements of the domestic abodes of a people are far more influenced by their manners, habits, and occupations, and by the climate in which they live, than their ecclesiastical edifices and public buildings; and there is, consequently, no department of architecture which is so varied and national as domestic architecture. But not only are the circumstances of each country different in this respect—the same is the case with every department of each country, with every town in each department, with every street in each town; and a domestic architecture which fulfils its object, will not only adapt itself to the necessities, but will make

the best, in point of artistic effect, of the specialties of every case with which it is called upon to deal. The circumstances of families, and even the tastes and fancies of individuals, are legitimate subjects of consideration in domestic architecture. To attempt to give to domestic architecture the beauty of uniformity, is consequently to mistake both its object and the source from which its charm is derived. When attained at all, uniformity is attained not in accordance with, but in defiance of, the utilitarian objects of domestic architecture. The results of this artistic falsehood may be seen in the monotonous and meaningless streets and squares that have been built in all our principal towns during the last eighty years. The legitimate charm of domestic architecture, because the only one which can arise from the complete fulfilment of its object, is the charm of variety. It is the charm which our ancestors sought during the whole of the great architectural period of the middle ages, and which our architects, who in this, as in so many other respects, are returning to their principles, are now beginning to cultivate. But here, as in all similar cases, it must be borne in mind that, in general, it is the principle alone that can be revived, and that the details by which it was carried out can be legitimately copied only in the exceptional cases in which circumstances and the objects to be attained remain unchanged. The position of an Englishman in the 19th differs in many respects from that of an Englishman in the 14th c.; and to construct for the former a house in all respects resembling that which was constructed for the latter, would be to commit an error the same in kind as if we had sought for either of them a model dwelling in Pompeii or Canton.

An account of the forms of English houses from the 12th c. downwards, will be found in Parker's *Glossary of Architecture*. Apart from our own earlier examples, the forms of domestic architecture most suggestive for present use in this country, are those which are to be found in such wonderful beauty and variety in almost all of the older continental towns of the north of Europe. It was from the domestic architecture of France and the Netherlands that that of Scotland, at its best period, was mainly borrowed; and if we wish to improve it now, we can scarcely do better than revert to its original source.

DOMESTIC MANAGEMENT, financially considered, may be defined as the art of making a given income go the furthest possible in procuring for a family the means of living—the word living being understood in its wider and higher sense. It being assumed, as a fundamental maxim, that the outlay shall be within the income, the leading object of the art is, rightly to apportion the outlay among the different requisites. How this is best to be done, can be discovered only by large experience; and if a young house-keeper were to begin her career without some indications of the path she should follow, she must fall into serious mistakes, occasioning loss and discomfort. Not that any amount of previous instruction, whether written or oral, can give the skill of experience; but attention to some of the more important maxims may help to avert very serious errors while the lessons of experience are being learned. By way of outline charts for this rather intricate navigation, we give here four schemes of household expenditure, based upon experience, and adapted to some of the more extensive classes of the British community, prefacing the schemes with a few general and miscellaneous observations.

It is a very safe rule, that the best quality of food is the cheapest in the end; 'it goes further'—i. e., it gives more nourishment; but those who require to practise economy may, by going to market themselves, purchase good meat at a cheaper rate than

they would if they sent for it, from reasons known to experienced buyers, such as the pieces they select not being called prime cuts, not being so well shaped, &c., which in no way takes from the wholesomeness of the article. Again, good cooking renders things more digestible and nourishing; bad cooking is absolute waste, to say nothing of the injury it does to the stomach. How meat is rendered tender by boiling or broiling, without having its nutritive qualities extracted, is described in the articles BOILING and BROILING. For the time necessary for roasting, baking, stewing, and frying, good instructions are given in the very useful works, *The Dictionary of Daily Wants*, and Mrs Beeton's *Book of Household Management*, where not only the mode of cooking, but the actual cost of each dish, is given.

Some books on housekeeping recommend that Coal should be bought when cheap, and that Groceries should be purchased in large quantities; but this is open to the objections, that coal occupies a larger space than can be spared in small houses; that many articles of grocery waste in quantity or deteriorate in quality by keeping, as sugar, which loses weight, and tea, which loses aroma; and that both coal and grocery in masses, are apt to be wasted by servants, children, and thoughtless persons, from the circumstance of having large quantities to go to. Groceries may be bought cheaper in this way, and it is only personal experience that can decide in every case as to their being really cheaper. Candles and soap are the chief things that certainly improve by keeping. Candles should be hung up, if dips; but moulds should be stored in boxes, and covered and kept in a dry place. Soap bought in bars, in as dry a state as possible, should be cut in lumps, six to the bar, and laid on shelves, to harden slowly.

A thorough knowledge of the art of choosing material for Clothing, and making and cleaning articles of apparel, is also highly necessary, and, like good marketing for food, can only be acquired by practice. Many things must be considered in this kind of purchase; the evenness of the threads in cotton and linen fabrics, softness of texture, freedom from what is called 'dress.' In printed goods, the same rule is to be observed as to evenness of weaving, in addition to which, these kinds should be selected that have the pattern printed through, so as to shew on the wrong side, and of a lilac or dark-blue colour, as being the best for washing. Flannel goods should be chosen for their regular make, good width, and softness; and flannel articles should be made larger and longer than necessary, to allow for shrinking when washed. Good patterns for making from should be obtained, well-fitting and appropriate dress lasting longer, and looking better than what is put together in an inconsiderate, slovenly manner; a clever needlewoman, like a clever cook, is the most truly economical one. The same remarks apply to furniture-chintzes and linens for sheetings, &c. Articles chosen for glare and shew, without regard to their being in keeping with the general style of the room or house, of a flimsy, irregular, or ill-printed make, must certainly turn out unsatisfactory and wasteful.

The accompanying scales relate to prices in London and other large English towns, and reckoned on the allowance of a loaf and a half of bread (weighing four pounds to the loaf) for each individual. Young children consume less bread than full-grown persons, but they require more milk and sugar; therefore the scale can be equalised according to circumstances. Puddings and vegetable food for the children must also influence the amount for butcher's meat. It is supposed in these scales that

DOMESTIC MANAGEMENT—DOMICILE.

the husband dines at home; if he dines in the city, or elsewhere, a reduction must be made in the butcher's, baker's, grocer's, and publican's bills. Half a pound of butter, and half a pound of sugar, are the usual weekly allowances for each person. If the children are too young to be educated, the money allowed in the following scales should be saved till they are older.

SCALE FOR AN INCOME OF £300 PER ANNUM, FOR A FAMILY CONSISTING OF HUSBAND, WIFE, THREE CHILDREN, A GENERAL SERVANT, AND OCCASIONAL ASSISTANT.

	£	s.	d.
Rent, taxes, water, and gas, . . . . .	45	0	0
Wages for servant and charwoman, . . . . .	14	0	0
Butcher meat, at 16s. weekly, . . . . .	41	12	0
Baker, 9 loaves at 8½d.; flour, 1s., . . . . .	19	3	6
Grocer (tea, 1s. 6d.; parlour sugar, 7d.; children's and servant's, 1s. 8d.; parlour butter, 1s. 6d.; children's, 9d.; servant's, 8d.; spices, 4d.; cheese, 1s. 4d.; bacon, 1s. 2d.; rice, eggs, and pudding materials, 1s. 6d.), 11s. weekly, . . . . .	23	12	0
Vegetables and fruit, . . . . .	8	0	0
Milk, 3s. 6d. weekly, . . . . .	9	2	0
Beer for parlour and servant, 4s. weekly, . . . . .	10	8	0
Fuel, . . . . .	15	0	0
Washing (all done at home), soap, soda, mangling, . . . . .	4	10	0
Clothing for five persons, . . . . .	33	0	0
Church and charities, . . . . .	3	0	0
Library and books, . . . . .	2	0	0
Fire insurance on £300, . . . . .	0	6	0
Insurance on life, . . . . .	3	0	0
Education, . . . . .	20	0	0
Replenishing furniture, crockery, glass, &c., . . . . .	5	14	0
Travelling (change of air), . . . . .	10	0	0
Doctor, . . . . .	5	5	0
Income-tax, at 4d. per pound, . . . . .	5	0	0
Omnibus, postage, and sundries, . . . . .	7	7	6
	£300	0	0

SCALE FOR AN INCOME OF £200 PER ANNUM, FOR A FAMILY CONSISTING OF HUSBAND, WIFE, THREE CHILDREN, AND A SERVANT.

	£	s.	d.
Rent and taxes, &c., . . . . .	32	0	0
Wages, . . . . .	5	0	0
Butcher, at 12s. weekly, . . . . .	31	4	0
Baker (9 loaves at 8½d.; flour, 9d.), 7s. 1½d. weekly, . . . . .	18	10	6
Grocer, 8s. weekly, . . . . .	20	16	0
Milk, 2s 4d. weekly, . . . . .	6	1	4
Beer, 1s. 6d. weekly, . . . . .	3	13	0
Vegetables and fruit, . . . . .	6	10	0
Fuel, . . . . .	10	0	0
Washing (soap, starch, soda, &c.), . . . . .	3	10	0
Clothing, . . . . .	17	10	0
Church and charities, . . . . .	1	10	0
Library and newspaper, . . . . .	1	10	0
Fire insurance, . . . . .	0	4	0
Insurance on life, . . . . .	6	0	0
Income-tax, at 4d. per pound, . . . . .	2	0	0
Education, . . . . .	12	10	0
Doctor, . . . . .	3	3	0
Replenishing, . . . . .	4	10	0
Travelling to sea-side, . . . . .	5	0	0
Omnibus, postage, sundries, . . . . .	8	13	2
	£200	0	0

SCALE FOR AN INCOME OF £100 PER ANNUM, FOR A FAMILY CONSISTING OF HUSBAND, WIFE, AND THREE CHILDREN.

[Rooms only should be rented, unless a lodger could be found, who would help to pay the rent of a cottage.]

	£	s.	d.
Rent, 5s. weekly, . . . . .	13	0	0
Butcher, 6s. weekly, . . . . .	15	12	0
Baker (7½ loaves at 7d.; flour, 8d.), weekly, 5s. 0½d., . . . . .	13	2	2
Grocer, 4s. weekly, . . . . .	10	8	0
Milk, 1s. weekly, . . . . .	2	12	0
Vegetables, 1s. 6d. weekly, . . . . .	4	6	8
Beer (occasional), . . . . .	1	6	6
Fuel, . . . . .	7	0	0
Washing (soap, starch, &c.) . . . . .	2	0	0
Clothing, . . . . .	12	12	0
Doctor, or sick fund, . . . . .	3	0	0
Education, . . . . .	6	0	0
Life insurance, . . . . .	2	0	0
Fire insurance, . . . . .	0	2	0
Charities, . . . . .	0	5	6
Holiday excursions, . . . . .	1	10	0
Replenishing household goods, . . . . .	1	15	4
Books, papers, and periodicals, . . . . .	1	0	0
Postage and sundries, . . . . .	2	7	10
	£100	0	0

SCALE FOR AN INCOME OF £52 PER ANNUM, FOR A FAMILY CONSISTING OF HUSBAND, WIFE, AND THREE CHILDREN.

	£	s.	d.
Rent of rooms, 3s. 6d. weekly, . . . . .	9	2	0
Baker (7½ loaves at 7d.; flour, 8d.), 5s. 0½d. weekly, . . . . .	13	2	2
Butcher, 1s. 6d. weekly, . . . . .	3	13	0
Milk, 7d. weekly, . . . . .	1	10	4
Tea (quarter lb. at 3s.), 9d. weekly, . . . . .	1	19	0
Sugar (½ lb. at 4d.), 6d. weekly, . . . . .	1	6	0
Rice, treacle, and pearl-barley, . . . . .	1	6	0
Butter (½ lb. at 1s. 6d.; dripping, 1 lb. at 3d.), 1s. weekly, . . . . .	2	12	0
Candles, average 6d. weekly, . . . . .	1	6	0
Mustard, salt, and spice, . . . . .	0	4	0
Vegetables, 1s. 6d. weekly, . . . . .	3	18	0
Coal and wood, 1s. 3d. weekly, . . . . .	3	5	0
Soap and soda, . . . . .	0	13	0
Schooling, 3d. weekly, . . . . .	1	10	0
Clothing fund, . . . . .	3	16	6
Sick fund, . . . . .	0	10	0
Holiday excursions, . . . . .	1	0	0
Postage, books, and sundries, . . . . .	1	2	0
	£52	0	0

[This income could be improved by having lodgers, who would help to pay the rent, and also if a plot of kitchen-garden ground could be obtained.]

These scales may be regulated to suit families of greater or smaller numbers than those mentioned here.

DOMICILE, a man's legal place of abode, or the place which the law will hold to be his residence. In determining questions of domicile, so often surrounded by difficulties, the law endeavours to follow the facts of each case, and, consequently, the legal as well as the natural view of the matter is expressed in that definition of a domicile in the code which says, 'every man has his domicile where he has placed his hearth and centred his fortunes, whence he goes not forth without an occasion, from which, when he is absent, he is said to be abroad, and to which, when he returns, he is said to cease to be abroad.'—Cod. 10, tit. 40, s. 7. Even in Rome, questions of domicile were not without importance, for the empire was divided for purposes of domestic government, and the inhabitant of one province was not subject to the magistrates of another. But it was in modern times, when Europe was divided into many independent kingdoms, and America was formed out of states having different local customs and laws, that the law of domicile assumed its full importance. It now constitutes one of the most difficult branches of private International Law (q. v.). The following are its most general rules: 1. The place of birth is the original domicile of every one, provided that, at the time of his birth, it was the domicile of his parents; but if his parents were then on a visit or on a journey, the home of the parents will be the domicile of birth, nativity, or origin (*domicilium originis*). 2. If the child is illegitimate, it follows the domicile of its mother. 3. The domicile originally obtained continues till a new one is acquired; unless it be lost by non-residence, under the provisions of a statute, as is the case with paupers, for the purposes of parish relief in Scotland. 4. Minors are generally deemed incapable of changing their domicile of their own accord, but it may be changed by a change in the domicile of the parents, which it follows. 5. If the father dies, his last domicile is that of his widow and children. 6. A wife follows the domicile of her husband. 7. The place where a man lives, if there be no ground for entertaining an opposite presumption, is his domicile. 8. If a person of full age, having a right to change his domicile, takes up his abode in a new place, with the acknowledged intention of remaining permanently fixed there (*animo manendi*), that place immediately becomes, and that which he has quitted ceases to be, his domicile. Questions as to what amounts to intention, or what circumstances constitute sufficient

proof of intention of remaining, or quitting a place of residence, are amongst the most difficult in the law of domicile. Most persons who are resident abroad have a sort of floating notion that, in certain conceivable circumstances, they would return to their native country, and to these vague feelings they give expression in a manner more or less vague. One of the most important effects of the law of domicile was as to the validity of the will which a deceased person leaves—the English rule being, that it must be according to the law of the domicile, wherever the will was made, though the law of Scotland allowed a will also to be good if it was executed according to the law of the country where it was made. A statute, however, was passed in 1861, to make the law uniform, so that the will of a British subject, as regards personal estate, made out of the United Kingdom, is deemed valid, wherever his domicile may be, if the will is conformable to the law of the country where made, or to the law of the domicile of origin. And by a later statute in 1868, even as regards real or heritable estate, an English will is to have effect given to it as regards property situated in Scotland. It is impossible, in our limits, to enumerate other effects of the law of domicile. Generally, it may be stated that it regulates the succession to personal or movable property, which is said to follow the person, and must be distributed after death according to the law of the country of which the deceased died a domiciled citizen. Heritable or real property, again, descends in accordance with the law of the land in which it is situated (*lex rei sitæ*). As to the effect of a domicile of citation in Scotland in actions of divorce, see DIVORCE, MARRIAGE.

**DOMINANT**, in Music, the fifth above the tonic: the ruling or governing tone of the key. Ancient writers called the dominant the *quinta toni*, from its being the next in importance to the tonic. The dominant chord is always a major chord, the third being the *subsemitonium modi*, or leading note, which always rises a semitone to the tonic. The dominant seventh is the major chord with the flat seventh above the dominant, and is the same in major and minor keys. The rules for the treatment of the dominant seventh, and for the chord of the ninth on the dominant, apply to all other chords of the seventh or ninth, which arise from the other degrees of the scale. The dominant seventh is a most important chord in modulation. The resolution of the dominant seventh is always into the chord of the tonic, when not interrupted. The dominant as a key is the nearest in relation to the tonic. Modulation into the key of the dominant is so frequent in composition, that its form may be said to be stereotyped. The subdominant, or under-dominant, stands next in importance to the dominant, and has its place on the fourth above the tonic, or, which is the same, on the fifth below. The chord of the subdominant is major or minor, according to the mode of the key. The chords on all other degrees of the scale, being either minor or diminished, give greater importance to the major chords of the tonic, dominant, and subdominant, in which chords all the notes of the scale are found, while the combination of these chords, giving the most perfect impression of a key, may account for their being of such importance in harmony.

**DOMINANT TENEMENT.** See **SERVITUDE.**

**DOMINGO, SAN,** a maritime city of Hayti, stands on the south-east coast, at the mouth of the Ozama, in lat. 18° 29' N., and long. 69° 57' W. It is the oldest settlement of European origin in America, having been founded in 1494 by Bartolomæo Columbus. The population numbers about

15,000; and the principal buildings are churches, including a cathedral, convents, hospitals, colleges, barracks, an arsenal and a light-house. Its name has been extended in various senses. It has been applied to the whole island, practically superseding the 'Hispaniola' of Columbus; and also to the French or west section of Hayti, as distinguished from the Spanish or east division, in which the place is situated. From it, also, the last-mentioned portion has derived its epithet of 'Dominican' as a separate territory. See **HAYTI**, and **DOMINICAN REPUBLIC.**

**DO'MINIC, St.** See **DOMINICANS.**

**DOMINICA** or **DOMINIQUE**, a British West India Island, lies in lat. 15° 18' N., and long. 61° 24' W., containing about 290 square miles, and (1870) 28,517 inhabitants. It is of volcanic origin, hot and sulphureous springs still attesting the fact. It is the loftiest of the Lesser Antilles, attaining, at one point, an elevation of 5314 feet, and nearly one-half of the surface consists of precipitous mountains and deep ravines. Where capable of cultivation, the soil is fertile; and, even on apparently inaccessible sites, the emancipated negroes have successfully established provision grounds. The principal productions are sugar, coffee, cocoa, cotton, tobacco, molasses, rum, copper ore, sulphur, indigo, rose-wood, and other cabinet woods. In 1856, the exports were £79,755; in 1866, £106,452; in 1870, £62,247. The imports in the same years were respectively £64,124, £62,188, and £60,278. In 1860, the tonnage entered and cleared was 18,777 tons; in 1865, 16,176; and in 1870, 19,160. In 1870, again, the revenue was £15,721, and the expenditure, including repayments of loans, was £15,248; while, in 1849, the returns had given £8877, and £10,539. The legislation of 1857 appropriated £700 for the purpose of affording aid, under statutory regulations, to schools of every denomination—a liberality which, while accepted by Protestants, whether of the Church of England or of dissenting bodies, does not appear to have been appreciated by the Roman Catholic priesthood. The abolition of slavery, independently of inferences to be drawn from correlative statistics, is admitted by all parties to have worked well in Dominica. In 1839, the planters at a public meeting acknowledged, 'with feelings of unmixed gratification, the peaceable and quiet disposition evinced by the labourers, as a body, since their entire emancipation;' and, in 1852, the lieutenant-governor officially adverted to the prosperity and contentment of the same class. It is even said that most of the 20 members of assembly are men of colour. The temperature, according to season and altitude, ranges from 88° F. down to chilliness; and even in the dry months, from February to August, rain frequently falls. D. was discovered by Columbus, on his second voyage, in 1493, on a Sunday (whence its name *Dominica*, i. e., the Lord's Day), being then thinly inhabited by Caribs. From the commencement of the 17th c. to the middle of the 18th, it may be described as having been a neutral island; but in 1759 it was captured by England, and permanently ceded by France in 1763. In 1802 it again came into the possession of France, but was finally handed over to England in 1814.

**DOMINICAL LETTER,** or **SUNDAY LETTER,** is one of the seven letters A, B, C, D, E, F, G, used in almanacs, &c., to mark the Sundays throughout the year. The first seven days of the year being marked in their order by the above letters in their order, then the following seven, and all consecutive sets of seven days to the end of

the year, are similarly marked; so that the 1st, 8th, 15th, 22d, &c. days of the year are all marked by A; and the 2d, 9th, 16th, 23d, &c., by B; and so on. The days being thus marked, it is evident that on whatever day the first Sunday of the year falls, the letter which marks it will mark all the other Sundays in the year, as the number of the letters and of the days in the week is the same.

As the common year consists of 52 weeks and one day over, the dominical letters go backwards one day every common year. If the dominical letter of a common year be G, F will be the dominical letter for the next year. As a leap-year consists of 52 weeks and two days, the letters go backwards two days every leap-year. If in the beginning of a leap-year the dominical letter be G, E will be the dominical letter for the next year. This extraordinary retrocession, however, is made to take place at the intercalary day (the 29th February) by the artifice of marking it by the same letter as the day preceding it, and thus the next Sunday is marked by the letter preceding that which marked the Sundays before the intercalary day. Suppose the 28th February in a leap-year to be a Sunday, and marked by F, it is evident that the dominical letter for the rest of the year will be E. As every fourth year is a leap-year, and the letters are seven in number, it is clear that the same order of letters must return in four times seven, or 28 years, which would, but for the leap-years, recur in seven years, and hence the Solar Cycle (q. v.). The dominical letters were first introduced into the calendar by the early Christians, to displace the nundinal letters in the Roman calendar. They are of use as a means of discovering on what day of the week any day of the month falls in a given year. See EASTER. Rules and tables for finding them are given in prayer-books, breviaries, &c., as well as in works on Dates (q. v.).

**DOMINICAN REPUBLIC**, a state formed of the Spanish or east section of Hayti (q. v.). Spain, in 1697, surrendered to France, by the treaty of Ryswick, the west part of the island, retaining the remainder down to 1795. In the year last mentioned, however, the Spanish portion became nominally French. In 1814—the west having vindicated its independence—France formally relinquished, in favour of Spain, all claim to the east. In 1822, the colony, in imitation of the continental possessions, threw off the yoke of the mother-country, to link itself, more or less closely, with its African neighbours. But, in or about 1843, it assumed a separate standing as the Dominican Republic. In 1861, after a troubled existence of seventeen or eighteen years, it exchanged its constituted anarchy for the somewhat despotic protection of its former masters. But in 1863 a revolt broke out, and, after some fighting, Spain again gave up the possession. It covers far more than half the area of the island; but, greatly inferior in proportion of population, it contains only 136,500 inhabitants. Since 1866, the republic has been disturbed by intestine struggles.

**DOMINICANS**, an order of preaching friars in the Roman Catholic Church (*Fratres predicatorum*), founded at Toulouse in 1215 by Dominic (Domingo) de Guzman. Dominic was born at Calahorra, in Old Castile, in 1170. He studied theology at Palencia, and in 1199 became canon and archdeacon of Osma in Castile. In 1205, along with his superior, Diego de Azebes, Bishop of Osma, he began to itinerate through the south of France, for the purpose of converting the 'heretical' Albigenses; and convinced that the ignorance of the people and the worldliness of the clergy were great helps to the progress of heresy, he instituted the order which

bears his name, for the express purpose of preaching and the cure of souls. Dominic, however, found it impossible to convert the Albigenses by this method, and therefore had recourse to another. In 1208, at the instigation of Dominic, the pope proclaimed a crusade against these 'heretics;' the barons of France were summoned to take part in it, and headed by De Montfort, committed horrible slaughter on these unfortunate people. The order of the D. was confirmed by Innocent III. and Honorius III. in 1216. The members followed the rule of St Augustine, somewhat modified; their dress was a white garment, resembling that of the Carthusians, with a black cloak and pointed cap of the same colour. In 1220 they took the vow of poverty. Dominic died at Bologna in 1221, and was canonised by Gregory IX. in 1233. He is said to have been ordinarily not a cruel or unfeeling man, but his religious passions were so vehement, that they entirely dried up the milk of human kindness in his heart, and his conduct towards heretics was merciless in the extreme. As early as 1206, he fomed an order of Dominican nuns, which, after 1218, when the first convent was established at Rome, spread far and wide. These nuns followed the same rule as the friars, and were solemnly pledged to habits of industry. A third Dominican order (the Knights of Christ) was established in 1224, and confirmed in 1279. It was originally a company of knights and nobles who had leagued themselves together for the suppression of 'heresy' by force of arms, but after the death of its founder, the order was changed into that of the *Penitents of St Dominic*. The members of this branch of the D. were also called the Tertiary Dominicans. They were not bound by any vows, but their special duties were to observe particular fasts and devotions, and to execute great ecclesiastical judgments. They retained all their civic and domestic privileges. There were also *female Penitents of St Dominic*, a few of whom, however, betook themselves to a conventual life, and became nuns. These few were chiefly in Italy; the most famous was St Catharine of Siena. The glory of apostolic poverty, which encircled the D., the privileges which they possessed—especially of preaching and hearing confession—and the circumstance that as early as 1230, only fifteen years after the foundation of their order, they secured a chair of theology in the great university of Paris, all helped to rapidly increase their numbers and influence. Within six years after their establishment, they had spread to England through one Gilbert du Fresney, and founded a monastery at Oxford. 'The monks,' writes the contemporary annalist, Matthew Paris, himself a Benedictine, 'did not, in three or four hundred years, ascend to such a height of greatness as the friars, minors and preachers, within twenty-four years after they began to build their first house in England.' Their progress was scarcely less rapid in Scotland, where they found a munificent patron in King Alexander II., who is said to have met St Dominic at Paris about the year 1217. In Britain, the Dominicans were called the *Black Friars*. In France, they received the name of *Jacobins*, from the Rue St Jacques (Lat. *Jacobus*) in Paris, where they first established themselves. Their monasteries arose throughout all Christendom, and were even to be seen on the shores of Asia, Africa, and subsequently America. Their monarchical constitution, which bound all the branches and congregations of the order under one grand head (*magister ordinis*), insured their progress and the co-operation of their efforts to secure influence in church and state. Through their preaching and proselytising, it is undeniable that they exercised, at the time of the

foundation of their order, and for a considerable time after, an influence alike extensive and beneficial. They have produced several great scholars and men of genius, such as Albertus Magnus; Thomas Aquinas, the normal theologian of the Roman Catholic Church; and Raymund de Pennafortc. They have, however, acquired a black reputation in history in connection with the Inquisition (q. v.), in which they were the chief agents. After 1425, when they obtained permission to accept endowments, they in some measure refrained from hegging, and engaged themselves more with politics and theology. Their great rivals were the *Franciscans* (q. v.), and the mutual animosity of the two orders was strongly exhibited in the disputes of the

Dominican, or Black Friar.

Thomists and Scotists. These two orders divided between them the honour of controlling the church, and often the Catholic states of Christendom, until the rise of the Jesuits in the 16th c., who gradually drove both from the schools and the court, when the D. were compelled to return to their original vocation. Their power was, however, again revived to a certain extent in 1620, when the censorship of books was conferred on the Master of the Vatican at Rome, who must always be a Dominican. In the 18th c., the order of D. possessed 1000 monasteries and convents, divided into 45 provinces, besides 12 separate congregations or sects. At present, the order flourishes only in Italy, France, Hungary, Switzerland, and America. The Dominican nuns, who are not numerous, have convents in Italy, France, Belgium, Hungary, Bavaria, and America.

DOMINIS, MARCUS ANTONIUS DE, an ecclesiastic whose career was both singular and checked. He was born in 1566 at Arba, on the coast of Dalmatia, and educated, first at Loretto, and subsequently at Padua, where he greatly distinguished himself both by his ability and the varied character of his studies. While at Padua, he taught mathematics, physics, and eloquence. Having completed his theological curriculum, he was, after some time, appointed Bishop of Segni, and two years later, Archbishop of Spalatro, in which capacity, however, he quarrelled with the

pope, and having, moreover, exhibited certain Protestant leanings, he found it expedient to resign his post. In 1616, he came to England, where he was hospitably received. King James appointed him Dean of Windsor; and while holding this office, he wrote his *De Republica Ecclesiastica*, a work in which he endeavoured to shew that the pope had no supremacy over other bishops, but was only *primus inter pares*. D. published one or two other productions between 1617 and 1618; but finding Anglicanism far from satisfactory, a revulsion of feeling occurred, and D. once more looked and longed for the unity of the Catholic Church. The motives that induced him to return to the Roman Catholic Church are not known. Most writers consider that he was actuated by avarice and ambition, but a critical appreciation of his character would lead us to doubt this harsh judgment. He was, it has been supposed, desirous of discovering a church broad enough to form the basis of a universal Christianity. Men holding such opinions are always misunderstood, and so D., even after his return to Rome, was still suspected of heresy. In consequence, he was imprisoned in the castle of St Angelo, where he died, September 1624. Being subsequently condemned as a heretic, his body was raised from its grave, and burned.

While at Padua, D. wrote his *De Radiis Visus et Lucis in Vitris Perspectivis et Iricle* (Venice, 1611). He was the first to point out that in the phenomenon of the rainbow, the light undergoes, in each rain-drop, two refractions and an intermediate reflection.

DOMINIUM, a Roman law-term, which has been received into the technical language of most of the legal systems of Europe. It may be described as a full legal right in and to an object—as the right from which alone legal possession could flow, but which actual possession alone could never confer, unless such possession had endured for the period of legal prescription. The right to possess is thus distinguished from the right arising from possession, which is the usufruct. Ownership or dominium may be either absolute—that is to say, it may include the beneficial interest in the subject—or it may be bare ownership, consisting in some limited power over it at the time, or some ultimate right to it at a future time. Dominium must not be confounded with Imperium (q. v.), which has a totally different signification.

DOMINO, the name formerly given to the garb worn in winter by priests while officiating in cold edifices. It is now used to signify a masquerade costume, consisting of an ample cloak or mantle with wide sleeves. See MASQUERADE.

DOMINOS, the name of a game, usually played with 28 oblong, flat pieces of ivory or bone, &c., each of which bears two numbers marked by points from nought to six. The party wins who has first played out his tablets, or, if this has been found impossible, who has the fewest points on the tablets still remaining. The game of dominos has been attempted to be traced back to the Greeks and Hebrews, and also to the Chinese. So much is certain, that it was introduced about the beginning of the 18th c. from Italy into France, where it immediately became popular in the larger towns. From Paris it spread to Germany, where, as in France, it is now played in every coffee-house. The Café de l'Opera, in Paris, long boasted of assembling the most expert players; an honour, however, which was warmly contested by the establishments of Rouen and Poitiers.

DOMINUS, the Latin word by which we commonly render lord, but which more properly

signifies master, as opposed to slave (*servus*). Aurchianus is said to have been the first emperor who adopted dominus as a title of honour on his medals, though it had long been made use of in conversation and in correspondence in that sense, as by Pliny in addressing Trajan. In legal phraseology, the *dominus litis* is the person really interested in the issue of an action, though not necessarily the pursuer.

DOMITIANUS, T. FLAVIUS, emperor of Rome from 81 to 96 A. D., was the son of Vespasian, and younger brother of Titus, whom he succeeded on the throne. The earlier years of his reign were on the whole advantageously occupied for the public benefit. Many good laws were passed, the provinces carefully governed, and justice rigidly administered. As he grew older, however, his ambition, his jealousy, and his pride, wounded by the failure of his campaigns against the Dacians and the Marcomanni, in 87 A. D., began to instigate him to the most atrocious cruelties. By murder or banishment, he deprived Rome of nearly every citizen conspicuous for talent, learning, or wealth. To win the army, he greatly increased the pay of the soldiers, and secured the favour of the people by prodigal largesses and gladiatorial shows and games, in which he sometimes took part in person. His cruelties became at length so intolerable, that a conspiracy—encouraged, if not organised—by his wife Domitia, whom he had doomed to death, was formed against him, and the tyrant fell under the dagger of the assassin, 18th September 96 A. D.

DO'MO D'O'SSOLA, a charming little town in the extreme north of Piedmont, at the foot of the Simplon, near the right bank of the Tosa, which flows into Lago Maggiore. Its general aspect is peculiarly Italian. It has some trade and several handsome buildings, but is chiefly noteworthy as being a starting-point for tourists who wish to make excursions up the southern valleys of the Alps. The chief places of interest in the vicinity are the Val Anzasca, the Val Vigizzo, and the Falls of the Tosa. From D. D. the Simplon can be ascended in seven hours. Pop. 2480.

DON (anc. *Ta'nais*), a river of Russia, has its source in a small lake in the government of Tula, in lat. about 53° 45' N., and long. 38° 10' E. It flows at first in a south-eastern direction through the governments of Tula, Riazan, Tambov, and Woronetz, and after winding south-west through the country of the Don Cossacks, it advances to its embouchure in the Sea of Azov, which it enters by three mouths, only one of which is navigable. The Don receives 80 affluents, of which the principal are the Sosna and the Donetz on the right, and on the left the Khoper, the Medveditz, the Sal, and the Manitch. Its total length is about 900 miles. Its course is obstructed by frequent sand-banks, which, when the water is low, render navigation impossible to any but flat-bottomed boats. From April to June, however, during which months it overflows its banks, and forms unwholesome swamps on either side, it is navigable as high as Zadonsk, 600 miles from its mouth. The Don is connected by a canal with the Volga, and by this means the produce and manufactures of the interior are conveyed to the southern provinces of Russia. The waters of the Don abound in fish, the traffic in which commodity is considerable, especially in its lower course.

DON, a river of Aberdeenshire, rising on the west border of the county in a peat-moss, 1640 feet above the sea. It runs north-east, then east, and lastly south-east, entering the sea a mile north-east of Old Aberdeen. It has a total course of 78 miles, but

only 42 in a straight line, and it drains a tract of 495 square miles, chiefly composed of granite and gneiss, with a little syenite and clay-slate. In the upper part of its course, it receives some large mountain streams, but its chief tributary is the Ury, which comes 21 miles from the north-west. Near the junction of the Ury and Don is a curious conical gravel hillock, called the Bass, the subject of a prophecy by Thomas the Rhymmer. The Don, at less than a mile from the sea, is crossed by the old 'Brig o' Balgownie,' of one Gothic arch. Lord Byron, while a youth, had a superstitious dread in crossing this bridge, from an old prophecy connected with it. To keep this bridge in repair, Sir Alexander Hay, in 1605, left an annuity of £2, 5s. 8½d., which sum has now accumulated to about £19,000, in addition to about £17,000 spent thirty years ago in the erection of a new bridge over the Don, a quarter of a mile lower down.

DON, or DUN, a river of the West Riding of Yorkshire, rising in the moors on the borders of Derbyshire and Cheshire. It runs 55 miles, first south-east to Sheffield, and then north-east by Rotherham, Doncaster, and Thorne, into the Aire, which soon afterwards unites with the Ouse. Its basin consists of Carboniferous and Permian strata. Its chief tributaries are the Rother, Dearne, and Wentle. It is navigable for the last 39 miles of its course below Sheffield, by the aid of artificial canals and cuts.

DON BENITO, a town of Spain, in the province of Badajoz, 55 miles east of the city of that name. It is situated near the left bank of the Guadiana, and is in general well built, with wide and tolerably clean streets. It has several squares, the chief of which is lined with the principal structures in the town, including the town-hall, prison, and a convent; and in the centre is a public promenade. D. B. has manufactures of woollens, wine, and oil, and its proximity to the Guadiana affords it great trading facilities. Pop. about 15,000.

DON CARLOS. See CARLOS.

DON JUAN is a legendary and mythical personage like Dr Faustus. The two have been made the representatives of two different tendencies, both proceeding from the same principle—from the principle, namely, of unbelief and godlessness, which necessarily turns self into either a god or a beast—the principle of subjectivism, or selfishness become dominant. In Faust, expression has been given to the subjective idealism of the Germanic nations, their tendency to subtle speculation and a rationalism antagonistic to faith. In D. J. appear the practical materialism and refined sensualism of the Romanic peoples, and the tendency of blind belief in a corrupt catholicism to pass into unbelief.

Although Faust and D. J. have thus the same source and the same termination, yet, as they proceed from opposite poles, they stand in contrast to each other, and, as was natural, have found different vehicles of expression—Faust in poetry, D. J. in music. The ideal of the D. J. legend is presented in the life of a profligate who gives himself up so entirely to the gratification of sense, especially to the most powerful of all the impulses, that of love, that he acknowledges no higher consideration, and proceeds to murder the man that stands between him and his wish, fancying that in so doing he had annihilated his very existence. Partly in wanton daring, partly to allay all uneasy misgiving, he then challenges that Spirit in which he disbelieves to demonstrate to him its existence in the only way he holds valid—namely, through the senses. When this actually happens, when the Spirit proves its existence and power by animating the marble statue

which he had, with daring mockery, invited as his guest, and summoning him to the final tribunal, compels him to acknowledge the supremacy of spirit, and the worthlessness of a merely sensuous, godless, and immoral existence, it is all over with him, he is crushed, and sinks into hell.

This ideal career is aptly enough localised in one of the most luxurious cities of the once world-monarchy of the Saracens—viz. Seville—and the characters wear the names of the ancient noble families of the place. The hero of the story, D. J., is described as a member of the celebrated family Tenorio, and is represented as living sometimes contemporary with Peter the Cruel, sometimes with Charles V. The chief aim of his sinful career is the seduction of the daughter of a governor of Seville, or of a nobleman of the family of the Ulloas. Being opposed by the father, he stabs him in a duel. He then forces his way into the family tomb of the murdered man, within the convent of San Francisco, causes a feast to be prepared there, and invites the statue which had been erected to his victim to be his guest. The stone guest appears at table as invited, compels D. J. to follow him, and, the measure of his sins being full, delivers him over to hell. At a later period, the legend came to be mixed up with the story of a similar profligate, Juan de Maraña, who had in like manner sold himself to the devil, but was at last converted, and died as a penitent monk in the odour of sanctity.

The genuine legend of D. J. was first put into form by Gabriel Tellez (Tirso de Molina), in *El Burlador de Sevilla y Convidado de Piedra*. This drama was transplanted to the Italian stage about 1620, and soon found its way to Paris, where numerous versions of it, among others Molière's *Festin de Pierre* (1669), made their appearance. It was brought on the English stage by Shadwell under the title of *The Libertine* (1676). In the end of the 17th c., a new Spanish version of Tellez's play was prepared by Antonio de Zamora, and brought on the stage. It is this version that forms the groundwork of the later Italian versions and of Mozart's opera. It was first put into an operatic form by Vincenzo Righini in *Il Convitato di Pietra* (1777); the text of Mozart's *Don Giovanni* was written by Lorenza da Ponte (1787). Through this famous opera the story became popular all over Europe, and has since furnished a theme for numbers of poets, playwrights, and writers of romance. A. Dumas has a drama, *Don Juan de Maraña*; Byron's *Don Juan* follows the name, and in so far the character, of the original; and Prosper Mérimée's novel, *Les Ames du Purgatoire, ou les Deux Don Juan*, is founded upon it.

**DON QUIXOTE.** See CERVANTES.

**DONABUE**, a town of Pegu, stands on one of the main branches by which the Irawaddy enters the Bay of Bengal, lat. 17° 10' N., and long. 95° 27' E. It is within the delta of this grand artery of the country, and is situated 63 miles to the north-west of Rangoon, and 54 to the north-east of Bassin, the principal seaports of the newly acquired British province. It is only on historical grounds, however, that the place is worthy of notice. Here the English were repulsed with considerable loss in both the Burmese wars; first in 1825, and again in 1853.

**DONAGHADEE**, a seaport in the north of the county of Down, on the Irish Channel, 18 miles English (14 Irish) east-north-east of Belfast, and 22 miles south-west of Portpatrick, Wigtonshire, with which it is connected by a submarine telegraph cable. It forms a crescent round the harbour, with two chief streets, one facing the sea. Its exports are cattle, grain, potatoes, &c. The embroidery of

muslin was established in D. about 50 years ago, and it still maintains its pre-eminence in this branch of manufactures, which gives employment to the greater part of the female population. Pop. (1871) 2664. On the north of D. is a conical mound, 140 feet high, 480 feet in circuit at the base, and surmounted by a modern miniature castle 50 feet high, whence there is a very extensive prospect, including the Scotch coast and the Isle of Man. The Danes, in 837, are said to have destroyed a university which stood on a level a little south of where D. now is.

**DONALDSON**, JOHN WILLIAM, was born in London, June 10, 1811. His father, Stuart Donaldson, a wealthy merchant, was descended from an old Scotch family; his mother was daughter of J. Cundall, Esq. of Snaile Green, Lancashire. He was educated first at the university of London, and afterwards at Trinity College, Cambridge. He graduated as B.A. in the year 1834, and obtained the second place in the first class of the classical tripos. The year following, he was elected Fellow. His first work was a volume, entitled *The Theatre of the Greeks*, partly original and partly compiled, which, having been carefully revised and improved in six successive editions, still holds its place as a school and college class-book. He was still resident at Cambridge, holding the office of assistant-tutor of Trinity, when he published the first edition of his *New Cratylus* (1839), a work remarkable for its research, erudition, and boldness, and as being the first attempt, on a large scale, to familiarise Englishmen with the principles of comparative philology, as established by the great scholars of Germany—Pott, Bopp, Grimm, and others. Availing himself largely, but not servilely, of the labours of these men, he developed their principles, and continued their researches, with a special application to the history, structure, and etymology of the Greek language. The third and last edition of the *New Cratylus* (1859), much altered and enlarged, is still the most important work which has been written in English upon the subject. Mr D. soon after married the daughter of Sir John Mortlock of Stapleford, and accepted the post of head-master of the grammar-school of Bury St Edmunds, having previously taken holy orders. Notwithstanding the engrossing nature of his duties as head-master, he found time to prosecute and extend his linguistic studies, embracing in their wide range Hebrew and Arabic, and most of the dialects of modern Europe. In the *Varronianus*, of which the first edition appeared in 1844, he undertook to accomplish for Latin philology what in the *New Cratylus* he had done for Greek. He dedicated the work to the Bishop of St Davids (Dr Thirlwall), in grateful recognition of the benefits derived from his Cambridge teaching. Among his other works of this period may be mentioned an edition of Pindar, of the *Antigoné* of Sophocles (with a verse translation), *Maschil le Sophar* (a treatise on Hebrew grammar), and finally *Jashar*, a book written in Latin, and published at Berlin, the object of which was, by critical tests, to distinguish the fragments of the lost book of *Jashar* imbedded in the Pentateuch. This book was violently assailed by the so-called 'religious press,' which did not prevent its undaunted author from issuing a second edition.

Soon afterwards he resigned his place at Bury St Edmunds, and returned to Cambridge, where he gave a course of lectures on Latin Synonyms, and occupied himself with tuition. Here he wrote a volume entitled *Christian Orthodoxy*. Some critics vehemently disputed its right to the title. A smaller volume on Classical Scholarship followed. He had previously issued a *Greek Grammar* and a *Latin*

Grammar for the use of schools. These, during his residence at Cambridge, he recast and enlarged, so as to rival in profundity and copiousness any other works on the same subjects. In 1856, he was appointed one of the Classical Examiners in the university of London, an honour which he owed chiefly to the strenuous support of Mr Grote, the historian of Greece.

He was engaged in superintending the compilation of a new *Greek Lexicon*, when his health, for the first time, began to shew symptoms of failure. A tour in Germany during the summer of 1860 did not produce any change for the better. Incipient disease of the brain, the result of overwork, shewed itself first by neuralgic pains, and afterwards by more alarming symptoms. He removed to London, and died in his mother's house, after some weeks of great suffering, borne with calm and patient courage, on the 10th of February 1861. In private life, he was distinguished by kindness of heart, ready wit, unflinching vivacity, and varied conversational powers. It ought, perhaps, to be mentioned that a little work, published anonymously under the title of *Phileleutherus Anglicanus*, which made no small sensation at the time of its appearance, has been very generally attributed to Dr Donaldson.

**DONALDSON'S HOSPITAL**, an extensive establishment at Edinburgh, of the character of Christ's Hospital, London. Its founder was James Donaldson, a successful printer in Edinburgh, son of Alexander Donaldson, publisher, of whom some notice is taken in the articles **BOOK-TRADE** and **COPYRIGHT**. In 1763, Alexander started the *Edinburgh Advertiser* newspaper, which was afterwards conducted by his son James, and became a lucrative concern in his hands. Dying in 1830, James bequeathed the fortune of two generations, amounting to about £215,000, to trustees, for the endowment and erection of a hospital for the maintenance and education of poor boys and girls. The building, which occupies a commanding situation to the west of Edinburgh, was begun in 1842, and finished in 1850, is a large and beautiful quadrangular structure, in the Elizabethan style, the late W. H. Playfair being the architect. The cost of the edifice and furnishings was nearly £124,000, but as this was defrayed by the accumulated interest, the original endowment remained untouched. The hospital can accommodate 300 children—150 boys and 150 girls: at present (1873) it contains 220 children (124 boys and 96 girls) of whom 93 (56 boys and 37 girls) are deaf and dumb. Those eligible for admission are declared to be, '1st, Poor children of the name of Donaldson or Marshall, if appearing to the governors to be deserving; 2d, Such poor children as shall appear to be in the most destitute circumstances and the most deserving of admission.' None are received whose parents are able to maintain them. The children are clothed and maintained in the hospital, and taught such useful branches of a plain English education as will fit the boys for trades, and the girls for being servants. The age of admission is from six till nine, and that of leaving the hospital fourteen years. The children wear a simple uniform of modern fashion.

**DONATELLO** (properly, **DONATO DI BERTO BARDI**), one of the restorers of the art of sculpture in Italy, was born at Florence in 1383. He belonged to the Donato family, which reckons several scholars among its members, and has given some doges to the republic of Venice. *Donatello* was a diminutive given to the artist in childhood. He received his earliest instructions from Lorenzo Bicci. His first great works in marble were the 'St Peter' and 'St Mark' in the church of St Michael in his native city.

His own favourite, however, was the statue of an old man in the garb of a senator, on the steeple of the same church. It is known under the name of *Zuccone* (the Gourd or Baldhead). He died at Florence, December 13, 1466. D.'s principal works, besides those already mentioned, are—a statue of 'St George' (in marble), 'Judith bearing the Head of Holofernes' (in bronze), the 'Crescenzio' (in wood), several statues of the 'Baptist' (executed in various materials), and a grand equestrian statue (in bronze) of Erasmus Gattamelata, erected on one of the public places of Padua. He also executed a number of bas-reliefs. The whole tendency of D.'s genius was towards a reproduction of the antique; and his style, though not free from harshness and the rudeness of early art, sometimes reminds one of the glorious productions of ancient Greece.

**DONATION**. A donation in prospect of death, *donatio mortis causa*, differs from a gift *inter vivos*, inasmuch as it is incomplete, and revocable during the donor's life, or ambulatory, as lawyers say. It differs from a legacy, on the other hand, in that it requires no probate, for it is not a testamentary act, the donee's title proceeding directly from the donor in his lifetime. In Scotland, following the law of Rome, it is common to distinguish between donations *pure*—or those which do not take place in anticipation of death, marriage, or any other specific event—and gifts. Such donations are in reality gifts, but gifts which are not intended to be immediately delivered. It was with reference to this species of donation that the equitable arrangement called the *beneficium competentis* was introduced, by which the donor was allowed to retain as much as was necessary for his own subsistence before fulfilling the obligation, if he was reduced to indigence. Another implied condition of a donation by the Roman law was, that when any one who had no children made a donation of the whole or the greater part of his estate, the donation became void if he had children afterwards; the presumption being, that he would not have given his property away if he had anticipated that he was to become the father of a family. It is a general principle of law, that a donation is never presumed; but this rule suffers an exception in the case of alimony given without an agreement to pay board, which is presumed to be gratuitous unless given by one who makes a livelihood of entertaining strangers. Minors, and persons incapable of contracting, are not presumed to have been alimoned gratuitously, unless their relationship to their entertainer be such as to warrant the presumption. Where the minor is possessed of an adequate separate estate, even the father may claim the expense of maintaining him, and the rule applies with greater force to all more distant relatives. Donations between man and wife (*inter virum et uxorem*) were by the Roman law, and are by the law of Scotland, revocable by the donor at any time during his or her life, *ne conjuges mutuo amore se spolient* (lest the spouses should despoil themselves from mutual love). But mutual grants for substantial considerations between the spouses are not revocable, if there be any reasonable proportion between the two. Thus, where there has been no ante-nuptial contract of marriage, the husband may provide for the wife in the event of her survival, and the provision will be effectual in so far as it is rational. It will be revocable only *quoad excessum*. Donations in the prospect of marriage (*donationes propter nuptias*) in the Roman law were given by the husband in security of the dowry or *dos*, which he was bound to pay back to the wife or her relatives on the dissolution of the marriage. When the *dos* was returned to the wife, the

donation was returned to the husband. In the law of Scotland, when donations *propter nuptias* are spoken of, we are to understand provisions made by the husband not with a view to the dissolution of the marriage, but as an equivalent for the dowry, or, as it is called in Scotland, the *tocher*.

DONATISTS were the followers of Donatus, a Numidian bishop who opposed the election of Cecilianus in 311 A. D. to the bishopric of Carthage, on the ground of the ordination having been performed by one who had been a Traditor, or traitor—that is, one who, during persecution, had given up the sacred books to the pagan authorities; and also because Cecilianus had exhibited great hostility towards the victims of the late persecution. After some time, the Council of Arles (August 1, 314 A. D.) decided against Donatus, who in a short time seceded from the Catholic Church, and formed a distinct sect, which, by 330, had as many as 172 bishops in Northern Africa. The D., like the Novatians (q. v.), went upon the principle, that the essence of the true church consisted in the purity and holiness of all its members individually, and not merely in its apostolical and Catholic foundation and doctrine. They therefore both excommunicated all lapsed and gross offenders, not receiving them again but on being re-baptized, and also held that the efficacy of the sacraments depended on the worthiness of the administrator. Driven to fanaticism by the oppression of the secular power, they not only denied to the state all right to meddle with ecclesiastical affairs, but bands of Donatist ascetics collected, attacked the imperial troops (348), and continued to devastate Mauritania and Numidia for a dozen years. In the beginning of the 5th century, they seem to have almost equalled the Catholics in number, and the eloquence of Augustine and the severities of Honorius were exercised upon the sect in vain; they continued to exist as a separate body. But by adopting a more prudent plan of proceeding, the Catholic bishops had, by the end of the 6th c., induced most of those that had left to return to the bosom of the church; and in the 7th c. the D. were extinct. Donatism is regarded by Neander (see *Dogmengeschichte*, translated into English by J. E. Ryland: Bohn, vol. ii. page 394) as a reaction against that form of Catholicism, 'which conceived the church to be an outward organism, continued by the succession of bishops, who formed the necessary medium of communication with Christ, and for partaking in the Holy Spirit and salvation.' 'Whoever is shewn to be a Christian in a right and lawful manner, is to me a Catholic,' was a saying of the D.; while the church in general, guided by Augustine, wished to let the worthy and unworthy remain mixed together, and to defer the separation to the final judgment.' Thus, while the D. had the merit of superior strictness of theory, it must be acknowledged that their views were less practical than those of their opponents.

DONATUS, ÆLIUS, a well-known grammarian and commentator, who taught grammar and rhetoric at Rome about 355 A. D., and was the instructor of St Jerome. He wrote treatises, *De Literis, Syllabis, Pedibus et Tonis, De Octo Partibus Orationis*, and *De Barbarismo, Solcismo, &c.*, the best edition of which is in Lindemann's *Corpus Grammaticorum Latinorum* (vol. i.). These writings form together a pretty complete course of Latin grammar, and in the middle ages were the only text-book used in the schools, so that Donat came, in the west of Europe, to be synonymous with grammar, or with the elements of any science. *The Donat into Religion* is the title of a book by an English bishop,

and there was an old French proverb, *Les diables estoient encore à leur Donat* (The devils were yet in their grammar). The Latin grammar of D. has formed the groundwork of the elementary treatises on that subject to the present day. Donatus was one of the first books on which the art of printing by means of letters cut on wooden blocks was tried, and copies of these Donatuses are reckoned among the greatest of bibliographical curiosities. The author also wrote a commentary on Terence, of which we possess only a part extending to five comedies, to be found in the edition of Terence by Kloz (2 vols., Leip. 1838).

From this D. we must distinguish a later grammarian, TIBERIUS CLAUDIUS DONATUS, from whom we have a very worthless life of Virgil, prefixed to many editions of that poet, and fragments of a commentary on the *Æneid*.

DONAUWÖRTH, a town of Bavaria, situated at the confluence of the Wernitz and the Danube, about 25 miles north-north-west of Angsburg. It is well built, in the form of an amphitheatre, round the side of a hill, and is surrounded by walls. It was formerly a free imperial city of considerable importance, but it has now sunk into an insignificant place of 3000 inhabitants. It is historically interesting, however, as the main cause of the Thirty Years' War; the severity of the punishment meted out to the inhabitants in 1607, in consequence of their adoption of the Reformed doctrines, and their assault on a Roman Catholic procession of the 'host,' having led to the formation of the Protestant League, and Catholic Union, the opponents in that long and severe struggle. It is likewise associated with the name of Marlborough, who stormed and carried the intrenched camp of the Bavarians here in 1704. Also, on the 6th October 1805, the French, under Soult, obtained a victory here over the Austrians, under Mack.

DONAX, a genus of lamellibranchiate molluscs, of the family *Tellinida*, with shell of two equal valves, which close perfectly, and are of a triangular form, prettily striated from the beak to the margin, the beak occupying the obtuse angle of the triangle. The species of D. are generally small. Several are found on the British coasts. The fossil species are not numerous, and belong to the coeene formation.

DONCASTER, a municipal borough in the West Riding of Yorkshire, on the right bank of the Don, on the Great North Road, 35 miles south of York. The country around is flat, but beautiful. Fine old elms line the broad and level road from the south. D. is very clean and well built. The High Street is a mile long. It has manufactures of iron, brass, sacking, linen, and agricultural machines. Its corn-market is one of the largest in the kingdom. Pop. (1871) 18,758. D. was the ancient *Danum*, and lay on the Roman road from York to Lincoln. Roman coins, urns, and a votive altar have been found here. It was the *Dona Castræ* of the Saxons. The Saxon Northumbrian kings had a palace here. D. was burned by lightning in 759, and frequently ravaged by the Danes. It has long been famous for its annual races, begun in 1703, and held a mile south-east of the town in the second week of September. Colonel St Leger, in 1776, founded stakes which have been yearly run for by the best horses in England. On an eminence five miles west-south-west of D. are the ruins of Conisborough Castle, a Norman-Saxon round tower, 37 feet in diameter and 86 feet high, with walls 15 feet thick, strengthened by square buttresses reaching the whole height. The door is arrived at by an external flight of 37 steps, and within is a cylinder open to the heavens.

**DONDRA HEAD**, the most southerly extremity of Ceylon, is in lat. 5° 55' N., and long. 80° 38' E. As compared with Cape Comorin, the corresponding point in the peninsula of Hindustan, it more directly faces the Indian Ocean, and lies nearer the grand thoroughfares of eastern commerce. An adjacent village of the same name numbers 900 inhabitants.

**DONEGAL**, a seaport in the south of Donegal county, at the mouth of the Eske, on a shallow creek of Donegal Bay, 11 miles north-north-east of Ballyshannon. It lies in a rich alluvial tract, surrounded on three sides by hills, behind which rise lofty picturesque mountains. Pop. (1861) 1516; (1871) 1502. D. exports corn and butter. On the river is Donegal Castle, formerly belonging to the O'Donnells of Tyrconnel. On the shore are the ruins of a Paganic monastery, founded in 1474 by Hugh O'Donnell. Near D. is a frequented sulphureo-chalybeate spa.

**DONEGAL**, a maritime county in Ulster province, and washed by the Atlantic on the north and west. Its greatest length is 85 miles; greatest breadth, 41; average, 27; area, 1865 square miles, one-third being arable, and  $\frac{1}{15}$  in wood. The coastline is 395 miles long, being indented by many deep bays and loughs, some 2 to 20 miles broad, and 15 to 25 long. Some of the coast cliffs rise from 500 to 800 feet. Of the many isles off the coast, 17 are inhabited. Except a small tract in the east and south-east, the surface is mountainous, moory, and boggy, with many small lakes and rivers, associated with endless fairy tales and traditions. The highest hill, Erigal, rises 2462 feet, and several other hills exceed 2000 feet. The mountain-ridges run north-east and south-west. The largest stream is the Foyle, running 16 miles north-east into Lough Foyle. Derg is the largest loch. D. is composed of granite, metamorphic rocks, and graywacke, with some Devonian and carboniferous limestone strata and trap. White marble occurs at Dunlewy. Except on the Foyle, the climate is moist, raw, and boisterous, from violent west and north-west winds. There are many ruins of houses and churches overwhelmed with sand. Of the Irish counties, D., in ratio to its area, has least land in cultivation and occupied in towns and woods. The soil is generally cold and poor on the primitive rocks, and light clay on the slaty. In 1872, 241,256 acres were in crop, far the largest proportion being oats, potatoes, and flax. There are manufactures of linen, worsted stockings, worked muslins, and kelp, and fisheries of cod, sole, plaice, herring, and mackerel. Trade is chiefly through Londonderry. Inaccessible retreats and abundance of turf-fuel made D. at one time the chief seat of illicit distillation in Ireland. It contains 6 baronies, 8 poor-law unions, and 51 parishes. Pop. (1841) 296,448; (1851) 255,160; (1871) 217,992, of whom 165,003 are Roman Catholics, 27,362 Episcopalians, 23,514 Presbyterians, and the rest of other denominations. D. sends two members to parliament. The towns are small, the chief being Lifford, the county town; Ballyshannon, Letterkenny, Rathmelton, Donegal, and Killybegs. Industrious farmers and artisans occupy the low fertile tracts. The population of the mountain districts has been much diminished by emigration. Till 1612, when James I. planted Ulster with English and Scotch settlers, the south part of D. was called Tyrconnel, and belonged to the O'Donnells, who, from the 12th c., were inaugurated as Princes of Tyrconnel on Doune Rock, near Kilmacrenan. D. has many ruins and traces of forts, of 30 religious houses, castles, and of the palace of the North Irish kings on a hill near Lough Swilly.

Near Derry is the coronation-stone of the ancient Irish kings. D. contains many memorials of St Columba. Warren, in 1798, captured a French fleet off Tory Isle, which contains the remains of seven churches, two stone crosses, and a round tower. St Patrick's Purgatory is on an isle in Loch Derg. Near Horn Head is a hole in the roof of a cave, called McSwiney's Gun, from which issue, at times, jets of water with loud explosions.

**DONGARPUR**, a fortified town of Rajputana, in Central India, is in lat. 23° 50' N., and long. 73° 45' E., and is 345 miles to the north of Bombay. It is the capital of a protected state of the same name, which contains 1000 square miles, and 100,000 inhabitants.

**DONG-NAI'** is the name of a river and a town in Anam or Cochín-China, an oriental state which has recently derived an adventitious interest from the combined attacks of France and Spain.—1. The river enters the Chinese Sea, by various mouths, about lat. 10° 20' N., and long. 107° E. It is navigable for large vessels as far up as Sai-gon, which, with a population of 180,000, and a trade of great value, stands 40 miles from the coast. From this city, a canal of 23 miles in length connects the D. with the Menam-kong, or Cambodia, which, in a more westerly channel, divides Anam from Siam.—2. The town is on an affluent of the river, being 25 miles to the north-east of Sai-gon.

**DONGOLA (New)**, or **MARA'KAH**, a town of Nubia, capital of a province of the same name, is situated on the left bank of the Nile, in lat. 19° 10' N., long. 30° 22' E. D., which is a military station, is also a place of considerable trade. Its exports are chiefly slaves, in return for which it receives goods of all kinds from Cairo. Its bazaar is well supplied, and it has an indigo-factory belonging to the Egyptian pasha. Pop. estimated at 5000 or 6000. In the vicinity, on the fertile river-island of Argo, are the ruins of old Ethiopian and Egyptian buildings, colossal statues, &c.—**OLD DONGOLA** is a ruined town on the right bank of the Nile, 75 miles south-south-east of New Dongola. On the east side, the desert in some places stretches down to the water-edge.

**DONIS CONDITIONALIBUS**, **STATUTE DE**, called also the Statute of Westminster the Second, 13 Edw. I. c. 1, is the statute which first established in England the power of creating an Entail (q. v.). Before the passing of this act, it had been held by the judges that a conveyance to a man and the heirs of his body was a fee-simple conditional, i. e., a Fee-simple (q. v.) on condition that the donee should have heirs of his body; and this condition having been purified by the birth of an heir, the donee was at liberty to alienate or burden the land, and thus to defeat the original gift. In this respect, however, the gift differed from a fee-simple, that if the donee failed to exercise his power of alienation, and died without issue surviving, the land descended not to the heirs of the donee, but to those of the donor. To counteract the decision of the judges above noticed, the statute *de donis* was passed. It provided 'that the will of the giver, according to the form in the deed of gift manifestly expressed, shall be from henceforth observed.' From the date of this act, the courts recognised two estates in the land—viz., that of the donee, which is called a Fee-tail (q. v.), and that in the donor, which was a reversion or expectancy, by which, on the termination of the estate-tail, the lands would revert to the original owner. As to the manner in which even this intention was defeated, see **ENTAIL**. Not only lands, but rents, dignities, &c., might be entailed under this act. *Co. Litt.* 20 a. See **ENTAIL**.

**DONIZETTI, GAËTANO**, a famous Italian composer, was born at Bergamo, in Lombardy, 1798. He learned the elements of music at the Lyceum of that town, and later, the art of composing under Simon Mayr. D.'s first compositions belonged exclusively to church-music, but the only success he obtained by them was an appointment as a chorister at the church of Basilica di San-Maggiore. D. gave up that position very soon, and after several vicissitudes, entered the military service of Austria. D. now devoted himself to the composing of operas, of which he has left more than sixty. *Enrico di Borgogna*, 1819, with nineteen others that followed, failed to produce any marked result; and it was not until 1831 that his renown began to spread beyond Italy. *Anna Bolena*, *L'Elisir d'Amore*, *Lucrezia Borgia*, *Marino Faliero*, *Lucia di Lammermoor*, *La Fille du Régiment*, followed each other in rapid succession, adding new lustre to his fame. D.'s last productions were *Don Sebastiano* and *Caterino Cornaro*. He died at Bergamo in 1848. Among modern Italian composers, D. is reckoned to be nearest to Rossini, whose style he imitated during the first stage of his career. D.'s music is praised not so much for melody as for dramatic truth and solidity of execution.

**DONJON**, or **DUNGEON**, the principal tower or keep (q. v.) of a castle (q. v.) or fortress. It was so called either from being placed on a *dun* or elevation, natural or artificial, or because, from its position, it dominated (Lat. *dominio*, corrupted into *domgio*, *dongeo*) or commanded the other parts of the fortress. From the circumstance that the lower or underground story of the donjon was used as a prison, has come the modern meaning of the word. See CASTLE.

**DONNE, JOHN, D.D.**, the son of an eminent merchant, cadet of an ancient family in Wales, was born in London in 1573. His parents were Catholics, and he was educated in that faith. At the age of eleven, he went to Oxford, where he remained three years; thereafter, he removed to Cambridge. Although he greatly distinguished himself at these seats of learning, the faith of his parents prevented him from taking a degree. At the age of 17, he entered Lincoln's Inn, to read for the bar; and while so engaged, he carefully studied the principal points in dispute between Catholics and Protestants, and finally joined the latter. About this time, he wrote several of his minor poems, the erotic heat of which contrasted strangely with the austerity of his later years. In 1594, he went abroad, and lived for three years in Spain and Italy. On his return, he was made secretary to Lord Ellesmere, then Lord Keeper of the Great Seal. Here he fell in love with that nobleman's niece, and they were privately married. When the union was discovered, D. was imprisoned by his enraged father-in-law. After his liberation, he recovered his wife by legal process, and, without settled employment, went to reside at the house of Sir Francis Wooley, a kinsman of his wife. After the death of Sir Francis, he removed to London, and lived with Sir Robert Drury, in Drury Lane. With Sir Robert he went to Paris; and on his return, at the instigation of James I., who was delighted with the *Pseudo-Martyr*, a book which D. had written against the Catholics, he entered holy orders. He was made D.D. by the university of Cambridge; and after accompanying an embassy to the queen of Bohemia, he was made on his return Dean of St Paul's, and vicar of St Dunstan's. A fever carried him off in 1631. His life has been written by Izaak Walton—forming one of the group of 'lives' so praised by Wordsworth in a celebrated sonnet.

D.'s works consist of satires, elegies, religious poems, complimentary verses, and epigrams: they were collected and published by his son in 1650. An earlier but imperfect collection appeared in 1633. D. is usually considered as the first of a series of poets of the 17th c. who, under the infelicitous name of the Metaphysical Poets, fill a conspicuous place in English literary history. The directness of thought, the naturalness of description, the rich abundance of genuine poetical feeling and imagery, now began to give way to cold and forced conceits, and elaborate exercises of the intellect. Yet it is generally acknowledged that, amid much rubbish, there is not a little real poetry, and that of a high order, in Donne. His fancy was rich and subtle, his wit singularly keen and poignant, and his word-painting such, that, if he had possessed, in addition, music and sensibility, he would probably have enjoyed a perpetual popularity.

**DOO, GEORGE THOMAS**, one of the best English historical engravers of the present day, was born in the parish of Christ Church, Surrey, January 6, 1800. He has made himself best known by his famous plate of 'Knox Preaching before the Lords of the Covenant,' after Wilkie; while his admirable rendering of Eastlake's 'Italian Pilgrims coming in Sight of Rome,' his exquisitely finished heads of women and children, after Lawrence, his engravings from Raffaele, Correggio, and others, have succeeded in winning for him a very high place in the estimation of the admirers of his laborious art. In 1851, he was elected a Fellow of the Royal Society, and, in 1856, a Royal Academician. He was appointed chairman of the Engravings Committee of the London International Exhibition of 1862. In 1864, he completed, after eight years' work, a large engraving of the 'Raising of Lazarus,' by Sebastian del Piombo.

**DOOM**, the old name given to the last judgment, and to those representations of it in churches which have a religious rather than an artistic object. Many of the dooms are executed in distemper. In the reign of Edward VI. most of them were washed over, or otherwise obliterated, as superstitious. There is a fine one still remaining in the church of the Holy Trinity at Coventry.

**DOOM or DUM PALM** (*Hypphone Thebaica*), a

Doom Palm (*Hypphone Thebaica*).

species of palm remarkable for the repeated forkings of its stem. It is a native of Upper Egypt and of

the central parts of Africa. In some districts, it is the most plentiful tree, sometimes even forming forests, sometimes growing amidst the very sands of the desert. Its leaves are fan-shaped. Ropes are made of the fibre of its leaf-stalks. Its fruit is about the size of an orange, but of a somewhat elongated irregular shape; the outer skin is red, and this being peeled off, a considerable thickness of a spongy dry substance is found within it—also part of the *pericarp*—which has an insipid sweetness, and a remarkable resemblance to gingerbread, so that the tree is sometimes called the GINGERBREAD-TREE. This substance is used as an article of food, and an infusion of it as a beverage. The infusion is cooling, gently aperient, and very salutary in fevers. The albumen of the seed is hard and semi-transparent, and is turned into beads and other little ornaments. Each fruit contains one seed. Egyptian bdellium (see BDELLIUM) is said to be an exudation of this palm.

DOOMSDAY BOOK. See DOMESDAY BOOK.

DOOMSTER. See DEEMSTER.

DOON, a Scotch river, rising in the south-east of Ayrshire in Loch Enoch. It runs north-west through Loch Doon (5 miles by  $\frac{3}{4}$  mile, amid treeless mountains), past Dalmeilington, Burns's Monument, and Alloway Kirk, to the Firth of Clyde two miles south of Ayr. It is 30 miles long. On leaving Loch Doon, the river flows through Glen Ness, a huge rocky and wooded ravine, not surpassed in picturesque beauty by any similar scenery in Scotland. On an islet in the loch are the ruins of Doon Castle, where Edward, brother of Robert Bruce, is said to have lived. Burns has immortalised the D. in song.

DOOR AND DOORWAY, in Art. The form of the doorway is determined by the architectural style of the building in which it is placed. In classical buildings, it is generally rectangular in form, though both Greeks and Romans, following the Egyptians, amongst whom the practice was almost universal, occasionally diminished the opening towards the top; and the Romans, in later times, very frequently threw over it the circular arch, which was the characteristic feature of their style. Egyptian doorways are known to us, for the most part, only by the examples which remain in monumental structures; and these, like the other members of the style as thus exhibited, are of gigantic proportions. The doorway of the temple at Edfu measures 74 feet to its summit, but the lintel and cornice which cover it are so deep and massy as to occupy a space of no less than 23 feet, so that the height of the aperture is only 51. With the Egyptians, the doorway was an architectural object of very great importance. On either side of it, colossal statues or obelisks were placed, and the approach to it was often lined with rows of gigantic sphinxes.

The Greek doorway was surrounded by mouldings, and as the lintel or top-stone which covered it projected on both sides beyond the jambs, the mouldings which ran round both jutted out at the place of meeting, forming a sort of shoulders, as in the accompanying example. This arrangement, however, was by no means uniform, the mouldings of the jambs being frequently quite separated from those of the architrave, as in the beautiful doorway of the Erechtheum, of which an illustration is copied from Mr Donaldson's work on Doors. The doors themselves, in antiquity, in private dwellings, were generally of wood; and in structures devoted to religious or public purposes, of metal, and occasionally of marble. They were generally panelled, and turned on pivots working in sockets. With the exception of the forms of the windows, and the tracery and foliage of the pillars, doorways are the most

characteristic feature in all the styles of Gothic architecture. In the earliest, which we in this country are in the habit of calling Saxon, and which on the continent is commonly known as Romanic, they are of course very plain.

There is seldom more than a few simple mouldings, surrounding a semicircular arch, and in some of the earliest examples, the head of the opening is covered by two flat stones, leaning upon each other in the centre, and their other ends being placed on the imposts, so as to form a triangle. In the Norman Doorway of Erechtheum.

style, they become gradually more ornamental. The arch still continued in general to be semicircular, though there are a few instances of the segmental or horse-shoe arch. As the style advanced, the mouldings and enrichments became more various. Of these, that which is most characteristic of the style is the zigzag moulding. Circular or octagonal shafts were now frequently placed in the jambs, and these, too, were often ornamented with zigzag or spiral mouldings, their capitals being enriched with foliage or grotesque heads or figures. The opening of the doorway often does not rise higher than the springing of the arch, and in this case it is generally flat, the semicircular space between it and the arch being frequently ornamented with a sculptured representation of some scriptural subject. The few Norman doors that exist are devoid of ornament, with the exception of projecting nails, and a simple iron scroll-work projecting from the linge, and stretching to a greater or less extent over the door. As the doorway adheres strictly to the characteristics of the style, early English doorways of course generally terminate in pointed arches. In these the mouldings are more numerous, the jambs contain a greater number of small shafts, some of which occasionally stand quite free, and on the whole the work is richer in form, and more finished in execution. The opening of the doorway is now frequently divided into two, either by a single shaft or a clustered column. In the decorated style, the doorways are not in general so deeply recessed as in the early English; and this circumstance takes from them in richness more than they gain in elegance by their greater height, and by the more delicate character of their ornamentation. In these, the mouldings are commonly enriched with flowers or foliage, either in running patterns or placed separately at short intervals. Of these, the commonest are the Ball-flower (q. v.), and a flower of four leaves, which often projects boldly, and produces a fine effect. The iron scroll-work on the doors resembles that in the former style, except that the terminations are more frequently worked into leaves or flowers. In other cases, the doors are panelled, and covered with characteristic tracery. In the perpendicular style, though the door continues to be arched, it is usually placed under a heavy square external moulding. The doorway in this style loses much of the depth and richness which belongs to it in the earlier styles which we have been considering. Shafts are still used in the jambs, though not always, and they are generally small and few in number; the capitals of the jambs rarely possess the same richness of foliage, and frequently consist merely of plain mouldings. One or more large hollows are often left in the jambs, forming small niches, which frequently

contain statues. This latter characteristic seems to be peculiar to the perpendicular style. In the doorways, as well as in the windows of this style, the four-centred arch came into general use, but

Perpendicular Doorway :  
From the Bishop's Palace, Lincoln.

two-centred arches, and, in small doorways, ogees, are frequently to be met with. The doors in the perpendicular style, when ornamented, are usually panelled, the upper parts being sometimes covered with tracery, but the fine iron scroll-work of the earlier styles had entirely disappeared.

DOOR, the movable panel by which the opening to an apartment, closet, or passage is closed. Doors are made of wood, iron, bronze, or stone. When moving horizontally on hinges, they are called *swing-doors*; when two such are used to close one opening, they are *foldding-doors*. *Sliding-doors* are those which move on rollers, and may be pushed aside. A *jib-door* is one which is concealed as much as possible when shut. A *trap-door* is one which opens vertically over a horizontal opening, as a hole in a floor, &c. When a small door closes an opening cut in a larger one, it is usually called a *wicket*.

Doors are commonly made of wood, and these we shall first describe. The most simply made door is constructed of several boards joined together at their edges by a *rebate*, or a *ploughed and tongued groove* (see CARPENTRY, figs. 19 and 20); these are held together by a transverse piece simply nailed to each board; this is called a *ledge*, and the door thus made, a *ledge-door*. These are commonly used for workshops, stabling, &c.; but when durability and appearance are to be combined, a stout frame is first made, its parts joined together by mortise and tenon. See CARPENTRY, fig. 9. This frame has one or more openings—usually four—which are filled with thin pieces called *panels*, fitted into grooves ploughed in the edges of the frame. The horizontal pieces of the frame are, according to their position, called the *top-rail*, *bottom-rail*, *lock-rail*, and *frieze-rail*. The *lock-rail* is that to which the lock is fixed, the *frieze-rail* intermediate between the middle and top-rail in large doors. The extreme vertical parts of the frame to which the rails are fixed are called *stiles*, and the intermediate vertical part, a *mounting*. Doors are named one, two, four, six, &c., panelled doors, and are further described

by the kind of moulding which surrounds the panel, and from the description of panel. The main object of framing, besides appearance, is to counteract the tendency of the wood to warp, by binding the different parts together with pieces having their fibres at right angles to each other.

In many old buildings, the outer, and even some inner doors are made of massive oaken planks, bound together with ornamental iron straps. Iron doors are chiefly used to intercept fire. For this purpose, they are best made of wrought iron, with double sides. Bronze doors are sometimes used for churches and other large buildings. They are usually ornamented with castings in high and low relief. Those of the Baptistery of the cathedral of Florence, by Ghiberti, and the Pantheon of Rome, are among the most celebrated examples. A few examples of marble doors exist, chiefly in cemeteries and some Belgian churches.

DOO'RA. See DURRA.

DOORN, in English, *Thorn*, is a common name in South Africa. It indicates various communes in the Cape Colony. It also designates two rivers, distinguished as *Great* and *Little*, both of them joining the Olifant, or Elephant, on the right, but the smaller from the south-east, and the larger from the north-east.

DOO'ENBOOM (*Acacia horrida*), the most common tree in the wastes of South Africa. The name D. (*Thorn-tree*), given to it by the Dutch colonists, and the botanical specific name, are due to the number and sharpness of its spines. It seldom much exceeds thirty feet in height, but its timber is hard and tough, and is much used for house-carpentry, &c. See ACACIA.

DOQUET, or DOCKET (from the same root as *dock*, to cut off or clip), a small piece of paper or parchment, containing a brief or summary of a large writing. All attestations or declarations annexed to written instruments are called doquets, more particularly those that are done by a notary. The notarial doquet is said to be the most ancient example of fixed style in Europe; and though latterly appropriated to the instrument of *sasine*, it was formerly common to all solemn instruments. It consisted of a Latin attestation, holograph of the notary, annexed to the notarial instrument prepared by him. The name of the notary was set forth, and the authority mentioned, by which he had been appointed to be a notary. In the case of an instrument of *sasine*, it stated that he was personally present with the witnesses; that he saw, knew, heard, and noted the circumstances mentioned in the *sasine*; that he prepared the instrument, and the number of pages it contained. In addition to his subscription, the notary was formerly in use in Scotland to add his *signum*, which was a flourish of the pen, called a *paraph* or *ruck*. Latterly, he only subscribed the document on each page; and on the last page, opposite to the doquet, he added to his subscription the motto which he had assumed on his admission as a notary. The notarial doquet of instruments of *sasine* was superseded by 8 and 9 Viet. c. 35, s. 5.

DOR. See DUNG BEETLE.

DOR, or MONT DOR (often written less properly Mont d'Or), a chain of mountains in France comprised in the great group of the Anvergne (q. v.) mountains in the department of Puy-de-Dome. They are clearly of volcanic formation, and rise in the Puy-de-Sancy, which is the highest peak of Central France, to the height of 6190 feet.

DORAK, a town of Persia, in the province of Khuzistan, situated on a marshy plain at the

junction of the Dorak with the Jerrahi, lat. 30° 35' N., long. 48° 50' E. It is surrounded by a mud-wall, and defended by a fort. The houses, which have sloping roofs, are built for the most part of sun-dried bricks. By a canal which unites the Dorak with the river Karun, a considerable trade is carried on. D. is also reported to have thriving manufactures. Pop. 6000.

**DORAMA**, a town of Arabia, 32 miles north-east of Derreyeh. The population, nearly 8000 in number, are chiefly engaged in agricultural pursuits. The caravans from Mecca to Persia halt here to obtain supplies. D. was taken by Ibrahim Pasha in 1818, and its inhabitants nearly all slaughtered.

**DORCAS SOCIETY**, the name given to an association of ladies who collect and dispose of garments with the benevolent object of giving aid to necessitous families. Sometimes the ladies connected with a congregation unite to form a Dorcas society, in order to afford employment to poor needlewomen. Societies of this kind are so called from what is recorded in Acts ix. 39: 'And all the widows stood by him weeping, and shewing the coats and garments which Dorcas made, while she was with them.'

**DORCHESTER**, a parliamentary and municipal burgh, the county town of Dorsetshire, in the south part of the county, on the right bank of the Frome, and on the South Downs, 115 miles south-west-by-west of London. It lies on a slight elevation, is nearly encircled by a fine avenue, and consists chiefly of three spacious streets. There is a cavalry barrack near the town. It has a considerable trade in ale and beer, and sends much butter to London. Pop. (1871) 6915. It sends one member to parliament. D. was the Roman *Durnovaria* or *Durnum*, a walled town with a fosse, and a chief Roman British station. Parts of the wall, six feet thick, remained till 1802. Near D. are the remains of the most perfect Roman amphitheatre in England, 218 by 163 feet, and 30 feet deep, the seats rising from the arena, cut in the chalk, and capable of holding 13,000 spectators. There is also a Roman camp with a ditch and high vallum. A large British station occurs near D., with three earthen ramparts, a mile and a half in circuit, and pierced by intricate passages, and enclosing barrows. The inner rampart is 60 feet high. Roman urns, coins, and tessellated pavements have been found near Dorchester. In 1613, 300 houses and 2 churches were burned in the town. In the Civil War, many battles occurred near Dorchester. Here, in 1685, Judge Jeffreys, in his 'bloody assize,' sentenced to death, in two days, 109 persons, implicated in Monmouth's rebellion.

**DORDOGNE**, a department in the south-west of France, formed of the ancient province of Périgord, with small portions of Limousin, Angoumois, and Saintonge, lies in lat. 44° 35'—45° 43' N., and long. 0°—1° 28' E. Area about 3500 square miles. Pop. 480,141. It is watered by the Dordogne, which flows from east to west through the south of the department, and by its tributaries, the Drome, and the Higher and Lower Vezere. The surface is for the most part hilly, and covered with broom and underwood, with here and there a valley of extraordinary beauty and fertility, enclosed with hills, the sides of which are generally clothed with vineyards. There is a great deficiency of corn, but the want, as an article of food for the inhabitants, is supplied to some extent by the immense produce of the chestnuts, which, with the walnut and the oak, are the prevailing trees in the forests. The climate is generally mild. Mines of coal, iron, and manganese are worked; marble, alabaster, and millstones

are quarried. The manufactures are coarse woollens, hosiery, brandy, oil, paper, &c. D. carries on considerable trade in iron, wine, hams, and trilled turkeys. The arrondissements are five in number—viz., Bergerac, Nontron, Périgueux, Ribérac, and Sarlat, with Périgueux as capital.

**DORDRECHT**. See **DORR**.

**DORR**, ANDREA, a noble Genoese, and one of the greatest admirals of his age, was born at Oneglia in 1468. At an early age, he took service in the guard of the pope, Innocent VIII., and afterwards distinguished himself in the battles which the Milanese and the French fought against Genoa and the kings of Aragon. It was D. who, in 1503, after a short campaign, crushed the rebellion in Corsica. When Genoa, in 1513, got rid of the French domination, D. was appointed captain-general of the galleys, in which capacity he carried on a war of extermination against the dangerous swarms of African pirates who infested the Mediterranean. During the war between Francis I., king of France, and Charles V., emperor of Germany, and king of Spain, D. commanded the French fleet, reinforced by his own galleys, and inflicted everywhere severe losses upon the enemy. After the defeat of Francis I. near Pavia, D. accepted the command of the papal fleet; but upon the return of the king from his captivity, entered once more the French service, with the title of High Admiral of the Levant. He blockaded Genoa, for having espoused the cause of the emperor, and putting to flight the party of the Adorni, took the town. On finding the independence of his country threatened by the French, D. with his whole force went over to the emperor, and by so doing hastened the deliverance of Italy from French domination. In 1529, D. entered Genoa without resistance, and refusing the title of sovereign, which was offered by the emperor, established there a popular form of government, which remained in vigour up to the end of the republic. The grateful country decreed him the title of 'Father of Peace;' and the emperor, in whose service D. continued, conferred upon him the order of the Golden Fleece, together with the principality of Melfi. In 1532, D. won a decisive victory over the Turks near Patras, and the conquest of Tunis (1535) was chiefly his work. He took part in the joint expedition against the Turks under Barbarossa in 1539, and in another against Algiers in 1541, where he lost eleven of his own galleys. The tranquillity of his last years was disturbed by the conspiracy of Fieschi. D. took fierce revenge upon the conspirators for the death of his nephew Gianettino. D. died without offspring, in 1560, at Genoa, in his 93d year.

**DORIANS**, one of the four principal peoples of Greece, who took their name, according to the legend, from Dorus, the son of Hellen, who settled in Doris; but Herodotus says that in the time of King Deucalion they inhabited the district Pthiotis; and in the time of Dorus, the son of Hellen, the country called Histiaotis, at the foot of Ossa and Olympus. But the statement of Apollodorus is more probable, according to which they would appear to have occupied the whole country along the northern shore of the Corinthian Gulf. Indeed, Doris Proper was far too small and insignificant a district to furnish a sufficient number of men for a victorious invasion of the Peloponnesus. In this remarkable achievement they were conjoined with the Heracleide, and ruled in Sparta. Doric colonies were then founded in Italy, Sicily, and Asia Minor. Strikingly as all the four nations of Greece differed from each other in language, manners, and form of government, the D. in particular differed from the

Ionians. The former preserved a certain primitive solidity and earnestness, but with it something coarse and hard. See O. Müller's *Die Dorier* (2 vols. Breslau, 1824; 2d ed. 3 vols., 1844). The *Doric dialect* bore the same character; it was harsh and rough, while the Ionian was soft and polished, yet the former had something venerable from its antiquity, and was therefore employed in hymns and choruses. In philosophy, the influence of the Doric character was particularly visible in the Pythagorean school and its attachment to the aristocracy. It is no less traceable in architecture in the strong unadorned Doric pillars, which form so marked a contrast to the slender and decorated Ionian columns.

**DORIC ORDER.** The oldest, strongest, and simplest of the three orders of Greek architecture. See COLUMN, ENTABLATURE, GREEK ARCHITECTURE.

**DORIS**, a genus of gasteropodous molluscs of the order *Nuditranchiata*, the type of a family called *Doridae*, and sometimes popularly SEA-LEMONS. The body is oval, the abdomen flat, the

Doris: a, gills.

back flat in some and elevated in others, the mouth a small proboscis with two small tentacula, the vent situated in the back, and surrounded by a circle of branched or plumed gills. The species are found in all seas, many in those of Britain; but they are more numerous in the southern hemisphere. Some of them attain a considerable size. Few of them inhabit deep water. They crawl on rocks, sea-weeds, &c., where they are often left by the tide, or swim in a reversed position; the foot, made concave by muscular action, serving to buoy them up. Some of them are pretty and interesting inmates of the aquarium. Gosse mentions, that specimens of *D. bitumellata* were 'very social in confinement, continually finding out one another, and crowding close up together.'—*A Naturalist's Rambles on the Devonshire Coast.*

**DORIS**, a small mountainous district of ancient Hellas, between Phocis, Ætolia, Locris, and Thessalia, was the earliest home of the Dorians. With its four towns, Boium, Cytinium, Erincus, and Pindus, it formed the Doric Tetrapolis, which was afterwards completely destroyed by the Macedonians, Ætolians, and other nations, so that at the time of the Romans, only a few remains of these towns were visible.—D. was also the name of a district in Asia Minor on the coasts of Caria, inhabited by colonists from the Peloponnesus; it formed a *Herapolis*.—In modern Greece, D. forms an eparchy of the government of Phocis.

**DORKING**, or **DARKING**, a town in England, in the middle of Surrey, stands in a picturesque valley on the left bank of the Mole, 23 miles south-west of London by road. It lies on the Roman road which ran between London and Chichester. Pop. (1871) 5419. Its chief trade is in flour, lime, and chalk from the adjacent pits. Dorking gives its name to a peculiar breed of domestic fowl. See POULTRY.

**DORMANT** (Fr. sleeping). In heraldic representation, an animal dormant has its head resting on its forepaws, whereas an animal couchant has its head erect.

**DORMANT VITALITY** is a term used to designate a peculiar condition which is manifested by many organised beings, and which is characterised by an apparent suspension of all the vital actions. Beings in this state can scarcely be said to

be *alive*, since they exhibit no vital activity, nor can they be designated as *dead*, since that implies their incapability of resuming their former state; hence, since they retain their peculiar attributes without manifesting them, the term dormant vitality seems the most appropriate for them. This condition may result either from the withdrawal of the stimuli necessary for the maintenance of vital actions (as water, heat, &c.), or it may proceed from some change in the organism itself, whereby its power of responding to these stimuli is for a time diminished or lost. We shall illustrate our meaning by a few striking examples of each kind of dormant vitality.

1. Dormant vitality from the withdrawal of the necessary stimuli.

Seeds deprived of access to air and moisture may retain their vitality for an enormous time. 'I have now before me,' says Dr Lindley, 'three plants of raspberries which have been raised in the gardens of the Horticultural Society, from seeds taken from the stomach of a man whose skeleton was found thirty feet below the surface of the earth, at the bottom of a barrow that was opened near Dorchester. He had been buried with some coins of the Emperor Hadrian, and it is probable, therefore, that the seeds were 1600 or 1700 years old.' A more remarkable illustration of the vitality of seeds is afforded by a case communicated to Dr Carpenter, and published in his *General and Comparative Physiology*, the facts of which may be shortly stated as follows: In a town in the state of Maine, about 40 miles from the sea, a well was being dug, and at a depth of about 20 feet a stratum of sand was found, which excited interest, from the circumstance that no similar sand was known to exist nearer than the sea-beach. It was, in the first instance, collected in a heap, but was subsequently scattered about the spot on which the heap had stood. In a year or two, when the very existence of the sand was almost forgotten, it was observed that a large number of small trees were growing up on the ground where it had been strewed. They turned out to be beach plum-trees, and they actually bore the beach-plum, which had never before been seen except immediately upon the sea-shore. These trees had therefore sprung up from seeds which were in the stratum of sea-sand that had been pierced by the well-diggers, and had probably retained their vitality through a period of time beyond the estimation of human calculation—the period, namely, in which the sea had gradually receded forty miles from its present limits.

Among the lower animals, we find several of comparatively complex structure, in which dormant vitality can be induced for a considerable period, as, for instance, several years by the abstraction of their *moisture*. The well-known rotifer, the wheel-animalcule, may be reduced to a state of perfect dryness, and kept in this condition for a great length of time (certainly three or four years, and some writers say far longer) without evincing a sign of life, and yet it will immediately revive on being moistened. The *Tardigrades*, an allied tribe, have been desiccated by the most powerful means which chemistry affords, and have been then heated to a temperature of 250°, and have still been revived by water, although in their active state a temperature of 120° destroys them. In Woodward's *Manual of the Mollusca*, cases are recorded of living snails crawling out of shells which were supposed to be empty, and in which they must have been dormant for several years, and the eggs of snails and others of the lower animals have a still greater power of revivification after drying. Sir James Emerson Tennent describes various fishes in Ceylon which bury themselves in the mud when the pools or

tanks dry up, and remain torpid until the periodic rains of that country ensue, and previous observers had noted similar facts in other tropical countries. Humboldt relates that crocodiles and boas are sometimes found alive, though torpid, in hardened mud, and revive on the application of water.

A diminution of temperature will induce this phenomenon in many animals. In one of Captain Sir James Ross's voyages, several caterpillars having been exposed to a temperature of 40° below zero, froze so completely, that when thrown in a tumbler they chinked like lumps of ice. When thawed, they resumed their movements, took food, and became transformed into the chrysalis state. One of them, which had been frozen and thawed four times, subsequently became a moth. In the North American lakes, frozen fishes are often found in the ice, which revive when gently thawed. Spallanzani kept frogs and snakes in a torpid state for three years in an ice-house, and then revived them by warmth. The same capability does not exist, at all events to the same extent, in the warm-blooded animals. A total suspension of vital activity in a bird or a mammal for any length of time, from the prolonged application of severe cold, or from any other cause, is never followed by recovery. The stories of certain birds burying themselves in the mud during winter, are regarded by the best authorities as more than questionable; and in hibernating mammals (see HYBERNATION), the suspension is not total. How we are to explain, or whether we ought to believe, the remarkable cases of certain Indian fakirs, who are stated to have the power of suspending all their vital activity for days, or even weeks, we do not know. The late Mr Braid of Manchester published a collection of these cases, directly obtained from British officers who had been eye-witnesses of them in India, in his *Observations on Trance or Human Hybernation*, 1850. We quote one of these, vouched for by Sir Claude Wade. The fakir was buried in an underground cell, under strict guardianship, for six weeks; the body had been twice dug up by Runjeet Singh (at whose court the exhibition came off) during the period of interment, and had been found in the same position as when first buried. In this and in all the other recorded cases, the appearance of the body when first disinterred is described as quite corpse-like, and no pulsation could be detected at the heart or in the arteries. The means of restoration employed were chiefly warmth to the vertex, and friction to the body and limbs.

2. Dormant vitality from changes within the organism.

The insect world affords us the chief illustrations of this variety of dormant vitality. The pupa or chrysalis stage of insect life is in itself one of dormant vitality, unconnected with any of the external influences which we have been describing. That this stage may be much shortened by artificial heat, and prolonged by artificial cold, has been known since the time of Reaumur; but, as the following case shews, there are other causes inherent in the animal itself, which tend at a certain time to prolong the pupa condition. In the *Papilio Machaon* there are two generations every year; for the butterfly that comes forth in the early summer lays eggs which rapidly pass through all the phases of insect life, and produce another set of eggs later in the season, whose larvae or caterpillars turn into pupae before the winter. The pupa stage of the first brood (in July) lasts only thirteen days, while that of the second brood (which commences in September) lasts nine or ten months, the butterfly not appearing until the following June. The difference of temperature is obviously quite insufficient to account for the great diversity between the two periods. Several other

similar cases may be found in Kirby and Spence's *Entomology*.

**DORMER**, or **DORMER WINDOW**, is a window placed in a small gable rising out of a sloping roof, often made use of for the purpose of enlarging and lighting the attic or garret-rooms of modern houses. It is also popularly known as a 'storm-window.' *Dormers* do not appear to have been invented before the middle of the 14th century.

**DORMITORY** (Fr. *dormitoire*, from Lat. *dormire*, to sleep), a sleeping apartment in a monastery, or other religious establishment. Dormitories are usually of considerable size, sometimes having a range of cells parted off on each side.

**DORMOUSE** (*Myoxis*), a genus of rodent quadrupeds, ranked by some naturalists in the family *Muridae* (Rats, Mice, &c.), and by others in the family *Sciuridae* (Squirrels, &c.); being, in fact, a connecting link between the one family and the other. Their habits resemble those of squirrels; the dentition, however, more nearly agrees with that of mice. There are four molar teeth on each side in each jaw: the upper jaw has not the anterior rudimentary fifth molar, characteristic of squirrels. The molars have their summits marked by transverse ridges. There are no cheek-pouches. The ears resemble those of mice. The fore-paws have each four toes and a rudimentary thumb; the hind feet have five toes. The fur is very fine and soft. The tail is long, and in the different species exhibits characters variously intermediate between those of mice and squirrels. This genus and the closely allied genus *Graphyurus* are remarkable as the only genera of rodents in which there is no cæcum. The species of *D.* are beautiful little animals, natives chiefly of the south of Europe. Some species are also found in

Dormouse (*Myoxis avellanarius*).

Africa, and the genus *Graphyurus* is entirely African. The only British species of *D.* is the COMMON *D.*, RED *D.*, or MUSCARDINE (*M. avellanarius*), an inhabitant of woods in some parts of England. It is about the size of a common mouse, with head proportionally large; has a rather pointed muzzle, large prominent eyes, and a flattened tail, thickly clothed with rather long hair; and is of a tawny red colour on the upper parts, and white beneath. It is extremely gentle and easily tamed, feeds on beechmast, acorns, hazel-nuts, grain, &c., and spends the colder parts of winter in a state of torpidity, although in mild weather it wakens up to consume a little of the store of food which, like squirrels, it lays up for that season. Before its hibernation begins, it is generally very fat, nor does it become emaciated by hibernating. It makes a nest of tangled or interlaced herbage opening from above, usually in copse or underwood; and produces about four young ones

at a birth. It often assumes a remarkable posture in feeding, suspending itself by its hind feet; more generally it sits upon its haunches, and holds its food in its fore-paws. This species is found in all parts of continental Europe, from the Mediterranean to Sweden.—The FAT D. (*M. glis*) is a larger species, grayish brown, about the size of a rat, with tail very like that of a squirrel, a native of the south of Europe, where it inhabits forests, leaping from branch to branch with great agility. It is eaten by the Italians, as it was by the ancient Romans, who highly esteemed it, and fattened it for the table in receptacles called *gliraria*.—The GARDEN D. (*M. nitela*), common in Europe as far north as Poland, is frequently found in gardens, and even in outhouses. It is often very destructive of the fruit of wall and espalier trees. It is rather smaller than the Fat D., grayish brown, black round the eyes, and has the tail tufted only at the extremity. All the species of D. hibernate; and from this circumstance the name seems to be derived (Lat. *dormio*, to sleep).

DORNBIRN, a town of Austria, in the north-west of Tyrol, about 8 miles south of the eastern extremity of the Lake of Constance, is situated on the Lossen, a small mountain stream. The houses are widely scattered. The women of D. are chiefly employed in muslin-embroidery; the men are for the most part carpenters, and are principally engaged in the construction of wooden houses, which are carried in detached pieces to the market-town (Bregenz), and are thence exported. Pop. 6600.

DORNICK, DORNIC, DORNOCK, a species of figured linen, for a full description of which see Ure's *Dict. of Arts and Manufactures*. Dornicks were formerly made in considerable quantity at Dornich, or Tournay, in the Netherlands, and hence their name. From this place, the manufacture was probably carried to Norfolk by the Dutch, who emigrated thither during the persecution of the Duke of Alva. By a statute, 5 and 6 Ed. VI. c. 24, this manufacture, or 'mystery,' carried on at Norwich, is carefully protected. All persons, except those residing in Norwich or Pulham, are forbidden to carry on the 'mystery,' under pain of forfeiture of the article, and of the sum of 6s. 8d. for every six yards so made. By 4 Will. and Mary, c. 5, s. 2 (68), a duty of 10 per cent., in addition to duties previously levied, is laid on all tapestry or dornicks imported, except from France. It is scarcely necessary to add, that these stringent provisions are no longer in observance.

DORNOCH, a royal burgh and county town of Sutherlandshire, situated near the entrance to the DORNOCH FIRTH—an inlet of the North Sea, running 25 miles inland, and separating Sutherland from Ross-shire. The cathedral stands in the centre of the town, and is an object of considerable attraction. It is said to have been begun in the 11th c. by St Bar, and was enlarged in 1270 by Bishop Gilbert Murray. It was burned in 1570, and thereafter partially repaired. In the year 1837, it was to a certain extent restored by the late Duchess of Sutherland. It is in the shape of a cross, and is surmounted with a tower and clock spire. The interior is fitted up and used as the parish church. D. was, in olden times, the residence of the Bishops of Sutherland and Caithness. The west tower of the Bishop's palace stands immediately opposite to the cathedral. Next to it is a handsome building, in the old English style of architecture, for the courts of law and public offices. The town has a neat, clean appearance, and is lighted with gas. It is considered one of the best bathing-places in the north, and has extensive 'links,' fit for archery, golfing, and other exercises. D. is one of the six

northern burghs which send a member to the House of Commons. It was constituted a royal burgh by Charles I. in 1628. The last victim in Scotland to the laws against witchcraft was burned here in 1722. Pop. (1861) 647. (1871—625.)

DORO'GH, a town of Hungary, 20 miles north-north-west from Debreczin, situated in the midst of a very fertile district. The population, 6640 in number, are chiefly engaged in agricultural pursuits.

DOROGOBU'SH, or DOROGOBOUGE, a town of Russia, in the government of Smolensk, is situated on the left bank of the Dnieper, about 50 miles east-north-east of Smolensk. It is a small town, but pretty, and well built, and has some manufactures. Pop. 5000. At D., the French, under Eugene, in their retreat from Moscow, encountered many disasters.

DORO'SMA, a town of Central Hungary, Little Cumania, 6 miles west-north-west of Szeged. It contains a Roman Catholic high school. Pop. 8800.

DORPAT, or DERPT (Russian, *Gurie*, Esthonian, *Tartolin*), a town of Russia, in the government of Livonia, is situated on the Embach, here crossed by a fine granite bridge, 150 miles north-east of Riga, and is built in the form of a semicircle. It consists of a town proper, with two suburbs. Its streets are straight and clean; its houses, which are mostly of one story, are built of brick or wood, have handsome fronts, and are often showily painted. It is the winter residence of the Livonian nobles and gentry. The Domberg Hill, at the north-west extremity of the town, is tastefully laid out in avenues and promenades; its summit, formerly the site of a cathedral, destroyed by fire in 1775, is now occupied by an observatory, the university library, schools of anatomy and natural history, museums, &c. The observatory—one of the most renowned in Europe, and long presided over by the celebrated Struve—possesses a great refracting telescope, presented by the Emperor Alexander I. The university, founded in 1632 by Gustavus Adolphus, suppressed in 1656 by the Muscovites, and re-established by Alexander I. in 1802, is also famous. It supports a large staff of professors (about 70), and is attended by 600 students, of every religious denomination, who are taught theology, ethics, law, medicine, natural philosophy, and natural history, which is here a favourite branch of study. It is also the chief school of the Protestant clergy in Russia, and the Reformed Synod of Wilna send their students thither. D. has a botanical garden, containing 18,000 plants, some of which cannot be obtained in any other botanical garden in Europe. D. was formerly a walled town, and the ramparts still exist, but have been converted into public walks. The chief employment of the people consists in supplying the wants of those connected with the University. Pop. 14,000.

DORRE ISLAND, lying to the north of Dirk-Hartog Island (q. v.), in lat. 25° 10' S., forms, like its southern neighbour, part of the breast-work of Shark Bay, in Western Australia. It is 20 miles long.

DORSE (*Gadus callarias*, or *Morrhua callarias*), a fish of the same genus with the cod, haddock, &c.; plentiful in the Baltic and in other northern seas, but scarcely known on the coasts of Britain. It never attains so great a size as the cod, being seldom more than two feet in length, but much resembles it in form and colour, although its colour is more variable, from which it has received the name of VARIABLE COD. It is also called the BALTIC COD. It differs from the cod in the greater length of the upper jaw. It enters the mouths of large rivers. It is in great request on the coasts of the Baltic, being esteemed the best fish of all this family.

## DORSET—DORY.

**DORSET, EARL OF.** See SACKVILLE.

**DORSETSHIRE, or DORSET,** a maritime county in the south of England, on the English Channel, between Devonshire and Hampshire. Its greatest length is 58 miles; greatest breadth, 40; average, 21; area, 1006 square miles; a third being arable, a ninth waste, and the rest in pasture. The coast-line is 75 miles long, with some cliffs and headlands. St Alban's Head is 344 feet high. Portland Isle (q. v.) is connected with the mainland by Chesil Bank. The surface is uneven and bleak. Chalk downs run along the south coast and through the middle of the county nearly from east to west. The highest point is Pilsden Pen, 934 feet. The chief rivers are the Stour, 65 miles long, and the Frome, 35. Geologically, D. consists of strata of plastic clay, chalk, oolite, lias, with some weald and greensand. Remains of colossal reptiles have been found at Lyme Regis. The chief mineral productions are the celebrated Purbeck and Portland building-stones, coarse marble, and white china and pipe clays. The climate is mild. The chalk hills or downs are covered with short fine pasture, on which countless numbers of South-down sheep are fed. The soil is chiefly sand, gravel, clay, and chalk. D. is mainly a pastoral county, producing sheep, cattle, cheese, and butter; but some wheat, barley, hemp, linseed, hops, &c., are raised. Sanfoin is grown on the chalk hills. There are manufactures of linen, silk, woollens, flax, hemp, buttons, stockings, and ale and cider. D. is divided into 34 hundreds, 12 poor-law unions, and about 390 parishes. The chief towns are Dorchester, Bridport, Poole, Weymouth, Melcombe Regis, Shaftesbury, Lyme Regis, and Wareham. D. sends 14 members to parliament, 3 for the county, and 11 for the above towns. Pop. (1861) 188,651. In 1851 (pop. being 184,207), there were 664 schools, with 25,004 scholars; 563 churches, 304 being of the Church of England, and 147 Methodists. D. has ancient British and Roman remains, as stone circles, cromlechs, barrows, camps with ramparts and ditches, Roman amphitheatre, three Roman stations. There are remains of 40 abbeys, priories, hospitals, &c. The ruins of Corfe Castle, a seat of the Saxon kings of Wessex, are among the grandest in England. (1871—pop. 195,544.)

**DORSTENIA.** See CONTRAYERVA.

**DORT, or DO'RDRECHT,** a town of the Netherlands, in the province of South Holland, situated on an island formed by the Maas, about twelve miles south-east of Rotterdam. An inundation in 1421, in which upwards of 70 villages were destroyed and 100,000 people drowned, separated the site upon which D. stands from the mainland. D. is fortified on the south side, and its position is naturally so strong, that though frequently besieged, it has never been taken. It is one of the oldest towns in Holland, and some interesting historical particulars attach to it. Here, in 1572, the states of Holland, after their revolt from Spain, held their first assembly, and declared the Prince of Orange to be the only lawful governor of the country. In 1618—1619, the conclave of Protestant divines known as the Synod of Dort, met here, and condemned the doctrines of Arminius as heretical, and affirmed those of Calvin. (For an account of the questions at issue, see ARMINIUS.) The Gothic building in which the synod sat, whose miraculous labours, according to the president's closing address, 'made hell tremble,' is now used as a public-house, and the particular room in which they met is degraded into a dancing-saloon. Among the principal buildings of D. are a Gothic church with a tall square tower, and containing a beautiful marble pulpit, and the town-hall. The town is traversed by canals, and

the Rhine and the Maas afford it great facilities for trade. Large ships can go quite up to the quays. Gigantic wood-rafts, valuing sometimes as much as £30,000 each, obtained from the Black Forest and Switzerland, come down the Rhine to D., which has numerous saw-mills, ship-building docks, salt and sugar refineries, bleacheries, and manufactures of tobacco, white-lead, &c. It has also a considerable trade in corn, flax, oil, timber, and salt-fish. Pop. 21,000.

**DORTMUND,** a town of Westphalian Prussia, on the Cologne and Minden Railway, is situated on the Emscher, in the midst of a fertile district, 47 miles north-north-east of Cologne. It is a walled city, whose history goes back into the earliest middle-age traditions, figuring in the time of Charlemagne under the names of Throtmanni, Tremonia, Trotmunde, and Dortmunde. Subsequently it became a free Hanse town, but was ceded to Prussia in 1815, at the Congress of Vienna. D. is not handsomely built, but possesses various fine religious edifices, among which the most worthy of notice are the churches of St Reinhold and St Mary. The town-hall of D. is one of the oldest in Germany. D. has flour and oil mills, and manufactures of woollen, linen, and cotton fabrics, tobacco, beer, and cutlery, and an important corn-market. Pop. 22,100.

**DORY (*Zeus*),** a genus of fishes, the type of a family, *Zeidae*, which is sometimes regarded as merely a group of the great family of *Scomberidae*, but is at least a very distinct group, characterised not only by an oval and much compressed form of body, but also by a protractile mouth. The teeth are feeble. The species of *Zeidae* are distributed in the seas of all parts of the world, although only three occur on the British coasts, and two of these are very rare (see BOAR-FISH and OPAH). In the D. genus, the general surface of the body is smooth and destitute of scales, but spiny scales or bony shields guard the dorsal and ventral edges. The anterior portions of the dorsal and anal fins are

John Dory (*Zeus faber*).

spiny, and are very distinctly separated from the spineless portions; the spines of the dorsal fin are prolonged into long filaments, and the tail-fin is rounded. The British species (*Zeus faber*), popularly known as the JOHN DORY, sometimes attains a considerable size: Pennant mentions one which weighed 12 lbs.; but it is seldom seen of much more than 18 inches in length. It is principally found on the southern, and particularly the south-western coasts of England, visiting them, apparently, in pursuit of pilchards; but becomes more rare towards the north. It is highly esteemed for the table, having among modern epicures pretty much the same reputation which it had among those of ancient Rome. It is common in the Mediterranean. The name D. is generally supposed

to be properly *dorée* (gilt), and to refer to the prevailing yellowish colour and golden lustre of the fish; whilst the familiar appellation, *John*, is in like manner derived from *jaune* (yellow), although it has been suggested that it may rather be from the Gascon *jan*, a cock—names signifying Cock, Sea-chicken, St Peter's Cock, &c., being given to this fish in different languages. The D. has a remarkable oval black spot on each side. An idle legend refers these spots to the finger and thumb of St Peter, and the D. thus disputes with the haddock the honour of being reputed the fish from whose mouth he took the tribute-money. Other species of D., very similar to the European, are found in the seas of other parts of the world—one of them Australian, exhibiting similar black spots.

**DOTIS**, a town in the north-west of Hungary, 37 miles west-north-west of Pesth. Between the town proper and its suburb, called *Lake Town*, from its situation on a small lake, are the remains of an old castle, said to have been a favourite residence of Mathias Corvinus, the Hungarian king. D. contains a splendid chateau, the property of the Esterházy family, the gardens adjoining which are laid out in the English fashion. Pertaining to this castle are some very extensive wine-vaults, one of them containing a tun capable of holding 34,700 English gallons. Pop. 12,600.

**DOTTEREL** (*Charadrius morinellus*), a species of Plover (q. v.), which in summer inhabits the northern parts of Europe and Asia, breeding chiefly in the highest latitudes, and migrates on the approach of winter to the countries around the Mediterranean and those of similar climate. It appears in Britain as a bird of passage, both on its northward migration in spring, and on its southward migration in autumn. Some breed in the

Dotterel (*Charadrius morinellus*).

mountains both of Scotland and of England, always at very considerable elevations. The D. is about nine inches and a half in its whole length. In summer plumage, the upper parts are of a brownish ash colour, the feathers edged with deep red; the checks, throat, and a band above the eyes, white; the breast bright rust-colour, with a white gorget on the upper part of it, bounded above by a blackish line; a conspicuous black patch on the middle of the belly; some of the tail-feathers tipped with white. The D. has become proverbial for stupidity; but the readiness with which it allows itself to be approached seems to be entirely owing to its coming from regions little frequented by man, and it becomes shy and watchful after a little experience. It is much esteemed for the table, and well known in the London market.

**DOUAI**, or **DOUAY**, a town of France, in the

department of Nord, situated on the river Scarpe, about 20 miles south of Lille, and 150 north-north-east of Paris. It is enclosed within old tower-flanked walls, the ramparts of which are now laid out in pleasant promenades. D. is in general well built, with good streets and some handsome buildings, the principal of which are the parish church, a Gothic town-hall, a cannon foundry, an arsenal, a tall picturesque belfry in the market-place, and a Catholic college, for the education of British Roman Catholics. D. has also a university academy, a royal college, schools of artillery, and of drawing and music, and a high court of justice, having jurisdiction not only over the whole department, but over Pas-de-Calais also. Its manufactures are lace, gauze, cotton, soap, glass, leather, paper, earthenware, beetroot-sugar, &c.; and it has a pretty extensive trade in corn, wine, wool, flax, linen, and brandy. A singular procession of the gigantic figure, made of osiers, of a man clad in armour, takes place every year in July, the monster being moved by eight men inside. Pop. 17,443. D. has existed since Roman times. It was long a bone of contention between the Flemish counts and the French rulers. It passed with the rest of Flanders under the dominion of Spain, but was taken by Louis XIV. in 1667. Marlborough captured it in 1710, but the French re-occupied it after his withdrawal, and were finally confirmed in the possession of it by the peace of Utrecht.

**DOUAY BIBLE.** See **BIBLE**.

**DOUBLE CONSCIOUSNESS.** Double or divided consciousness has likewise been designated double personality. The term comprehends a group of morbid mental conditions involving some modification in the clearness of the idea of personal identity. Individuals are often encountered with confused notions of the 'me' and 'not me;' others conceive that parts or properties of their frame belong to another person, or that they are inhabited and ruled by a spirit or entity acting in opposition to their will and interests; and there are others who, at different times and under different circumstances, such as when influenced by, or free from moral or physical stimulation, conceive that they are different persons, and endowed with different qualities and powers. These manifestations, however, do not fully illustrate the state under consideration, which has been described as exhibiting, in some measure, two separate and independent trains of thought, and two independent mental capabilities in the same individual, each train of thought and each capability being wholly dis severed from the other, and the two states in which they respectively predominate, subject to frequent interchanges and alternations. In the most marked or perfect form of this phenomenon, the individual is conscious of the two independent trains of thought, and conceives, in consequence of the apparent independence of these, that he is two distinct persons at the same time. There are few instances of this mental affection on record (see Wigan *On Duality of Mind*, Abercrombie's *Inquiry into Intellectual Powers*, Ellicott in Combe's *System of Phrenology*, 3d edition). A servant-girl, at the period of puberty, gave evidence of double personality for three months. In an advanced stage of the affection, the circumstances which occurred during the paroxysm were completely forgotten by her when it was over, but were perfectly remembered during subsequent paroxysms. She was, for example, taken to church while in her abnormal state. She shed tears during the sermon, particularly during an account given of the execution of three young men, who had described, in their dying

declarations, the dangerous steps with which their career of vice and infamy commenced. When she returned home, she recovered in a quarter of an hour, was quite amazed at the questions put to her about the sermon, and denied that she had been in church; but next night, when taken ill, she mentioned that she had been there, repeated the words of the text, and gave an accurate account of the tragical narrative of the three criminals by which her feelings had been so powerfully affected (*Philosophical Transactions*, Edin. 1822). This description assimilates the patient to the class of somnambulists. But such perversions of the faculties generally involve a more palpable and complete duality of mind. The personal identity seems to be lost or impaired. A. B. conceived that he was himself and another person at the same time; he acted as if this belief were sincere, and could not divest himself of the conviction that in his body were two minds or persons suggesting courses of conduct widely opposed. He was certain that his original self, A. B., was a base, abandoned scoundrel, tempting his other, or new, or better self—to whom, it should be noted, was attached the emphatic *Ego*—to commit crimes or acts of which he altogether disapproved. The second person in this duality repelled, struggled with these abominable solicitations, such as that he should commit suicide; and loathed the tempter or first person. This struggle sometimes became real and visible, when the hands, acting under the will of No. 2, or the virtuous and opposing principle, beat and bruised the legs, body, or head, which, it may be presumed, were supposed to belong to No. 1, the vicious or tempting impulse. The object of the one was obviously to inflict pain upon the other. The blows were so severe as to leave marks for days; and when these were adverted to, the answer was, as if from No. 2: 'Don't justify him, he deserved it.' Such conflicts generally occurred during the night, and the interference of the night-watch was required to part or pacify the combatants.\* In this case the manifestations of disease might be attributed to the abstruse but vain philosophical inquiries of the mind during health.

While it is quite intelligible that habits of protracted self-analysis, or of that abstraction which loses all idea of distinct personality in the act of thinking, or in the subject occupying attention, may induce such a condition, a more physical explanation has been sought in the alternate morbid activity of different parts of the brain, in the non-consentaneous or independent and alternate activity of the two hemispheres of the brain, which, when acting together, are held to be the organ of the mind in its unity and entireness. Latterly, the views of Sir William Hamilton have been brought to bear upon the point; and still more recently, the theory called 'unconscious cerebration,' which supposes certain impressions to exist unperceived, and to become objects of consciousness only under certain conditions, has been applied to the same purpose; but, in so far as the impairment of the conviction of personal identity is concerned, the problem still awaits solution.

**DOUBLE FLAT**, a musical character used to lower the note before which it is placed two half-tones.

**DOUBLE FLOWERS**. See FLOWER.

**DOUBLE SHARP**, a musical character the reverse of the double flat.

**DOUBLE SHOTTING** is, as its name implies,

an augmentation of the destructive power of ordnance, by doubling the shot fired off at one time from a gun. Sometimes three shots are fired at once, in which case the piece is said to be 'treble-shotted.'

**DOUBLET** (so called from being originally lined or wadded for defence) was a close, tight-fitting garment, the skirts reaching a little below the girdle, as in the accompanying cut, from Fairholt's *Costume in England*. It was almost identical with the jerkin. The sleeves were sometimes separate, and tied on at the arm.

**DOUBLING THE CUBE** was a celebrated geometrical problem among the ancients. The object was, to find the side of a cube whose content should be twice that of another given cube; and various accounts are given of how the problem was suggested. One legend brings the matter into connection with Delos (hence the name of 'the Delian problem'), and relates that the oracle of Apollo in that island, being consulted by the inhabitants during the prevalence of a pestilence, gave for answer, that they should make the altar of Apollo, which was in the form of a cube, as large again. This was done, and yet the pestilence continued; and the oracle being again consulted, replied, that the altar must retain its cubic form, which had not been attended to in the enlargement. This problem perplexed the Delians, as it did mathematicians of after-ages. Even Plato, whom they consulted on the difficulty, could give them no solution, and had recourse, according to the story, to evasion.

The problem, however, is older than Plato; before his time, it had occupied Hippocrates of Chios (not the physician Hippocrates), and was studied afterwards by Eratosthenes, Nicomedes, Hero, and others. Apollonius applied conic sections to the solution of the question, as did also Menæchmus; Nicomedes invented a curve, which he called the conchoid, for the express purpose, and Diocles the cissoïd. The analytical method introduced into geometry by Descartes shewed this problem in its true light. It was seen to be only a special case of the solution of a cubic equation—a solution which is impossible by geometry, i. e., by the use of the circle and straight line. It may, however, be represented by the intersection of two conic sections, of which one may be a circle. Descartes made use of the parabola with the circle, which is the simplest way. With numbers, the question is merely one of the extraction of the cube root. If the side of a cube be one foot, its solid content is  $1 \times 1 \times 1 = 1$  cubic foot. The side of a cube of double that content, or 2 cubic feet, is  $\sqrt[3]{2} = 1.259921$ .

**DOUBLINGS**, the heraldic term for the linings of robes or mantles, or of the mantlings of achievements. See MANTLING.

**DOUBLOON** (Sp. *dublone*, double) is the name of a gold piece coined in Spain and Spanish America. The Dublon de Isabella, coined since 1548, is of 100 reals, and equivalent to 25.84 French francs, or 20s. *8d.* The older Spanish doubloons vary in value from 85 to 81 francs.

**DOUBS**, a department of France, on the eastern frontier, separated from Switzerland by the Jura

\* Fifth Annual Report, Crichton Royal Institution, 1844, p. 13.

Mountains, is situated in lat. 46° 35'—47° 31' N., and long. 5° 42'—7° 4' E. Area about 2000 square miles. Pop. 286,888. D. is traversed by the river Doubs, a tributary of the Saone, and is separated, on the north-west, from the department of Haute Saone by the Oignon, also a tributary of the Saone. The surface is hilly, being crossed by four parallel ranges of the Jura Mountains. The climate is more rigorous than that of most districts in a similar latitude. Among the eastern valleys, where crops chiefly of oats are grown, the harvest operations are often stopped by snow-falls, which lie until April or May. About one-third of the surface is arable; but the greater part is covered with forests. The pine and the walnut attain a huge size, and the common orchard trees thrive well. Maize, potatoes, hemp, and flax are raised. The pasturage is excellent, and rears good breeds of horned cattle and horses, which are exported. In the valleys, great quantities of butter and cheese are produced. The rivers are well stored with fish. Mines of iron and coal are worked, and gypsum and marble are abundant. The trade is principally in iron, cattle, horses, and dairy produce. D. is divided into the four arrondissements of Besançon, Baume-les-Dames, Montbelliard, and Pontarlier. The capital of D. is Besançon.

**DOUCHE.** See BATH and HYDROPATHY.

**DOUGH** is the name given to the moistened and kneaded flour in the first stage of making Bread (q. v.).

**DOUGLAS**, the largest town and principal seaport of the Isle of Man, is so called from its being situated near the junction of two streams—the *Dhoo* (black) and *Glass* (gray). D. lies on the margin of a highly picturesque bay, on the east side of the island. From the excellence of the sea-bathing, and its central position, it is fast increasing in importance as a watering-place.

The old town, standing on the south-western edge of the bay, consists of narrow tortuous streets, and presents a vivid contrast to the handsome modern terraces and villas which occupy the rising ground beyond. Conspicuous in the centre of the crescent of the bay stands Castle Mona, formerly the residence of John, Duke of Athol, but now converted into a first-class hotel. The Tower of Refuge, a picturesque object, occupies a dangerous rock, in the southern area of the bay, called Conister, and was erected in 1833 for the safety of shipwrecked mariners, by the late Sir William Hillary, Bart., who, during his residence at D., founded the Royal National Life-boat Institution. D. is the principal packet station of the island, and possesses telegraphic communication with England. Pop. (1861) 12,389.

**DOUGLAS, THE FAMILY OF.** Archeology has failed in its efforts to pierce the obscurity which veils the origin of the heroic race of which it has been said:

So many, so good as of Douglas blood have been,  
Of one surname, in one kingrick, never yet were seen.

A legend of the 16th or 17th c. told how, about the year 770, a Scottish king, whose ranks had been broken by the fierce onset of a Lord of the Isles, saw the tide of battle suddenly turned by an unknown chief; how, when the victory was won, the monarch asked where was his deliverer; how the answer ran in Erse, *Sholto Du-glas* ('Behold that dark-gray man'); and how the warrior was rewarded with that Clydesdale valley which, taking from him its name of Douglas, gave surname to his descendants. This fable has long ceased to be believed. Equal discredit has fallen on the theory which, sixty years ago, the laborious Chalmers

advanced in his *Caledonia*, that the Douglasses sprang from a Fleming of the name of Theobald, who, between the years 1147 and 1164, had a grant of lands on the Douglas Water from the Abbot of Kelso. There is no trace of any connection between the Flemish Theobald and the Douglasses; nor were the lands which he acquired on one side of the stream any part of their old domain on the other. What was boasted of the Douglasses by their historian, two centuries ago, therefore still holds true. 'We do not know them in the fountain, but in the stream; not in the root, but in the stem; for we know not who was the first mean man that did by his virtue raise himself above the vulgar.' It was thought likely, in the beginning of the 15th century, that the Douglasses and the Murrays had come of the same stock, and in this old conjecture all that is known on the subject must still be summed up.

1. *William of Douglas*, the first of the family who appears in record, was so called, doubtless, from the wild pastoral dale which he possessed. He is found witnessing charters by the king and the Bishop of Glasgow between 1175 and 1213. He was either the brother or the brother-in-law of Sir Freskin of Murray, and had six sons, of whom Archibald, or Erkenbald, was his heir; and Brice, a monk of Kelso, rose to be Prior of Lesmahago (a dependency of Kelso, on the outskirts of Douglas-dale), and in 1203 was preferred to the great bishopric of Murray. He owed this promotion, no doubt, to the influence of his kinsmen the Murrays, and it contributed not a little to the rising fortunes of his own house. He was followed beyond the Spey by four brothers, of whom one became sheriff of Elgin; another became a canon of Murray; a third, who had been a monk of Kelso, seems to have become Archdeacon of Murray; and a fourth, who had been parson of Douglas, appears to have become Dean of Murray.

2. *Sir Archibald, or Erkenbald, of Douglas* is a witness to charters between 1190 and 1232. He attained the rank of knighthood, and beside his inheritance of Douglas, held the lands of Hailes, on the Water of Leith, from the monks of Dunfermline, and had a grant of the lands of Levingston and Hirdmanston from the Earl of Fife. He is said to have acquired other lands in Clydesdale by his marriage with one of the two daughters and heiresses of Sir John of Crawford.

3. *Sir William of Douglas*, apparently the son of Sir Archibald, figures in record from 1240 to 1273. He appears in 1255 as one of the Scottish partisans of King Henry III. of England; and in 1267 is found in possession of the manor of Fawdon, in Northumberland, by gift of the king's son (afterwards Edward I.). He seems to have had a brother, Sir Andrew, the progenitor of the Douglasses of Dalkeith and Morton, and certainly had two sons.

4. *Hugh of Douglas*, the elder, acquired land in Glencorse, in Lothian, by marriage with the sister of Sir Hugh of Abernethy; and dying without issue about 1287, was succeeded by his younger brother.

5. *Sir William of Douglas*, distinguished in the family traditions as *William the Hardy*, had all the daring and restless spirit which was characteristic of his descendants. His first appearance is in 1267, when his head was nearly severed from his shoulders in defending his father's English manor from a foray of the men of Redesdale. Twenty years later, he is found at the head of an armed band, carrying off his future wife, a wealthy widow, Alionora of Louvain, from the manor of her kinsfolks, the La Zouches, at Trunent, in Lothian. We hear of him immediately afterwards as spoiling the monks of Melrose, deforming the king's officers in the execution of a judgment in favour of his mother, unlawfully

imprisoning three men in his castle of Douglas, and beheading one of them. He was the first man of mark who joined Wallace in the rising against the English in 1297; and for this his lands of Douglas were wasted with fire and sword, and his wife and children carried off, by Robert Bruce, the young Earl of Carrick, then a partisan of England. But the Knight of Douglas soon left the insurgent banners, and submitting to his old patron, King Edward I., to whom he had again and again sworn fealty, was sent prisoner to the castle of York, where he died about 1302. It appears that he possessed lands in one English, and in seven Scottish counties—Northumberland, Berwick, Edinburgh, Fife, Lanark, Ayr, Dumfries, and Wigton.

6. The history of his son, the *Good Sir James of Douglas*, is familiar to every one, as Bruce's greatest captain in the long War of the Succession. The hero of seventy fights, he is said to have won them all but thirteen, leaving the name of 'the Black Douglas'—so he was called from his swarthy complexion—as a word of fear by which English mothers stilled their children. He was slain in Andalusia, in 1330, on his way to the Holy Land with the heart of his royal master, and dying unmarried, was succeeded by his brother.

7. *Hugh of Douglas*, of whom nothing is known except that he made over the now great domains of his family, in 1342, to his nephew, *Sir William of Douglas* (son of a younger brother of the Good Sir James—Sir Archibald of Douglas, Regent of Scotland, slain at Halidon Hill in 1333).

EARLS OF DOUGLAS.—Hitherto, the Douglasses had no higher title than that of knight; but in 1357, Sir William of Douglas, who had fought at Poitiers, and distinguished himself in other fields, was made Earl of Douglas, and afterwards by marriage became Earl of Mar. His ambition aimed at still greater things, and in 1371 he disputed the succession to the Scottish crown with Robert II. (the first of the Stewarts). He claimed as a descendant of the Baliols and Cummings; and his pretensions were abandoned only on condition that his son should marry the king's daughter. He died in 1384. His son James, second Earl of Douglas and Mar, the conqueror of Hotspur, fell at Otterburn in 1388; and as he left no legitimate issue, the direct male line of William the Hardy and the Good Sir James now came to an end. His aunt had married for her second husband one of her brother's esquires, James of Sandilands, and through her Lord Torphichen is now the heir general and representative at common law of the House of Douglas.

The earldom of Douglas, meanwhile, was bestowed on an illegitimate son of the Good Sir James—Archibald, Lord of Galloway, surnamed the Grim. By his marriage with the heiress of Bothwell, he added that fair barony to the Douglas domains; and having married his only daughter to the heir-apparent of the Scottish crown, and his eldest son to the eldest daughter of the Scottish king, he died in 1401. His son and successor, Archibald, fourth Earl of Douglas, was, from his many misfortunes in battle, surnamed 'the Tyneman,' i.e., the loser. At Homildon, in 1402, he was wounded in five places, lost an eye, and was taken prisoner by Hotspur. Next year, at Shrewsbury, he felled the English king to the earth, but was again wounded and taken prisoner. Repairing to France, he was there made Duke of Touraine, and fell at Verneuil in 1424. He was succeeded by his son Archibald, who distinguished himself in the French wars, and dying in 1439, was buried in the church of Douglas, where his tomb yet remains, inscribed with his high titles of 'Duke of Touraine, Earl of Douglas and of Longueville, Lord of Galloway, Wigton, and Annan-

dale, Lieutenant of the King of Scots.' His son and successor, William, a boy of sixteen, is said to have kept a thousand horsemen in his train, to have created knights, and to have affected the pomp of parliaments in his baronial courts. His power and foreign possessions made him an object of fear to the Scottish crown; and, having been decoyed into the castle of Edinburgh by the crafty and unscrupulous Crichton, he was, after a hasty trial, beheaded, along with his brother, within the walls of the castle, in 1440. His French duchy and county died with him; his Scottish earldom was bestowed on his grand-uncle (the second son of Archibald the Grim), James, surnamed the Gross, who in 1437 had been made Earl of Avondale. He died in 1443, being succeeded by his son William, who, by marriage with his kinswoman (the only daughter of Archibald, fifth Earl of Douglas, and second Duke of Touraine), again added the lordship of Galloway to the Douglas possessions. He was, for a time, all-powerful with King James II., who made him lieutenant-general of the realm; but afterwards losing the royal favour, he seems to have entered into a confederacy against the king, by whom he was killed in Stirling Castle, in 1452. Leaving no child, he was succeeded by his brother James, who, in 1454, made open war against King James II., as the murderer of his brother and kinsman (the sixth and eighth Earls of Douglas). The issue seemed doubtful for a time, but the Hamiltons and others being gained over to the king's side, Douglas fled to England. The struggle was still maintained by his brothers, Archibald, who by marriage had become Earl of Murray, and Hugh, who in 1445 had been made Earl of Ormond. They were defeated at Arkinholm in May 1455, Murray being slain on the field, and Ormond taken prisoner, and afterwards beheaded. Abercorn, Douglas, Strathaven, Thrieve, and other castles of the Douglasses, were dismantled; and the earldom of Douglas came to an end by forfeiture, after an existence of 98 years, during which it had been held by no fewer than nine lords. The last earl lived many years in England, where he had a pension from the crown, and was made a Knight of the Garter. In 1484, he leagued himself with the exiled Duke of Albany to invade Scotland. He was defeated and taken prisoner at Lochmaben, and, on being brought to the royal presence, is said to have turned his back upon the king. The compassionate James III. spared his life, on condition of his taking the cowl. 'He who may no better be, must be a monk,' muttered the old man, as he bowed to his fate. He died in the abbey of Lindores, in April 1488; and so ended the elder illegitimate line of the Douglasses.

EARLS OF ANGUS.—Meanwhile a younger illegitimate branch had been rising to great power. William, first Earl of Douglas, was the faithless husband of a faithless wife. She was believed to have had a paramour in Sir William Douglas of Liddesdale. Her jealous husband, who slew that 'flower of chivalry,' had himself shared the affections of the wife of his wife's brother, Margaret Stewart, Countess of Angus and Mar. The issue of this amour, which in that age was accounted incestuous, was a son George, who in 1389 had a grant of his mother's earldom of Angus; married, in 1397, the youngest daughter of King Robert III.; was taken prisoner at Homildon in 1402, and died of the plague in England in the following year. He was succeeded by his son William, who, dying in 1437, was succeeded by his son James, who died without issue, when the title reverted to his uncle. George, fourth Earl of Angus, took part with the king against the Douglasses in 1454; his loyalty was rewarded by a grant of their old inheritance

of Douglas-dale; and so, in the phrase of the time, 'the Red Douglas'—such was the complexion of Angus—'put down the Black.' He died in 1462, being succeeded by his son Archibald, surnamed Bell-the-Cat, and sometimes also called the Great Earl. After filling the highest offices in the state, and adding largely to the family possessions, he retired to the priory of Canons Regular at Whithern, in Galloway, where he died in 1514. Having outlived his eldest son, he was succeeded by his grandson, Archibald, who, in 1514, married the Queen-dowager of Scotland, Margaret, sister of Henry VIII. of England, and widow of James IV. of Scotland. The fruit of this marriage was a daughter, Margaret, who, marrying the Earl of Lennox, became the mother of Henry, Lord Darnley, the husband of Queen Mary, and father of King James VI. The Earl of Angus had for a time supreme power in Scotland, but in 1528, the young king, James V., escaped from his hands, and sentence of forfeiture was passed against Angus and his kinsmen. The king swore that while he lived the Douglasses should have no place in his kingdom; and he kept his vow. On his death in 1542, Angus returned to Scotland, and was restored to his honours and possessions. He died at Tantallon in 1556. His nephew, who succeeded him, died two years afterwards, leaving an only son, Archibald, eighth Earl of Angus. This 'Good Earl,' as he was called, died in 1588, when his title devolved on his kinsman William, the grandson of Sir William Douglas of Glenberrie, second son of Archibald Bell-the-Cat. Dying in 1591, he was succeeded by his son William, who next year obtained from the crown a special recognition of his high privileges as Earl of Angus, of taking the first place and giving the first vote in parliament, of leading the vanguard in battle, and of bearing the crown in parliament. He seems to have been a man of scholarly tastes, and is said to have written a history of the Douglasses. Having turned Roman Catholic, he was forced to leave Scotland, and spent his latter years in exercises of devotion at Paris, where he died in 1611, being succeeded by his son.

**MARQUISES AND DUKE OF DOUGLAS, AND LORDS DOUGLAS.**—William, eleventh Earl of Angus, was created Marquis of Douglas in 1633, and dying in 1660, was succeeded by his grandson James, who died in 1700, leaving issue one son and one daughter. The son Archibald, third Marquis of Douglas, was created Duke of Douglas in 1703, and died childless in 1761, when his dukedom became extinct, and his marquise devolved on the Duke of Hamilton, as descended in the male line from William Earl of Selkirk, third son of the first Marquis of Douglas. His grace's sister, Lady Jane Douglas, born in 1698, and married in 1746 to Sir John Stewart of Grandtully, was said to have given birth at Paris to twin sons in 1748. One of them died in 1753; the other, in 1761, was served heir of entail and provision general to the Duke of Douglas. An attempt was made to reduce his service, on the ground that he was not the child of Lady Jane Douglas; but the House of Lords, in 1771, gave final judgment in his favour. He was made a British peer in 1790, by the title of Baron Douglas of Douglas Castle, which became extinct on the death of his son James, fourth Lord Douglas, in 1857, when the Douglas estates devolved on his niece, the Countess of Home. The title of Earl of Angus was claimed in 1762, as well by the Duke of Hamilton as by Archibald Stewart, afterwards Lord Douglas; but neither urged his claim to a decision, and the title is still in abeyance. The right attached to it of bearing the crown of Scotland, was debated before the Privy Council in 1823, when it was ruled

that Lord Douglas's claim to that honour, being a claim of heritable right, fell to be decided in a court of law. It has been supposed that the motto of the Douglas arms, *Jamais arriere*, 'Never behind,' alludes to the peculiar precedence inherent in their earldom of Angus. The bloody heart commemorates Bruce's dying bequest to the Good Sir James; the three stars which the Douglasses bear in common with the Murrays, seem to denote the descent of both from one ancestor.

**EARLS OF MORTON.**—Sir Andrew of Douglas, who appears in record in 1248, was apparently a younger son of Sir Archibald, or Erkenbald, of Douglas, the second chief of the house. He was the father of William of Douglas, who, in 1296, swore fealty to King Edward I. for his lands in West Lothian, and who was probably the father of Sir James of Douglas—surnamed of Lothian, to distinguish him from his kinsman of Clydesdale—who, in 1315, had a grant from Bruce of the lands of Kincauld and Calder-clere. He died about 1320, being succeeded by his son, Sir William of Douglas of Liddesdale, who acquired the lordship of Dalkeith (by resignation of the Grahames), the barony of Aberdour in Fife, lands in Tweeddale, and great territories in Liddesdale, Eskdale, and Ewesdale which had been forfeited by the Souleses and Lovels. In 1335, he had a grant of the earldom of Athol, but resigned it in 1342. The Knight of Liddesdale—as he was called by his contemporaries, who regarded him as 'the flower of chivalry'—was assassinated in 1353 by his kinsman, William first Earl of Douglas, partly to revenge his wife's dishonour, partly to revenge the death of Sir David of Barclay, who had been assassinated at the instance of the Knight of Liddesdale, in revenge for the slaughter of his brother John. Dying childless, he was succeeded by his nephew, Sir James of Douglas of Dalkeith. This great chief, who died in 1420, saw Froissart sit as a guest at his board; himself possessed books of law, grammar, logic, and romance; and enjoined in his will that all the volumes which he had borrowed from his friends should be returned to them. His alliances were as princely as his life. His first wife was a daughter of 'Black Agnes,' the heroic Countess of Dunbar; his second was a sister of King Robert II.; and he matched his eldest son, Sir James of Douglas of Dalkeith, with a daughter of King Robert III. Their grandson married a daughter of King James I., and in 1458 was created Earl of Morton. His grandson, the third earl, dying without male issue in 1553, the earldom devolved on his daughter's husband, the Regent Morton—James Douglas, great-grandson of Archibald Bell-the-Cat. After his fall, the title went to Archibald eighth Earl of Angus; and when he died childless in 1588, it passed to the lineal male descendant of Sir Henry of Douglas (the son of Sir John of Douglas, the brother of the Knight of Liddesdale), Sir William Douglas of Lochleven, who thus became seventh Earl of Morton. His losses in the great civil war compelled him, in 1642, to sell Dalkeith to the Earl of Buccleuch, and his Tweeddale and Eskdale lands to others; but Aberdour and other old domains of the family still remain with his successor, the Earl of Morton, who, there is every reason to believe, descends legitimately in the male line from William of Douglas, the great progenitor of the race in the 12th century.

**EARLS, MARQUISES, AND DUKES OF QUEENSBERRY; EARLS OF MARCH, AND EARLS OF SOLWAY.**—James, second Earl of Douglas and Mar—the hero of Otterburn—had an illegitimate son, Sir William of Douglas of Drumlanrig, whose descendants were created Viscounts of Drumlanrig in 1628, Earls of Queensberry in 1633, Marquises of Queensberry in 1682, Dukes of Queensberry in 1684, Earls of March in 1697,

and Earls of Solway in 1706. On the death of the fourth Duke of Queensberry in 1810, that title, with the barony of Drumlanrig and other lands, went to the Duke of Buccleuch; the title of Marquis of Queensberry, with the baronies of Tinwald, Forthorwald, &c., went to the heir-male of the family, Sir Charles Douglas of Kelhead; and the title of Earl of March, with the barony of Neidpath, went to the Earl of Wemyss. The title of Earl of Solway had become extinct in 1778.

EARLS OF SELKIRK, FORFAR, AND DUMBARTON; VISCOUNT BELHAVEN, AND LORDS MORDINGTON. —In 1616, the third son of the first Marquis of Douglas was created Earl of Selkirk. In 1651, the eldest son of the same marquis was created Earl of Ormond, and in 1661, Earl of Forfar. In 1675, the fourth son of the same marquis was created Earl of Dumharton. In 1641, the second son of the tenth Earl of Angus was created Lord Mordington. In 1633, Sir Robert Douglas of Spot, a descendant of the Morton family, was created Viscount of Belhaven. Of all these titles, that of the Earl of Selkirk is the only one not now dormant or extinct.

A *History of the Houses of Douglas and Angus*, by David Hume of Godscroft, was published at Edinburgh in 1644 in 1 vol. fol., and reprinted in 1748 in 2 vols. 8vo. It preserves the traditions of the family, and has some literary merit, but its accuracy is not to be trusted. The earlier history of the Douglasses has been critically examined by the late George Chalmers in his *Caledonia*, vol. i. pp. 579—584 (Lond. 1807); by Mr Riddell in his *Remarks upon Scotch Peerage Law*, pp. 174—178 (Edin. 1833); by Mr Cosmo Innes, in the *Registrum Episcopatus Moraviensis*, pp. xlv.—xlvii. (Edin. 1837); and the *Liber S. Marie de Calchoh*, vol. i. pp. xxvii., xxviii. (Edin. 1846); and by Mr Joseph Robertson in the *Origines Parochiales Scotiæ*, vol. i., pp. 152—160 (Edin. 1851). The descent of the Houses of Angus and Dalkeith was first ascertained by Mr Riddell in his *Remarks upon Scotch Peerage Law*, pp. 154—164 (Edin. 1833); and in his *Stewartiana*, pp. 82—84, 137—142. The charters and correspondence of the Morton family have been edited for the Bannatyne Club by Mr Cosmo Innes in the *Registrum Honoris de Morton* (Edin. 1853, 2 vols. 4to).

DOUGLAS, GAWIN, a Scottish poet, was the third son of Archibald, fifth Earl of Angus, and was born in the year 1474 or 1475. He was educated for the church, and rose through a variety of inferior offices to the bishopric of Dunkeld. Political events compelled him to leave Scotland. He went to England, where he experienced the most courteous attention at the court of Henry VIII. According to Holingshed, he even received a pension from that monarch, but did not long enjoy it, being suddenly cut off by the plague in 1521 or 1522. He was buried in the Savoy Church. One of D.'s earliest poetic efforts was a translation of Ovid's *Remedy of Love*, but it has not been preserved. In 1501, he wrote his *Palace of Honour*, addressed to King James IV. The leading idea of the poem, and some of the details, strikingly resemble the *Pilgrim's Progress*; yet Bunyan could hardly have seen the poem, and even if he had, could not have spelled his way through it. *King Hart*, the only other long poem of D., presents a metaphorical view of human life. It was probably composed in his later years. But the most remarkable production of this author was a translation of Virgil's *Æneid* into Scottish verse, which he executed in the years 1512 and 1513, being the first version of a Latin classic into any British tongue. It is generally allowed to be a masterly performance, though in too obsolete

a language ever to be popular. D.'s verse is far from rhythmical to modern ears; yet the felicitous character of his allegories, and the rich beauty of his descriptions, might well tempt the lovers of genuine poetry to give him a trial. His works, with the exception of his Virgil, have been seldom reprinted, and are very rare.

DOUGLAS, JOHN, D.D., was the son of a respectable shopkeeper of Pittenweem, Fifeshire, and was born there in 1721. In 1736, he entered St Mary's College, Oxford, where he took his bachelor's degree after five years' study. D.'s life is little more than a chronicle of his very numerous preferences, which ended in his being translated to the see of Salisbury in 1791. He died 18th May 1807. D. only occasionally resided on his livings. He generally spent the winter months in London, and the summer months at the fashionable watering-places, in the society of the Earl of Bath, who was his great patron. He was devoted to literature; but most of his productions were only interesting to his own time. Among other works chiefly of a pamphlet kind, he wrote a *Vindication of Milton from the Charge of Plagiarism*, addressed by Lauder (1750); *A Letter on the Criterion of Miracles* (1754); an ironical pamphlet directed against the Hutchinsonians and Methodists of his day, entitled *The Destruction of the French foretold by Ezekiel* (1759); and the *Introduction and Notes to Captain Cook's Third Voyage* (1781).

DOUGLAS, GENERAL SIR HOWARD, Bart., G.C.B., son of Admiral Sir C. Douglas, who received his title for having forced a passage up the St Lawrence to the relief of Quebec in 1776. Born at Gosport, 1776. Entering the army when young, he took part in the expedition to Walcheren, and in the battle of Corunna. He served in Spain and Portugal in 1805 and 1809, in which year he succeeded to the baronetcy, and again in Spain in 1811 and 1812, receiving the cross of Charles III. He was governor of New Brunswick from 1823 to 1829, and an unsuccessful candidate for the representation of Liverpool in 1832 and 1835. He was Lord High Commissioner of the Ionian Islands from 1835 to 1840, and from 1842 to 1847 was M.P. for Liverpool. In 1851 he became a general in the army, and colonel of the 15th Regiment of foot. He has written several treatises, among which are *An Essay on the Principles and Construction of Military Bridges*, and the *Passage of Rivers in Military Operations* (Lond. 1816); a treatise on *Naval Gunnery* (1819; 4th edit., 1855); *Observations on Carnot's Fortification*, &c. His treatise on *Naval Gunnery* is regarded as a standard authority in foreign countries, although his recommendations were not acted upon by the British Admiralty until thirteen years after the publication of his work. He censured the conduct of the war in the Crimea in 1855, and declared that Sebastopol could not be reduced unless by a change in the plan of operations, such as he traced. His prophecy was verified by the event. He also published *Considerations on the Value and Importance of the British and North American Provinces*. A treatise, entitled *Naval Evolutions*, states the claims of his father to a brilliant naval manœuvre in 1782, in which year Sir Charles acted as captain of the fleet in Rodney's action with the Count de Grasse. He died November 1861.

DOUR, a town of Belgium, in the province of Hainault, nine miles west-south-west of Mons. It is well built and prosperous, and has several schools and a literary society. Coal and iron mines are worked in the vicinity; there are also many quarries, and to some extent, weaving, bleaching, and leather-dressing are carried on. Pop. about 6000.

**DOURO** (Span. *Dueiro*, Port. *Doiro*), the name of one of the largest rivers of Spain and Portugal, rises in the province of Old Castile, about 30 miles west-north-west of the town of Soria. From its source it flows south-east to Soria, then winds towards the west, and pursues a general westward direction till it reaches the Portuguese border; it then flows south-west, forming for about 60 miles the boundary between Spain and Portugal; then crossing Portugal and flowing west, it falls into the Atlantic below Oporto. Its Portuguese tributaries are comparatively small. The total length of the river is about 500 miles. The D. is a noble river, and flows through some of the most imposing rock-scenery in the world, as at Barca d'Alva; but is rapid, and of difficult navigation, on account of rocks, sand-banks, &c. It passes through a large portion of the wine-country of Portugal, and conveys the produce to Oporto for exportation in flat-bottomed boats, containing from 30 to 70 pipes each.

**DOVE** (probably from the same root as *dive*, owing to its habit of ducking the head; compare Lat. *columba* with Gr. *kolumban*, to dive), a name sometimes extended, as the name Pigeon also is, to the whole family of *Columbidae*, sometimes like it restricted—at least when used without prefix—to the genus *Columba* of the more recent ornithological systems. No distinction between the terms dove and pigeon is sanctioned either by constant scientific or general popular use. Audubon attempts to make a distinction, giving the name pigeon to those species of which many nests are built close together on the same trees, and dove to those which are solitary in their nidification; but this distinction is quite unsuitable to the European species, and contrary to British usage. See PIGEON.

**DOVE**. In Christian art, the dove is employed as an emblem of the Holy Ghost, no doubt from the fact of this being the form in which the Spirit descended on our Lord at his baptism. From the dove being also used to symbolise purity, it is generally represented white, with its beak and claws red, as they occur in nature. In the older pictures, a

Pyx in the form of a Dove.

golden nimbus surrounds its head; the nimbus being frequently divided by a cross, either red or black. In stained glass windows we see the dove with seven rays proceeding from it, terminating in seven stars, significative of the seven gifts of the Holy Spirit. Holding an olive branch, the dove is an emblem of peace. When seen issuing from the lips of dying saints and martyrs, it represents the human soul purified by suffering. A dove with six wings is a type of the church of Christ; and when so employed, it has the breast and belly of silver, and the back of gold, two wings being attached to the head, two to the shoulders, and two to the feet. The pyx or box for containing the Host (q. v.) in Catholic

churches, is sometimes made in the form of a dove, and suspended over the altar; and the dove is often placed on the covers of fonts. In this position it may still be seen in parish churches in England.

**DOVÉ, H. W.**, one of the most celebrated living physiologists of the continent, was born in 1803, at Liegnitz, in Silesia, where his father was a merchant. He studied at Breslau and at Berlin, at the latter of which he took the degree of Doctor in 1826. He was successively 'privatdocent' and assistant professor of natural philosophy in Königsberg. Having been transferred to a similar post in Berlin, he subsequently became full professor, and was elected to a seat in the Royal Academy of Sciences. His writings, which are very numerous, are to be found in the Memoirs of that Academy, and in Poggenorff's *Annalen*, besides several published separately. The most celebrated of these refer to Meteorology, Climatology, Induced Electricity, and Circularly Polarised Light. We may mention among his works *Ueber Maas und Messen* (2d edition, Berlin, 1835), a treatise on the art of measuring, and the origin and comparison of the metrical standards of different nations; *Meteorologische Untersuchungen* (Berlin, 1837), a remarkable treatise; *Ueber die nicht periodischen Aenderungen der Temperaturvertheilung auf der Oberfläche der Erde* (4 vols., Berlin, 1840—1847); *Untersuchungen in Gebiete der Inductionselectricität* (Berlin, 1843). In conjunction with other distinguished German philosophers, D. commenced, in 1837, the publication of an extensive series of treatises on different branches of natural philosophy. This work, called *Repertorium der Physik*, remains unfinished, but many of the treatises it contains, and especially one of several by D. himself, are admirable. To him is due, amongst a great variety of optical discoveries, the application of the stereoscope to the detection of forged bank-notes—an ingenious and useful idea. To English readers, D. is best known by his treatise on the *Distribution of Heat on the Surface of the Globe*, which was published in 1853 by the British Association. In this work he enters fully into the causes of periodic variations of temperature at different parts of the globe, and lays down in admirable charts the monthly and annual isothermal and isabnormal lines—thus tracing the variations in form and position of the different isothermals throughout the year. In addition to the above, D., who is an exceedingly clear and able lecturer, has published several popular volumes on different parts of his subject, among which may be noticed the volume *Ueber Electricität* (Berlin, 1848).

**DOVECOT**. It is enacted by the Scottish statute 1617, c. 19, that no person shall build a dovecot or pigeon-house either in town or country, unless he be possessed of lands or tennds of the yearly value of ten chalders of victual, lying within at least two miles of it. It is also declared, that no person having such qualification shall build more than one dovecot within the 'bounds foresaid.' It has been held that the statute imposes no restraint on proprietors possessed of a greater rent, beyond limiting them to one dovecot for each portion of ground that yields ten chalders yearly. The statute does not extend to dovecots already built, and if a dovecot be challenged, it must be proved to have been built subsequently to the date of the statute, otherwise the contrary will be presumed. If an estate be purchased, or otherwise acquired from a person who was legally entitled to build a dovecot, the dovecot may be legally retained, but cannot be rebuilt if it become ruinous. The statute 2 Geo. III. c. 29, for the protection of pigeons, does not extend to Scotland. See PIGEONS. Dovecot breakers are

guilty of theft, and very severe punishments were assigned to them by the old statutes.

**DOVER**, a parliamentary and municipal borough and seaport in the east of Kent, on the Dover Strait, 66 miles east-south-east of London, at the nearest point of Britain to the continent, being 21 miles from Cape Grisnez, and 25½ from Calais, on the other side of the Strait. It lies at the entrance of a deep depression in an amphitheatre of chalk hills and cliffs. The streets of the old town are narrow and irregular, the chief one being a mile long, running north-west up the valley, but facing the sea there are lines of elegant and commodious houses of recent erection, and the town has, on the whole, been much improved, and is well adapted for a watering-place. East of D., on the chalk cliffs, 320 feet high, is Dover Castle, a formidable collection of works, which, begun in Roman times, have since that period been at intervals enlarged and strengthened, and although not yet complete, it occupies 35 acres within the walls, and includes tower forts and underground works; a bomb-proof magazine; a well 300 feet deep; barracks for 2000 men, excavated in the chalk, with a subterranean passage to the town down 420 steps; and keep 108 by 128 feet, with walls 24 feet thick, and turret 468 feet above the sea. There are batteries on the heights west of the town, the fortifications of which are being much strengthened and enlarged. Between Folkestone and D., the South-eastern Railway, within three miles of D., is tunnelled 1½ mile through Abbot's Chalk Cliff, and nearly one mile through Hay or Shakspeare Chalk Cliff, which is 350 feet high. Between these tunnels, in 1843, a mass of chalk, 300 feet long, 375 feet high, and 70 thick, was removed by blasting with a charge of 80 barrels of gunpowder. The harbour of D. is now protected by a splendid stone pier, called the 'Admiralty' Pier, built of solid masonry, 60 feet in width, and which, when completed, will extend 1800 feet into the sea. D. is the chief port of communication between England and the continent; steamers constantly ply between it and Calais and Boulogne. D. imports eggs, fruit, and other rural produce from France. Pop. (1861) 24,970. D. returns two members to parliament. Julius Cesar made his first attempt to land in Britain at Dover. It was the Roman *Dubris*, with walls and gates, and at the end of the Roman Watling Street. Edward the Confessor made D. one of the Cinque Ports, to guard the coast. It was early reckoned the key of England, and fortified. The Conqueror burned it. Here King John submitted to the pope. The French twice besieged Dover Castle, and the Parliamentarians held it in the Civil War. The military works of Dover Castle were increased in 1745, and again when Bonaparte threatened to invade Britain. The first submarine cable telegraph was laid from D. to Calais in 1850; there is now another to Ostend. The Corporation have lately restored the ancient hospital of the Maison Dieu, and converted it into a town-hall. In 1860, 1362 vessels, of 120,281 tons, entered and cleared the port. (1871—pop. 28,270.)

**DOVER, STRAIT OF** (*Fretum Gallicum, Pas de Calais*), the narrow sea-channel between England and France, and connecting the English Channel and North Sea. It is 18 to 25 miles broad, average 22, and 6 to 29 fathoms deep, but at Warne and Ridge Shoals only 1½ to 4 fathoms. The English side of the strait consists of chalk cliffs 300 to 600 feet high, succeeded on the south by lower greensand. The French side, from Calais to Cape Grisnez, has a similar succession of strata. The tides of the English Channel and North Sea meet in Dover

Strait. Britain and the continent of Europe seem to have been once united across Dover Strait by an isthmus.

**DOVERON**, or **DEVERON**, a river of the north-east of Scotland, rising in the west of Aberdeenshire, a little south of the Buck of the Cabrach (2377 feet high). It runs 55 miles north-east, or 36 in a straight line, through adjacent parts of the counties of Aberdeen and Banff, and partly dividing them, past Huntly to the North Sea at Banff. It drains a basin of 410 square miles, composed of syenitic greenstone, metamorphic rocks, graywacke and old red sandstone.

**DOVER'S POWDER** is a preparation of powder of ipecacuanha 1 drachm, opium in powder 1 drachm, and sulphate of potash 1 ounce. The whole is thoroughly mixed, and the ordinary dose is from 5 to 10 grains. Occasionally, saltpetre is added. It is a most valuable medicine, and acts as a sudorific, increasing the proportion of sweat or sensible perspiration. In feverish conditions, where there is the dry furred tongue, and the dry skin, and the brain out of order, Dover's powder is reckoned to prove injurious; but where the tongue is moist, the skin moist and soft, and the brain comparatively unaffected, Dover's powder is of great service.

**DOVRE FJELD**. See SCANDINAVIA.

**DOW, DOU, or DOUW, GERARD**, one of the most exquisite of all the Dutch *genre*-painters was born at Leyden in 1613. He received his first instructions in drawing from one Dolendo, a draughtsman, and at the age of 15 entered the school of Rembrandt. That marvellous genius for colour which the latter possessed, fascinated the young painter, who soon shewed a similar mastery over *chiaroscuro*, but at the same time developed artistic qualities of a wholly different kind from those of his master. The most insignificant incidents of daily life were precious to D., and were delineated with a delicacy, neatness, and care, that could not be surpassed. In his workshop, the utmost cleanliness prevailed. D. was true to nature in a degree positively wonderful. The richness, transparency, vigour, and harmony of his colouring are beyond all praise. In consequence, his pictures, though generally small in size, are considered gems of art, and have brought astonishing prices. One of his best works, 'The Dropsical Woman,' is valued at 30,000 guilders. Among his other pieces may be mentioned 'The Village Grocer,' 'The Dutch Cook,' 'The Mountebank,' 'The Fiddler,' 'The Dentist,' and 'The Interior of a Household.' His works, which are pretty numerous, are in all the great European collections. D. died at Leyden in 1680.

**DOWAGER** (Fr. *douairière*, from *douaire*, dowry, dower, derived from the Greek and Lat. *dos*, a thing given, verb *do*, to give), a widow with a Dover (q. v.); but commonly the title is applied only to the widows of persons of high rank. The queen-dowager, as the widow of the king, enjoys most of the privileges which belonged to her as queen-consort. But it is not high treason to conspire her death, because the succession to the crown is not thereby endangered. Still no man can marry a queen-dowager without special licence from the king. Though an alien born, the queen-dowager is entitled, by the common law, to dower after the king's death, though it was not till recently that this privilege belonged to the alien widow of a subject. A queen-dowager, though she should marry a subject, does not lose her regal title, as peeresses-dowager, when commoners by birth, lose their peerages when they marry commoners.

**DOWER** (Lat. *dos*, in Domesday, *Maritagium*), 'in the common law, is taken for that portion of lands

or tenements which the wife hath for terme of her life of the lands or tenements of her husband after his decease, for the sustenance of herselfe, and the nurture and education of her children."—*Coke upon Litt.* 30 *b*. Formerly, a widow's right to dower was protected by the law, and could only be defeated by certain prescribed means; but by 3 and 4 Will. IV. c. 105, a husband, by simple conveyance of his land, or by burdening it with debt, may defeat the right of his widow to dower. He may effect the same purpose by introducing into the deed of conveyance to himself, or into his last will and testament, a simple declaration of his intention to bar his widow's right of dower. Though the right of dower has thus lost much of its importance, the history of this right forms an interesting chapter in the English common law. In feudal times, when personal property was small, a widow depended almost exclusively on her right to dower for maintenance after her husband's death. Three things, says Lord Coke, 31 *a*, were necessary for dower—marriage, seisin, and the death of the husband. The usual amount of dower was a third of the land in which the husband died seised; but, by custom, as Gavelkind (q. v.), it amounted sometimes to a half, and in certain cases to the whole.—*Litt.* s. 57. Besides dower at common law, and dower by custom, three other species of dower are noticed by Littelton—viz., *dower de la plus belle*, s. 47; *dower ad ostium ecclesie*, s. 39; and *dower ex assensu patris*, s. 40. The first of these was where a man died possessed of lands held partly by Knight's Service (q. v.), and partly by Socage (q. v.), leaving a child under 14, the widow could be compelled, as guardian in socage, to take her dower out of the socage lands. This species of dower fell with the military tenures by 12 Car. II. c. 24. The last two species of dower mentioned above were both made at the time of the celebration of the marriage. *Dower ad ostium ecclesie* was when the husband, being of full age, at the church door specially endowed his wife in the whole or a part of his lands. In *dower ex assensu patris*, the bridegroom's father being alive, the same form was observed, with the sanction and consent of the father. In both of these cases, the widow was entitled, on death of her husband, to enter at once upon the land without any assignment. These species of dower were abolished by 3 and 4 Will. IV. c. 105, s. 13. In dower at common law, and dower by custom, which are still suffered to exist, a widow cannot enforce her claim until certain lands have been assigned to her for her dower by the heir or by writ of the sheriff.—*Co. Litt.* 34 *b*. In early times, it was necessary to pay a duty to the lord for this assignment, but this exaction was abolished by Magna Charta. In its general principles, the right to dower in England resembled the right of Terce (q. v.) in Scotland. In both countries, the amount allowed by law was a third of the husband's lands, and in both a certain process was necessary before the widow could enforce her right. A woman forfeits her right to dower by eloping from her husband (13 Edw. I. c. 34), by the treason of her husband, by divorce *a vinculo*, but not by divorce *a mensa et thoro*. The right to dower was also barred by levying a Fine (q. v.) of lands, by conveyance to uses in bar of dower, and by the settlement of a jointure upon the wife. See FINE, JOINTURE.

**DOWLAS**, a kind of coarse strong linen, used by working-people for shirts, and manufactured largely at Knaresborough in Yorkshire, at Dundee, and at Newburgh and other places in Fifeshire. Since the introduction of calico, the home demand for dowlas has very much diminished, the article being little used except in the iron districts. The principal exports of dowlas are to Spain, and the countries

inhabited by peoples of Spanish origin, in North and South America.

**DOWLATABAD** (in English, *Abode of Prosperity*), a strongly fortified town of Hindustan, within the Nizam's dominions, near their north-west frontier, in lat. 19° 57' N., and long. 75° 18' E. The town is commanded by a rock-fortress, which, with a height of about 500 feet, is scarped into a perpendicular for the lowest third of the altitude. This stronghold is all the more formidable from its being completely isolated, being fully 3000 yards distant from any other eminence. The town of D. has recently greatly decayed, and only a small portion of it is now inhabited.

**DOWN**, a maritime county in the south-east of Ulster Province, Ireland. It is 51 miles long, and 38 broad, with an area of 967 square miles,  $\frac{2}{5}$ ths being arable, and  $\frac{3}{10}$ ths in wood. It has a coast-line of 67 miles, or 125 by the inlets, mostly low and rocky, and with many isles off it. The chief inlets are Belfast Lough, or Carrickfergus Bay, 3 miles broad, and 15 deep; Strangford Lough,  $\frac{1}{2}$  to 3 miles by 10, with many isles on which are old castles and abbeys; Dundrum and Carlingford Bays. The Mourne Mountains cover 90 square miles in the south, and rise 2796 feet in Slieve Donard. The other parts of D. are mostly undulating and hilly, with plains and fine meadows along the rivers. The chief rocks are Lower Silurian—covering most of the county—and granite, composing the Mourne and Croob mountains. The chief rivers are the Upper Bann and the Lagan. The Newry Canal, which connects Carlingford Lough with the Bann, and thus with Lough Neagh, admits vessels of 50 tons, and with the Ulster Canal opens communication through almost all Ulster. Marl beds, five feet thick, occur in morasses and alluvial tracts. The soils are chiefly stony and clayey loams. In 1858, nearly half the county was in crop. The chief crops are oats, potatoes, turnips, wheat, flax, and barley. Many pigs are reared. The chief manufacture is linen, especially the finer fabrics, as muslin, woven in the houses of the small farmers. Hosiery, leather, salt, thread, and woollens are also made. These, with corn, butter, pork, and hides, are the chief exports. D. is among the best cultivated of the Irish counties, and has more resident gentry (almost all Protestants, of English and Scotch descent) than any other Ulster county. It contains 11 baronies, 5 poor-law unions, and 70 parishes. The chief towns are Downpatrick, Newry, Newtownards, Banbridge, and Donaghadee. D. sends four members to parliament. Pop., 1851, 320,817; 1861, 299,866. Presbyterianism prevails in the towns and low country, and Roman Catholicism among the mountains. D. has many ancient remains, as raths, cronlechs, round towers, castles, and abbeys. On the top of Slieve Croob (1755 feet high) are 23 stone cairns, one being 54 feet high, and 77 yards circuit at the bottom, and 45 at the top. D. was part of the ancient principality of Dalriada (q. v.).

**DOWNHAM MARKET**, a town in the west of Norfolk county, on a hillside, on the right bank of the Ouse, 40 miles west of Norwich, and 10 $\frac{1}{2}$  south of Lynn Regis. It lies amid fen and dairy land. Pop. about 3000. It has a bell-foundry, and a celebrated butter-market. By the Ouse and Cam, vessels proceed from Lynn on the coast to Cambridge, 30 miles above Downham Market. A market was confirmed here in the time of Edward the Confessor. D. M. had once a Benedictine priory.

**DOWNPATRICK** (Mount of Patrick), or **DOWN**, a maritime town, parliamentary and municipal burgh, and cathedral city, in the south of

Down, of which it is the county town. It is situated near the mouth of the Quoyle, which flows into the south-west end of Lough Strangford, 74 miles north-north-east of Dublin, and 21 miles south-south-east of Belfast. It has many public buildings, and four main streets meeting in the centre. It is divided into English, Irish, and Scotch quarters. The diocesan cathedral was restored in 1790 on the site of one built in 1112, and burned in 1538 by Lord Deputy Grey. Vessels of 100 tons reach the quay a mile from Downpatrick. It has manufactures of linen, soap, leather, and malt liquors. Pop. (1861) 3685. It sends one member to parliament. To the north-west of D. are the remains of great earthworks,  $\frac{3}{4}$  mile in circuit, enclosing a conical rath 60 feet high and 2100 in circumference. D. is said to be the oldest city in Ireland, and was famous long before the arrival of St Patrick, who founded religious establishments here. D. was burned by Edward Bruce in 1315, and plundered by O'Neil in 1552. The four holy wells of Strud or St Patrick,  $\frac{1}{2}$  mile east of D., where stood St Patrick's monastery, are resorted to by Roman Catholic pilgrims from all Ireland.

DOWNNS, TIER, an important roadstead or shelter for shipping, off the south-east coast of Kent, opposite Ramsgate and Deal, between North and South Foreland, and protected externally by the Goodwin Sands—a natural breakwater with one to four fathoms water, and often partly dry at low tide. This large natural harbour of refuge is eight miles by six, with an anchorage of four to twelve fathoms, but having many sands and overfalls partly or wholly dry at low water. It is resorted to temporarily by outward and homeward bound vessels, and squadrons of ships of war, and is unsafe only in south winds. It is defended by Deal, Dover, and Sandown Castles.

DOWNNS (Ger. *dünen*, Fr. *dunes*, from the root *dun* (q. v.), common to the Gothic and Celtic languages, signifying a *hill*), a term usually applied to hillocks of sand thrown up by the sea or the wind along the sea-coast. It is also a general name for any undulating tract of upland too light for cultivation, and covered with short grass. It is specially applied to two broad ridges of undulating hills south of the Thames, beginning in the middle of Hampshire, and running eastward, the one (the North D.) through the middle of Surrey and Kent to Dover (about 120 miles), and the other (the South D.) through the south-east of Hampshire and near the Sussex coast to Beachy Head (about 80 miles). Between the two ranges lies the valley of the Weald (q. v.), from which the chalk strata are supposed to have been removed by denudation. Towards the Weald, the descent from both D. is rapid, and presents cliffs as of a sea-margin; while the opposite slopes are gradual. The highest point of the North D. is Botley Hill, 880 feet; and of the South D., Ditchelling Beacon, 858 feet. These uplands are covered with fine short pasture, which, from its aromatic quality, forms excellent feeding-ground for the famous South Down sheep. The valleys occurring among the hills are usually fertile, and admit of cultivation, so that an excellent field is furnished for mixed husbandry. By pasturing the sheep on the D. during the day, and folding them on the arable fields at night, the latter are highly fertilised.

DO'WNTON, a town in the south-east of Wiltshire, on the right bank of the Avon, here split into three branches, six miles south-east of Salisbury. It chiefly consists of one long street with the houses irregularly placed. Pop. (1861) 3381. It has a paper-work, and an ancient cross. D., in the middle ages, had a castle, of which the mound

or moat remains, and is a singular earthwork, on which Saxon justice was dispensed. Two miles north of D. is the mansion and estate of Standlich, the national gift to the heirs of Lord Nelson, for which parliament voted £100,000.

DOXOLOGY, a Greek word, signifies an exclamation or prayer in honour of the majesty of God, such as Paul uses at the close of his epistles, and sometimes even in the middle of an argument (Romans ix. 5). The hymn of the angels (Luke ii. 14) is also called a doxology by the Christian Church; so likewise is the close of the 'Lord's Prayer.' The so-called 'Great Doxology' is simply an expansion of the angelic hymn, and is sung in the Roman Catholic Church at the celebration of the Lord's Supper, and at matins. It commences with the words, *Gloria in excelsis Deo* ('Glory to God in the highest'). The ordinary doxology, 'Glory be to the Father, Son, and Holy Ghost, as it was,' &c., is repeated at the end of each psalm in the service of the Church of England; there is a similar doxology in verse to suit different metres.

DOYLE, RICHARD, son of the celebrated caricaturist H. B., whose name was John Doyle, was born in London in 1826. He became a contributor to *Punch*, and furnished its pages with the well-known sketches of 'Ye Manners and Customs of ye English.' In 1850, his connection with that publication ceased, and since that period he has employed himself in the illustration of books. Among his works of this nature may be mentioned the *Adventures of Brown, Jones, and Robinson*, and the illustrations to the *Newcomes* and the *Scouring of the White Horse*. At present (1861), he is supplying 'Sketches of Modern Society' to the pages of the *Cornhill Magazine*, which are distinguished, like everything from his pencil, by the most genial humour, and the most graceful drawing.

DOZY, REINHART, one of the most learned orientalist of the present day, was born 21st February 1820, at Leyden. He belongs to a family of French origin, which settled in Holland after the revocation of the Edict of Nantes. He studied at the university of his native town, and devoted himself to philological and historical, but especially to oriental studies. In 1844, he took his degree of doctor, and in 1850 was appointed extraordinary professor of history at Leyden. Apart from his lesser writings in the *Journal Asiatique* and other periodicals, which, however, exhibit the profoundest knowledge of the Arabic tongue and literature, D. has published *Dictionnaire détaillé des Noms des Vêtements chez les Arabes* (Amst. 1845), *Historia Abbadidarum* (Leyden, 1846—1852), and editions of Abdo'l Wâhid al Marrékoshi's *History of the Almohades* (1847), of Ibn-Badrûn's *Historical Commentary on the Poem of Ibn-Abdun* (1848), with introduction, notes, glossary, and index, and of Ibn-Adheri's *History of Africa and Spain* (1848—1852). In 1849 appeared what is probably his most masterly performance, *Recherches sur l'Histoire politique et littéraire de l'Espagne pendant le Moyen Age*. A second edition enlarged and completely recast, was published in 1860. In this work, D. has exposed, with admirable good sense and enlightened criticism, the gross and wilful corruptions of the monkish chroniclers, who persisted in falsifying history for the benefit of Christianity, and who could form no more rational idea of the Moors than that they were 'devils,' or abetted by the devil, and sent to torment them because of their *sins*. The passages devoted to Comte Julian and the Cid are worthy of the highest praise.

DRA'CHENFELS ('Dragon's Rock'), a mountain on the Rhine, one of the range called the

*Siebengebirge*, is renowned through Byron's verses commencing

The castled crag of Drachenfels  
Frowns o'er the wide and winding Rhine.

It is situated on the right bank of the river, about eight miles south-east of Bonn, and has an elevation of 1056 feet. It is of volcanic origin, consisting of lava, trachyte, and basalt. D. rises abruptly from the river, and is covered with brushwood almost to the top, whence the prospect is magnificent, extending down the river as far as Cologne, and having a charming foreground in Bonn, with its university, and numerous villages, and time-worn castles. The cave where the dragon—from which the mountain takes its name—was wont to abide, is pointed out to the traveller. The ruins of an old castle crown the summit, and add picturesqueness to the Drachenfels.

**DRA'CHMA, DRACHM, DRAM.** The drachma was a silver coin, the unit of the money-system in ancient Greece. It varied in value in different parts of Greece and at different times. The Attic drachma is estimated as equivalent to  $9\frac{3}{4}$  d. of our money—very nearly a French franc. The Æginetan drachma was considerably more. But whatever its absolute worth, it always remained the 6000th part of the *talent* (about £24), and the 100th part of the *mina* (about £4), and was divided into six obols. There were also coins of two, three, and four drachmas. The drachma (originally a *handful*) was also the name of a weight, and 100 drachmas made a *mina*, in weight, as in money. The weight of the drachma is stated at from  $\frac{1}{4}$  oz. avoirdupois to little more than half as much. At this lowest estimate, the *mina* = 1 lb. nearly. The unit in the monetary system of modern Greece, since 1833, has also been called *drachma*; it is equivalent to  $\frac{88}{1000}$  of a franc, or about  $8\frac{1}{2}$  d. sterling, and is divided into 100 *lepta*. In the British system of weights, there are two drachms or drams; the avoirdupois *dram*—equal to  $27\frac{1}{2}$  troy grains—and the apothecaries' *dram*, equal to 60 troy grains, or  $\frac{1}{8}$  of an ounce troy. It is this last which is the representative of the ancient drachma.

**DRACO** (Gr. *Drakon*), an Athenian lawgiver and archon, who, in the year 624 B. C., was appointed to draw up new laws for the disordered state. These, however, effected little change in the form of the state; but by being committed to writing, put an end to the arbitrary administration of justice on the part of the archons, and resulted in the establishment of a court of appeal—that of the *Epheta*. D.'s legislation had a beneficial and permanent effect upon the political development of Athens. The extraordinary severity of these laws, however, which punished the slightest theft, or even laziness, with death, no less than sacrilege, murder, and treason, caused them to be often neglected, and made them so hated, that Solon was appointed to draw out a new code. Solon, though he softened their severity in most instances, retained that law which punished a murderer with death. D., at a later period, went to Ægina, where, after having introduced his laws, he is said to have been stilled in the theatre by the garments thrown upon him as a mark of respect by the people. The severity of his laws gave rise to a pun by Herodotus, who declared that D.'s laws were those of a dragon (Gr. *drakon*) and not of a man. Hence also originated the metaphorical remark of Demades, 'that they were written not in ink but in blood.' Extremely severe and sanguinary laws are still called *Dracomic*.

**DRA'CO**, a constellation in the northern hemisphere. The star  $\gamma$  Draconis is celebrated as the one used in determining the co-efficient of

aberration of the fixed stars. It is a bright star, nearly in the solstitial colure, and consequently the minor axis of the small ellipse which its apparent place describes in the heavens, lies in the meridian at its transit. Moreover, at the two equinoxes, when its apparent place is at the extremities respectively of this minor axis, it can be observed on the meridian at one equinox about sunrise, and at the other about sunset, so that both observations may be made without the interference of a too bright daylight. These two observations, therefore, are easily taken, and the difference in the north polar distance which they give, is the minor axis of the ellipse described by the apparent place of the star.

**DRACO'NTIUM**, a genus of plants of the natural order *Aracea*, of which one species, *D. polyphyllum*, a native of Guiana, Surinam, and also of India and Japan, has a powerful action on the nervous system, and is useful in asthma; although at present its chief reputation is the somewhat doubtful one of curing the bite of a snake, to which its mottled stem gives it some resemblance. The flower, when it first expands, emits an intolerable stench.

**DRAFT**, an order addressed to a debtor by his creditor, calling upon him to pay a certain sum either to the drawer or to a third party. See **BILL, CHEQUE**.

**DRAFT**, or **DRAUGHT**, a tentative copy of a legal document, or other formal writing, made for the purpose of adjusting the matter afterwards to be admitted into the fair copy, or engrossed, as it is called. Manuscripts and proof-sheets are the drafts of printed works.

**DRAG**, a mechanism for slackening the speed of carriages, by operating on one or more of the wheels. The form of drag best known to old travellers by coach is that of the 'shoe,' a hollow piece of iron attached by a chain to the carriage, which being put below one of the hind wheels partially reduced the vehicle to the quality of a sledge; by which dragging process the carriage was suitably retarded on going down-hill. As the shoe-drag required to be applied and removed with some inconvenient detention of the vehicle, a step was made in advance when a method of retarding a wheel without detention was discovered. This new process, which is known as the patent drag, consists of a connected piece of mechanism, altogether operated upon by the driver without moving from his seat. A handle affects a series of rods and levers by which a species of shoe is pressed against one of the wheels, so as to slacken its motion. Such is the kind of drag now very generally attached to gentlemen's travelling-carriages, omnibuses, and other vehicles for passengers on the roads of Great Britain. It is of French origin. Applied in either form, the use of the drag, independently of its safety, is to allow horses to continue running at ordinary speed down-hill, without being unduly pressed on by the carriage behind them. A similar contrivance, but of a more powerful kind, called a *break* or *broke*, is applied to arrest the motion of railway-trains. See **RAILWAYS**.

**DRA'GOMAN**, from the Turkish *trukéman*, the general name given in Turkey to an interpreter, or to a guide to foreigners. The common dragoman corresponds exactly to the Italian *cicerone*, or the French *commissionaire* or *valet de place*. There are several connected with the hotels at Constantinople and other Turkish cities, who pounce eagerly upon European travellers, to perform every imaginable service. The diplomatic dragomen are, however, important personages, being the medium of communication between the Christian ambassadors and the Sublimé Porte. Though usually natives, they

## DRAGON.

and their families enjoy the privilege of being under the protection of the embassy they serve, and are subject to the laws of the country of that embassy, and not to the Turkish law. This privilege, which is also enjoyed by all the subjects of the great Christian powers resident in Constantinople, &c., is much valued, on account of the greater severity of the Turkish laws, and the summary manner in which they are executed. These dragomans are mostly of Italian extraction, either descendants of the old Genoese and Venetian merchants or Maltese. Strange stories are told of their tricks in garbling the communications they have to make, when private interests can be served by such means, and bribes obtained; and there is no doubt that newly appointed consuls, quite ignorant of the Turkish language, are in some respects almost completely in their power, and that this power is frequently used very unscrupulously.

**DRAGON**, a name applied in modern natural history, both popularly and by scientific authors, to different kinds of saurian reptiles. Some of these

Fringed Dragon (*Draco fimbriatus*).

(the genus *Draco* of Linnaeus) are remarkably characterised by false ribs extending from the sides, so as to support a membrane which is used as a parachute. These are called Flying Dragons (q. v.) or Flying Lizards. Another reptile which has received the name *D.*, and is also called *D. LIZARD* (*Ada*), belongs to a family of saurians. *Teyidae*, found only in America, closely allied to the *Varanidae* of the Old World, and to which, in common with them, the names **MONITOR** and **SAFEGUARD** have sometimes been given, in consequence of their being supposed—although erroneously—to give warning by a hiss of the proximity of a crocodile or alligator. It inhabits the marshy plains of Guiana, climbs trees with facility, bites severely, has a long compressed tail, the back and tail crested, the tongue forked like that of a serpent, and attains a length of about six feet. Both its flesh and eggs are used as articles of food.

**DRA'GON**. In the mythical history and legendary poetry of almost every nation, the *D.* appears as the emblem of the destructive and anarchic principle, as it manifests itself in the earlier stages of society—viz., as misdirected physical power and untamable animal passion. Like the serpent, the *D.* is always a minister of evil, of the principle which aims at negation, opposition, and contradiction, the object of which is to fight against order, harmony, and progress. But whilst the serpent

seeks the attainment of its object by cunning and deceitful artifices—crawling on its belly, and always assuming ostensibly characteristics the very opposite of its own—the *D.* proceeds openly to work, running on its feet, with expanded wings, and head and tail erect, violently and ruthlessly outraging decency and propriety, spouting fire and fury from both mouth and tail, and wasting and devastating the whole land. The destruction of this disorderly element was one of the first objects of human energy, but it was an object which was unattainable by merely human means, and mankind were accordingly indebted for its accomplishment to that intermediate class of beings known as heroes in classical antiquity. As the highest ideal of human strength and courage, the task properly fell to Hercules; but it was not confined to him, for we find both Apollo and Perseus represented as dragon-slayers. From legendary poetry, the *D.* passed into art, some of the earliest efforts of which probably consisted in depicting it on the shield, or carving it for the crest of a conqueror's helmet. The *D.* does not seem to have been a native emblem with the Romans, and when they ultimately adopted it as a sort of subordinate symbol, the eagle still holding the first place, it seems to have been in consequence of their intercourse with nations either of Pelasgic or Teutonic race. Amongst all the new races which overran Europe at the termination of the classical period, the *D.* seems to have occupied nearly the same place that it held in the earlier stages of Greek life. In the *Nibelungen Lied*, we find Siegfried killing a *D.* at Worms; and the contest of Beowulf (q. v.), first with the monster Grendel, and then with the *D.*, forms the principal incident in the curious epic which bears the name of the former. Even Thor himself was a slayer of dragons (J. Grimm, *Deutsche Mythologie*, ii. 653). Among the Teutonic tribes which settled in England, it was from the first

St George and the Dragon.

depicted on their shields and banners; and Dr Plott, in his History of Oxfordshire, ascribes the origin of the very ancient custom of carrying the *D.* in procession at Burford, in great jollity, on Midsummer Eve, to the fact of a banner adorned with a golden *D.* having been taken by a king of the West Saxons from a king of Mercia. The custom, however, is

said by Brand, on the authority of Aubanus, to have prevailed in Germany, and was probably common in other parts of England (Brand's *Pop. Antiq.* i. 321). Nor was the D. peculiar to the Teutonic races. Amongst the Celts, it was the emblem of sovereignty, and as such borne as the sovereign's crest. Mr Tennyson's *Idylls* have made every one familiar with 'the dragon of the Great Pendragonship,' blazing on Arthur's helmet, as he rode forth to his last battle, and 'making all the night a stream of fire.'

The fiery D., or Drake, and the flying D. in the air, were meteoric phenomena, of which we have frequent accounts in old books, and, indeed, as Brand remarks, 'the dragon is one of those shapes which fear has created to itself,' and which appears in circumstances, and clothes itself in forms, as various as our fears.

In Christian art, the D. is the emblem of sin, the usual form that is given to it being that of a winged crocodile. It is often represented as crushed under the feet of saints and martyrs, and other holy personages. Sometimes its prostrate attitude signifies the triumph of Christianity over paganism, as in pictures of St George and St Sylvester; or over heresy and schism, as when it was adopted as the emblem of the Knights of the order of the D. in Hungary, which was instituted for the purpose of contending against the adherents of John Huss and Jerome of Prague.

The D. is often employed in heraldry; and other animals, such as the lion, are sometimes represented with the hinder parts resembling dragons. An animal so represented is said to be *dragonné*. See GRIFFIN. A D. without wings is called a lindworm, or lintworm, which Grimm (*Deutsche Mythol.* ii. 652) explains to mean a beautiful or shining worm.

**DRAGON, GREEN** (*Dracunculus vulgaris*), a plant of the natural order *Araceæ*, which receives its name from its spotted stem. It is a native of the south of Europe. Its flowers are black, remarkably fetid, and give out exhalations which cause headache, giddiness, and vomiting. The root is emetic, and, probably for no better reason than the peculiar appearance of the stem, has been supposed useful for curing serpent-bites.

**DRAGON ROOT** (*Arisæma atrorubens*, formerly *Arum triphyllum*), a plant of the natural order *Araceæ*, a native of North America, the tuber of which is a powerful local irritant, and is used as a stimulant of the secretions in chronic bronchitis, asthma, rheumatism, &c. The powder, made into a paste with honey, is beneficially applied to the mouths and throats of children in aphthæ; and milk, in which the root has been boiled, is a useful ointment in cases of scalled head, ringworm, &c.

**DRAGONET** (*Callionymus*), a genus of fishes of

Gemmeous Dragonet (*Callionymus lra*).

the Goby (q. v.) family (*Gobiada*), remarkable for having the gill-openings reduced to a small hole on

each side of the nape, and the ventral fins placed under the throat, separate, and larger than the pectorals. They have no air-bladder. The species are pretty numerous; most of them finely coloured, as the GEMMEOUS D. (*C. lra*) of the British coasts—called *Gowdie* (*gowd*, gold) in Scotland—a fish about ten or twelve inches long, the prevailing yellow colour of which is varied with spots of sapphirine blue, &c.

**DRAGON-FLY** (*Libellula*), a Linnaean genus of neuropterous insects, now constituting the family *Libellulide*. They are in general very beautiful, rivalling butterflies in their hues, and like them loving the sunshine. They are, however, easily distinguished from butterflies, even at a distance, by their more slender form and comparatively narrow gauze-like wings; and differ from them still more widely in their habits, as they do not feed on the nectar of flowers, but prey on other

Dragon-fly and Nymph (*Libellula depressa*).

insects, which they pursue with rapid flight. Dragon-flies have a large head; the mouth is formed for mastication, and its parts, especially the mandibles, possess great strength.—See the article *COLEOPTERA* for an explanation of the structure of the mouth in *masticating* insects, and the names of its parts.—The antennæ are short, awl-shaped, and of few joints. The eyes are large, lateral, and projecting. The wings—four in number—are equal in size, or nearly so, long, very thin, and very much reticulated. The legs are short. The abdomen in some is compressed, in others slender and cylindrical, in some remarkable for its extreme slenderness. The French name *demoiselle*, given to these insects, seems to be due to their beauty. They are, however, equally remarkable for their voracity. The Great D. (*Aeshna grandis*), an insect about four inches long, the largest of the British species, has been seen to dart upon a large cabbage-butterfly which passed as it was flitting up and down in search of prey; and then settling on a twig, it bit off the wings, and in less than a minute devoured the body.

Dragon-flies are usually most abundant in the vicinity of lakes, rivers, and marshes. They deposit their eggs in water, and the larvæ and pupæ are entirely aquatic, living chiefly at the bottom of the water, and creeping on the submerged parts of aquatic plants. They are as ravenous as the perfect insect, which in general form they pretty much resemble; aquatic insects are their food. The pupæ, unlike those of the greater number of insects, are active. They are provided with the means of drawing water into their bodies to supply air for respiration, and expel it again by the same

orifice at the extremity of the abdomen, with such force, that they thus propel themselves through

Dragon-fly, Transformation from Pupa to Perfect Insect :

a, perfect insect, half protruded from the pupa-case ; b, same, just emerged ; c, perfect insect nearly ready for flight.

the water, whilst their legs are at rest. When the final transformation is about to take place, the D. pupa crawls out of the water on a stick, rush, or other object ; fixes itself by hooks, with which its legs are furnished ; and the skin then splitting at the back, the perfect insect comes forth, but with body and wings quite soft and moist, and the wings still folded up into small compass. In the sub-family of *Agriionidae*, the wings are elevated vertically in repose : in the true *Libellulidae* (*Libellula*, *Aeshna*, &c.), they are extended horizontally.

Dragon-flies extend even into very northern regions, but are most abundant in warm climates.

**DRAGONNADES**, the name applied to a series of religious persecutions which took place in France in the reign of Louis XIV. and that of his successor, and which were intended to compel the Protestants of that country to renounce their religion. They consisted of armed expeditions, led by a bishop, an intendant, a sub-delegate, or a priest, who marched through the provinces, demanding of the heretics that they should abjure their faith, and leaving such as were refractory to be dealt with by the unscrupulous troops. Foremost among the armed force rove dragons, who, from the fact of their taking the precedence, and also from the merciless treatment to which they subjected the Protestants, had the menial honour of giving a name to the persecutions. Louis XIV., who had been entirely misinformed as to the means employed in the D. by the courtiers and fanatics who surrounded his throne, was delighted to find that from 250 to 400 Protestants were daily being received into the bosom of the church, and in consequence, on the 23d October 1685, a few months after the date of the first of the D., he revoked the Edict of Nantes (q. v.), that the good work might be fully accomplished.

**DRAGON'S BLOOD**, sometimes called Gum Dragon, an astringent, resinous substance, obtained from several trees of different natural orders, natives of warm countries. The greater part of the D. B. of commerce is probably the produce of *Pterocarpus Draco*, a large South American tree of the natural

order *Leguminosæ*, sub-order *Papilionaceæ*, which at some seasons appears as a magnificent mass of yellow blossom. A similar substance is yielded in the East Indies, by the Red Sandal-wood tree (*Pterocarpus santalinus*) ; and *Dalbergia monettaria*, a tree of the same order, yields it in Guiana. Mexican D. B., used in Mexico as a vulnerary and astringent, is obtained from *Croton Draco* (see *CROTON*), of the natural order *Euphorbiaceæ*. The best kind of all is supposed to be produced by *Calamus Draco*, an East Indian palm, and part of it is said to be obtained from the fruit of the palm.—D. B. exudes from the surface of the leaves, and from cracks in the stem of the, **DRAGON TREE** (*Dracæna Draco*), a tree of the natural order *Liliaceæ*, remarkable for the size which it sometimes attains, rivalling even the baobab, and of which a celebrated specimen near Orotava, in the island of Tenerife, was found by Humboldt in 1799 to have a stem about 45 feet in circumference, and is described as having been of similar gigantic size in the beginning of the 15th century. The stem of the dragon tree is, however, generally short in proportion to its thickness,

Dragon Tree (*Dracæna Draco*).

and its head consists of numerous short branches, terminating in tufts of sword-shaped leaves. It is not supposed to yield any of the D. B. of commerce.

D. B. is opaque, of a deep reddish-brown colour, brittle, smooth, with a shining shell-like fracture, and when burned, emits an odour resembling that of benzoin. It is nearly insoluble in water, but is soluble in alcohol, and the solution will permanently stain heated marble, for which it is often used, as well as for staining leather and wood. It is also soluble in oils and turpentine, and enters into the composition of brilliant and much-esteemed varnishes. It was formerly employed in medicine, but is now almost out of use.—An astringent resin obtained from the *Eucalyptus resinifera* of New Holland is there called Dragon's Blood.

**DRAGON'S MOUTH**, or, in Spanish, **BOCA DEL DRAGO**, is the name of two straits or passages in the New World. One of them is in South America, separating Trinidad from the mainland, and connecting the Gulf of Paria with the south-east extremity of the Caribbean Sea. The other is in

Central America, being on the north-east coast of Veragua, the most north-westerly portion of New Granada, and it communicates between the Carib-bean Sea and Lake Chiriqui.

**DRAGOON.** From the old fable that the dragon spouts fire, the head of the monster was worked upon the muzzles of a peculiar kind of short muskets which were first carried by the horse-men raised by Marshal Brissac in 1600. This circumstance led to their being called dragoons; and from the general adoption of the same weapon, though without the emblem in question, the term gradually extended itself till it became almost synonymous with horse-soldier. Dragoons were at one time a kind of mounted infantry, drilled to perform the services both of horse and foot. At present, *dragoon* is simply one among many designations for cavalry, not very precise in its application. In the British army, the *heavy* dragoons and the *light* dragoons are so nearly alike in the weight of the men, horses, and appointments, that the meaning of the distinction is nearly lost. The first dragoons in the army were the Scots Greys, established in 1683.

In the British army, there are at present seven regiments of 'Dragoon Guards,' and eighteen regiments of 'Dragoons.' See HORSE GUARDS.

**DRAGUIGNAN**, a town of France, in the department of Var, on a tributary of the Argens, about 40 miles north-east of Toulon. It is charmingly situated, in the midst of a valley surrounded by hills, the slopes of which are covered with vineyards and olive plantations. It is tolerably built; and its streets are adorned with numerous fountains and trees. Its principal structures are the prison, the court-house, a hospital, and a stately clock-tower. It has manufactures of coarse woollens, leather, hosiery, silks, soap, brandy, oil, and earthenware. Pop. 8827. D. is an ancient place. During the middle ages it was strongly fortified. The fortifications were destroyed in the civil wars, but were reconstructed in 1615.

**DRAINAGE**, in Husbandry, is the art of carrying off water from the soil and subsoil of land by means of open or closed drains or trenches—the term, however, is generally understood of closed drains. By its means, the fertility of wet land has been greatly increased. When the drains are put in every six or ten yards, it is called *furrow or frequent* draining.

The vast amount of capital which has been expended in drainage within a quarter of a century, attests its utility and necessity. Before the introduction of furrow-draining, stiff and tenacious clays were of comparatively little value. They were cultivated at much expenditure of labour, and the crops which grew upon them were influenced to a great extent by the variations of the seasons. A system by which wet and worthless land could be rendered dry and valuable, was an improvement so patent to practical men, that we need not wonder at its general adoption.

Drainage by open ditches was no doubt the first mode of freeing land from superfluous water. The Roman agricultural writers mention the good results arising from covered drains, which were formed of wood and other substances, which served so far to render the land dry. More than a century ago, a large extent of clay-land was drained at narrow intervals in Norfolk and Essex, by putting in brush-wood and even straw in the bottom of the drains. The progress of draining, which is now regarded in many soils as essential to economic culture, was slow and partial, until Mr Smith of Deanston (about the middle of the 19th c.) reduced the practice to

a system, and shewed the principles upon which its efficiency depended. Through the exertions of this advocate, furrow-draining soon became a *sine quâ non* in the culture of clay-soils, or indeed any soil, in most climates.

The great majority of practical men consider the line of greatest fall, or quickest descent, as the best for cutting drains in a field. This, it may be remarked, is also usually the direction for ploughing the land and forming the ridges; so that the drains are commonly put into the *furrows*, and hence the distinguishing appellation, *furrow-draining*. The smaller drains are usually conducted into larger or *main* drains, instead of each discharging its quota of water into the open ditch. This is rendered necessary, as the mouths of the smaller drains would be more liable to be choked up by the growth of weeds; while the collecting of water into main drains secures a fuller flow to sweep out any matters which might accumulate where the discharge was small.

The most efficient, and at the same time cheaply cut drain, is one represented at fig. 1. It is made so that a pipe of a cylindrical form may be laid along the bottom, which should be of no greater width than what is necessary to allow of the pipes being properly laid.

Fig. 1.

Drains of this form are cut with a set of spades which are of different widths—the broader being used for taking out the top, and the narrowest for the bottom. The one which cuts the last spit is called the *bottoming tool*, and its introduction has effected a considerable saving in cutting drains.

Before the general use of pipes, stones were the common materials with which drains were formed. Mr Smith recommended that they should be broken so small, that they might pass through a ring two inches and a half in diameter. From nine inches to a foot in depth was the quantity which was commonly put in. This was found to be a most efficient way of making drains; but unless the stones could be gathered from the fields, or quarried in the neighbourhood where they were used, an immense amount of labour was involved in filling them.

When tiles and pipes were first used, it was even thought necessary to have some gravel, or small stones, placed above them in the drains, for the purpose of enabling the water to find its way into them, as seen at fig. 2. It was soon found, however, that tile-drains were quite as efficient without any stones or gravel; and that they were less liable to be choked up, as the clay or earth acted as a filter in preventing the intrusion of any kind of solid matter.

Fig. 2.

Many kinds of tiles and pipes have been tried, but the cylindrical form is now most used. At one time, a bore in the tile of an inch in diameter was thought sufficient, but two-inch tiles are now preferred. They are usually made about fifteen inches in length. The continuity of the drain is maintained completely by *collars*, which should always be used as a means for securing efficiency and permanency.

Much discussion has taken place in regard to the proper depth of drains, as well as the distance at which they should be placed. Mr Smith at first advocated the making of drains from two and a half to three feet deep, and at intervals of from ten to forty feet, according to the nature of the land. Experience, however, has been gradually favouring deeper drains, at wider intervals. Mr Parkes went

the length of recommending a depth of from four to six feet, at intervals of from 24 to 66 feet. If the deep drainage of land which this distinguished engineer has advocated cannot be successfully carried out in all cases, the graphic manner in which he has described his own experience, and illustrated the principles of draining, has been productive of good results. Even on the most tenacious soils with subsoils of *till*, few now think of having drains less than three feet in depth, though the distance apart should not in many cases be more than from 15 to 18 feet.

The mere tenacity of clays is not the element which determines the depth of drains, or the distance at which they should be placed apart. It is now well understood that the success of draining by pipes depends upon the fissures which are produced in the subsoil by the droughts of summer never entirely closing up; and thus minute channels are formed, which lead the water into the drains. The coarse tenacious clays which are to be found in the chalk-valleys of England, *crack* readily by the droughts, and form deep fissures, which render them comparatively easily drained. On the other hand, in the moist climate of Scotland, the subsoils which are of *till* are long in cracking; and the drains in such land should not be so deep, and at shorter distances apart. As the properties of clays become better understood and classified, practical men will soon come to be more at one in regard to this important point connected with the economy of drainage.

The principal advantages of drainage are, the deepening of the staple soil, and rendering it more friable, so that a superfluity of water, which would cause the formation of those chemical compounds that are found in stagnant water, is prevented. The greater depth of mould, and more perfect culture, render the soil more absorbent of moisture in dry weather. As crops can usually be sown sooner on drained lands, they also ripen earlier, and produce more abundantly. In short, while drained land obtains a greater capacity for moisture and manure, it imparts to plants greater capabilities for economically working up the materials which they find both in the soil and atmosphere, seeing they are maintained in the most healthy conditions of growth.

Drainage in its various forms has, as is well known, not only improved the fertility and value of land in Scotland, but materially changed the aspect and climate of the country. Mosses and wet rushy lands have been transformed into dry and productive fields, while by the removal of all superfluous pools, the air is freed from those hovering vapours which are injurious to general amenity and salubrity. To the farmer, the more immediate advantage of drainage consists in that rapid running off of the water which falls as rain, so as to admit of working lands without any undue delay. This universal system of draining has had a remarkable effect on rivers, which, no longer fed by slow percolation from adjoining lands, are suddenly swollen after rain, and as suddenly diminished in volume. See RIVERS.

DRAKE, SIR FRANCIS, was born about the year 1539, in a cottage on the banks of the Tavy; in Devonshire. His father was a yeoman, and had a family of twelve sons. He was a zealous Protestant, and during the persecution under Queen Mary, he fled from Devonshire into Kent, in which county his family was brought up. He obtained some kind of clerical appointment among the seafaring-men of the district, and in consequence, D.'s younger years were passed among sailors. He was at an early age apprenticed to a neighbour of his father's, who possessed a bark, and occasionally made voyages to

Zealand and France. When his master died, D. fell heir to the vessel, and carried on the old trade with considerable success. While coasting about, he heard of the exploits of Hawkins in the New World, and the recital took such a hold of his imagination, that, selling his ship, he proceeded to Plymouth, and joined Hawkins in his last expedition to the Spanish Main. The adventure was disastrous to all concerned, and D. came home much poorer than when he set out. Undismayed, however, he gathered around him wild and reckless spirits, and having raised sufficient money, they fitted out a vessel, and under the command of D. made several voyages to the West Indies. In 1570, he obtained a commission from Queen Elizabeth, and cruised in the West Indies, enriching himself with plunder. In 1572, he again sailed for the Spanish Main, and, assisted by some other English ships, he plundered the town of Nombre de Dios. He then crossed the Isthmus of Darien, and beholding the Pacific, prayed God to grant him leave to sail an English ship in that sea. On Sunday the 9th August 1573, he came into Plymouth laden with spoil; and when the news spread of his arrival, the people forsook the preacher, and came out to gaze on the brave and successful sea-rovers.

Under the sanction of Queen Elizabeth, D. again set sail in 1577, taking with him five vessels. He sailed to South America, and plundered the coasts. In September of that year he entered the Pacific. During his voyage, he was singularly successful. He sacked the Spanish towns on the coasts of Chili and Peru, and he captured a royal galleon laden with plate. He then steered for the north-east, hoping to find a passage back to the Atlantic; but the severity of the cold discouraged his crew, and he took shelter in Port San Francisco. He stayed there several weeks, and formally took possession of the country in the name of the queen of England. He then steered across the Pacific for the Moluccas; reaching Ternate, he sailed for Java, thence he stretched right across the Indian Ocean for the Cape of Good Hope, which he doubled in safety, and arrived at Plymouth on Sunday the 26th September 1579. He was graciously received at court. Elizabeth banqueted on board his vessel, and conferred on him the honour of knighthood.

During part of 1585 and the whole of 1586, D. was employed, with a fleet of 21 ships, against Philip II. of Spain, chiefly in the West Indies and the coasts of South America. In this, as in his former voyages, he plundered many towns, and enriched himself with spoil. During this voyage, he visited Virginia, which colony had been recently planted by Raleigh. Thence he returned home, and it is said brought tobacco with him.

Spain was now preparing an Armada for the invasion of England, and Elizabeth sent D. with a fleet of 30 sail to destroy the enemy's ships in their own harbours. He entered the Roads of Cadiz, passed the batteries on the morning of the 19th April 1587, and before night, destroyed 100 vessels, and possessed himself of immense booty. He then sailed along the coast burning and plundering. He entered the Tagus, and flouted the Marquis Santa Cruz, who was lying in that river with a large force of galleys. Having done all the mischief in his power to Spain, D., with that keen appetite for plunder which never forsook him, steered for the Azores, on the look-out for homeward-bound treasure-ships. He was fortunate enough to encounter a richly laden carraek, of which he took possession. On his return, he spent a considerable portion of his prize-money in supplying the town of Plymouth with water.

D. was next employed as vice-admiral in the fleet

under Lord Howard, which scattered the Armada, and broke the naval supremacy of Spain. In 1589, he was sent to Portugal with a fleet, to expel the Spaniards, who had taken possession of that kingdom; but the expedition was unsuccessful. On his return, he was elected member of parliament for Plymouth. In 1595, along with Sir John Hawkins, he was sent with a fleet to the West Indies. In the course of the expedition, the commanders quarrelled. Hawkins died before reaching Puerto Rico. Attacking the place, D. received a repulse. Sailing away, he burned and plundered several towns. He came to anchor in Nombre de Dios, where a deadly disease broke out among the soldiers and sailors of the fleet. D. was at last smitten, and after struggling 20 days with the malady, he expired on the 27th December 1595. On the day of his death, the fleet anchored at Puerto Bello, and there the bold sailor and buccaner received his sea-funeral.

DRAKE, FRIEDRICH, a celebrated German sculptor, born at Pymont, 23d June 1805, and trained under Rauch of Berlin. Among his principal works are a 'Madonna with her Infant' (purchased by the Empress of Russia), a 'Dying Soldier,' a 'Vintager,' 'The Eight Provinces of Prussia' (colossal allegorical figures, adorning a hall in the royal palace at Berlin), and a 'Warrior crowned by Victory,' which is reckoned one of the master-pieces of Prussian sculpture. But D. owes his celebrity chiefly to statues, busts, and medallions. There are few great countrymen of his of whom he has not preserved a marble memorial. His statues of Schinkel, the two Humboldts, Rauch, Justus Moeser, his bust of the naturalist Oken, and his two colossal statues of Frederick William III., king of Prussia, the one at Steitin, and the other at Berlin, deserve especial mention. D. is at present professor of sculpture in the Academy of Fine Arts at Berlin, and chevalier of the third rank in the order of the Red Eagle.

DRAMA (Gr. *drama*, from *draō*, I act), or dramatic poetry, in its most general signification, represents *actions*, which are not stately narratives, as in epic poetry, or which do not aim at the musical expression by language of mental emotions, as in lyric poetry. The drama consists of an impersonal representation, by the dramatist, of an animated conversation of various individuals, from whose speech the movement of the story is to be gathered. Thus, it is contrasted, on the one hand, with dialogue, or the dull and changeless flow of discourse, and on the other, with every other species of poetry, whether epic or lyric. In simple dialogue, the minds of the speakers remain unchanged; in the drama, the movement of the thoughts is so lively, and the expectation of the issue so vivid, that this species of poetry surpasses every other in interest and in intensity. In epic poetry, persons are frequently introduced engaged in lively conversation, and this is sometimes the case even in lyric poetry, but the prevailing tone of the epopee is descriptive and indirect. A novel, or an epic poem, can only be described as dramatic when it abounds in animated conversations, or when direct action prevails over description. All dramatic poetry may be divided into *tragic* and *comic*. Tragic poetry has for its aim to interest the earnest mind, while comic poetry merely endeavours to produce amusement. Tragic poetry may be described as that which interests the mind in the highest degree possible, and comic poetry as that which engages it in the most complete lawlessness. In comedy, gloom, sadness, sobriety, have no recognised existence; while in tragedy, gaiety, joviality, riotous mirth are unknown.

While the drama, doubtless, arose from that

natural love of imitation peculiar to man, and from the childlike liveness with which a simple narrator loves to recount anything which he has heard or seen, yet the creation of dramatic composition was, nevertheless, a feat of singular boldness. This arises from the wide difference there is between the disjointed elements of occasional imitation and the perfect invention of the genuine drama. The Old Testament, no doubt, contains numerous instances of dramatic dialogue, as in the Book of Job; and of lyric poems placed in a dramatic connection, as Solomon's Song; but there is no instance in Hebrew literature of the existence of the drama properly so called. The Hindus have an early dramatic poetry, but, unfortunately, this poetry only dates back to a time when the intercourse between Greece and India was close and frequent. It is to Greece alone that we, accordingly, must look for the invention of the drama, and to Athens, in particular, for its perfection. But even here it was originally exhibited only at a few festivals of a single god, Dionysus. There can, then, be no doubt that the origin of the drama is to be sought for in the enthusiasm attendant on the worship of Bacchus. The ancient Greek writers tell us, that the drama originated in a choral song; and Aristotle (*Poet.* 4), that it had its origin in the singers of the dithyramb. Supposing that it originated in the pantomimic dances, the dramatic art, like every other, was only slowly purified from extraneous mixtures. Even the origin of the word tragedy has been disputed, although the inventor of it, Arion (580 B.C.), the celebrated dithyrambic poet, is known. Tragedy (*tragœdia*, from *tragos*, a goat, and *œdē*, a song) is said to have taken its rise from the fact of the old dramas being exhibited when a goat was sacrificed, or because a goat was the prize, or because the actors were clothed in goatskins. Comedy, again (*kômœdia*, either from *kômos*, a revel, or *kômē*, a village), signifies, literally, either the *revellers' song* or the *village song*, from the practice of strolling-players publicly exhibiting their dramatic skill about the streets. Thespis (536 B.C.) introduced the regular dialogue into the choral representations, and joined a person to the dithyrambic songs, who was the first actor. Phrynichus (512 B.C.) used this single actor of Thespis for the representation of female characters, although with him the lyric element predominated over the dramatic. No further improvement of any note was introduced into tragedy before the time of Æschylus.

Comedy, again, arose about 580 B.C., with Sausarion, who travelled about through Greece, ridiculing, from a small movable stage, the follies and vices of his time. Tragedy, from its first recognition, was deemed worthy, by reason of its superior gravity and staidness, to entertain the refined inhabitants of cities; while comedy, at the outset, from its riotous fun and jollity, was judged more in harmony with the rustic habits of the country people. In time, comedy made its way into the city, and Epicharmus (485 B.C.), besides modelling this form of dramatic wit, after its more successful rival, tragedy, likewise introduced a number of distinguished comedians to the notice of the Athenians. Phormes, Magnes, Crates, Cratinus, Eupolis, Pherecrates, and Aristophanes, are the highest names in connection with the old Greek comedy, the last mentioned being, however, by far the greatest. Tragedy, both from its ideal character, and from the stately cothurnus and long masks in which the actors of it appeared, aimed at a representation of what was dignified, noble, and grand in human nature. Comedy, again, from its style of caricature, its low-heeled sock, and its grotesque masks, tried to degrade humanity beneath its natural level. Comedy,

during the Greek period of its history, divides itself into three forms—viz., Old Comedy, Middle Comedy, and New Comedy. The old comedy is the directly opposite of tragedy; its form is essentially sportive, and a seeming aimlessness reigns throughout it. It is, in the opinion of A. von Schlegel (*Lectures on Dramatic Literature*), the only genuine poetic species of comedy, while the other forms of it shew a tendency to decline into prose and matter of fact. In the new comedy, again, the form is rather serious than otherwise, and it is regularly tied down to the accomplishment of a certain aim. This is what is understood by comedy at the present day. It is a mixture of tragedy and comedy proper, of earnestness and mirth. Only fragments of Menander and of Philemon, the genuinely witty poets of the new comedy, have come down to us. The middle comedy, again, which came in between the old and the new, arose after the termination of the Peloponnesian war. The new oligarchy strictly prohibited the introduction of living persons by name on the stage; and the chorus, till then the chief instrument of vituperation, is said to have been abolished.

With Æschylus, Greek tragedy properly begins. He instructed his actors himself in the rehearsal of his pieces. In his dramatic compositions he aimed more at sublimity than beauty, more at the heroic than the human. Sophocles, again, who was, perhaps, superior to Æschylus in his appreciation of human nature, strove more to depict idealised men than to paint heroic excellence. He introduced a third actor on the scene, and materially improved the mechanism of the stage. Euripides was too much of a nice speculator to attain to the highest forms of poetic expression. Instead of quietly contemplating life as Sophocles did, he seems to have been morose and peevish; but in point of moral denunciation, no dramatist surpasses him. With these three great poets, Greek tragedy may be said to close. With them it ceased to be the tragedy which Aristotle has described in his celebrated definition of it. 'Tragedy,' he says (*Poetics*, 6), 'is the imitation of some action that is serious, entire, and of a proper magnitude; effecting, through pity and terror, the refinement of these and similar affections of the soul.' In the hands of the subsequent authors this form of the drama grew lax and effeminate, and in the performances of Theocletes especially, tragedy was made to give way to rhetoric. (See the works of Böckh and Welcker on the Greek tragedians; also, Müller's *Literature of Ancient Greece*.)

The Romans were not a great dramatic people. They borrowed, according to the common account, during a period of national despondency occasioned by a desolating pestilence (A. D. C. 391), their first idea of a play from the Etrurians; their effusions of sportive humour, their *Fabula Atellana*, from the Oscans; and the higher class of dramatic compositions from the Greeks. Philology, likewise, countenances this story; for *histrion*, the Latin word for a player, is pure Etruscan. No remains of any note have come down to us of the comic writers of Rome, except Plautus and Terence. The former was a poor day-labourer, the latter a Carthaginian slave. The habits of each appear in their writings. Plautus has a degree of rough vigour and broad jocularly, born of the hand-mill and the plough, while Terence is more refined and delicate in his wit and characterisations. Both these writers borrowed largely from the Greeks. Of the early period of Roman tragedy no remains exist, but it is probable that its poets were merely translators or imitators of Greek models. The tragedians of the Augustan age were ambitious of rivalling

the Greeks. Unfortunately, none of these grand attempts have come down to us, except ten bombastical and frigid dramas, that go under the name of Seneca.

Ancient art fell with pagan Rome. In the early ages of Christianity, any one connected with the theatre was not allowed baptism. The unwise zeal of the fathers was followed by an edict of the Emperor Julian to the same effect. The two Apollinarii, father and son, and Gregory of Nazianzen, attempted to introduce religious plays or mysteries, drawn from the Scriptures, to amuse the Christian people during the operation of Julian's law. In a short while, instead of the drama proper, there was nothing to lighten up the surrounding darkness but such productions as the saturnalian pageants, the Feast of Fools and the Feast of the Ass.

The Italians are the first people of Europe, who, after the long sleep of the true dramatic spirit in the middle ages, strave to enkindle the ancient fire upon Roman hearths that had for long years been cold. Early in the beginning of the 16th c., the first regular modern drama was published. It was called *Sophonisba*, and the writer was a very commonplace author, by name Trissino. Shortly after, this tragedian was followed by Ariosto, by Babbiena, and by Macchiavelli, all distinguished cultivators of the classic comedy. Towards the end of the century, Giambattista de la Porta, philosopher and comic writer, exhibited a number of pieces of a familiar, and sometimes even farcical kind, but full of happy invention and agreeable originality. The political influence of Spain was now at its height on Italian territory, and the romantic drama of the west gradually found favour in Italy. Even so early as 1529, Ricchi had attempted to overthrow the classic taste in Italy, but without success. It remained for Borghini, Oddi, and M. A. Buonarroti, the nephew of the great artist, and one or two other writers, to break in upon the current taste, and to do much to introduce the romantic drama in Italy. In the 17th c., Rinuccini, by the union of music with the romantic drama, succeeded in establishing the *melodrama*. Tragedy and comedy were now entirely laid aside as antiquated, and nothing but the *musica opera* was heard of from Milan to Ravenna. Maffei led the way in reforming the Italian stage. The political preponderance of Spain had now given way to that of France, which facilitated his labours not a little. His *Merope* is a fine attempt to restore the tragic drama to Italy, but as Lessing says of it, in his *Dramaturgie*, it is rather the production of a 'learned antiquary' than of a great tragic poet. The musical drama had now to be rendered classic, and this task was undertaken by Zeno and Metastasio. The latter, who has all the attractiveness for the Italians that the classic Racine has for the French, by subtle harmony and grace in his songs, by his power of painting pathetic situations, and by his melting effeminacy of manner, charmed the hot southerners as no other poet yet had done. After Goldoni, a great comic authority in Italy, and a careful student of Macchiavelli and Molière, except Riccoboni and Gozzi his rivals, we have few dramatists of any note till we come down to last century. The bold and passionate Allieri inaugurated a new era in Italian tragedy. He is a follower of the classic school, and a strict observer of the Aristotelic unities. His successors have relaxed more their adherence to classic forms, and have produced some very admirable dramas. Among the most estimable of those writers are Monti, Manzoni, and Niccolini.

In the other European nations as soon as dramatic composition rose to any degree of purity, it became thereby disconnected with the church.

But in Spain this is by no means the case, for their best poets, while writing for the stage, have busied their pens in the composition of religious dramas. Passing over the names of Villena, Santillana, Naharro, and Rueda, as diligent but comparatively weak builders of the fame of the Spanish drama, we come to the periods of Cervantes, of Lopez de Vega, and of Calderon, when the Spanish stage may be regarded as in its best condition. In his *Numantia* particularly, Cervantes, whose genius was more decidedly epic than dramatic, has left to the world a specimen of tragic invention and of moral dignity which it is not likely to forget. While the critics were clamouring about the classic rules and the Aristotelic unities, Lopez de Vega appeared on the scene, to set nearly all the dramatic laws at defiance. He is the most fertile dramatic writer in the world, besides being one of the best. Yet he prostituted his pen to serve the public, and sacrificed his future fame to his living popularity. Calderon, who succeeded him, possessed all his advantages, with the important additional merit of being thoroughly devoted to dramatic art as to a mistress. So great was Calderon reckoned in the composition of religious plays, that by letters-patent he enjoyed a monopoly of these productions for 37 years. The brilliant period of the Spanish theatre, comprising the first half of the 17th c., had with the death of Calderon well-nigh closed. Except Moreto, Tirso de Molina, and Solis the historian, there is no writer of any note to engage the attention.

We come now to France, where the unities, as they are called, have been observed with as much strictness as if the country had been an old Grecian province. This is chiefly owing to the influence of the criticisms of Boileau, who adopted the dramatic unities in all their severe rigour. The critics of other nations, particularly of Germany and of England, have chosen to condemn this exposition of the drama, and sometimes to despise even the Stagirite as a dramatic critic. The dramatic unities are threefold—Action, Time, and Place. According to the French, these unities have the following significance: 1. That the action of the drama must be one—that is, that the interest or attention must not be distracted by several plots, but everything must be subservient to the main action; 2. That all the actions must take place on the same spot, or very nearly so, in order that the illusion may not be disturbed; and 3. Everything should happen on the same day for the same reason. Much has been written for and against these rules. Suffice it to say, that these are the landmarks on which the classic dramatist fixes his eye. Previous to Jodelle, or indeed to Corneille, hardly any progress had been made in the regular drama in France. A number of writers, of more or less ability, had produced *mystères*, *soeties*, *moralités*, *farces*, in which, in numerous instances, the romantic or anti-classical tendencies of human nature had manifested themselves; but neither in the case of the Brethren of the Passion, nor in the case of the *Enfants sans Soucis*, was there any progress made in the proper business of dramatic composition. Jodelle was the first writer who composed a regular five-act tragedy, and he publicly exhibited it in the presence of the court of Henry II. of France. He composed other pieces of equal, many of superior, merit, but nothing of any importance in the drama appeared before the time of Corneille. This writer, who appeared in the reign of Louis XIV., during the time that the star of Richelieu was in the ascendant, had to humour the court by humouring the academy, and to please the academy he endeavoured to observe the rules of Aristotle. He

produced seven plays, as cold and as severe as if they had been written by Sophocles, but of great elegance and dignity of style, when it struck him that he might give more free scope to his romantic tendencies in the tragedy of the *Cid*. All Paris rang with its praises, but the academy gloomed, and poor Corneille had to betake himself again to the dignity and severity of the Greek drama. He got what he longed for, however—a seat among the members of that institution which had been so instrumental in repressing the spontaneous outflow of his genius. It was more than his successor, Molière, obtained, who insisted to the last on playing his part as well as penning his pieces—an abuse which the dignified academicians could by no means tolerate. The genius of this dramatist was decidedly comic, and it may perhaps be questioned, whether, in all the essentials of true comedy, Molière's is not the very foremost name in the history of the stage. He borrowed much from the Spaniards, though perhaps less than Corneille; a great deal from the Latins; and more perhaps from the Italians. But the favourite tragic poet of the court of Louis XIV. was Racine. His genius lay decidedly towards the serious and the exalted, so that he had no temptations, like Corneille, to trespass the bounds of the academic proprieties. In tenderness and elegance, all French writers give way before him. In his *Athalie*, his last and best drama, he gave to the Parisian public a composition, such as in breadth, in elegance, and in severe grandeur, it could nowhere find out of the Greek theatre. But we must push through the crowd of lesser lights which shone on the decline of Racine and Molière, and glance at that bright and fitful luminary—Voltaire. He pressed boldly forward, and astonished all Europe with the force and power of his romantic dramas, a style of composition which, since the *Cid* of Corneille, had been altogether excluded from the theatre. His spirit of intolerance was perhaps felt in his dramas, and his increasing warfare with superstition and fanaticism was too distinctly experienced even in the theatre. But his genius and spirit have earned for him a place beside Corneille and Racine as one of the tragic names whom France delights to remember. Boursault, Regnard, Legrand, Lemercier, Victor Hugo, Dumas, and Alfred de Vigny, would all require to be noticed in a full view of the French drama.

The German drama is almost wholly dependent for its fame on the names of Lessing, Goethe, and Schiller. For while Rosenpluet, Hans Sachs, and Ayer were original, and some of them fertile; while Gryphius, Gottsched, Gellert, and Schlegel shew a decided advance in the appreciation of the laws of dramatic composition; yet from the feebleness of the writers, and from the backward state of theatrical taste in the end of the 17th and the beginning of the 18th centuries, very little was done towards a clear and distinct recognition of the excellence of dramatic literature, till the critic Lessing, in his *Miss Sara Sampson*, taught Germany to appreciate the productions of the romantic drama. As a critic, he blamed the French, praised Shakspeare, and professed belief in Aristotle. He held more than one dramatic heresy, and his antipathy to versification was among the number. Goethe is, without doubt, one of the greatest geniuses which the world has seen, but whether he is entitled to so high a place for his theatrical dramas remains an open question. As his aim was more emphatically the culture of his genius in its fullest form, the circumstance of his writings assuming the dramatic form is rather an accident than otherwise. From first to last he seems to have been distinctly aware of this, and in

the prologue to his last, and by far his grandest production, he declares why he could not accommodate his genius to the demands of a mixed theatre. Yet his *Faust* must ever be regarded as one of the grandest and most remarkable compositions which modern Europe has witnessed. Schiller was more expressly the dramatic poet of Germany than Goethe. While Goethe's genius was fuller and more complete, Schiller made up for what he wanted in breadth of vision by the moral intensity of his genius. From his wild play of the *Robbers*, down to his last drama of *Wilhelm Tell*, he worked with a vehemence such as has very seldom been witnessed. But he filled Germany, and indeed all Europe, with his tragic fame, and his name is one which 'posterity will not willingly let die.'

Dramatic exhibitions in England, if they did not originate in the church, were nevertheless speedily appropriated by the clergy. Ecclesiastics were frequently the composers of the religious pieces, or mysteries, and they were found not seldom to be the actors. The mass of the people, no doubt, owed a good deal of grotesque amusement, and even of occasional information, to the biblical and legendary history, which those rude attempts at the drama were fitted to convey. Those old religious plays are generally divided into two classes—*miracles* or miracle-plays, and *moralities* or morals. The former were founded on Scriptural narratives, or on the legends of the saints; the latter arose from the former, by the increased introduction of imaginary features. These pious pastimes existed long before the Reformation, and were not overthrown by that great revolution in the opinions and beliefs of the country. See MIRACLE-PLAYS and MORALITIES. It was about the middle of the 16th c. that the drama extricated itself completely from these ancient fetters. By this time both comedy and tragedy had begun to exist in a rude reality in England. The oldest known comedy (before 1557), that of *Ralph Roister Doister*, was written by Nicholas Udall, a schoolmaster of considerable learning, probably about the middle of the 16th century. Ten years after appeared our first tragedy, known variously as *Gorbudoc*, or as *Ferrex and Porrex*, by Mrs Norton and Lord Buckhurst. And not only is this work the earliest tragedy in our language; it contains, beside, the first application of blank verse to dramatic composition. But the play is dull, heavy, and declamatory. The drama lingered in this incipient condition until very near the time of Shakspeare. Bishop Still's *Gammer Gurton's Needle* is no improvement on *Roister Doister*. The names of Kyd, Lodge, Greene, Lyly, Peele, Marlow, Nash, &c., must pass before us almost without comment. Many of these writers are not without their merits, particularly Marlow, whose plays of *Edward II.* and of *Dr Faustus* are acknowledged by Charles Lamb to contain passages that Shakspeare himself has not surpassed. Marlow, besides, is the first author who introduced blank verse upon the public stage. But all these dramatists are obscured by their nearness to the great luminary of the English drama. Shakspeare is now almost universally acknowledged to be the greatest dramatic genius that has ever appeared in the world. He brought the romantic drama to a perfection which it is not likely to surpass. His writings present the finest example of the depth, sublimity, refinement, and variety of which the drama is capable; and they are abundantly marked by those peculiar characteristics which sprung from the union, in the person of its author, of such wonderful powers of conception with such familiar experience of theatrical management. Of course he despised the unities, or rather, we might

say, he worked in ignorance of them, for he knew nothing of Aristotle and Boileau; and the rest of the French critics were not born when he died. Hence his drama is known in literature as 'irregular;' and, we fear, human nature is likewise very irregular. The poet trusted to his own instinctive judgment, and of its exercise we have all fortunately plenty of examples. The principal of Shakspeare's contemporaries are Ben Jonson, and Beaumont and Fletcher. Like Shakspeare, Jonson wrote both tragedies and comedies. Milton speaks of 'Jonson's learned sock,' and thus hits off the main feature of his character as a dramatist in a phrase. Beaumont and Fletcher, who were, like many brotherly men in that age, joint-workers, have the honour of standing next to Shakspeare in the romantic drama of England. But, like Lopez de Vega, they wrote too much for the mere success of the moment to be ranked in the foremost file of England's dramatic writers. With Massinger, Ford, and Shirley, the old English drama is closed. Dryden, the literary chief of his age, who flourished during the latter half of the 17th century, wrote some fine pieces of Frenchified declamation. Lee, and the unfortunate Otway, bring down the drama to the beginning of the 18th century. For, while Gay, Congreve, Cibber, Wycherley, Vanbrugh, and Farquhar, all display considerable dramatic spirit and invention, their works are, nevertheless, morally considered, the foulest things in the language. They paint well the externals of society, and have left behind them good specimens of the 'comedy of manners,' as it has been called; but vice is both warp and woof of nearly everything they have produced. Addison, Johnson, Young, Thomson, &c., wrote some good poetry, but poor dramatic verse; while Lillo, Moore, Garrick the actor, Goldsmith, the Colmans, and Cumberland, nearly all took to prose instead of verse. They produced agreeable comedies, but nothing of a very marked kind in the history of the drama appears until the time of Sheridan, who gave an impulse to 'genteel comedy,' such as has placed him ever since at the head of the writers of that species of composition. Holcroft, Mrs Inchbald, 'Monk' Lewis, and Maturin, mostly influenced by inferior German writers, have left behind them a legacy of terror and of wonder fit to render their period marvellous, if for nothing else. Joanna Baillie and Sheridan Knowles remind the reader of the excellences of the old English drama, and the *Lady of Lyons* of Bulwer Lytton is a favourite with playgoers of the present day. Byron, Coleridge, and Henry Taylor, are the authors of fine meditative dramas, but they are more suitable for the closet than for the stage. Our sketch of the drama would not be complete without allusion to the labours of Talfourd, Jerrold, Shirley Brooks, Westland Marston, Tom Taylor, and Charles Reade, who have each, after his fashion, endeavoured to sustain the stage of England from falling into utter disgrace in the present day.

DRAMATIC WORKS, COPYRIGHT IN. Dramatic and musical works enjoy a legislative protection peculiar to themselves. By 3 and 4 Will. IV. c. 15, it is provided that the author of any dramatic piece not printed or published by him or his assignee, shall have, as his property, the sole liberty of representing it, or causing it to be represented, at any place of dramatic entertainment; and the author of any published dramatic work shall have the same privilege during his life, or his assignee for twenty-eight years from the date of publication. By 5 and 6 Vict. c. 45, s. 20, the provisions of the former statute are extended to musical compositions; and the term of copyright provided for other works (see COPYRIGHT) is

applied to the liberty of representing dramatic pieces and musical compositions. The following section (21) reserves to the proprietors of dramatic works the remedies given them by 3 and 4 Will. IV. c. 15, s. 2. These are the power of exacting from every offender a sum not less than forty shillings, or the full amount of the benefit or advantage arising from the representation, or a sum equivalent to the loss sustained by the plaintiff, 'whichever shall be the greater damages.' The action must be brought within a year. The provisions of the act extend to both sexes.

**DRAMMEN**, a seaport town of Norway, in the province of Aggerhuus, on both sides of the river Drammen, which here discharges its waters through the Drammen fiord into the Gulf of Christiania, about 24 miles south-west of Christiania. D., which is built in a valley, is divided into three quarters—Bragenes on the north bank of the river, and Stromsoe and Tangen on the south, united to the first-mentioned quarter by a handsome bridge. The chief streets, which run along each side of the river, are composed, for the most part, of warehouses. The manufactures of D. are leather, ropes, sailcloth, tobacco, spirits, and earthen-ware; but the inhabitants are chiefly engaged in connection with the export of timber. Pop. 12,000.

**DRAPERY** (Fr. *drap*, cloth), any kind of woollen cloths for dress, the dealers in which in England are known as Drapers. In London, the Drapers' Company is one of the more wealthy civic corporations, with a Hall and Almshouses.

**DRAPERY in Art.** From the very great difficulties with which the artist has to struggle in dealing with the arbitrary and ungraceful forms of modern dress (see **COSTUME**), we are often led to regard drapery as an impediment, in place of an aid and accessory, to the representation of the human form in plastic art. The erroneous nature of such a conception will be manifest at once to those who direct their attention to the study of drapery in antique art, with a view to discovering not so much how as why it was employed by a people whose national customs admitted of their almost wholly dispensing with it had they felt so disposed. Such a study will convince us that, when properly disposed, drapery tends, in many cases, to exhibit the form, to enhance the characteristics, and to intensify the attitude, whether in action or in repose. It tells, moreover, something of the circumstances in which the action takes place beyond what could possibly be told by the naked figure. The waving drapery of a hunting Diana, or an Apollo shooting with the bow, tells us at once that the action is taking place in the open air, with the fresh breezes of the Ægean blowing around them. On the other hand, that repose which is the peculiar characteristic of sovereignty, is indicated by the still and heavy character of the drapery which surrounds a Jupiter on Olympus, or a Caesar on his throne. The simple rule—simple in principle, though by no means always easy in practice—for the disposal of drapery, seems to be that it shall never be employed without an object; and that every fold shall, so to speak, be a logical result, either of the form of the figure, or of the circumstances in which it is placed, or of some previous fold to which the latter is subordinated.

**DRAUGHT** or **DRAFT OF WATER**, in maritime affairs, is a technical name for the depth to which a ship sinks in the water when fairly afloat. The draught is marked on the stem or stern-post, or both, from the keel upwards. When a ship is in good trim, the draught does not differ much at the two ends. Ships with sharp bottoms draw more water, or have a 'greater draught,' than those of

flatter construction. For draught as applied to ploughs, wagons, &c., see **TRACTION**.

**DRAUGHTS**, like chess, is a game played with 'men' on a checkered board. As far as the *science* of the game is concerned, it falls far short of chess, but is nevertheless a favourite recreation with many classes of people. In France, it is called *Les Dames*, from its having been a favourite game with ladies; and in Scotland, the draught-board is called the *Dambrod*. The following is a representation of the draught-board, numbered for the sake of illustration:

	1		2		3		4
5		6		7		8	
	9		10		11		12
13		14		15		16	
	17		18		19		20
21		22		23		24	
	25		26		27		28
29		30		31		32	

Two persons usually play this game, each having a set of twelve men—one set black, the other white. The men may be placed either on the black or white squares, but the whole must be placed on one colour only. Thus, in England, it is usual to play upon the white squares, with a black square to the lower right, as above shewn; and in Scotland upon the black, with a white square to the lower right. The above illustration, therefore, shews the English method, and as such we shall consider the mode of playing the game. In chess, the men may be moved straight forward, sidewise, or diagonally, and over many squares at once; but in draughts, the men may be moved diagonally only, and by *one* square at a time. If an enemy's man stand in the way, no move may take place unless there be a vacant square beyond into which the piece can be lifted. The man leaped over is then taken and removed from the board. The grand object of the game is, therefore, to clear the board of the enemy's men, or to hem them in so that they cannot be moved, and whichever party does so first, wins the game. As no piece can move more than one step diagonally at a time, there can be no taking till the antagonists come to close quarters; and the advancing of them cautiously into each other's neighbourhood is the chief art of the game. When a man on either side has made his way either by taking or by a clear open path, to the opposite side of the board, he is entitled to be 'crowned,' which is done by placing another man on the top of him. Crowned men may move either backwards or forwards, but always diagonally and by one square at a time, as before; and this additional power thus gained gives a great advantage to the player who owns the greatest number of crowned heads, and usually decides the game in his favour.

**DRAUGHTSMAN.** A draughtsman differs from a designer inasmuch as he lays no claim, in that capacity at all events, to the character of an originator.

**DRAVE** (Ger. *drav*), a river of Austria, rises in the east of Tyrol, in lat. 46° 45' N. and long. 12° 25' E., flows north-east through the Pusterthal towards Lienz, where it is joined by the Isel. It then flows east through Carinthia, passes Villach, where it becomes navigable, after which it passes Marburg, receives the Dran from the right, and the Mur, its principal affluent, from the left; then turning towards the south-east, it forms the boundary between Croatia and Slavonia on the right, and Hungary on the left, and pours its waters into those of the Danube at a point ten miles east of Essek, the capital of Slavonia. The D. is nearly 400 miles long. In the first part of its course, it is a mountain torrent, rushing furiously through the mountain passes of Tyrol; but joined by numerous streams, its volume increases, and its course becomes more staid. The valleys through which it flows in its course through Carinthia, Styria, and Croatia, are distinguished by great fertility and picturesque scenery, while the population upon its banks is numerous and industrious. In Slavonia, the D. is frequently bordered by dense forests.

**DRAWBACK**, a term in commerce, employed in connection with the remitting or paying back of excise duties on certain classes of articles exported. Excise duties, as a matter of course, enhance by so much the natural price of the commodity on which they are imposed. Were these duties not remitted, the commodity so taxed would not be ordered from those foreign countries where articles of the same kind could be purchased free of such duties. To afford facility for the exportation of these articles, the state resorts to the expedient of returning to the exporter a sum equal in amount to what he or the manufacturer had paid to the excise. Such is drawback. Among other matters of fiscal policy, Adam Smith, in his *Wealth of Nations*, discusses the propriety of giving drawbacks, and sees in them nothing that is adverse to a sound political economy. 'To allow,' he says, 'the merchant to draw back upon exportation, either the whole or a part of whatever excise or inland duty is imposed upon domestic industry, can never occasion the exportation of a greater quantity of goods than what would have been exported had no duty been imposed. Such encouragements do not tend to turn towards any particular employment a greater share of the capital of the country than what would go to that employment of its own accord, but only to hinder the duty from driving away any part of that share to other employments. They tend not to overturn that balance which naturally establishes itself among all the various employments of the society, but to hinder it being overturned by the duty: they tend not to destroy, but to preserve, what it is in most cases advantageous to preserve, the natural division and distribution of labour in the society.' Correct as is this view in general principle, it could perhaps be shewn, by the closer experience of the present day, that the practice of giving drawbacks is liable to abuse; as, for example, when an excisable article falls greatly in value, and it is exported in order to get the drawback, with little or no reference to sales abroad, or in the hope that the drawback will at least bring the amount of the freight. So far, therefore, the state is made to foster an improper species of commerce. To prevent deceptions as far as is practicable, certain rules and formalities have to be attended to by exporters, to which we shall briefly refer.

In preparing goods for drawback, they must be packed in presence of an excise officer, who sees them weighed, if the drawback depends on weight. When the package is completed, he encloses it with a tape, which is properly fixed with a seal. Under

this seal it is transferred to the port of shipment, and cleared for export by a person authorised by licence from the officers of customs. In the case of press-packed goods, the quantities and qualities must be verified by the oath of the master-packer or his foreman. Drawback is given only on goods which have been charged with duties within three years, and no drawback is given on damaged or decayed goods. It is payable only to the real owners of the articles shipped. It is not payable for a certain period after shipment and departure; but cannot be demanded later than two years after shipment. As a verification of the principal particulars mentioned, the excise-officer concerned executes a certificate or Debenture (q. v.), and under its operation the drawback is paid by the inland revenue department.

**DRAWBRIDGE.** See BRIDGE.

**DRAWER OF A BILL.** See DRAFT, BILL.

**DRAWING** is the art of delineating form, as opposed to colour and light and shade. The term is not confined to the first outline produced by the pencil or crayon, though this is a narrower sense in which it is also used, and what we commonly mean when we speak of a drawing. In its wider sense, drawing is used to describe what is in reality the most important feature of a finished painting of Raphael or Correggio, as well as of an outline by Flaxman or Retch. Drawing, in this sense, has been termed the grammar of art. But the analogy is incomplete; for the one quality which is requisite in the application of grammar, is correctness, whereas drawing, even when correct, even when faultless, admits of degrees of perfection. It may be more or less powerful, more or less free, more or less graceful; and indeed there is no characteristic in which the great artists of the Italian and Flemish schools more unmistakably excel all their successors, than in the power and beauty of their drawing. Neither is there any feature which more unmistakably stamps the individuality of the artist upon the picture.

**DRAWING AND QUARTERING.** The punishment for treason still is, that the offender be *drawn* to the place of execution on a Hurdle (q. v.); that he be hanged by the neck till he be dead; that his head be severed from his body, and that body be divided into four parts, or *quartered*. The sovereign may, and now certainly would, by a warrant under the sign-manual, countersigned by a principal secretary of state, change the sentence into beheading. In the case of females, the quartering is dispensed with. *Stephen's Commentaries*, iv. 231. See TREASON.

**DRAWING-BOARD**, a board on which drawing-paper is strained for painting on in water-colours. The paper is wetted for the purpose of being strained, and when attached at the edges, it is permitted to dry and contract. Formerly, the drawing-board was fitted into a frame, the edges of the wet paper being made fast by the pressure of the frame on the board. But the much simpler drawing-board which is now in use is made of a flat piece or pieces of wood, held together, and prevented from warping by an edging of other pieces, the grain of which runs in the opposite direction. The wet paper is attached to the edges of the board with paste or thin glue, and when dry, becomes perfectly firm and flat. When the work is finished, the paper is cut beyond the drawing with a knife.

**DRAW-PLATE**, a steel-plate with a graduated series of holes, through which metals are drawn in making them into wires or bars.—Also a name given to a plate of metal placed before a fire or before the lateral opening between the top of the fireplace and the throat of the chimney. Its use is to force the

air to pass through the fire on its way into the chimney, instead of allowing it to pass over the fire.

DRAYTON, MICHAEL, was born in 1563 at Hartshill, in Warwickshire. Of the events of his life but little is known. He is supposed to have studied at the university of Cambridge, and to have been in the army when young. His earliest work, *The Shepherd's Garland*, was published in 1593. He afterwards published the *Barons' Wars, England's Heroical Epistles, &c.* The *Polyolbion*, the work by which he is best known, appeared in 1613. He was poet-laureate in 1626; he died in 1631, and was buried in Westminster Abbey.

As a poet, D. is but little known, save to readers like Charles Lamb, who delighted in the obscure corners of literature. His *Polyolbion* is a topographical poem; and passages from it, now and then met with in county histories and works of an antiquarian character, surprise the reader with their stately rhythm, their nervous force, and their felicity of diction.

DRA-YTON-IN-HALES, or MARKET DRAYTON, a town in the north-east of Shropshire, on the Tern, near the Birmingham and Liverpool Canal, 19 miles north-east-by-north of Shrewsbury. Pop. (1861) 5242, chiefly agricultural. There are manufactures of paper, and of hair-seats for chairs. The parish church was built in Stephen's reign, but quite altered by repairs in 1787. Here, in 1459, the Yorkists defeated the Lancastrians.

DREAMING. In complete sleep, there is probably an entire absence of consciousness of external things. Usually, however, there is a certain amount of mental activity, of which we are more or less conscious at the time, and of which we have more or less subsequent remembrance. This is the state known as dreaming. The chief feature of this state is 'an entire absence of voluntary control over the current of thought, so that the principle of suggestion—one thought calling up another, according to the laws of association—has unlimited operation.' We seem to perform all the actions of life; we experience every kind of mental emotion, and sometimes our reasoning processes are remarkably clear and complete. Thus, when the mind, during sleep, takes up a train of thought on which it had been previously engaged during the preceding waking hours, intellectual efforts may be made during sleep which would be impossible in the waking state. Such cases, however, are not common. To name two instances (quoted by Dr Carpenter in his essay on Sleep in the *Cyclopædia of Anatomy and Physiology*): Condorcet saw, in his dreams, the final steps of a difficult calculation which had puzzled him during the day; and Condillac states that, when engaged with his *Cours d'Etude*, he frequently developed and finished a subject in his dreams which he had broken off before retiring to rest.

Occasionally, but by no means commonly, dreams seem to possess a remarkable coherence and congruity in reference to the reasoning processes, or the combinations of the imagination. Most of our readers are probably acquainted with the incident narrated by Coleridge of himself, that his fragment, entitled *Kubla Khan*, was composed during sleep, which had come upon him in his chair whilst reading the following words in Purchas's *Pilgrims*: 'Here the Khan Kubla commanded a palace to be built, and a stately garden thereunto; and thus ten miles of fertile ground were enclosed within a wall.' Coleridge continued for about three hours apparently in a profound sleep, during which he had the most vivid impression that he had composed between 200 and 300 lines. The images, he says, 'rose up before him as things, with a parallel production of the

correspondent expressions, without any sensations or consciousness of effort.' On awakening, he had so distinct a remembrance of the whole, that he seized his pen and wrote down the lines that are still preserved. Unfortunately, he was called away to attend to some business which lasted more than an hour, and on his return to his study, he found, to his intense mortification, that 'though he still retained some vague and dim recollection of the general purport of the vision, yet, with the exception of some eight or ten scattered lines and images, all the rest had passed away like the images on the surface of a stream into which a stone had been cast.' In other cases, a dream may leave a strong general impression on the mind, although particulars, even immediately on waking, cannot be recalled. Tartini is said to have composed the *Devil's Sonata* under the inspiration of a dream, in which the archfiend challenged him to a trial of skill. The dreamer lay entranced by the transcendent performance of his distinguished visitor; but on awakening and seizing his violin, although he was unable to reproduce the actual succession of notes, he produced from his general impressions the celebrated composition which we have named.

Generally, however, dreams are wanting in coherence; all probabilities, and even possibilities of 'time, place, and circumstance' are violated. Friends long since dead appear and converse with us; and events long since past rise up before us with all the vividness of real existence. We may be conveyed to the antipodes, or even to worlds beyond our own, without the difficulty of the distance at all standing in the way. We are not aware of the grossest incongruities, probably because we are unable to test the probability of the phenomena by our ordinary experience; hence nothing that we see or do in a dream surprises us. Professor Wheatstone observes, that 'we may walk along the brink of a precipice, or see ourselves doomed to immediate destruction by the weapon of a foe, or the fury of a tempestuous sea, and yet not feel the slightest emotion of fear; though during the perfect activity of the brain we may be naturally disposed to the strong manifestation of this feeling. Again, we may see the most extraordinary object or event without surprise, perform the most ruthless crime without compunction, and see what in our waking-hours would cause us unmitigated grief, without the smallest feeling of sorrow;' and Cicero, who long previously had made dreaming his study, justly remarks (*De Divinatione*, 59), that if it had been so ordered by nature that we should actually do in sleep all that we dream, every man would have to be bound down on going to bed. Occasionally, however, in place of this passive condition, the emotions may be highly excited; thus, for example, the sailor's wife is apt, especially in stormy weather, to dream of shipwreck, and to shriek with terror from its attendant miseries; and those who have once in their lives been exposed to some fearful danger, are apt to have the scene recalled to them in their dreams, either with all its appalling and lifelike exactness, or possibly in a grotesque and impossible modification.

Although the predisposing causes of dreams may be sought for in more than one direction, they are probably in general referable to some peculiar condition of the body, and are often called into action through the agency of the external senses. Dr Gregory relates, that having occasion to apply a bottle of hot water to his feet at bedtime, he dreamed that he was walking up Mount Etna, and found the ground insufferably hot. Dr Reid having had a blister applied to his head, dreamed that he was scalped by a party of Indians. M. Gizon de

Buzereinges made a series of pre-arranged experiments, with the view of seeing how far he could determine at pleasure the character of his dreams. In his first experiment, having allowed the back of his head to be uncovered during sleep, he thought that he was at a religious ceremony in the open air; the custom of the country in which he lived being to keep the head covered, except on some rare occurrences, among which was the performance of religious ceremonies. On waking, he felt cold at the back of the neck, as he frequently had felt when present at the real ceremonies. He repeated the experiment in two days with the same result. In a third experiment, he left his knees uncovered, and dreamed that he was travelling at night in the diligence; and all travellers know, he observes, that it is chiefly at the knees that they feel cold when travelling by that conveyance at night.

One of the most remarkable phenomena of dreaming, is the rapidity with which long trains of thought pass through the mind. A dream requiring hours for its accomplishment, is begun and terminated in a few seconds. A person who was suddenly aroused from sleep by a few drops of water sprinkled in his face, dreamed of the events of an entire life in which happiness and sorrow were mingled, and which finally terminated with an alteration upon the borders of an extensive lake, in which his exasperated companion, after a considerable struggle, succeeded in plunging him. Dr Abererombie relates a similar case of a gentleman who dreamed that he had enlisted as a soldier, joined his regiment, deserted, was apprehended, carried back, tried, condemned to be shot, and at last led out for execution. After all the usual preparations, a gun was fired; he awoke with the report, and found that a noise in an adjoining room had both produced the dream and aroused him from sleep. Dr Carpenter mentions the case of a clergyman falling asleep in his pulpit during the singing of the psalm before the sermon, and awakening with the conviction that he must have slept for at least an hour, and that the congregation must have been waiting for him; but on referring to his psalm-book, he was consoled by finding that his slumber had lasted not longer than during the singing of a single line. Sir Benjamin Brodie, in his *Psychological Inquiries* (1854), mentions the following anecdote of the late Lord Holland: 'On an occasion when he was much fatigued, while listening to a friend who was reading aloud, he fell asleep and had a dream, the particulars of which it would have occupied him a quarter of an hour or longer to express in writing. After he woke, he found that he remembered the beginning of one sentence, while he actually heard the latter part of the sentence immediately following it, so that probably the whole time during which he had slept did not occupy more than a few seconds.' Many facts of the same kind are on record, and as the author from whom we have quoted remarks, 'if we were to pursue this subject, it would lead us to some curious speculations as to our estimate of time, and the difference between the real and the apparent duration of life.' It is from cases of this nature that Lord Brougham has been led to the opinion, that *all* our dreams really take place in the act of falling asleep or of awaking. We cannot, however, explicitly accept this doctrine. 1. There is no sufficient proof of its being true. 2. We have a proof to the contrary in the fact, that it is common for people to moan and even talk in the middle of a sleep; and every one who has kept a dog must frequently have observed him dreaming (from the outward manifestations which he makes in the form of snarling or growling), though he still remains asleep. Some, on the other hand, have argued that the mind can never be entirely inactive,

and that every one is dreaming throughout the whole period of sleep, although the dreams may not be remembered in the waking state. We know of no facts that can be adduced in favour of this hypothesis, and the following case goes strongly to disprove it. A woman, aged 26, who had lost a portion of the scalp, skull, and dura mater, so that a portion of her brain was exposed to view, was a patient in 1821 in the hospital at Montpeller. When she was in a dreamless state, or in profound sleep, her brain was comparatively motionless, and lay completely within its bony case; but when the sleep was imperfect, and the mind was agitated by dreams, her brain moved and protruded from the skull, forming what is termed cerebral hernia. This protrusion was greatest when the dreams, as she reported, were most vivid; and when she was perfectly awake, especially if actively engaged in conversation, it attained its highest development, nor did this protrusion occur in jerks, alternating with recessions, as if caused by arterial action, but remained permanent while the conversation continued. If the *data* of this case are to be depended on, the appearance of the brain during profound sleep seems to indicate that during that state there is a total or nearly total suspension of the mental faculties.

The author of *Psychological Inquiries* suggests the question: Do dreams answer any purpose in the economy of living beings? We regret that he has not given us a very definite answer, but he obviously inclines to the view that they cannot be purposeless. No one has hitherto offered any certain explanation of the uses of the spleen, of the thyroid gland, or of the supra-renal capsules; yet no one believes the formation of these organs to be merely incidental, or doubts that they have some special (although at present unknown) function to perform. 'Dreams are,' he observes, 'at anyrate, an exercise of the imagination. We may well conceive that one effect of them may be to increase the activity of that faculty during our waking-hours, and it would be presumptuous to deny that they may not answer some purpose beyond this in the economy of percipient and thinking beings.'

Dreams have, in all ages and countries, been believed in as indications of the future; and of all forms of superstition, this is perhaps the most excusable. Whatever is mysterious as to its cause, and beyond the power of the will, appears as supernatural; and what more so than dreams! The thoughts in dreams, too, arise out of the past and present circumstances of the dreamer, and therefore are not altogether without connection with his future destiny, as most other omens are. In the Homeric age, it was firmly held that 'dreams come from Zeus.' In the most ancient civilised communities of which we have any record—those of Egypt and Babylon—to interpret the monarch's dreams was one of the most important state offices, and was confided to a college of wise men. A common way of consulting the Greek and Roman oracles (q. v.), was for the inquirer to sleep a night in the temple, after performing sacrificial and other rites, when his questions were supposed to be answered in dreams. Grave philosophers wrote treatises on the interpretation of dreams, as they did on astrology. Even Bacon, although he confesses that the interpretation of dreams is mixed with numerous extravagances, yet speaks as if he thought that something might be made of it. In modern times, and among European nations, dreams are seldom heeded except by the very ignorant or superstitious; and 'as idle as a dream' has become a proverb. Nothing can be conceived more arbitrary than the pretended rules of interpretation; e. g.,

'that to dream of gold is good-luck, but of silver ill.' See Brand's *Popular Antiquities*, by Ellis, where a 'Dictionary of Dreams' is given. As to the actual coincidences that sometimes happen between dreams and events, it is only surprising, considering the countless fancies that are passing through our minds while asleep, that the coincidences are not ten times more numerous than they are.

**DRED SCOTT CASE.** This was a case brought for final decision before the supreme court of the United States in 1856, which excited much interest in America as well as in Europe. The plaintiff was a negro named Dred Scott, who, with his wife and two children, had been held as slaves by a Dr Emerson, in the state of Missouri. After the death of Emerson, Dred Scott with his family claimed to be free, on the ground that they had resided for some time with their late proprietor in a free territory—so that having, as Scott alleged, been free in that territory, they could not now be held to slavery. The result of the litigation was, that Dred Scott and his family did not become free by having been taken to a free territory, and were accordingly still held to be slaves.

**DREDGE,** a machine for dragging or dredging the bottom of seas, rivers, or lakes, in order to bring up oysters and other animals that lie on the bottom. The common oyster-dredge is a bag-net, made of iron rings, linked together to form the meshes; the mouth is made of sheet-iron, which acts as a scoop when the dredge is let down and drawn

along the bottom as the boat sails on. The dredge has of late been very extensively used by the naturalist with very important results, among the most remarkable of which are those obtained by the late Professor Edward Forbes, shewing the existence of zones of animal life corresponding with different depths of the ocean. The naturalist's dredge is of a lighter construction than that of the oyster-fisher, and its meshes should be smaller. For dredging a sandy bottom, the best form of dredge is one like the net used by the Kentish shrimpers. These are twine-nets, bag-shaped, and of the length of the boat. The lower side of the mouth of the net is stretched upon a wooden pole, and the other side is held up while the lower is drawn along the bottom. The quantity and variety of animals drawn up by these large shrimp-nets are astonishing. The dredge used for catching soles is similar in construction to the shrimp-net; but all dredges must be modified to suit the bottom on which they are used.

**DREDGING-MACHINE,** a machine used for clearing out or deepening the channels of rivers, harbours, &c. Dredging-machines are variously constructed, the simplest being like the oyster-dredge described above, only having a perforated cowhide bag instead of the chain-net, and a stronger 'spoon' or iron mouth to the bag. This is attached to the end of a pole, and worked with tackle by men from a barge in such a manner that the loose matter of the bottom is scooped up into the barge. The bucket dredging-machine is much more efficient. It consists of a long stage or framework

Section of a Dredging-machine.

overhanging the side of the barge. This frame has a wheel at each end, upon which works a powerful endless chain, to which is attached a series of perforated iron buckets, each with a shovel-shaped steel mouth projecting considerably on one side. The overhanging framework forms an inclined plane, along which the buckets run, descending on one side, and ascending on the other. They are so arranged that they descend empty, and on reaching the bottom, the projecting shovel or scoop-mouth digs into the bottom, and partially fills the bucket with the silt; it then turns round on the wheel at the lower end of the incline, and runs up it till near the top, when it turns over the upper end, and in doing so its contents are emptied into a second attendant barge. This action is continued by every succeeding bucket of the endless chain. The perforations are for the passage of the water. By varying the inclination of the framework, the working depth may be increased or diminished. The machine may be set in motion by a steam-engine, by a horse walking round a circular path on the barge, or simply by the action of the tide upon a large undershot water-wheel, the barge being moored, and the stream passing under it. Perhaps nowhere has river-dredging been carried such a length as in the case of the Clyde, which, by this process of

scooping, has at and below Glasgow been converted from a river navigable only for small vessels into an estuary capable of bearing the largest ships. The dredgers employed for this purpose are moved by steam, the materials scooped out being carried off by lighters, which are attached. A dredger of this kind, just adapted to the cleansing of the harbour at Greenock (1861), is of the following dimensions: The hull is of iron, 110 feet in length by 23 feet in breadth. The frame for buckets, on which there are 37, is 70 feet, and is capable of dredging to a depth of from 27 to 30 feet.

**DREISSENA,** a genus of lamellibranchiate molluscs, generally regarded as belonging to the mussel family (*Mytilidae*), although, whilst the shell very much resembles that of the true mussels, the animal differs in having the mantle closed except at the anal and branchial slits, and a small aperture through which the foot and byssus protrude.—*D. polymorpha* is an interesting mollusc, because, having of late been accidentally introduced into British estuaries and canals, it has fully established itself, and is now abundant in many of them, and in the rivers with which they are connected. Originally, it is believed, a native of the rivers which flow into the Caspian Sea and Lake Aral, it has extended to the canals and rivers of Germany,

Holland, &c. It is capable of living a long time out of water with its valves closed, and it is supposed that it may have come to Britain on timber imported from the continent.

**DRENTHE**, a frontier province of the Netherlands, is bounded on the E. by Hanover, on the N. and E. by Groningen, on the W. by Friesland, and on the W. and S. by Overijssel, in lat.  $52^{\circ} 37' - 53^{\circ} 23' N.$ , and long.  $6^{\circ} 12' - 7^{\circ} 10' E.$  Area, 1017 square miles. Pop. 94,472. The soil is in general poor, only about one-half of the surface being capable of cultivation, the remaining portion covered chiefly with heath and morass. The principal crops are rye and buckwheat, but barley and oats are also raised. The inhabitants are chiefly employed in agriculture, pasturage—the cattle reared in D. being famous—and in digging and exporting peat. Two pauper colonies in the west of the province, the *Fredericksoord* and *Willensoord*, established in 1818, are employed by the state in bringing waste land under cultivation, and in brick-making, weaving, and other occupations.

**DRESDEN**, the capital of the kingdom of Saxony, situated in a charming valley on both sides of the Elbe, in lat.  $51^{\circ} 3' 16'' N.$ , and long.  $13^{\circ} 44' E.$  It is 116 miles south-east of Berlin, and 72 miles east-south-east of Leipsic. It is composed of the Altstadt (Old Town), on the left bank of the Elbe; and of the Neustadt (New Town), on the right or northern bank. D. is a pleasant, though not exactly a beautiful town. It contains several open squares both in the Old and New Towns. Pop. 117,750. On account of its architecture and splendid collections in art, it has been justly called the 'German Florence.' Of the churches, the finest are the *Frauenkirche*, with a tower 335 feet in height; the Roman Catholic Church (1737—1756), with a celebrated organ by Silbermann, and numerous statues and pictures; the *Sophienkirche*; and the *Kreuzkirche*, with an altar-piece by Schönau. The synagogue of the Jews, built in the oriental style by Semper, is also worthy of mention. Among the other important buildings may be mentioned the Royal Palace, a shapeless edifice, begun by Duke George, 1534, and completed by Augustus II.; the Prince's Palace, erected by Augustus II. in 1718; the Zwinger, only the vestibule of a palace in the almost too elaborate old French style of architecture, but containing many valuable antiquarian and scientific collections; the theatre, the academy, the Brühl Palace, &c. The Old and New Towns are connected by two bridges, both *chefs-d'œuvre* of architecture.

D. possesses many excellent educational and charitable institutions. The Academy of Art opened in 1764, to which a school of architecture was added in 1819. This celebrated institution and the musical choir render D. of no small importance to the progress of art in the present day.

The most important branches of industry are gold and silver manufactures, straw-plait, paper-hangings, excellent painters' canvases, colours, artificial flowers, chocolate, porcelain, &c. An impulse was given to the corn-trade by the opening of the Corn Exchange in 1850.—The environs of D. are delightful. (1871—pop. 177,089.)

The most important of the D. collections are: 1. The Royal Public Library in the Japan Palace, amounting to nearly 300,000 volumes. It contains many curiosities, and is particularly complete in the departments of literary history and classical antiquity, as well as in histories of France and Germany. 2. The Cabinet of Coins, likewise in the Japan Palace. 3. The Museum of Natural History in the Zwinger, particularly complete in the miner-

logical department. 4. The Historical Museum, formed in 1833. 5. The collection of mathematical and physical instruments, likewise in the Zwinger. 6. The renowned Picture-gallery, containing upwards of 1500 paintings, mainly by Italian and Flemish masters. Among the former, those especially worthy of notice are the pictures of Raphael ('The Sistine Madonna'); of Correggio ('La Notte,' and the 'Madonna of St Sebastian'); of Titian ('The Tribute-money,' and 'The Venus'); of Andrea del Sarto ('Abraham's Sacrifice'); of Francia; of Paul Veronese; of Giulio Romano ('The Virgin with the Pitcher'); of Leonardo da Vinci ('Francesco Sforza'); of Garofalo, Bellino, Pietro Perugino, Annibale Caracci, Guido Reni, Carlo Dolci, Cignani, &c. Of the Flemish school, the collection boasts 41 pictures by Rubens, 21 by Van Dyck, many by Rembrandt, admirable specimens of Snyder's, Johann Breughel, Ruysdael, Wouvermann, Gerard Dow, Teniers, &c. Of works of the German school, the gem of the collection is Hans Holbein's Madonna. Of the French school, several pictures by Nicolas Poussin, and some admirable landscapes by Claude Lorraine, are the most remarkable. 7. The Cabinet of Engravings in the Zwinger is arranged in twelve classes, marking distinct periods in the history of art. 8. The collection of Antiques in the Japan Palace, including several admirable sculptures. 9. The 'Green Vault' in the Royal Palace, a valuable collection of precious stones, pearls, and articles wrought in gold, silver, and ivory. 10. The collection of Porcelain in the Japan Palace.

D. is known in history as far back as the year 1206. It is officially mentioned as a town in 1216. Henry the Illustrious selected it for his capital in 1270. From the close of the 15th c., its prosperity gradually increased. Several successive sovereigns contributed to its embellishment, particularly Augustus I. and Augustus II. It suffered severely, however, during the Seven Years' War; and again in 1813, when Napoleon selected it as the central point of his operations. During the revolution of 1849, also, immense damage was inflicted upon the town, but it is again rapidly improving.

**DRESDEN, BATTLE OF.** In August 1813, when the war between Napoleon and the allies, after a short truce, broke out afresh, the armies of the latter gathered from all sides towards Dresden, which they regarded as the key of the French position. It was held by St Cyr with a force of about 30,000 men, the main body of the French under Napoleon being in Silesia, where the emperor expected the contest was to be waged. On the 23d, the grand army of the allies appeared before Dresden. Previous to this, however, couriers had been despatched to Napoleon urging him to return. The town would in all probability have been quickly stormed, had not Schwarzenberg and the Austrians insisted on waiting the arrival of the left wing under Klenau. This delay saved the French, for at half-past nine, on the morning of the 26th, Napoleon with his Guards entered the town. All day the French troops poured into the town under a frightful fire of balls and bombs. At four o'clock in the afternoon, Schwarzenberg, the commander-in-chief of the allies, gave orders for the attack. A hundred guns vomited forth their deadly contents on the batteries and buildings of the beautiful city, while six deep and massive columns advanced in the finest order against the redoubts. At various points, the assault was irresistible, but the opportune arrival of the 'Young Guard' enabled Napoleon to baffle a sally, which was as unexpected as it was successful. The allies fell back everywhere; but not dispirited, renewed the fight next day. Towards noon, Moreau was mortally wounded by a cannon-ball at

Alexander's side on the height of Räcknitz, and Napoleon obtained a decided advantage over the left wing of the allied army, which Murat, by a skilful manœuvre, contrived to outflank, taking 10,000 prisoners, among whom was General Metsko. Several other successes in other parts of the field determined the allied armies, especially after hearing that Vandamme was advancing towards Pirne, to retreat, which they did during the night of the 27th August. Dresden, however, was not yet delivered from the miseries of war. When Napoleon finally quitted the city on the 7th October, nearly 30,000 men still remained behind. As all access was cut off by the Russians, the city suffered severely from famine. A capitulation was at length brought about (11th November 1813) between St Cyr and Klenau, according to which the garrison were to withdraw unmolested from the 12th to the 16th November, on condition that they laid down their arms. The capitulation was nevertheless rejected by Prince Schwarzenberg, the garrison declared prisoners of war, and treated as such. The battle of Dresden, as Alison observes, was the *last* pitched battle, on a scale commensurate with his former victories, that Napoleon ever gained.

**DRESS**, the collective name for the artificial coverings worn in greater or less quantity by all but the most savage of the human race, and always combining the two objects of warmth and ornament. It seems, indeed, from what we read of savage nations, that it is rather in the desire for ornament that the wearing of dress begins, than with a view to protection from cold (see **FASHION**, under which head some notice will be given of the more singular caprices to which the forms of dress have been subjected; see also **CRINOLINE**, **BLOOMERISM**). The earliest coverings would consist of such articles as the skins of animals, and the leaves and inner bark of plants, which, as civilisation advances, are mostly supplanted by various textures of wool, flax, silk, and other vegetable and animal substances. Some account of these textures is given under the appropriate heads, and the regulation of dress with a view to health is treated under **HEALTH**. As will be shewn more fully under **FASHION**, the tendency in modes of dress—notwithstanding occasional aberrations—is towards simplicity and appropriateness.

**DRESSINGS**, in Architecture, is a term loosely used to signify mouldings and all the simpler kinds of sculptured decorations.

**DREUX**, an ancient town of France, in the department of Eure-et-Loir, is situated on the river Blaise, 22 miles north-north-west of Chartres, and 45 miles west of Paris. It is tolerably well built, and lies at the foot of a hill crowned with the dilapidated ruins of an ancient castle, formerly the possession of the Comtes de Dreux. From among the ruins rises a beautiful chapel, in the form of a Greek temple, surmounted by a cupola, erected by Louis Philippe. It contains the tombs of two of the children of Louis Philippe, and of others of his relations. The town-hall and the parish church, both handsome specimens of Gothic, are the only other buildings worthy of note. D. has extensive manufactures of coarse cloth, serge, &c., with a trade in sheep and cattle, also various tan-yards, iron-foundries, and dye-houses. Pop. 5342. In 1562, one of the bloodiest battles recorded in the religious wars of France took place at D., in which the Catholics, under the Constable Montmorency, defeated the Huguenots, and took their leader the Prince of Condé prisoner.

**DRIFFIELD**, GREAT, the chief town in the Wolds, in East Riding, Yorkshire, at the south base

of these hills, near one of the sources of the Hull, 28 miles east-by-north of York, and 20 miles north-north-west of Hull. It lies in a fertile district, and consists chiefly of one long and broad street. It has a chemical work, flour, and bone-mills, and a considerable corn and cattle trade. Pop. (1861) 4000. Near D. many ancient tumuli have yielded human and horse skeletons, accoutrements, flint spear-heads, urns, and a variety of ornaments.

**DRIFT**, in Navigation, is a technical name for the deviation which a ship's course receives by the action of a contrary wind.

**DRIFT**, a name given to the boulder-clay, a deposit of the Pleistocene epoch. More fully, it is called the Northern Drift, Glacial Drift, or Diluvial Drift, in allusion to its supposed origin. For an account of the formation, see **BOULDER-CLAY**.

**DRIFT-WOOD** is wood carried by tides and currents to a distance from its native locality. Specimens thus transported have been observed in the marine strata of the Chalk, London Clay, and other formations.

**SAND-DRIFT** is sand driven and accumulated by the wind. Deposits thus formed are occasionally found among the stratified rocks, but compared with other strata they are few, though, from their anomalous character, an acquaintance with their phenomena is of importance to the geologist. Moving sands are at the present day, in many places, altering the surface of the land. In the interior of great dry continents, as Africa, India, and Australia, extensive districts are covered with moving sands. The continuous blowing of a steady wind in one direction often covers a rich tract with this arid material. But the influence of the wind on loose sand is most evident along low sandy coasts, where hills, called 'dunes,' are formed entirely of it; they sometimes attain a considerable height, as much, for instance, as 200 or 300 feet. Dunes are advancing on the French coasts of the Bay of Biscay at the rate of about 60 feet per annum, covering houses and farms in their progress. Similar accumulations are forming on the coasts of Norm, Cornwall,

Section of Culbin's Sand-hill, in Nairnshire.

Wexford, and other parts of the British Isles. The Culbin Sands, in Nairnshire, cover a large district which at a period not very distant was rich arable land. The prevailing wind is from the west, hence the hills are slowly moving in an easterly direction, at the rate of a mile in somewhat less than a hundred years. A singular stratification exists in these hills. The prevailing west wind lifts, or rather rolls the particles of sand up the gentle incline of the western aspect of the hill, until they reach the summit, where they fall, forming a steep declivity to the east, equal to the angle of repose for sand. A shower consolidates the surface of the new bed, or a land-breeze carrying fine dust separates it by a very thin layer of finer material from the one that follows, and thus, as the hill moves eastward, a regular series of strata is formed at a very high angle, as is shewn by the diagram. The progress of the hill is represented by the dotted outline. Little can be done to arrest the progress of these devastating sand-drifts. It has been recommended to plant *Carex arenaria* and similar sand-loving plants, which have long creeping roots: they certainly check to a considerable extent the influence of the wind.

## DRILL—DRINKING USAGES.

**DRILL** (*Cynocephalus leucophaeus*), a species of Baboon (q. v.), a native of Guinea, similar to the mandrill, but rather smaller and less ferocious.

**DRILL** is a general name for the exercises through which soldiers and sailors are passed, to qualify them for their duties. It is subject to numerous varieties, according to the number and organisation of the men drilled at one time, and the kind of weapon to which the exercises relate. The infantry, the cavalry, and the artillery all have different kinds of drill. The militia and the volunteers differ from the regulars, if not in the kind of drill, at least in the circumstances under which it is carried on; the squad-drill, company-drill, and battalion-drill, vary both in the numbers concerned and in the routine of exercises. And so likewise in the navy, the drilling of seamen varies in kind, according to the duties likely to be required.

It is generally considered that four months' drill is required to fit an infantry recruit for service. The progress depends greatly on the intelligence of the men. It is on this ground that the Rifle Volunteers, enrolled in such large numbers in 1860, have been so advantageously placed; composed almost entirely of young men, whose intelligence has been developed by a moderately good education, the corps have advanced to a degree of proficiency which has attracted the marked attention of military officers.

Manuals of Drill have been prepared for all the various branches of the two services. Drill-grounds, as at Aldershot, are now sometimes made with roofs for shelter.

**DRILL**, a fine linen fabric of a satiny finish, used for summer dresses for gentlemen. Drills are worked with five shafts, except fancy patterns, which are wrought with eight shafts.

**DRILLING, DRILL**. Drilling is the name applied to the mode of sowing in regular rows, as distinguished from broadcast sowing, and the drill is the name of the implement employed in this process; the term *drill* is also frequently applied to a row of drilled crop, as a drill of potatoes, corn, or turnips. In all countries in which maize and Indian corn are grown, the principle of drilling has been long known and acted upon. In gardening it has been practised everywhere from time immemorial; but its extension to field-culture is comparatively of recent date. Jethro Tull invented a drilling-machine in the early part of last century, and did much to shew its merits in the culture of grain and root crops. Since his time, the use of this implement, in the case of both white and green crops, has in many districts become general. The crops which are now most generally drilled are clover, flax, cereals, beans, peas, potatoes, turnips, beet-root, cole-seed, and carrots. Of these, clover and flax are sown in drills at about 3 or 4 inches apart; cereals from 6 to 10 inches; and beans, potatoes, and turnips at from 25 to 28 inches apart; the general rule, however, with most green crops, being that the space between the rows should admit of the passage of a light plough or hoe, drawn by a horse, without danger to the plants. A great variety of drills are now in use. At present, that formed on the principle of lifting the grain in small cups, which empty themselves into tin tubes, by which the grain is conducted to the coulters, is chiefly used in the level parts of England. Garrett of Saxmundham, Suffolk, a cut of whose corn-drill is given, and Hornsby of Grantham, are favourite makers of corn and turnip drills. The usual English drills, however, are too heavy for the uneven soil of a great part of Scotland, and consequently a lighter, but otherwise less perfect machine, of a similar nature, and more suitable for hilly land, is made in

the Lothians. One powerful recommendation of drilling is, that by means of it a considerable saving of seed is effected in the sowing of white crops; but the great advantage is, that in the case of green crops, it enables the farmer more readily to clean

Garrett's Corn-drill.

the land, both by the hand and by the horse-hoe. Drilling is of more importance in dry than in moist climates, as in the former, weeds are more apt to spring up, and injure the crops. To keep the soil stirred and pulverised, which can only be properly done where the crops have been drilled, favours the retention and absorption of the moisture. In sowing by drill, the seed being more evenly deposited beneath the surface, springs up with greater regularity, the straw is stiffer, and the ground is more easily cleaned until the crops cover it fully.

In England, turnips are frequently drilled by a machine on the flat; while in Scotland, they are always sown on ridges or drills formed by the double-moulded plough, which, in consequence of its being used for forming wide ridges on which the turnips are sown, is called also the drill-plough. Some turnip sowing-machines or drills are so constructed as to be able to deposit manure and seed at the same time.

**DRILLS** are tools used for boring or drilling holes in metal, bone, ivory, hard woods, &c. They are usually made of a square steel bar, flattened out at the cutting end; this part is brought to an angular point like a spear-head, and the cutting edges forming the angle are bevelled in opposite directions. Those which have a projecting pin in the centre, and chisel-shaped cutting edges on each side of the pin, are called 'centre bits.' There are various contrivances by which the drill is made to revolve. For drilling iron, steel, and large brass work, the lathe is commonly used, the drill being fitted into a square-hole chuck, and the work pressed against it while revolving by the screw and centre of the puppet. The *brace* or *drill-stock* is commonly used by carpenters for centre bits, and occasionally for metal work. This is a curved handle, which is made to revolve by the hand, while one end is pressed against the chest. Small drills for metal work are mounted with a *ferule* or pulley, or are fitted into a stock with such a pulley on it; a piece of cane or spring-steel is mounted with a string like an archer's bow, but loose enough to wind round the ferule. By drawing the bow lengthwise, the drill is made to revolve, and is at the same time pressed against the work by means of a *breast-plate*, which is held against the chest of the workman; this breast-plate has indentations upon it, which serve as sockets, into which the end of the drill-stock or drill works.

**DRIMYS**. See WINTER'S BARK.

**DRINKING USAGES**. Some of these are of great antiquity, and all are interesting in connection with the history of manners. Besides sacrifices of animals and articles of food, the Hebrews made drink-offerings a solemn religious service. To mark the spot where he communed with God, Jacob set up a pillar of stone, and 'poured a drink-offering

thereon.—Gen. xxxv. 14. We learn that such sacrifices were not made alone to the true God; for women are said to have poured out ‘drink-offerings unto other gods.’—Jer. vii. 18. Such a statement is amply verified by pagan writers. Among the Greeks and Romans, the pouring out of a libation to the gods was a common religious observance. A libation was made on the occasion of solemn prayers, and also before meals. These libations were usually of undiluted wine, but they were also sometimes of milk diluted with water, or water flavoured with honey. There are many references to these libations by Sophocles, Æschylus, Pliny, and other writers. The libation at meals consisted of pouring a small quantity of liquor from the cup on the ground—so much waste being a kind of propitiation, or an act somewhat equivalent to the asking of a blessing. See SACRIFICE.

From these and similar usages in remote times sprung the ceremonial observance of drinking healths, or the uttering of a pious, heroic, or friendly sentiment before quaffing liquor on festive occasions. It has been stated that the practice of pledging, or saying ‘I pledge you,’ originated in England in the 10th c., it being then necessary for one to watch over the safety of his companion when the cup was at his lips. But the custom of drinking healths, as just mentioned, is of far higher antiquity, and was derived immediately from the boisterous convivialities of a Scandinavian and Teutonic ancestry (see VALHALLA), if not with equal likelihood from the usages of the early Britons, who were of Celtic origin. A story is told of a feast given by Hengist (5th c.) at his stronghold of Thong-caster, in Lincolnshire, to the British king Vortigern, and of the bewitchment of the royal guest by the charms of Rowena, the young and beautiful daughter of his entertainer. Rowena’s address, as she gracefully knelt and presented the wine-cup to the king, *Liever kyning, wass heal*, or, ‘Dear king, your health,’ is often quoted as the origin of our still existing expressions, wassail and wassail-cup; though wassail means pledging or health-drinking independently of the saying of Rowena, and certainly was not then uttered for the first time. Wassail is derived from the old Anglo-Saxon *Was hal*, ‘Be in health;’ and *Was heal* and *Drinc heal* were the usual ancient phrases in quaffing among the English, and synonymous with ‘Here is to you,’ and ‘I’ll pledge you,’ of later times. The explanation of wassail by an old writer, Robert de Brunne, may be appropriately quoted:

‘This is ther custom and her gest  
When thei are at the ale or fest,  
Ilk man that levis wware him think  
Salle say *Wosselle*, and to him drink.  
He that biddis salle say, *Wassail*,  
The tother salle say again, *Drinkaille*.  
That says *Wosselle* drinkis of the cop,  
Kissand his felaw he gives it up.’

The learned Selden, in a note on the *Polybion*, says: ‘I see a custom in some parts among us; I mean the yearly Was-haile in the country on the vigil of the new year, which I conjecture was a usual ceremony among the Saxons before Hengist, as a note of health-wishing (and so perhaps you might make it Wish-heil), which was express among other nations in that form of drinking to the health of their mistresses and friends. “Bene vos, bene vos, bene te, bene me, bene nostram etiam Stephanium,” in Plautus, and infinite other testimonies of that nature in him, Martial, Ovid, Horace, and such more agreeing nearly with the fashion now used; we calling it a health, as they did also in direct terms.’ For further particulars concerning wassail

and wassail-bowl, we may refer to Brand’s *Popular Antiquities*, edited by Ellis. It is enough here to quote from that authority the following passages. ‘Milner on an ancient cup (*Archæologia*, xi. 420), informs us that “the introduction of Christianity amongst our ancestors did not at all contribute to the abolition of the practice of wasselling. On the contrary, it began to assume a kind of religious aspect, and the wassel-bowl itself, which in the great monasteries was placed on the abbot’s table, at the upper end of the refectory or eating-hall, to be circulated amongst the community at discretion, received the honourable appellation of ‘*Poculum charitatis*.’ This, in our universities, is called the grace-cup.” The poculum charitatis is well translated by the toast-master of most of the public companies of the city of London by the words, a “loving cup.” After dinner, the master and wardens “drink to their visitors, in a loving cup, and bid them all heartily welcome.” The cup [a silver flagon containing warm spiced wine] then circulates round the table, the person who pledges standing up whilst his neighbour drinks to him.’

While the drinking of healths is thus of old date, the application of the word ‘toast’ is modern, having had its origin in the practice of putting a piece of toasted bread in a jug of ale, hence called ‘a toast and tankard.’ The custom of so using the word is said to have had its rise at Bath, in the reign of Charles II. It happened that on a public day a celebrated beauty of those times was in the cross [or large public] bath, and one of the crowd of her admirers took a glass of the water in which the fair one stood, and drank her health to the company. There was in the place a gay fellow half-tipsy, who offered to jump in, and declared, though he liked not the liquor, he would have the toast. He was opposed in his resolution; yet this whim gave foundation to the present honour which is done to the lady we mention in our liquors, who has ever since been called a toast.—*Taiter*. Begun in the form of toasting beauties at private parties, toasts were in time given on all sorts of subjects at public festivities, accompanied with rounds of cheers and hurrahs, these noisy demonstrations being now called ‘the honours.’ The fatigue of announcing these exciting sentiments is so great, that in all well-ordered large assemblies a toast-master is employed. Standing behind the chairman, this official, besides proclaiming the toasts, acts as a fagman to regulate the clapping of hands and the ‘hip, hip, hurrahs’ of the company. ‘Toasts, certainly, in this guise look more like a medium for taking an indefinite quantity of wine, than that spontaneous effusion of the heart in honour of some cherished individual, which they originally were. On certain occasions, these signals are hushed, and the convivial glass is taken “in solemn silence.” The effect is certainly rather startling. A convivial glass to the memory of one departed has surely something in it of practical absurdity.’—Mrs Stone’s *Chronicles of Fashion* (1845). The absurdity of the whole toasting system has incurred the reprehension of temperance societies, without any perceptible abatement; but the old custom of drinking healths at private parties is now given up in good society, along with the excesses which were formerly practised.

Space is not afforded in the present work to do more than glance at the diversity of drinking usages in connection with domestic events and social intercourse. There were, as is well known, at one time drinkings on the occasion of births, baptisms, marriages, and even deaths; these last, which included the gloomy festivities of the *Lylk-wake*, or wake over the corpse of the deceased, being

a relic of a very ancient custom, as was that, at least in Scotland, of drinking the *dredgy* (dirge) after the funeral solemnities were completed. In whatever manner these, as well as many other drinking usages, originated, it cannot be doubted that they were long maintained from the force of custom, along with that demand for artificial stimulus provoked by the naturally phlegmatic character of a northern people. For the long nights of a cheerless climate, there seems to have been sought the solacement of those intoxicating agents, in which it would have been fatal to indulge—where they were not needed—under the sunny skies of the south. We believe this is really the philosophy of the subject, if there be any philosophy in it; and it cannot fail to be observed, that just in proportion to an increase in the number of comfortable homes, the cultivation of mental resources, and the spread of a taste for harmless recreations, the more odious of the old convivialities disappear. Latterly, many amusing traditions respecting the drinking habits of a past age in Scotland, where they longest flourished without alteration, have been given in the *Memoirs of Lord Cockburn*, the *Autobiography of the Rev. Dr Alexander Carlyle*, and the *Reminiscences of Changes in Social Life in Scotland*, by the Very Rev. Dean Ramsay (1860).

As regards miscellaneous drinking observances at one time common, we can refer but to a few of the more prominent. Perhaps the most offensive of all was that customary among tradesmen of imposing fines to be consumed in liquor. Apprentices, on being introduced to a workshop, paid so much entry-money to be spent in drink, and similar exactions were made from journeymen on entering a new employment. This was called paying their *footing*. When Benjamin Franklin, on his getting employment in a printing-office in London, refused to comply with this mischievous custom, he experienced, as he tells us, a variety of petty annoyances. Among shipwrights, the penalty of non-payment was flogging with a hand-saw from time to time, and other maltreatment. We refer to Dunlop's *Drinking Usages of Great Britain* (1839) for many curious details of this kind. Happily, the abolition of these usages has kept pace with the increasing intelligence of the working-classes, and of such outrages little is now heard. Prisoners, on being lodged in jail, as related in the novels of Smollett and others, were obliged to pay *garnish* for drink to the brotherhood of which they had become members. This pitiless exaction is now totally gone, through the efficacy of modern prison-discipline.

The giving of *rails* (Lat. *vale*, farewell) to servants on quitting a gentleman's house, which became so intolerable in the 18th c., as at length to be given up by universal consent, meant, doubtless, a gift to be spent in drink to the health of the donor, and was analogous to the custom of giving a *trink-geld* in Germany, and a *pour boire* in France, to servants, drivers of carriages, and others. There were, at one time, numerous drinking usages connected with departures. We need only notice the *bonaillie* (Fr. *bon allez*), or, as it is sometimes called, a *joy* (Fr. *voie*), a festive drinking at the away-going of servants or of persons in a still higher degree, once common in the Lowlands of Scotland; also the *stirrup-cup*, or, as it is called in the Highlands, *doch an dorris*, or drink on getting on horseback, and being ready to set off.—For the moral and physical evils connected with drinking usages, and the means taken to redress them, we refer to the article TEMPERANCE. W. C.

DRIP, the projecting edge of a moulding, so channelled as that the rain will drip from it instead of trickling down the wall.—*Parker*.

DRIPSTONE (Fr. *larmier*). The dripstone is a projecting moulding or tablet placed over the head of a Gothic doorway or window, for the purpose of throwing off the water, whence it is also known as a water-table or weather-moulding. Though such was, no doubt, its primitive use, the dripstone latterly became a mere ornamental appendage, which served to enrich and define the outline of the arch. It does not generally extend lower than the springing of the arch, though this rule is by no means without exceptions. When the tracery extends to a lower level, the external dripstone usually accompanies it, and Parker mentions that, at the north doorway of Otham Church, Kent, it descends the whole length of the jamb. The dripstone is not so constant a feature in continental as in English Gothic.

DRIVER, on shipboard, is the name of a large sail, occasionally set upon the mizzen yard or gaff. A

a, the Driver.

boom, called the *driver-boom*, extends the foot of the sail a good way over the stern, like a cutter's mainsail.

DRIVING, FURIOUS. This, which was always an offence at common law, was made a statutory offence by 1 Geo. IV. c. 4, which provides that if any person shall be maimed, or otherwise injured, by reason of the wanton and furious driving or racing, or by the wilful misconduct of any coachman, or other person having the charge of any stage-coach or other public carriage, the offender shall be guilty of a misdemeanour, and punishable by fine and imprisonment. Special penalties are imposed by the general and local Road Acts; and 2 and 3 Will. IV. c. 120, by which the laws relating to stage carriages and horses let for hire were consolidated, enacts that any driver, conductor, or guard, guilty of furious driving, shall forfeit £5 (s. 48). The owners are liable for the penalty where the driver or guard is not known, or cannot be found. As to cabs, see HACKNEY CARRIAGES. Within the metropolis they are regulated by 1 and 2 Will. IV. c. 22, 1 and 2 Vict. c. 79, and 16 and 17 Vict. c. 33.

DROGHEDA (Ir. 'bridge of the ford'), a parliamentary and municipal burgh and seaport, in a county by itself of nine square miles, on the borders of Meath and Louth, on both sides of the Boyne, 4 miles from its mouth, and 31 miles north of Dublin. It is well built. The chief part of the town is on the north bank of the river, and on higher ground. The Dublin and Belfast Railway crosses the Boyne here by a viaduct 95 feet high. There are linen and cotton manufactures, tanning and brewing works, and an iron foundry. It has a considerable trade, chiefly with Liverpool, 140 miles east-south-east. Its chief exports are corn, meal,

flour, cattle, provisions, linen, hides, and butter. Great quantities of ale are sent to the colonies. Vessels of 500 tons reach the quay, and barges of 50 tons ply 19 miles up the Boyne to Navan. Pop. (1861) 18,094. D. sends one member to parliament. The parts of D. on the opposite sides of the river formed two opposing corporations till 1412, when a sermon by a monk induced them to get a charter of union from Henry I. From the 14th to the 17th c., D. was the chief military station in Ulster. Many Irish parliaments were held here in the 15th c., and D. had then the right to coin money. In 1649, Cromwell stormed D., and put 2000 of the garrison to the sword. Poyning's laws were enacted here. D. surrendered to William III. the day after the battle of the Boyne, which was fought in 1690 at Oldbridge, four miles west of Drogheda. Some buttresses, and two of the four gates of D., still remain. There are here the ruins of many friaries and monastic institutions. In 1860, 1362 vessels, of 226,192 tons, entered and cleared the port.

**DROGUE AMÈRE** (Fr. bitter drug), a celebrated stomachic bitter; of which the basis is creart root, and the other ingredients are mastic, frankincense, myrrh, and aloes, all steeped for about a month in brandy, which is then strained and bottled.

**DRO'HOBICZ**, a town of Austria in the province of Galicia, is situated on the Tyszmanika, a tributary of the Dniester, in lat. 49° 25' N., and long. 23° 30' E. The town is in general ill built, but it contains several interesting edifices, including a Basilian monastery, a castle, a high school, and two very handsome churches. D. has extensive salt-works, which produce about 3700 tons of salt yearly. There are also in the vicinity iron-mines and pitch-wells. D. has likewise a good trade in wine, linen, cotton, leather, and grocery. It has, besides, corn and cattle markets. Pop. about 10,000, seven-eighths of whom are Jews, who carry on most of the commerce of this town.

**DROIT D'AUBAINE** (Lat. *alibi nati*). By the old custom of France, the king was entitled, on the death of a foreigner who had taken up his fixed residence there, to claim his movable estate, notwithstanding any testamentary settlement which he might have left. But when a foreigner went to France as a traveller, merchant, or foreign minister, without any intention of fixing his residence there, the droit d'aubaine was excluded. The Swiss, Savoyards, Scotch, and Portuguese were exempted. This antiquated piece of injustice was abolished in 1819.

**DROITS OF THE ADMIRALTY.** See ADMIRALTY DROITS.

**DROI'TWICH**, a parliamentary and municipal borough in Worcestershire, containing four parishes and three churches, seven miles north-north-east of Worcester, in the narrow valley of the small river Salwarp, on the Bristol and Birmingham and West Midland Railway, and on a canal connected with the Severn, which admits vessels of 60 tons. It has direct communication, also, by means of other canals, with Birmingham and London and the intermediate district. Its chief trade is salt, for which it has been famous from remote times, and which is esteemed the best in Europe. In the middle of the town, rising from a depth of 200 feet, through beds of new red-sandstone and gypsum, are the celebrated wyes, or brine-springs, yielding 100,000 tons of salt a year, nearly the half of which is exported to foreign countries. Pop. (1861) of the municipal borough, 3123; of the parliamentary, 6540. D. sends one member to parliament. It was the Roman Salinæ. The remains

of a Roman villa were found here, with tessellated pavements, &c. (1871, pop. parl. borough, 9510.)

**DROME**, a department of France, on the east bank of the Rhone, to the south of the department of Isere. Area, 2496 square miles. Pop. 324,760. In the west of the department, running from north to south along the Rhone, stretches a sandy plain of from five to eight miles in breadth, but toward the east the surface is hilly; a spur of the Alps traversing the eastern boundary, and sending offshoots of about 3500 feet in average height westward across almost the entire area of Drome. These heights, whose sides are covered with forests of pine, oak, and beech, afford excellent pasturage in summer and autumn. The general direction of the rivers of D. is westward, toward the Rhone, and the most notable of them are the Drome, from which the department takes its name, and the Isere. Vines and mulberry, chestnut, walnut, and olive trees are extensively grown. About 8,600,000 gallons of wine are produced annually. Many of the vineyards are famous, but perhaps the most celebrated is that of L'Hermitage, near Tain, on the banks of the Rhone, which yields red and white wines hardly surpassed by any in the world. D. has several iron-mines, also copper, lead, and to some extent coal. The manufactures consist chiefly of woollen cloth, silk, hosiery, serge, and cotton yarn. The department is traversed by the Lyon and Avignon Railway. It is divided into the four arrondissements of Valence, Montelimart, Die, Nyons, with the town of Valence for capital.

**DROMEDARY**, a name sometimes given, probably at first through mistake, to the Arabian or one-humped camel (*Camelus dromedarius*), but properly belonging to a variety of that species, distinguished by slenderness of limbs and symmetry of

Dromedary.

form, and by extraordinary fleetness. It has been well described as 'bearing much the same relation to the ordinary camel as a race-horse or hunter does to a cart-horse.' The word dromedary is derived from the obsolete Greek *dromo*, to run. The pace of the D. is a trot, which it can maintain without intermission for a prodigious length of time; often at the rate of nine miles an hour for many hours together; whilst a journey of upwards of 600 miles is performed at a somewhat slower rate in five days. Even its more rapid pace can be maintained for twenty-four hours at a stretch, without sign of weariness and without stopping to bait; and if then it is allowed a little refreshment, of a ball of paste made of barley and powdered dates and a little water or camel's milk, it will resume its journey, and go on with undiminished speed for twenty-four hours more. The jolting to the rider is terrible. The gallop is a pace unsuitable to the D., and at

which it very soon fails. Dromedaries are sometimes trained to run races. White dromedaries are particularly prized in some parts of the East. See CAMEL.

**DROMORE** (*Druim Mor*, Great Ridge), an Episcopal city in the north-west of the county of Down, on the Lagan, 14 miles south-west of Belfast. It has linen manufactures. Pop. (1861) 2526. In the peat-bogs here were found the remains of an elk, the space between the extremities of whose horns measured 10 feet 3 inches. North of D. is a mound or rath, 60 feet high, with three concentric intrenchments, and great outworks towards the Lagan. The see of D. was founded by St Colman in the 6th c., but is now united with those of Down and Connor. Jeremy Taylor, when bishop here, built the present church.

**DRONE.** See BEE.

**DRO'NTHEIM.** See THRONDIJEM.

**DROORAJAPATA'M**, or **DOOGOORAUZE-PATA'M**, a town on the Coromandel coast of Hindustan, possesses remarkable facilities for navigation, both maritime and inland. It stands on an inlet, which connects Blackwood Harbour with Pulicat Lake, the former being the only safe haven on the west side of the Bay of Bengal, and the latter being artificially continued as far as Madras. The place is 60 miles to the north of Madras, and 34 to the south of Nellore, in lat. 13° 59' N., and long. 80° 13' E.

**DROPSY** (Gr. *hydrops*, from *hydōr*, water), a class of diseases always of serious import, though not often, perhaps, directly fatal. D. is rather a symptom than a disease; it consists of the effusion of watery fluid from the blood into the skin and subjacent textures, or into the cavities of the body. When the effusion is chiefly in the superficial parts, the dropsy is called *Anasarca* (*ana*, upon; *sarr*, the flesh); when it is in the abdoeum, it is termed *Ascites*; when in the chest, *Hydrothorax*. Dropsy most commonly depends on disease of the heart (q. v.) or kidneys (q. v.); in cases of ascites, the liver and spleen are often at fault. The treatment of dropsy is chiefly by diuretics (q. v.), and other evacuant remedies, which remove the fluid from the textures by unloading the blood of its excess of serum. It is, however, a matter of some difficulty to find the proper remedy in each individual case. In all cases of dropsy, the internal organs should be, if possible, submitted to a strict medical examination, and the treatment regulated accordingly.

**DROP'WORT.** See SPIRÆA and WATER DROP'WORT.

**DROSERA'CEÆ**, a natural order of exogenous plants, consisting entirely of herbaceous plants, which generally inhabit marshy places, and are often covered with glands. The leaves are frequently all radical, and they and the flower-stalks are rolled up in bud like the fronds of ferns. There are five sepals, five petals, five, ten, fifteen, or twenty stamens; the fruit a one-celled capsule, with numerous seeds. About 100 species are known, distributed over most parts of the world, many of them plants of very delicate appearance; and many of them, as the species of *Drosera* or SUNDEW, natives of Britain, are remarkable for their glandular hairs, which secrete a viscid fluid, and by means of it often fatally detain flies which alight on them. *Rosidula dentata* is placed in houses in South Africa on this account. Venus's Fly Trap belongs to this order. See DIONÆA. Acid and stimulant properties prevail in the Droseraceæ.

**DROSTE-HÜLSHOFF**, ANNETTE ELIZABETH, a distinguished lyric poetess of Germany, born 12th January 1798, on the estate of Hülshoff, near Münster. Of a delicate constitution, and living in complete seclusion from the world, she nevertheless received an excellent scientific education. In the year 1825 she was first introduced into a wider circle of distinguished men and women at Cologne and Bonn, but in a short time retired again to her maternal estate of Rischhaus, near Münster, where she lived almost exclusively for science, nature, and poetry. She died at a place near Lake Constance, 24th May 1848. While occupying a distinguished place among the literary women of the time, she retained all the characteristic timidity of her sex, avoiding those eccentricities into which many women fall who think they have a mission to regenerate society. Her *Gedichte* (Poems) appeared at Stuttgart in 1844, and of her posthumous works *Das geistliche Jahr nebst einem Anhang religiöser Gedichte* at Stuttgart in 1852. The poems are not only perfect as regards form, but unite a womanly gentleness and poetical creative power in a degree seldom seen in the writings of women.

**DROUET**, JEAN BAPTISTE, COMTE D'ERLON, French marshal, was born 29th July 1765, at Rheims, entered a regiment of volunteers in 1792, and took part during the years 1793—1796 in the campaigns of the Moselle, Meuse, and Sambre. His important services quickly obtained him promotion. His conduct in the peninsular war was highly distinguished, and elicited the warmest eulogiums from Massena. After the fall of Napoleon, the Bourbons tried to secure his services, and gave him the command of the 16th division, but he was shortly after arrested on the charge of conspiring against the royal family. Managing to escape, he remained in concealment in Lille until the return of Napoleon from Elba, when, putting himself at the head of the troops, he seized the citadel and held it for the emperor, who made him a peer of France. At the battle of Waterloo he commanded the first *corps d'armée*. After the capitulation of Paris, he fled to Bavaria, where he resided until the July revolution, when he returned to France, and received in 1832 the command of the army of Vendée. During 1834—1835, he held the important office of governor-general of Algeria, and in 1843 was elevated to the rank of marshal. D. died 25th January 1844.

**DROUYN DE LHUYS**, EDOUARD, an eminent French diplomatist and politician, was born at Paris, November 19, 1805, and studied at the college of Louis-le-Grand and the Ecole de Droit. He was at first attached to the embassy at Madrid, whither he proceeded in 1830. In 1840 he was placed at the head of the commercial department under the Minister of Foreign Affairs, and shortly after was elected *député* for Melun; but taking a part hostile to the government, of which he was a subordinate member, he was deprived of his situation by M. Guizot. This gave him fuller scope for the advocacy of his political opinions. He now became an active member of the *Reforme* party, and after the famous banquet of the 12th arrondissement had been interdicted, he signed, along with the other chiefs of the opposition, the accusation drawn up against M. Guizot and his colleagues. Elected representative of the people to the Constituent and Legislative Assemblies, by the department of Seine-et-Marne, he was made first a member and then president of the Committee of Foreign Affairs. Here he acted generally with the moderate party. In the first cabinet formed by Louis Napoleon after his election to the presidency

(December 1848), he became Minister of Foreign Affairs, and directed the French policy in all the difficult European complications of the year. In 1849 he went to London for a short time as ambassador, and after the *coup d'état* became one of the vice-presidents of the Imperial Senate. He took part also in the Vienna conferences of 1855 relative to the Crimean war, but being reluctant to advance the war-policy of his master, he resigned his office, and subsequently withdrew from the senate altogether.

**DROWNING.** See ASPHYXIA.

**DROWNING**, as a mode of capital punishment, has only lately ceased in Europe, and is probably still in use in some other quarters of the world. Tacitus, writing about the end of the 1st c., tells us that the Germans hanged their greater criminals, but that meaner and more infamous offenders were plunged under hurdles into bogs and fens. By the law of the ancient Burgundians, a faithless wife was to be smothered in mud. The Anglo-Saxon codes ordered women convicted of theft to be drowned. The punishment was in such common use throughout the middle ages, that grants of capital jurisdiction ran '*cum fossa et furca*,' i. e., 'with pit and gallows.' The pit, ditch, or well, was for drowning women; but the punishment was occasionally inflicted on men. The doom of the parricide was to be put into a sack and cast into the sea. A canon of Prague, afterwards enrolled in the catalogue of saints, was drowned in 1383, for refusing to reveal the secrets of the confessional. In this instance, perhaps, drowning was allowed to the offender as a matter of favour. So in Scotland, in 1556, a man convicted of theft and sacrilege, was sentenced to be drowned, 'by the queen's special grace.' So lately as 1611, a man was drowned at Edinburgh for stealing a lamb. By that time, the punishment of drowning had become obsolete in England. It survived in Scotland until 1685. The last execution by drowning in Switzerland was in 1652, in Austria in 1776, in Iceland in 1777. It was abolished in Russia early in the 18th century. In Saxony, a woman convicted of child-murder, was sewn up in a sack, along with a cat, a dog, and a snake, and thus drowned, in 1734.

**DRUGGET**, a common felt or other coarse woollen fabric, chiefly used for covering carpets, or as a substitute for a carpet. At one time, also, it was largely used as an article of clothing by the humbler classes, and even yet the *drugget petticoat* is far from uncommon, although it is gradually giving place to cotton fabrics, which have the advantage of greater cleanliness, and of being less liable to retain infectious and contagious poisons.

**DRUGS**, a name applied to all material agents used in the treatment of disease, when in their crude or commercial forms. The medicines ordered by the physician consist of drugs prepared by the apothecary or chemist, and made up according to the prescription (q. v.). The business of the druggist is now to a considerable extent separated from that of the medical practitioner, with which it was formerly associated. See CHEMISTS AND DRUGGISTS, and APOTHECARIES.

**DRUIDISM.** This institution was, perhaps, common to all Celtic nations, but we have detailed accounts only of the form under which it existed in Gaul. Caesar gives the following description of the character and functions of the Druids: 'They attend to divine worship, perform public and private sacrifices, and expound matters of religion. A great number of youths are gathered round them for the sake of education, and they enjoy the highest honour in that nation; for nearly all public and

private quarrels come under their jurisdiction; and when any crime has been committed, when a murder has been perpetrated, when a controversy arises about a legacy, or about landmarks, they are the judges too. They fix rewards and punishments; and should any one, whether a private individual or a public man, disobey their decrees, then they exclude him from the sacrifices. This is with them the severest punishment. The persons who are thus laid under interdict are regarded as impious and wicked people; everybody recoils from them, and shuns their society and conversation, lest he should be injured by associating with them. They cannot obtain legal redress when they ask for it, nor are they admitted to any honourable office. All these Druids have one chief, who enjoys the highest authority amongst them. When he dies, he is succeeded by the member of the order who is most prominent amongst the others, if there be any such single individual; if, however, there are several men equally distinguished, the successor is elected by the Druids. Sometimes they even go to war about this supremacy. At a certain time of the year, the Druids assemble on the territory of the Carnutes, which is believed to be the centre of all Gaul, in a sacred place. To that spot are gathered from everywhere all persons that have quarrels, and they abide by their judgments and decrees. It is believed that this institution was invented in Britannia, and thence transplanted into Gaul. Even now-a-days, those who wish to become more intimately acquainted with the institution, generally go to Britannia for instruction's sake.

The Druids take no part in warfare; nor do they pay taxes like the rest of the people; they are exempt from military service, and from all public burdens. Attracted by such rewards, many come to be instructed by their own choice, while others are sent by their parents. They are reported to learn in the school a great number of verses, so that some remain there twenty years. They think it an unhallowed thing to commit their lore to writing, though in the other public and private affairs of life they frequently make use of the Greek alphabet. . . . Beyond all things, they are desirous to inspire a belief that men's souls do not perish, but transmigrate after death from one individual to another; and they hold that people are thereby most strongly urged to bravery, as the fear of death is thus destroyed. Besides, they hold a great many discourses about the stars and their motion, about the size of the world and of various countries, about the nature of things, about the power and might of the immortal gods; and they instruct the youths in these subjects.'

It is easy to comprehend that this powerful priesthood did all they could to uphold the national cause against the Roman conquerors, and urged the people to rebellion; so much so, that the Emperor Claudius found it necessary to interdict formally the practising of Druidical rites, which seem, however, to have continued down to the extinction of paganism. Besides being priests and teachers of religion (see the article CELTS), the Druids appear also to have been adepts in the magic arts and the mysterious powers of animals and plants. The oak-tree was especially sacred among the Druids. In oak-groves, they frequently performed their rites, and they even derived their name from this custom. See the article CELTS. They also had a special reverence for the mistletoe, when growing on an oak. According to Pliny, a Druid, clothed in white, mounted the tree, and with a knife of gold, cut the mistletoe, which was received by another, standing on the ground, in his white robe. The same author gives a curious account of the 'serpent's

egg,' worn as a distinguishing badge by the Druids. It was formed, he says, by the poisonous spittle of a great many serpents twined together. Gathered at moonlight, and afterwards worn in the bosom, it was a mighty talisman. All these particulars refer properly to the Druids of Gaul, but Cæsar's testimony leaves no doubt that the Druidism of Britain was essentially the same.

In all the countries anciently inhabited by Celts, there are found rude structures of stone, one of the most common forms of which is the so-called *cromlech* (see that article). The older archaeologists assumed that these were Druidical altars, but there is no proof that such was their destination or origin: similar structures are found in Scandinavia and many parts of Germany, and to assume in all these countries the presence of Celts, seems too hazardous. The same doubts prevail as to the larger monuments of this kind—the supposed Druidical temples of Amesbury, of Carnac in Brittany, and of Stonehenge (see that article).

DRUM, a Celtic word signifying a round knoll, or a bare round hill, enters into the composition of many names of places, especially in Ireland, as Drumecondra, Drumglass, Drumsheugh.

DRUM (Ger. *trommel*; Fr. *tambour*—a modification of *tamour*; *timbrèl* and *tambourine* are other forms of the word *tamour* or *tambour*), a hollow cylinder of wood or metal, having skin (parchment) stretched across one or both ends, upon which the drummer beats with an instrument of wood or metal called a *drumstick*. The drum is used as an instrument of music along with other instruments in bands, and particularly for military purposes. The military drum serves for giving various signals as well as for music. There are three kinds of drum—the *side drum*, the *big* or *base drum*, and the *kettle drum*. Since 1858, the British infantry are supplied with brass side drums, three pounds lighter than those formerly in use, and tuned with screws instead of straps and ropes. The cavalry drum is a copper or brass hemisphere, thus resembling a *kettle*, with a parchment lid. The big drum has both ends covered with parchment. The ancient Romans used small hand-drums—some resembling tambourines, others kettle-drums—in their religious dances; and the Parthians are said to have used them in war to give signals. They are believed to have been first brought into Western Europe by the Crusaders.

DRUM, a name given to a fashionable and crowded evening-party about the middle of the 18th c., at which card-playing appears to have been the chief attraction. The names Drum, Rout, and Hurricane, by which these gay assemblies were known, sufficiently indicate their noisy, promiscuous, and irrational character. Lady Mary Wortley Montagu, writing from Louvère to her daughter in 1753, hints that ladies gave these entertainments to make money at cards to support their extravagance; and adds: 'I find I should be as solitary in London as I am here, it being impossible to live in a *drum*, which, I think, so far from a cure of meanness, that it is, in my opinion, adding one more to the heap.' See *ROUT* and *SOIRÉE*.

DRUM, SACRED, an object of religious veneration and instrument of magical incantation among the Laplanders in former times. It was hollowed out of a piece of the trunk of a pine or birch, in which certain peculiarities were required, and was covered with skin on the upper side only, the wood being partly left on the under side to serve as a handle. Figures were painted in red on the skin; the drumstick was a reindeer's horn; and to the drum were appended a large copper ring and some

smaller rings. The drum was considered a necessary part of the furniture of every family. The motions of the rings, when the drum was beaten, which might be done only by the head of the family, were supposed to afford indications concerning the results of disease and other future events. The beating of the drum was accompanied with songs, and the person by whom it was beaten often fell into a trance, during which revelations were supposed to be made to him. The sacred drum seems to have been somehow connected with the worship of the sun.

DRUM-MAJOR, as a component member of a regiment, was not much known in the English army till the time of Charles I. There was in earlier times an officer in the royal household called the *drum-major general*, without whose licence no one except royal troops might use a drum; but this office fell into disuse. The drum-major, when regularly established, received orders from the major of the battalion concerning the necessary beats or signals, and communicated them to the drummers. The management of the big drum, and the teaching and control of the drummers generally, still devolve upon the drum-major. The 'beats' at present adopted by the British infantry were composed by Drum-major Potter of the Coldstream Guards.

DRUMMER is a component member of every British regiment. His position is slightly superior to that of the private soldier, but still he is reckoned as one of the rank and file. Besides his ordinary duties (see *BEAT OF DRUM*), the drummer performs the *drumming out*, when a soldier is discharged with ignominy. See *DISCHARGE*. To the drummers is also intrusted the repulsive duty of flogging, when that sentence is passed upon soldiers. A *Drum-head Court-martial* (not now much adopted) has no particular connection with the drummers, but is a hasty council or court-martial held in the field around the big drum.

DRUMMOND, CAPTAIN THOMAS, R.E., was born at Edinburgh in 1797, and during his professional training at Woolwich and Chatham displayed high mathematical and mechanical abilities, with much aptitude for the application of scientific principles to practical affairs. In 1820, he was engaged by Colonel Colby to assist in the trigonometrical survey of the United Kingdom. The incandescence of lime having been brought under his notice at a lecture on chemistry, the idea occurred to him that it might be advantageously used on the survey to render distant objects visible: he accordingly made experiments, which, with their results, and the first application of the Drummond Light (q. v.) in Ireland, are described by him in the *Philosophical Transactions* for 1826. A heliostat (q. v.) of his invention, described in the same paper, has ever since been employed with success in the survey. Experiments which he made with the view of adapting his 'Light' to light-houses, are detailed in the *Philosophical Transactions* for 1830. When exhibited at Purfleet, it was powerful enough to cast shadows at Blackwall, distant ten miles. Practical difficulties, not yet overcome, prevented the fulfilment of his hopes in this direction; his attention having been diverted to political life, for which he soon proved himself to be eminently fit. As the head of a commission appointed by Lord Grey's government to superintend the fixing of the boundaries of the boroughs under the provisions of the Reform Bill, he performed most ably that laborious and important work. He next acted as private secretary to Lord Althorp, chancellor of the exchequer; and finally, in 1835, went to Dublin with Lord Mulgrave, as under-secretary for Ireland.

Here the knowledge of Irish character and feelings which he had acquired in the survey was of great advantage to him, and by his impartiality, sound judgment, conciliatory disposition, indefatigable energy, and hearty devotion to the work before him, he at once gained the confidence and affection of the people. It was in a letter written by him to the magistrates of Tipperary on the 22d of May 1838 that the memorable words occurred—'Property has its duties as well as its rights'; an aphorism which instantly flew over Ireland, and continues everywhere to exercise a wholesome influence. But it was perhaps as the head of a commission appointed in 1836 to report on a railway system for Ireland, that D. rendered that country his greatest service by the admirable Report which he had the main labour of producing. So far as the routes recommended have been followed, the expectations of the commissioners have been fulfilled or exceeded; and it is the opinion of good judges, that it would have been well for Ireland had the carefully digested scheme been more fully adopted. By these multiplied labours, however, D.'s strength was overtasked, and he sank on the 15th of April 1840, amidst the grief of the Irish people, and of his intimates in public life, who had hoped to see him rise to some of the highest offices in the state. A statue by Hogan was erected to his memory by public subscription, in the Royal Exchange at Dublin; and a memoir of his professional life (abridged in Knight's *English Cyclopædia of Biography*, ii. 647) was published in 1841 by Captain Larcom, R.E., in the 4th volume of *Papers on Subjects Connected with the Duties of the Corps of Royal Engineers*.

DRUMMOND, WILLIAM, OF HAWTHORNDEN, a poet of considerable celebrity, was descended from a very ancient and noble Scottish family, and was born 13th December 1585. He was educated at the High School of Edinburgh, and afterwards at the University of that city, where he took his degree of M.A., July 27, 1605. On leaving college, he was sent to the continent in order to study law, for which he exhibited great aptitude. He returned in 1609, and his father dying in the following year, he retired to the paternal estate at Hawthornden, which, according to the learned Ruddiman, 'was a sweet and solitary seat, and very fit and proper for the muses;' and there, with an interval of eight years of foreign travel, spent his life in his favourite literary pursuits. He died 4th December 1649; his death, it is said, being hastened by his excessive grief for the fate of Charles I.

His principal works are the following: *Tears on the Death of Mœliades*—Prince Henry, son of James I.—(Edin. 1613); *Poems: Amorous, Funerall, Divine, Pastoral, in Sonnets, Songs, Sextains, Madrigals* (1616); *Forth Feasting, a Panegyricke to the King's Most Excellent Majesty* (1617); *Flowers of Stion* (1623); *Polemia Middinia* (Oxford, 1691). A new edition of the works of D., with Life by Peter Cunningham, was published in 1833, and another by W. B. Turnbull in 1856. His literary celebrity gained him the close friendship of many men of eminence, among whom may be mentioned Michael Drayton, and the 'rare' Ben Jonson. The latter, in the winter of 1618—1619, travelled down to Hawthornden to visit the poet, and D. is now perhaps best known by his *Notes of Ben Jonson's Conversations with William Drummond of Hawthornden*, January 1619.

D.'s verse abounds in the conceits, antitheses, and hyperboles of the period, and gives indication of a mind indulging itself in melancholy. His sonnets are the best specimens of his muse, although even in them one looks in vain for sustained harmony or great originality of thought.

DRUMMOND ISLAND, within the limits of Canada, is in Lake Huron, being the most westerly of the Manitoulin chain. It measures 20 miles by 10, and lies about 30 miles to the east of Mackinaw, an island in the strait of the same name, which pours Lake Michigan into Lake Huron.

DRUMMOND LIGHT, or LIME-BALL LIGHT. The heat given out during the combustion of a mixture of hydrogen and oxygen gases, or of coal-gas and oxygen, is very intense; and when the mixture is directed on an infusible substance such as lime, a most brilliant light is evolved. Captain Drummond, R.E., originally proposed the employment of this light in the trigonometrical survey of Great Britain, and constructed apparatus for its production. See DRUMMOND, THOMAS. The most convenient form of the apparatus is represented

Drummond Light Apparatus.

In the figure, where the mixed gases escaping by the jet *a*, being set fire to and made to impinge upon the cylinder of lime *b*, raise the surface of the latter nearest the jet to a white heat, accompanied by a dazzling light. As minute portions of lime become detached and are volatilised from the spot on the lime on which the jet of burning gases strikes, it is necessary to expose a new surface of lime to the gases, and for this purpose the screw *C* may be turned by the hand or by clockwork. The hydrogen and oxygen ought to be confined in separate gas-holders or bags, and to be brought by different tubes, *H* and *O*, provided with separate stop-cocks, to within a short distance of the exit jet. The common tube through which the mingled gases pass to the jet is about six inches long by two-thirds of an inch in diameter; and in Mr Hemming's construction the tube is very closely packed, full of very fine brass wire, which is afterwards wedged in by a stout wire being driven down the centre. The object of the fine wires is to prevent the return of the flame, which might lead to a disastrous explosion. When the rays from this light are concentrated by a parabolic reflector, it can be seen at immense distances. Thus, on the 31st December 1845, at half-past 3 P.M. (daylight), the light was exhibited on the top of Slieve Donard, in county Down, and was seen from the top of Snowdon, a distance of 108 miles; and in other instances the D. L. has been seen at distances up to 112 miles. The employment of coal-gas instead of hydrogen has greatly increased the applications of the D. L., and it is now often used in magic-lanterns and other apparatus where great brilliancy and penetration of light are required. By its brilliancy and want of colour, it enables the photographer to work by night as easily as by day. Great caution should at all times be exercised in the preparation, storing, and employment of the gases, as many dangerous explosions have occurred. Little heat is evolved from the D. L., nor does it vitiate the surrounding air, or consume its oxygen.

DRUNKENNESS. See INTemperance, and also TEMPERANCE.

DRUPE, in Botany, a succulent fruit containing a single seed or kernel, usually enclosed in a hard

'stone,' the *endocarp*. The succulent part is the *mesocarp*. Examples are familiar in the fruits generally known as stone-fruits, the peach, plum, cherry, &c. In the almond, the *mesocarp* is not succulent, yet the fruit otherwise possessing all the characters of a D., receives that name. It may be regarded as intermediate between a D. and a nut. The fruits of the genus *Rubus* (Raspberry, Bramble) are composed of many small aggregated drupes, upon a common receptacle. The date is a D. in which the hard 'stone' is represented by a membrane.

DRURY, DRU, a goldsmith, silversmith, and cutler, in London, where he was born, 4th February 1725; was devoted to the study of entomology and the collection of exotic insects. His *Illustrations of Exotic Entomology* (2 vols., Lond. 1773—1782), a work unrivalled at the time of its publication for the accuracy and beauty of its figures, is still in high repute as a book of reference. D. was also assiduous in his endeavours to acquire information concerning the habits of insects. He died 15th January 1804.

DRUSES, a remarkable people who inhabit a district in the north of Syria, comprising the whole of the southern range of Mount Lebanon and the western slope of Anti-Lebanon. In this district they hold exclusive possession of about 40 towns and villages, and divide the possession of about 200 more with the Maronites (q.v.), while 80 villages in other parts of Anti-Lebanon are peopled by them. The inhabitants of the Lebanon afford a remarkable illustration of the amalgamation of races. After the second captivity of Israel, Esarhaddon re-peopled the wasted strongholds of Samaria with certain fierce tribes, some of whom, called in the Scriptures Cuthites, and known in subsequent times to the Greeks as Carduchi, and familiar to us as Kurds, settled in Lebanon. From them the present D. are supposed to have originally sprung. More than a thousand years later, a fresh colonisation took place. The Mardi, a warlike tribe who dwelt to the north of the Caspian, originally of Persian extraction, were transplanted thither by Constantine IV., in 686 A.D., to the number of 12,000, to act as a bulwark against Mohammedan invasion. The Arabs also, in sweeping through the mountain-fastnesses, left a permanent impression there. Thus, Cuthites, Mardi, and Arabs, or rather Mohammedans of various races, have combined to form that strange being—the modern Druse. It has also been supposed by some that there runs in his veins not a little of the blood of the Crusaders, but this is doubtful. No immigrations, however, of any importance into the country of the Druses took place after the close of the 10th c.; and this period seems naturally to conclude the first great section of Druse history.

The nationality of these mountaineers having now been consolidated, their peculiar and mysterious religion began gradually to be developed. Hakem Biam Allah, or Bemrillah, calif of Egypt, and a Nero in cruelty, was the author of this system. He affirmed that he was the representative of God, and, having enlisted his confessor, Darazi, in his cause, he prepared to propound his doctrine. In the 407th year of the Hegira (1029 A.D.), the divine nature of Hakem, or rather the incarnation of the Spirit of God in him, was publicly announced at Cairo. This revelation, however, was unfavourably received by the mob. Hakem's confessor, Darazi, narrowly escaped the fate of a martyr to the impositions of his master. Retiring, however, to the fastnesses of the Lebanon, he there began to inculcate the principles of the new faith; and although he

never acquired any mastery over the sympathies of the mountaineers, he at least left his name to them; for there can be little doubt that the name Druses is derived from that of Darazi. Hamzè, a Persian mystic, and successively the disciple and vizier of Hakem, introduced into the newly promulgated religion all the elements of attraction and strength which it possesses; and him the D. venerate as the actual founder of their faith.

The D. form one of the very few sects among whom proselytism is discouraged. They are remarkable conservatists. For 800 years they have maintained a distinct religious and political independence and nationality. Into their faith the doctrines of the Pentateuch, the Christian gospel, the Koran, and the Sufi allegories, are wonderfully interwoven. They reject, however, the seven points of Islamism, substituting for them the following seven:—1. Veracity (to each other only); 2. Mutual protection and resistance; 3. Renunciation of all other religions; 4. Profession of the unity of Hakem as God; 5. Contentment with his works; 6. Submission to his will; 7. Separation from those in error, and from demons. They believe in one God in whom there are no parts, to whom they ascribe no attributes, before whom the tongue ceases to utter, the eyes to behold, but who has revealed himself ten times upon the earth under the form and name of mortal men. In Hakem, so Hamzè taught, had God revealed himself for the tenth and last time. They also believe that the number of existing souls never varies, and that all the souls in life now, have lived, vested in some human form, from the beginning of the world, and will so continue to exist till the end of it; that when a man dies, his soul pnts on a fresh humanity, which occupies a rank in moral dignity corresponding to the purity or impurity of the past life. But although they believe, in this sense, in the transmigration of souls, they also believe that after the lapse of ages, when the soul will have been purified from every stain, there will come a period of rest. As a religious body, the D. are divided into two classes: the Akals, or those initiated into the Druse mysteries; and the Djahils, the uninitiated. The former do not adorn themselves with gold, or wear silk, embroidered, or fanciful garments; they forbear using wine, spirits, tobacco, and other luxuries, never swear, utter obscene language, or lie. The latter are free from all religious duties. But, however rigid the profession of the Akal or initiated Druse, he is taught that his practice may be conducted in some cases on the principle of expediency. To be truthful, he is taught, is desirable; but when concealment is necessary, then equivocation, or even falsehood, may be practised.

Previous to 1840, Druse and Maronite lived on terms of intimacy and friendship. At that period, however, dissension sprung up between the two tribes, and proved to be the introduction to years of intermittent warfare. The strife reached its climax in 1860. From May to October of that year, accounts of the fearful barbarities practised by the D. upon the Maronites followed each other with appalling frequency, until the indignation of Europe was roused against them; and in August of the same year, an expedition was sent out from France to Syria, with the consent of the Great Powers, for the purpose of protecting the Christian residents and the so-called Maronite Christians, and of restoring tranquillity. But by the official despatches of 1860—1861 from Her Majesty's consuls in Syria, it was clearly proved that, in the words of Lord Dufferin, 'however criminal may have been the excesses into which the Druses were betrayed, the original provocation came from the Maronites, and that they are themselves, in a great measure,

responsible for the torrents of blood which have been shed.' Although the lives of women and children were indubitably lost in considerable numbers, yet it was not the D. who were in general guilty of such abominable crimes. It is ascertained beyond all doubt, that with these the Turks, particularly the low fanatical mob of Damascus (who have frequently been confounded with the D., because they fomented their passions), are mainly chargeable; while the retaliation of the Maronites, who took refuge in the French camp, was equally vindictive and horrible. The number of lives lost in the Syrian massacres was never definitely ascertained, but must have amounted to many thousands. It may be added, as illustrative of the blood-thirstiness of the Maronite leaders (who in most cases were bishops), that on being asked to furnish sworn lists of such of the D. as, from the unusual atrocity of their crimes, were worthy of death, they sent in a list demanding 4946 heads; refusing, however, to bring forward any particular charges against them.

The D. were, until lately, governed by a Grand Emir subject to the Porte; but at the conclusion of the late troubles, it was resolved that one ruler, and he a Christian—the Maronites are, in proportion to the D., as three to one—should be appointed as their governor. Accordingly, after some deliberation at the Porte, Daoud Eliendi, formerly Director-general of Telegraphs, was appointed to the Lebanon to act as governor, with full powers, June 22, 1861.

The D. are about 80,000 in number; they are a brave, handsome, and industrious people, and are almost all taught to read and write. Polygamy is unknown among them. They have, with incredible toil, carried the soil of the valleys up and along the hillsides, which are laid out in terraces, planted with mulberry, olive, and vine. From the produce of these, the hardy mountaineers draw the greater part of their sustenance. Their chief trade is the manufacture of silk. Corn is also raised, though in very small quantity. Deir-el-Kamner is the principal town. See *Druses of the Lebanon*, by the Earl of Caernarvon (Lond. 1860).

DRUSUS, the name of a distinguished family of the gens Livia, which contributed a large proportion of eminent men to the Roman commonwealth. The most conspicuous of the Drusi were: 1. M. LIVIUS DRUSUS, tribune of the people in 122 B.C., who made it the business of his public life to thwart the democratic policy of his colleague, C. Gracchus, and uphold the cause of the senate and nobles, which he did with much skill and ultimate success. 2. His son, who bore the same name as himself, and whose dangerous and daring political intrigues, conducted partly for the benefit of the aristocratic party whose sympathies he inherited, and not less for his own aggrandisement, kept Rome in perpetual turmoil and disorder from 100 B.C. till his death in 91 B.C. Though identified by birth and sympathy with the patricians, Drusus, to win the people, renewed some of the most liberal measures of the Gracchi, and carried agrarian and frumentarian laws. During the latter years of his life, he contrived to gather into his own hands the threads of the various political movements which resulted in the Social War; but his almost incredible pride and arrogance had made him so many enemies, that his death, in the flower of his age, was regretted as little by his friends as by his foes. 3. The most illustrious of the Drusi was Nero Claudius Drusus, commonly called Drusus Senior, the stepson of the Emperor Augustus, and younger brother of the Emperor Tiberius. He was born in 38 B.C., and as he grew up, developed splendid personal qualities as well as the highest capacity for civil and military affairs. He began his public career in 19 B.C., and signalled himself when

only 23 years old by his defeat of the Rhaeti and other Alpine tribes which infested the north of Italy. In 13 B.C., he was sent into Gaul, then in revolt, and, after crushing the rebels there, pushed across the Rhine in pursuit of their German allies. In this campaign he subdued the Sicambri and Frisii, and forced his way to the German Ocean, being the first Roman general who had done so. From this time he made the business of his life to establish the Roman supremacy in Germany, partly by conquest, and partly by the execution of great military works. Among these latter may be mentioned the canal joining the Rhine with the Yssel, the two bridges over the Rhine itself, and the embankments of the Vahalis, the Waal. In 11 B.C., he conquered the Usipetes, the Cherusci, and the Suevi; in the following year, the Chatti, the Nervii, and was prosecuting the work of subjugation in 9 B.C., when a fall from his horse cut short his brilliant career in his 30th year. For his exploits in Germany, Drusus was rewarded with the title of Germanicus, but care must be taken not to confound him with the celebrated Germanicus, his own son. See GERMANICUS.

DRY PROCESS, in Photography. By a reference to the article COLLODION PROCESS, it will be seen that the collodionised glass-plate, on being withdrawn from the bath, previous to, and during exposure in the camera, has mechanically adhering to its surface a quantity of solution of free nitrate of silver, and it is partly upon the presence of this salt that the extreme sensitiveness of wet collodion plates depends. This, however, is not the sole cause of sensibility to actinic rays; carefully conducted experiments fairly lead to the assumption, that the molecular arrangement of the ultimate particles of iodide of silver, and of the pyroxyline, forming, as it were, the network of the film while wet, materially affect this necessary condition; and it is the object of what is termed a *dry process* to preserve this molecular arrangement as far as possible unaltered, notwithstanding the disturbing influence which would necessarily be exerted by the desiccation of the film. This desirable end for travelling photographers is accomplished with more or less certainty by the employment of solutions of various substances, which are poured over the film after the adhering nitrate of silver has been removed by copious washing with water. The heterogeneous character of the substances so used goes far to prove that their action is principally *mechanical*, they being selected from the animal, vegetable, and mineral kingdoms. Among the first may be mentioned honey, gelatine, glycerine, milk, and albumen; among the second, syrups, gum, wine, beer, balsams, and resins added to the collodion, and linseed tea; and among the third, chloride of calcium, nitrate of zinc, and nitrate of magnesium. The plate, on its removal from the sensitising bath, being well washed with water, any one of these substances is dissolved in water in suitable proportion, and applied to the surface of the plate by pouring on and off several times. It is then set up to drain and dry on folds of bibulous paper in a dark closet or box. The plate is then ready for use. The pictures obtained on plates so prepared do not suffer by comparison with those taken by the wet collodion process; the only drawback to their use being a slight diminution in the degree of sensibility to light.

DRY ROT, a kind of decay, often very rapid, to which timber is subject, without the presence of much moisture. It has proved ruinous to many valuable edifices, and has been the cause of many serious accidents. The ends of joists are often affected by it, so that upon being burdened with even

a slight additional load, they are ready to break off by the wall; and the process of destruction has often gone far without a suspicion being entertained of anything wrong. Dry rot is occasioned by *Fungi*, the *mycelium* of which diffuses itself through the substance of the timber, destroying its texture, and reducing it to a fragile or even friable mass. *Merulius lacrymans*, *M. rustator*, and *Polyporus destructor* (see AMADOU), are species very commonly productive of this mischief; the first being the most common and formidable dry-rot fungus in Britain, and the last having the same pre-eminence in Germany. Its German name is *Hauschwamm*. Other fungi, however, produce the same effects where none of these are present; but besides the species which are well ascertained, there are some forms of mycelium not unfrequently occurring as dry rot, of which it is uncertain to what fungus they ought to be referred, as they have not been observed to develop themselves in any perfect form, whilst also it is not known what different modifications of appearance the mycelium of the same fungus may exhibit in different circumstances. Very destructive ravages have been ascribed to different species of *Sporotrichum*, particularly in the naval yards of Britain; but the genus is altogether a doubtful one, and not improbably consists of mere forms of undeveloped mycelium. Several species of fungi are often present together in timber affected with dry rot. Some of them penetrate deeply into the substance of the timber, others spread more superficially, but attract moisture from the atmosphere, which hastens decay. This is the case with *Merulius lacrymans*, which first appears in small white points; a filamentous substance radiating from these gradually forms broad patches, sometimes many feet in diameter; from these long creeping shoots often proceed, and a net-work of filaments penetrates into every crevice. The species of *Polyporus* more generally fill the whole mass of the timber with delicate filaments, which destroy the cohesion of its fibres. *Dactylea quercina* appears in the form of leathery laminae, often in the strongest oak, and the delicate threads of mycelium penetrate every duct and cavity, reducing the whole to a fungous mass. Beautiful orange tufts sometimes appear, supposed to be the mycelium of species of *Coprinus*.

Of the causes of dry rot, stagnation of air, as behind a wainscot or under a floor, is certainly one of the chief, and a knowledge of it suggests means of prevention which may often be easily and most advantageously employed. Another principal cause is insufficient drying of the timber itself; and much of the prevalence of dry rot is not improbably due to the practice of felling oak in spring for the sake of the bark, when the wood is full of sap. Any circumstance which may tend to render the sap acidulous, greatly increases the liability to dry rot. The production of fungi takes place with unusual rapidity when by fermentation or otherwise an acidulous condition of organic substances is produced. A fermentation and chemical change in the albuminous constituents of the wood, is not improbably the immediate cause of dry rot, providing a soil suitable for the vegetation of fungi.

For the prevention of dry rot, various processes have recently begun to be employed, the object of which is to fill the pores of the wood with some chemical substance. Sir William Burnett used chloride of zinc; Mr Bethell used creasote; and Mr Payne, lime, with silicate of potash. The process most generally approved, and apparently most successful, is that of Kyan, called *Kyanising* (q. v.), in which a solution of corrosive sublimate is introduced into the pores and cells of the timber by means of

an air-pump. The salts of mercury have been found to be more unfavourable to the development of fungi than any other chemical substances.—But without the use of any such means, we have abundant evidence that well-seasoned timber, in favourable circumstances, may remain unassailed by fungi for many centuries. England contains structures of which the timber is known to be nearly 1000 years old; wood in a state of perfect preservation was brought by Lord Elgin from behind the frieze of the Parthenon, where it must have been placed more than 2000 years ago; and the British Museum contains a block of charred wood found by Mr Layard in his excavations at Nineveh.

**DRY STOVE**, in Gardening, a hothouse in which the air is kept less moist than in the bark stove. In structure and in management, except that the temperature is kept higher, it agrees more nearly with the green-house. The dry stove is particularly adapted to succulent plants. As free an admission of air is allowed in the dry stove as is consistent with the maintenance of the temperature.

**DRYADS**, an inferior order of deities in the mythology of Greece. Their name is derived from the Greek word for an oak-tree (*drus*). They were looked upon as the guardians of the larger kinds of forest trees, along with which they came into being, and with which they died.

**DRYDEN**, JOHN, was born at Aldwinckle, in Northamptonshire, on the 9th August 1631. His father, Erasmus Driden, was the third son of Sir Erasmus Driden, created a baronet in 1619. D. received the rudiments of his education at Tichmarsh, and was afterwards admitted a king's scholar at Westminster School, under Dr Busby. Here, in 1649, he wrote an *Elegy on the Death of Lord Hastings*, and some commendatory verses on the *Divine Epigrams* of his friend John Hoddesdon; both of which performances were published in 1650. In May 1650, he was elected to a scholarship in Trinity College, Cambridge; he took the degree of Bachelor of Arts in 1653—1654; and was made Master of Arts in 1657. His father dying in 1654, put him in possession of an estate worth £60 per annum, of which sum his mother had life-interest in a third. After leaving the university, he proceeded to London, under the patronage of Sir Gilbert Pickering, who was faithful to the Protector, and seems to have aroused for the time the same feeling in his protégé, whose first poem of importance was entitled *Heroic Stanzas on the Death of Cromwell*. On the return of Charles II., D., with equal splendour of diction, and perhaps with equal sincerity, congratulated the Restoration.

The publication of a poem, entitled *Astræa Reducæ*, led to a breach between the poet and the family of Sir Gilbert Pickering, and he now became author by profession. He turned his attention to the stage, planned *The Duke of Guise*, and wrote his first acted play, *The Wild Gallant*. In December 1663, he married a daughter of the first Earl of Berkshire, with whom he received a portion; and in 1670 he was appointed poet laureate and historiographer, with a salary of £200 a year. He afterwards entered into an engagement with the theatres to supply them with three plays each year, for which he was to receive annually from £300 to £400; but as he did not fulfil his share of the contract, it is not probable that the theatres fulfilled theirs. In 1671, the Duke of Buckingham produced his attack on the English heroic drama, of which D. was the head. This satirical piece was entitled *The Rehearsal*, and when it was brought on the stage, the town was amused. Although personally satirised, D. endured his castigation in silence, and, waiting his opportunity,

immortally revenged himself on the witty and profligate duke in the *Absalom and Achitophel*. This magnificent satire arose out of the political commotions of the times, and is an elaborate defence of the king against the Whig party. Charles II. is *David*; Monmouth, *Absalom*; Cromwell, *Saul*; Buckingham, *Zimri*; and Shaftesbury, *Achitophel*. Its success was amazing; it ran through five editions within the year. This great poem appeared in 1681; and enraged at its success, D.'s enemies hovered around him like a cloud of venomous gnats. In the same year he published *The Medal*. Elkanah Settle, one of the most virulent of his foes, replied with some effect; and D., thoroughly roused, issued next year the *Mac Flecknoe*, and the second part of *Absalom and Achitophel*. These satires were as overwhelming as the Italian battles of the first Napoleon; D.'s enemies were crushed for ever, and he remained during his lifetime the undisputed king and lawgiver of English literature.

After the death of Charles II., D. became a convert to the Roman Catholic faith. This event was announced to the world by the publication of *The Hind and Panther*, in 1687. For this change of faith, he has been much abused. Macaulay calls him 'an illustrious renegade.' Mr Bell, his latest biographer, strenuously defends his conscientiousness. At the Revolution, he was deprived of his laureateship, and somewhat straitened in circumstances, he fell back upon his old occupation of writing for the stage. His translation of *Virgil* was begun in 1694, and completed by the close of 1696. A month after the publication of *Virgil*, appeared the *Ode on Alexander's Feast*. In 1698, he commenced his *Fables*, and completed them in a year and a half. His last work was a masque, with prologue and epilogue. He died on the 1st May 1700, and was buried in Westminster Abbey, where a monument was erected to his memory by John, Duke of Buckingham.

Although the great bulk of D.'s works are composed of plays, and although these are, for the most part, devoid of character, feeble in sentiment, false to all external nature, and exaggerated in expression, he remains one of the prime glories of English literature. His *Satires* and his *Fables* are masterpieces. In these, he is almost always masculine and natural, and his versification flows on broad, deep, and majestic. Nor is he famous only as a writer in verse; in his prefaces, and his *Essay on Dramatic Poesy*, he proves himself to be a master of what he so finely calls 'that other harmony of prose.'

**DRYING-MACHINES.** The ordinary process of drying clothes and fabrics by exposure in the open air, has been found too tedious for the bleacher, dyer, and for large laundry establishments; and hot-air chambers have been extensively used; but a great improvement has been lately made by using the principle of centrifugal force to throw off the greater part of the moisture. The drying-machine commonly used consists of two drums or cylinders open at the top, the inner one, into which the goods are packed, is perforated at its sides, and made to revolve with great velocity either by steam, water, or hand-power. The action of the drying-machine is precisely the same in principle as that witnessed when the housemaid is *trundling* a mop, or of the dog when he shakes himself on coming out of the water. The use of the outer cylinder is merely to catch the drops of water thrown out, and prevent the inconvenience that would result from its distribution through the apartment. A pipe connected with this outer drum carries the water away. The drying is not, however, quite completed by such machines; a very slight degree of moisture, just perceptible to the touch if the goods are pressed

against the cheek, still remains. This is expelled by open-air or hot-chamber drying. These drying-machines are commonly called 'extractors' by dyers. A simpler and cheaper drying-machine has been lately introduced for domestic use. It consists of two wooden rollers mounted parallel, and one above the other, with an adjustment to vary the distances between them. One end of the article to be dried is inserted between the rollers, which are then brought as close as possible together, and one roller is turned by a handle, the other, being free to revolve, turns also as the clothes pass between them—the moisture in this case being extracted by pressure, as in the common process of 'wringing.'

**DRYING OILS.** See OILS.

**DRY'NESS**, a technical term in painting, used to indicate a style in which the drawing is hard, angular, and formal, and the colour deficient in harmony and mellowness, though not necessarily in power or richness. The earlier works, both of the Italian and Flemish schools, all more or less partake of this defect; and it is the most prominent characteristic of those of their imitators to whom the name of pre-Raphaelites has been given.

**DRYOBALANOPS.** See CAMPHOR.

**DRY'OPHIS**, a genus of serpents of the family *Colubridæ*, allied to *Dendrophis*, and, like those of that genus, of very elongated form, and living mostly among the branches of trees, but distinguished by a projecting muzzle—a curious prolongation of the upper jaw, which in some is slender, in some leaf-like. They are natives of the East Indies, Madagascar, and tropical America.

**DRY'-POINT**, a sharp etching-needle, used to incise fine lines in copper, without the plate being covered with etching-ground, or the lines bit in by acid. See ENGRAVING. The work produced by the dry-point is not only very delicate, but it wears less in printing than lines produced by the action of acid. Fairholt's *Dictionary of Art Terms*.

**DU'AL**, in Grammar, is the form given in some languages to a noun or a verb, when only two things are spoken of. Thus, in Greek, *pater* is father; *patere*, two fathers; *pateres*, fathers. To have a dual number in addition to a plural, is often spoken of as a refinement of language. It argues, however, a higher degree of abstraction to be able to conceive every subject as one, or more than one, than to require three classes—one, a pair, and more. Accordingly, it is only in some of the more ancient languages that we find traces of a dual number, and it becomes lost as the power grows of analysing concrete impressions. Sanscrit, ancient Greek, Arabic, and Hebrew have the dual number, the last only in nouns. Modern Greek has lost the dual. The only trace of it in Latin is in the two words *duo*, two, and *ambo*, both. It is wanting in the Germanic languages, with the exception of the ancient Gothic, which had a dual form of the verb. In Anglo-Saxon, there was a separate form of pronoun for 'we two' (*wit*) and 'ye two' (*git*).

**DU'ALISM** is the name given to a philosophical theory, according to which some two principles, of different nature, original, and incapable of being derived the one from the other, lie at the bottom of everything; as, for example, the ideal and the real, or the material and the thinking substance. In a narrower and theological sense, dualism means the assumption of two original beings, a good and an evil, as in the doctrine of Zoroaster, or of two distinct principles in man, a bodily and a spiritual. The opposite of dualism is Monism.

**DU BARRY, MARIE JEANNE GOMARD DE VAUBERNIER**, COMTESSE, favourite of Louis XV.,

was born August 19, 1746, at Vaucoulenrs. Her mother was a dressmaker, and her father, or rather her reputed father, was an exciseman named Vaubernier. After the death of her father, she stayed for some time at a convent, but left it when fifteen years of age; went to Paris, and assuming the name of Mademoiselle Lange, succeeded in obtaining employment in the establishment of a fashionable milliner; but in a short time renounced all honest occupation, and forming a connection with a disreputable house, met there the Comte Jean Du Barry, one of the most noted *roués* of his day, who made her his mistress. This person afterwards introduced her to Lebel, valet-de-chambre of Louis XV., who presented her to his royal master, then nearly 60 years of age. She was at this time remarkably handsome, to some extent witty, and had a frankness, or it might be, a vulgarity of manner that amused the dotting monarch. Desirous that *la petite Lange* should obtain a title, and be introduced to court, Louis prevailed upon Comte Guillaume Du Barry, brother of the comte already mentioned, to marry, and thereby confer his title upon, the favourite. Accordingly, in 1769, she was presented to court as the Comtesse Du Barry. After this period, many of the most powerful courtiers abased themselves before her. D'Aiguillon became her confidant, and in concert with her, ruled the dotting king; the Chancellor Maupeou claimed a remote relationship with her, and by her influence succeeded in dismissing and exiling the parliament in 1771; the Abbé Terray, comptroller-general of finance, was *suave* to her, though insolent to all the rest of France. At no period, perhaps, was the court of France more openly and outrageously immoral than during the supremacy of this strumpet.

On the death of Louis, however, in 1774, Du B. was dismissed from court, and sent to live in a convent near Meaux. She was afterwards removed to her residence of Luciennes, and while living there was allowed a pension by Louis XVI. Some time after the outbreak of the Revolution, she went to London to dispose of her jewels. On her return, Robespierre caused her to be arrested, July 1793. In November, she was tried before the Revolutionary Tribunal, and accused of 'having wasted the treasures of the state, of conspiracy against the republic, and of having, in London, worn mourning for the late king.' She was condemned to death, and was sent to the guillotine 7th December 1793. Of all the women who mounted the scaffold during the Revolution, Du B. exhibited the least courage. She implored the 'good people' to deliver her, and Monsieur the executioner to prolong her miserable life for one moment only. The single good thing that history records of her, is her patronage of various artists and men of letters, but there is little reason to believe that it originated in anything higher than her dread of epigram and caricature. She had neither taste nor knowledge, and cared only for sensual gratifications and excitement. It is estimated that she cost France 35,000,000 francs. The *Mémoires* published under her name (6 vols., Par. 1829—1830) are not reliable. The only work, it seems, which can be consulted with confidence is Lacretelle's *Histoire de France pendant le 18me Siècle*.

DUBITZA, a fortified town of European Turkey, is situated on the northern frontier of Bosnia, on the right bank of the Unna, and at a point about ten miles from its confluence with the Save, of which it is a tributary. During the 16th and 17th centuries, it was a bone of contention between Austria and the Porte, and was repeatedly lost and regained by the latter. It is chiefly notable, however, for its heroic but unavailing resistance to the Austrians in 1788.

D. was subsequently restored to the Turks, to whom it now belongs. Pop. 6000.—Over against Turkish D., on the opposite bank of the Unna, stands Austrian Dubitza, a strongly fortified market town in Austrian Croatia.

DUBLIN, a maritime county in the east of Leinster Province, Ireland, and containing the metropolis of that country; bounded, N., by Meath; E., by the Irish Sea; S., by Wicklow; and W., by Kildare and Meath. It is the smallest but two of the Irish counties, being 32 miles long, and 18 (average 12) broad; area, 354 square miles, of which  $\frac{2}{5}$ ths are arable, and  $\frac{1}{10}$ th in wood. The coast, from its indentations with creeks and bays, is 70 miles long, and off it lie several isles. Dublin Bay, one of the finest in the kingdom, is 6 miles broad, 6 deep, with a sweep of 16 miles. It has two precipitous hills, about 500 feet high at its north and south ends; but the head of the bay is low and sandy. The coast is defended by 26 martello towers. The surface is mostly a level rich plain, with slight undulations, but rising in the south in a hill-range, the highest point of which is Kippure, 2473 feet. North of this range, the only prominent eminences are Lambay Isle, or Ireland's Eye, and Howth Head, 503 feet. The only river of note is the Liffey, which runs through Dublin city into Dublin Bay. The Royal and Grand Canals run west through the county, and unite the Liffey and the Shannon. The chief rocks are carboniferous limestone, granite, and some metamorphic rocks and greenstone. There are copper and lead mines near Scalp. Fullers-earth and potters-clay occur. Iron and manganese are found on Howth peninsula. Granite and limestone are much used in building. There are many mineral springs, including ten saline purgative ones, within the city of Dublin, and some tepid ones of 75° F. The climate is mild. The soil is generally a shallow calcareous gravelly clay. In the north and west are grazing and meadow farms, and around Dublin city, villas, kitchen-gardens, dairies, and nurseries. D. is the best cultivated county in Ireland. In 1858, half the county was in crop. The chief crops are oats, wheat, and potatoes. There are important fisheries along the coast of turbot, brill, sole, plaice, cod, ling, haddock, whiting, and oysters. The manufactures (chiefly of cottons, stockings, and embroidered muslins) are mostly confined to the city and the vicinity of the metropolis, and are of more value than in any other Irish county. Balbriggan is famed for its hosiery. The chief exports are from Dublin city. D. is divided into 9 baronies, 4 poor-law unions, and 83 parishes. The chief towns are Dublin, the capital of Ireland, and Kingston. Pop., exclusive of Dublin city, 1841, 140,047; 1851, 146,731. D. is the only Irish county whose population increased between 1831 and 1841, and from 1841 to 1851. In 1851, D. had 148 national schools, with 27,272 scholars. The county sends six members to parliament—two for D. county, two for Dublin city, and two for Dublin University. The manners, appearance, dress, and cabins of the lower orders of D. county differ less from those of the interior of Ireland than would be expected from the vicinity to the metropolis. There are numerous antiquities in different parts of the county. (1871—pop. 160,000.)

DUBLIN (Irish, *Dubh-linn*, 'black pool'; the *Eblana* of Ptolemy), the capital of Ireland, stands on the river Liffey, where it disembogues into Dublin Bay, in lat. 53° 20' 38" N., and long. 6° 17' 30" W. It covers an area of 1300 acres, but its parliamentary boundary comprises an area of about 5000 acres, and its municipal boundary nearly 4000 acres. Much of D. is built on land reclaimed from the sea;

and the ground is generally flat, with a very few undulations, scarce deserving the name of hill. The river, running from west to east, divides the city into two almost equal portions. The aristocratic parts are the south-east and north-east, containing many beautiful squares, with splendid streets and terraces. The centre, and the north-west quarter are the great emporiums of trade, and the residence of the middle classes, many of whom, however, have their private houses in the suburbs. The south-west division, part of which is called the 'Liberties,' once the seat of the silk trade, is the most filthy and degraded portion of the city. The streets in this quarter, which is the oldest part of the town, are narrow, crooked, and irregular, while in the fashionable portions they possess a totally opposite character. The city is surrounded by a 'Circular Road' of nearly nine miles in length, which forms a favourite walk and drive for the inhabitants. The diameter of this road is about 2½ miles.

In the newer parts of D., the streets run at right angles to one another, and are remarkable for their breadth and the uniformity of their architecture which, however, is so varied as to avoid monotony. The most imposing one is Sackville Street, which is perpendicular to the river. It is 120 feet broad, and nearly 700 yards long; at its north end stands the Rotunda, with Rutland Square—in its centre, the beautiful Ionic portico of the General Post-office, and Nelson's Monument (upwards of 130 feet high)—while on the south, it is terminated by Carlisle Bridge, and a wedge-like block of noble houses formed by the converging sides of Westmoreland and D'Olier Streets. A peculiar feature of D. is its squares, which are very numerous, spacious, and well kept. Stephen's Green, the largest, occupies an area of nearly 20 acres, and is about a mile in circuit. Somewhat smaller, but more elegant and aristocratic, is Merrion Square (13 acres). The large park and squares of Trinity College occupy more than 40 acres.

The public buildings of D. are famed for their number and grandeur, and appear to more advantage since the dwelling-houses are built of brick. In the first class may be mentioned the Bank of Ireland (formerly the House of Parliament), Trinity College, the Custom-house, and the Four Courts, which, from the chasteness of their design, and the massiveness of their proportions, have a very imposing effect. The castle has no pretensions to architectural beauty. There are monuments to William III., in College Green (once a *green*, but now a paved street); of Nelson, in Sackville Street; of the late Duke of Wellington, in the Phoenix Park, with several others. The benevolent and charitable institutions of D. are very numerous, and are liberally supported.

Within the limits of the Circular Road, the Liffey is crossed by nine bridges (two of iron), and throughout the whole extent of the city the banks of the river are faced with granite walls and parapets. On each side of these 'quays' there is a spacious roadway, with tall houses and excellent shops, the whole forming a remarkable contrast to the untidy and filthy margins of the Thames. The quay proper extends eastward from Carlisle Bridge. Near the Custom-house, there are several large docks for the accommodation of vessels from distant ports with excisable cargoes. These docks are also in communication with the Royal and Grand Canals, the former connecting Dublin with the northern course of the Shannon and the west of Ireland, the latter with the southern portion of the same river and the south. The harbour has been much improved in late years by the completion of two large breakwaters, the north and

south walls, which have both deepened the water, and rendered the harbour more safe. There is a bar at the mouth of the harbour, but even there, the least depth at low tide is about 11 feet.

The chief manufacture of D. is poplin, which is much celebrated. This, with some glass-works, foundries, distilleries, breweries, and those workshops which are necessary to supply domestic wants, are the main branches of industry. In this regard, D. is much more of a capital, and less of a manufacturing and export city than London. People flock to D. to spend money, not to make it; and the trade of the city and port is therefore very much regulated by the wants of this gay population. The direct foreign trade, though increasing, is very limited, Glasgow, Liverpool, and Bristol intercepting the greater portion of it. Much of the inland traffic is carried on by the canals above mentioned, and by the railways (now extending to all parts of Ireland), and consists principally of articles of dairy and farm produce from the central counties. The principal banks are the Bank of Ireland, the Royal, the National, Provincial, and Hibernian, with some private establishments.

The great educational institution of D. is Trinity College and University. See DUBLIN, UNIVERSITY OF. In regard to schools, D. is not well supplied. There is no public school such as the High School of Edinburgh, but the education of the upper- and middle classes is left entirely to private enterprise. For the humbler classes, much has been done by the National Board (whose model schools are attended by large numbers of children), by the Church Education Society, and other agencies. There are many literary and scientific societies, dealing with subjects of general knowledge, or with matters of local or national interest. There are two botanic gardens—one at Glasnevin, belonging to the Royal Dublin Society, and one near Donnybrook, connected with the university.

The municipal affairs are under the control of a town-council, which consists of a lord mayor, 15 aldermen, and 45 councillors. The revenue which they derive from property and other sources varies from £30,000 to £40,000. There is a large police force, which has charge of the city and of all the surrounding country as far as eight miles from the castle. The city sends two members to parliament. The population of city and suburbs, in 1861, was 295,964.

The environs of D. are especially beautiful. Rathmines, a southern suburb, has become a large township, and is the favourite residence of the wealthier part of the mercantile community. Glasnevin, on the north, deserves special notice as the favourite residence of the poet Tickell, of Addison, Steele, Parnell, Swift, Sheridan, and many other celebrated men. In the cemetery at Glasnevin lie the remains of Curran, O'Connell, and Tom Steele. The Phoenix Park is a magnificent area of nearly 2000 acres, in some parts level, in others with broken ground, having a large amount of timber and brushwood, which shelter immense herds of deer. It affords ample scope for military reviews, and is most extensively used by the inhabitants of D. of all classes for recreation. D., as a whole, with its magnificent bay—which has often been compared to the Bay of Naples—splendid park, massive public buildings, wide streets, spacious and well-kept squares, clean and elegant quays, and beautiful environs, is one of the most handsome and delightful capitals of Europe. The residence of the Lord-lieutenant brings to the city many of the Irish aristocracy and country gentry, and thus keeps alive a vestige of the trade which was so brisk before the Union.

There are 66 Protestant places of worship, 9 Roman Catholic, with 3 monasteries, 8 convents, 5 friaries, a Jesuits' church, and a Jewish synagogue. The Archbishop of Dublin and 'Primate of Ireland' has a revenue of £7786 a year.

The number of vessels entered inwards in the port of Dublin was, in 1859, 7242, with a tonnage of 965,185; cleared outwards, 4560, with a tonnage of 719,193. The customs revenue in 1859 was £1,053,511. (1871—pop. without suburbs, 245,722.)

**DUBLIN, UNIVERSITY OF.** The first university of Dublin was established in connection with St Patrick's Cathedral in 1320; but for want of proper endowments, it never prospered, and dragged out a miserable existence till, probably, the dissolution of the cathedral by Henry VIII.

**Foundation.**—The existing university was founded in 1591—1592, and stands in the position of being a college with university powers. Trinity College, indeed, was intended merely as the *nucleus* of a university, but as no colleges have since been added, it remains in undisputed possession of all university privileges. Queen Elizabeth provided the charter, the corporation of Dublin bestowed the ground and ruins of the suppressed monastery of All-Hallows, and the Irish gentry supplied by subscription the funds necessary for the erection of the buildings. The income of the college was very limited and very precarious, till James I. endowed it with certain estates in the province of Ulster, and a yearly pension of £388, 15s., English money, from the public purse.

**Constitution.**—By Queen Elizabeth's charter, the corporation was to consist of a provost, three fellows, and three scholars, in the name of more, with the power of purchasing, taking, and possessing any manors, tenements, &c., from the sovereign, or from any other person. On a vacancy in the provostship, the fellows were entitled to elect a fit successor, and the election of fellows and scholars lay with the provost and fellows. The provost and fellows had full powers to enact statutes, confer degrees, and prescribe the necessary exercises for graduation, and to do all the work of tuition. Defects soon began to show themselves in this constitution, but they were remedied by the new statutes of Archbishop Laud, which were definitively published in 1637, and which are in the main still in force. By these the election of provost was given to the crown.

**Parliamentary Representation.**—In 1613, James I. conferred on the university the right of sending two members to the Irish parliament. One of these was taken away at the Union in 1800, but was again restored by the Reform Bill of 1832. The electors were formerly the provost, fellows, and scholars; but, in 1832, the privilege was extended to masters of arts, and those of higher degree.

**Board.**—The provost and senior fellows form the board of management of the college. They meet every Saturday, and transact all the financial and other business.

**Officers.**—The government and working of the university are intrusted to the following officers: the chancellor, vice-chancellor, provost, two proctors (one chosen from the senior, and one from the junior fellows), a senior lecturer (who regulates the public examinations), two deans, and a censor, librarian, registrars, an auditor, university preachers, professors, and examiners.

**Senate.**—The chancellor (or, in his absence, the vice-chancellor or *pro vice-chancellor*), all masters of arts, and doctors of the three faculties, whose names are on the college books, form the senate of the university. The senate elects the chancellor, and confers degrees.

**Caput.**—The caput of the senate consists of the

chancellor, vice-chancellor, provost (or vice-provost), and senior master *non-regent*, who is chosen by the senate. Every *grace* (for the bestowal of a degree) must first receive the sanction of the provost and senior fellows, be afterwards approved of by the caput (each member of which has a *negative* vote), and finally be confirmed by the senate in public congregation.

**Provost.**—The provost, who is appointed by the crown, must be a clergyman not under thirty years of age, and at least a bachelor in divinity. He enjoys an income of about £3000 a year.

**Fellows (Senior).**—The fellows are all chosen, in the first instance, by examination; but the seniors are promoted from the juniors, in order of seniority. They have no stated duties, except those connected with the general management of the college affairs. Some of them, however, hold professorships and other offices, such as senior lecturer, senior proctor, bursar, &c. The income of a senior fellow ranges from £1200 to £2000 a year.

**Fellows (Junior).**—The junior fellows are elected by examination. They form the great teaching staff of the college, and do all the duties of lecturing and examining the undergraduates. Most of them are tutors, and their income, which may average £600 a year, is derived partly from a salary given by the college, and partly from their duties as tutors, lecturers, and examiners. All the fellows must be members of the English Church, and all must be in priests' orders, except five—a *medicus*, two *juriste juris civilis*, and two *juriste juris Anglici*. The number of the junior fellows has been altered from time to time, but by a queen's letter recently issued, it is now fixed at twenty-three—the present number of twenty-seven being gradually reducible. The law of celibacy, imposed in the reign of Charles I., was repealed in 1840.

**Professors.**—There is a very complete staff of professors, who represent almost all subjects of human knowledge. Besides a full complement of lecturers in divinity, natural philosophy, mathematics, law, and medicine, there are professors of ancient, oriental, and modern languages (Irish, Arabic, and Sanscrit being among the number), moral philosophy, oratory and English literature, modern history, political economy, natural history, botany, geology, mineralogy, civil engineering, and many others.

**Scholars.**—Of the scholars, who are elected from among the undergraduates, there are two classes—foundation and non-foundation. The former (70 in number) must be members of the Episcopal Church, the latter not necessarily so. The former are members of the corporation, and have the university franchise; but the latter are deprived of both these privileges. Scholarships (which are tenable for five years) are gained by public competition—some being assigned for classics, and others for science—the provost and senior fellows, assisted by some of the junior fellows, if desired, are the examiners. The various emoluments of a scholar, arising from salary, remission of fees, rooms, commons, &c., amount to about £50 per annum. Besides these, there are minor scholarships for the encouragement of the study of divinity and the Irish language; while others are connected with the royal and endowed schools.

**Students.**—There are four grades of students. 1. Noblemen, sons of noblemen, and baronets, who have certain special privileges; the first two being allowed the degree of B.A. *per specialem gratiam*. 2. Fellow-commoners, who obtain degree with one examination less than pensioners, and who dine at the fellows' table. 3. Pensioners, who form the great body of the students. 4. Sizar, who have rooms and commons free. The sizar is limited to 30;

they are elected by competitive examination, and hold their sizarships (worth about £37 per annum) for four years. Each rank has a dress peculiar to itself.

*Entrance.*—Students are admitted to the college after an examination over a prescribed course of classics, arithmetic and algebra, English history and composition, and modern geography. The honour of *first place* at entrance examination is keenly contested; and there are, besides, prizes of £5 and £2 for excellence in special branches of the entrance course, and also for Hebrew.

*Tutors.*—Each student must at entrance place himself under one of the 18 junior fellows who are tutors. These tutors stand to their pupils *in loco parentis*, and also have charge of their tuition, though each tutor does not necessarily teach his own pupils.

*System.*—To proceed to the degree of A.B., a student must keep terms for four years, two terms at least being necessary in each year. Terms may be kept either by residence, and attendance on lectures, or by simply appearing on a stated day in the public hall, and passing a creditable examination over a prescribed course. Lectures are delivered on the different subjects of each term examination by the tutors, the honour examiners, and the university professors; and prizes of the value of £4 and £2 are awarded at the Michaelmas examination to the *first* and the *second* honour men respectively. In the other terms (Hilary and Trinity), parchment certificates reward the diligent. At the end of the fourth year, gold and silver medals are awarded to the senior and junior moderators. Students of the first year are called junior freshmen; those of the second, senior freshmen; of the third, junior sophisters; and of the fourth, senior sophisters. All students must pursue the following course: *first year*, Latin, Greek, mathematics; *second year*, Latin, Greek, mathematics, logic, and metaphysics; *third year*, Latin, Greek, physics, logic, and metaphysics; *fourth year*, Latin, Greek, physics (both mathematical and experimental), astronomy, and ethics. For those who aspire to honours, the course is much more extensive than that for mere *pass*.

*Degrees.*—Term examinations having been duly passed, the student is promoted to the degree of A.B., which is conferred by the senate in full congregation. The *comitia* for granting degrees are held three times in the year—on Shrove Tuesday, the last Wednesday in Trinity term, and the last Wednesday in Michaelmas term. Those students who, at the final ordeal of the fourth year, stand highest in an examination over an extra course in (1) mathematics and mathematical physics; (2) classics; (3) ethics and logics; (4) experimental and natural science; (5) history, political science, and English literature, are called (according to merit) senior or junior moderators. These form the first class of graduates, the second being called respondents. The third consists of 'unclassified candidates.' The higher degrees are procurable after the lapse of a fixed number of years, and on the performance of certain exercises, and the payment of fees.

*Fees.*—For entrance and first half-year the fees are—Noblemen, £60; fellow-commoner, £30; pensioner, £15; sizar, £5, 1s. 3d. Other half-years, £33, 12s., £16, 16s., and £8, 8s.—the sizarships being exempt. This does not include rooms and commons. For degrees, the fees for pensioners are—A.B., £8, 17s. 6d.; A.M., £9, 16s. 6d.; LL.B., £11, 15s.; LL.D., £22; B.D., £13, 15s.; D.D., £26; M.B., £11, 15s.; M.D., £22.

*Divinity, Medical, and Engineering Schools.*—Connected with Trinity College there are schools for divinity, medicine, and engineering. Graduates in

medicine and in engineering must previously graduate in arts. The divinity testimonium is obtained after two years' attendance on lectures, with an examination at the end of each term.

*Church Patronage.*—The university has in its gift 21 valuable church livings, which are, in the first instance, offered to the fellows, should any wish to abandon a college for an ecclesiastical life.

*Studentships.*—In 1859, 14 studentships were founded, worth £100 a year each, tenable for seven years, to encourage graduates in the pursuit of some special branch of study which they may afterwards be called on to teach, should they become fellows and lecturers. Two are given every year, and are open to persons of all religious denominations. The provost and senior fellows are the electors.

*General Remarks.*—The university of Dublin is well equipped for carrying education to a high degree of perfection. The teaching staff is numerous, and in the actual work of tuition, the tutorial and professorial elements are more largely combined than in any other British university. Many distinguished men have, in past generations, gone forth from her halls. The names of Ussher and Berkeley; of Ebrington, Lloyd, Magee, Sir W. Hamilton, Romney, Robinson, Maccullagh, Archer Butler; and of Burke, Sheridan, Curran, Swift, and Goldsmith, with a host of others celebrated in politics, in law, in science, and in literature, are sufficient to indicate the success which has attended her sons.

DUBNITZA, a town of European Turkey, in the province of Rumili, is situated on the banks of the Djerma, a tributary of the Stroma, in lat. 42° 10' N., and long. 23° 20' E. It has extensive ironworks, which afford employment to the mass of the inhabitants. Vines are grown in the vicinity. Pop. 6000.

DUBNO, a town in the south-west of European Russia, in the government of Volhynia, is situated on the left bank of a small feeder of the Styr, in lat. 50° 27' N., and long. 25° 45' E. It is very irregularly built; its streets are narrow and crooked, and destitute of pavements, and the houses are almost entirely built of wood. The people trade chiefly in corn, flax, tobacco, fish, and cattle. A large fair is also held here at Whitsuntide. Pop. 8000, of whom a great many are Jews.

DUBOIS, GUILLAUME, cardinal, was born 6th September 1656, at Brives-la-Gaillarde, in Auvergne, where his father was an apothecary. At the age of twelve, he came to Paris, and entered the college of Saint Michel, as a domestic of the principal. Here he made such good use of his opportunities for acquiring knowledge, that he was afterwards selected as tutor to the son of a merchant named Mauroy, and gradually rose till he became tutor to the young Duc de Chartres. Although of an ugly exterior, he contrived, by his mixture of wit and hypocrisy, to win the esteem of the boy's mother, while he possessed the most unlimited confidence of his pupil, partly through their common love of letters, and partly because he took upon himself the odious office of pander to his vices. His public career commenced after the marriage of his pupil, in 1692, with Mademoiselle Blois, a natural but legitimatised daughter of Louis XIV. He then received from that monarch for his services in bringing about the match, a gift of the abbey of St Just, in Picardy. He was next attached to the French embassy at the court of London, where he formed some important political connections. On his return, he became private secretary to his old pupil; and when the latter (now Duke of Orleans) became regent in 1715, D. became virtually the most powerful man in France. The great act of his life was the famous treaty signed at La Haye, 14th January 1717, and

known as the *triple alliance*, between England, Holland, and France. The importance of this act lies in the circumstance that it effectually changed the foreign policy of France, in spite of the French princes, in spite of the traditions of Louis XIV., in spite of the dislike of the English king for the Regent, and finally, in spite of Cardinal Alberoni himself, the Spanish minister. In reward for his brilliant dexterity, D. received the office of Minister of Foreign Affairs, and in 1720, on the solicitation of George I. of England, was appointed to the vacant archbishopric of Cambrai. In 1721, he obtained the cardinal's hat, and in the following year became prime-minister of France, when his authority seemed unbounded. He died 10th August 1723, a victim to hard work and the wildest debauchery.

**DUBOVKA**, a town of European Russia, in the government of Saratov, is situated on the eastern slope of the Sarpa Hills, on the right bank of the Volga, in lat. about 49° N., and long. 44° 45' E. It is a dépôt for goods brought from the northern provinces, which it forwards to Katschalinskala, a town about forty miles distant from D., and situated on the Don. The produce is thence conveyed by the Don to the southern provinces. D. has some trade in wood, oil, iron, and manufactured articles. Pop. (1855) 10,000.

**DUCANGE**. See DUFRESNE.

**DUCAT**, one of the most extensively used names for a coin, mostly of gold. Ducats were first coined in the 12th c. in Sicily, and took their name from the legend found on those early Sicilian pieces: *Sit tibi, Christe, datus, quem tu regis, iste Ducatus* (ducatius means duchy). Such coins were extensively issued after the 12th c. in Italy, especially at Venice. Venice ducats were called *Zecchini*, from *Zecca*, where the mint was situated. The ducat was adopted in 1559 by the imperial diet of Germany into the currency of the empire, and was afterwards coined in the several German states, and over the whole of the north of the European continent, Russia included. Many of the German states have ceased to issue ducats. The ducat varies in weight and fineness; by far the most common, which is current in Austria, Russia, Hamburg, &c., weighs 54 troy grains, sterling value about 9s. 4d. The modern Italian ducat is of much less value. The gold ducat of Venice is valued at 6s. In the (late) kingdom of the Two Sicilies, the ducat (ducatò del regno) is a silver coin and money of account, forming the unit of the currency, being divided into 100 grani, in the island of Sicily into 100 bajocchi. There are few silver ducats, however, in existence, the common coin being the piastra or dollar = 120 grani. The ducat = 3s. 4d. sterling. There are various kinds of the Spanish *Ducado*, generally translated dollar. The *ducado de plata*, or silver ducat, hard = 4s. 2d.

**DUCATO**, CAPE (anciently, *Leuca-tés*), a headland at the southern extremity of a promontory of Santa Maura, one of the Ionian Islands, in lat. 38° 34' N., and long. 20° 32' E. Cape D. was in ancient times dreaded by mariners, and the modern Greek sailor still fears the strong currents and the fierce gales which he has to encounter there. A point on the western side of the *Leucadian* promontory is called *Sappho's Leap*, as it was supposed that here the poetess precipitated herself into the sea. It is a white broken cliff, rising perpendicularly from the water to the height of about 2000 feet. On its summit stood a temple dedicated to Apollo, the substructure of which still exists.

**DUCHESNE** (in Latin, *Andreas Chesnius*, or *Duchenius*, or *Queretanus*), the father of French history, was born at Ile-Bouchard, in the

old province of Touraine, in May 1584, and studied at Loudun and Paris. History and geography were his favourite studies from his youth, and under Richelieu's ministry he was appointed royal geographer and historiographer. He died 30th May 1640, by a sad accident, having been crushed against a wall by a carriage in a narrow street. His collection of the *Historiæ Francorum Scriptores Coetanei ab ipsius gentis origine ad Philippum IV. tempora* (5 vols., Paris, 1636—1649), is particularly important. It was continued from the third volume by his son, FRANÇOIS DUCHESNE (born 1616, died, after having likewise been appointed historiographer, in 1693), and contains much that may be sought for in vain in Bouquet's collection. Of his other numerous writings, we may mention, as deserving of special notice, the *Historiæ Normannorum Scriptores Antiqui* (Paris, 1619); *Histoire Généalogique de la Maison de Montmorency et de Laval* (Paris, 1624); and *Histoire Généalogique de la Maison de Vergi* (Paris, 1625). The last two throw much light upon the history of France. D.'s industry was extraordinary; he is said to have left more than a hundred folios in manuscript.

**DUCHOBORTZI**, a Russian religious sect, of the origin of which nothing is very certainly known, and which, although conjecturally referred by Count Krasinski to the Patarcnes (q. v.), cannot be historically traced beyond the middle of the 18th c., when it was found to exist in different parts of Russia; and its members became exposed to penalties by their refusal to serve in the army. The D. hold the doctrine of the Trinity, and are chiefly distinguished by their holding that human souls existed before the creation of the world, and fell in that former existence, from which the fall of Adam and a continual tendency to fall have proceeded; and by their ascribing hidden mysterious meanings to all parts of the Bible, for the knowledge of which they depend on inward light. They are extreme mystics. They reject the use of pictures common in the Russian Greek Church. They neither observe baptism nor the Lord's Supper. In their religious meetings they salute each other with bows and kisses: they pray, sing psalms, and exhort or expound the Scriptures. They are, however, generally very illiterate and ignorant. On the accession of the Emperor Alexander I., they received the most complete toleration, and were allowed to settle by themselves on the bank of the Molochna in the south of Russia. Here, however, an impostor named Kapustin prevailed on them to receive him as a prophet, taught them the transmigration of souls, and made them believe that he himself was animated by the soul of Jesus Christ; and it would appear that, in consequence of disputes arising among them concerning him, great numbers were buried alive, and otherwise put to death by the rest, on which the settlements on the Molochna were broken up in 1841, and great part of the people transferred to the provinces beyond the Caucasus.

**DUCK**, a kind of plain linen of a coarse heavy make, highly glazed, used for smock-frocks by the English agricultural labourers, and for working-dresses by those employed at smelting furnaces and iron forges.

**DUCK**. See ANAS. The broader bill, laminated and not toothed, distinguishes the Linnean genus *Anas* from *Mergus* (including Smews, Mergansers, and the Goosander). In recent ornithological systems, however, it is divided into numerous genera, but three chief groups are usually recognised, corresponding to swans, geese, and ducks of popular nomenclature. See GOOSE and SWAN. The group to which the name duck is sometimes extended,

both by scientific writers and in popular language, is characterised by greater breadth of bill than either the swans or geese. Their food is chiefly animal, whilst that of both swans and geese is in great part vegetable. Their legs are shorter and placed further backward than those of geese, so that they move with greater difficulty and with a more waddling gait on land, and their necks are shorter than those of geese, and much shorter than those of swans, although in this character there is a considerable difference between different species. There is a very marked difference in plumage between the males and females, which is not the case in any corresponding degree in swans and geese. They exhibit also a peculiar anatomical character in a large dilation of their trachea (wind-pipe) on each side at its bifurcation. This great group of Ducks is subdivided into two sections; one section characterised by a webbed or broadly margined hind-toe, the other by a hind-toe destitute of membrane. These characters are connected with important differences in other respects, and particularly in habits; the ducks of the first section being chiefly oceanic, living more exclusively on animal food, and diving readily and frequently in pursuit of it; whilst those of the second section are more generally inhabitants of lakes and other inland waters, shewing a preference for shallow waters. Those of the first section also have the feet placed further backward than those of the second; those of the second have generally longer wings than those of the first, and a longer neck by which they are adapted for seeking their food by dabbling in muddy shallows, they less frequently dive, and when alarmed generally seek safety by taking wing. Many of both sections are migratory, and spend the summer in arctic and sub-arctic regions. Not a few of them are common to the northern parts of both the eastern and western continents. Their plumage is remarkably thick, soft, and compact. The tongue, which, unlike that of most birds, is large and fleshy, assists in the selection of food. To the first or oceanic section of ducks belong Scoters, Garrots, Eiders, Pochards, Scaups, Harlelds, &c.; to the second section belong Shieldrakes, Shovellers, Musk Ducks, Summer Duck, Pintails, Gadwalls, Teals, Wigeons, Blue-wings, &c.—See these articles.

The COMMON DUCK, or DOMESTIC DUCK (*Anas boschas*), known also in its wild state as the WILD DUCK or MALLARD, belongs to a genus, or sub-genus, of the second section, characterised by a flattish broad bill, longer than the head, not contracted, nor much dilated, towards the tip, and not much elevated at the base, destitute of a tubercle at the base, the denticulations of the upper mandible (ends of the laminae) scarcely projecting beyond the margin, and a short and rather pointed tail of sixteen feathers. Even as thus characterised, it includes TEALS (q. v.), which are by some ornithologists constituted into a separate genus. The male (drake) of the common duck has the four middle tail-feathers recurved. The deep emerald green of the head and upper part of the neck, the white collar which separates the green from the dark chestnut of the lower part of the neck, and the deep blue iridescent *speculum* of the wing—formed by the outer portion of the outer web of the secondaries—are also marked characteristics of this beautiful bird; the plumage of which exhibits greater brightness of colours—during the breeding season at least—in the wild than in the domestic variety. At the close of the breeding season, the male of the wild-duck assumes for a time a plumage more sober, and resembling that of the female; but before winter, the splendid plumage proper to his sex

is again acquired. The mallard or wild-duck is a widely distributed bird, being found in the northern parts of Europe, Asia, and America, and extending southward as far as Florida—where it is abundant—and the West Indies, although in the Old World it is not known as belonging to regions of similar climate. It was formerly much more abundant than it now is in Britain, the drainage of marshes having apparently tended more than any other cause to the diminution of its numbers. Multitudes of mallards, however, still visit the fen counties of England in winter; and great numbers are taken in decoys, along with other *Anatidæ*, and sent to the London market. See WILDFOWL. Many wild-ducks, however, still breed in Britain, sometimes near the lakes or rivers which they frequent, sometimes in more elevated moorish districts, from which the parents often take opportunity of bringing their very young brood to the lower waters, by swimming down the streams on some occasion of their being swollen by rain, and it is interesting to see the little creatures hurried on, without injury, by the current, and passing along narrow rapids and over waterfalls of considerable height, much as pieces of cork might do, and with as little apparent injury. The nest is composed of grass, intermixed and lined with down, and the eggs are usually nine to twelve in number.

This species, in a wild state, always pairs, but in domestication it becomes polygamous, and the care of the young is left entirely to the female. It has been long common in the poultry-yard, being valued for its eggs and its flesh; and there are breeds, as the Aylesbury duck, &c., remarkable for their great size and delicacy of flesh. In situations where they have ready access to a lake, pond, or stream, ducks are easily managed, and very useful poultry. In other circumstances, they cannot be kept with advantage.

The species most nearly allied to the common duck is said to be the JAVANESE DUCK (*A. javanensis*). The BLACK DUCK or DUSKY DUCK (*A. obscura*) of North America is also very nearly allied to it, and is generally distributed from Labrador to Texas. The Summer Duck or Wood Duck of North America, and the Mandarin Duck or Chinese Duck, belong to a nearly allied genus or sub-genus (*Dendrocygna*), with shorter bill and pendant occipital crest. See SUMMER DUCK. The TREE DUCK (q. v.), or WHISTLING DUCK, of the warmer parts of America, also belongs to a distinct but nearly allied genus or sub-genus (*Dendrocygna*).

DUCK-BILL (*Ornithorhynchus*, or *Platypus*), a genus of *Mammalia* of the order *Monotremata* (q. v.). Only one species is fully ascertained (*O. paradoxus*, or *P. anatinus*), generally called WATER MOLE in the Australian colonies. It inhabits the rivers of New Holland and Van Diemen's Land. The first descriptions of this singular quadruped were received with incredulity, and even when a stuffed specimen was brought to England, it was suspected to have been ingeniously fabricated. The whole length, including bill and tail, is usually from 20 to 23 inches. The body is rather long and compressed, thickly covered with very glossy hair, among the roots of which there is a layer of soft short waterproof felt or wadding. The head is small and round, with small bright eyes, and no external ears, although the internal ears are perfectly developed, and the hearing acute; and instead of the muzzle, mouth, and teeth of an ordinary quadruped, the creature is furnished with a bill like that of a duck, but broader in proportion, near the extremity of the upper mandible of which the orifices of the nostrils are placed. The bill is covered with a leathery membrane. There are

no true teeth, but the bill has small transverse laminae, like the bill of a duck; and at its base, on each side of each jaw, are two horny protuberances without roots or bulbs. The tongue is beset with villosities, does not extend to the extremity of the bill, and bears at its base what has been described as another tongue of a thicker form, and with two little fleshy points in front. The legs are short; the forefeet have each five toes, with strong burrowing claws, and a connecting membrane for swimming,

Duck-Bill or Water Mole (*Ornithorhynchus paradoxus*).

which extends even beyond the claws, but is capable of being folded back, so as not to impede their use in burrowing. The hind-feet are smaller than the forefeet; they have each five toes armed with claws, and webbed, but the web does not extend beyond the base of the claws. The hind-feet of the male are armed with sharp spurs, like those of a cock, which are merely rudimentary in the female. These spurs were at one time erroneously supposed to be venomous. The tail is strong, broad, and flattened, about half as long as the body, covered with longer and coarser hairs, and nearly naked on its under surface. The D., besides the characteristics of the *Monotremata*, exhibits other anatomical peculiarities which resemble those of birds, and some—principally osteological—which even resemble those of saurian reptiles. It lives chiefly in the water, and seeks its food by means of its bill in the mud, like ducks. Its food consists chiefly of aquatic insects, molluscs, &c.; but it is said also to feed on small fish, and even on vegetable food; and in confinement, it can be fed on worms, minced meat, or egg, and bread and milk. It makes serpentine burrows of great length—twenty or even fifty feet—in river-banks, entering near the water's edge, and enlarged at the termination into a receptacle or nest, which is furnished with dry weeds for the accommodation both of parents and young. The young are produced in a very imperfect state; the D. is indeed strictly ovoviviparous; the fœtus receives no nutriment from the parent before birth, except what it derives from the ovum, which, however, is hatched within the body of the parent; but the young are suckled, and the mouth is adapted to this by the comparative shortness of the bill and greater length of the tongue at this period of life. The D. is lively and active, and so readily alarmed by the appearance of danger as not to be easily shot, diving before aim can be taken. It is usually to be seen with only its head above the surface of the water. It prefers the twilight to the glare of day. Its voice resembles the growl of a small puppy. It carefully dresses and pecks its fur. When asleep, it rolls itself up into a ball.

DUCK CREEK, a water-course of Central Australia, is the largest of the channels which drain into the Darling (q. v.).

DUCKING-STOOL, an apparatus at one time in use in Britain for the punishment of scolding wives. The ducking-stool grew out of the cucking-stool, which was not, as many have supposed, a mere difference of name for the same thing. The cucking-stool of itself did not admit of the ducking of its occupants. It was a simple chair in which the offender was placed, usually before her or his (for the cucking-stool was not so specially for women as the ducking-stool) own door, to be pelted and insulted by the mob. In conjunction with another instrument of degradation, however—the tumbrel—the cucking-stool was occasionally used for ducking; but the ducking-stool *par excellence* was specially made for purposes of immersion. There were various examples of the ducking-stool. Sometimes it consisted of a rough strong chair attached to one end of a beam, which worked on a pivot on a post bedded into the ground at the edge of the dam, or the river, as the case might be. 'The woman was placed in the chair with her arms drawn backwards; a bar was placed across her back and in front of her elbows; another bar held her upright, and there were cords to tie her securely in. The executors of the punishment then took hold of a chain at the opposite end, and gave her a ducking on the 'see-saw' principle.

Fig. 1.  
Ducking-stool until lately in existence at Broadwater, near Worthing.

Fig. 1 is an illustration of this kind of ducking-stool, which was in use at Broadwater, near Worthing. In fig. 2 there is an example of a tumbrel and ducking-stool combined, which was in use for actual

Fig. 2.  
1. Tumbrel preserved at Leominster; 2. Ducking-chair in the museum at Scarborough.

ducking at Leominster as recently as 1809. The beam to which the chair was attached was 23½ feet in length, the ducking being administered in the manner previously described. A representation of a ducking-chair, preserved in the Scarborough Museum, is also given in fig. 2. Other ducking-stools

consisted of an upright and transverse beam, either movable or fixed, from which the chair was suspended by a rope or chain. The practice of ducking commenced in the latter part of the 15th c., and prevailed generally throughout the kingdom until the first part of the 18th c., and in isolated cases, as we have seen, even into the 19th century.

For the facts of this article, as well as for the cuts, we are indebted to a paper by Mr Llewellynn Jewitt in the *Reliquary* (published monthly at Derby).

**DU'CKWEED** (*Lemna*), a genus of plants, referred by many botanists to the natural order *Araceæ*, but regarded by others as the type of a small natural order, *Lemnaceæ*, which consists chiefly of floating plants, mere flat green fronds, with roots hanging loosely in the water, and unisexual flowers—destitute of calyx and corolla—bursting through a membranous spathe in their margin. The *Lemnaceæ* are distributed throughout all parts of the world. Several species of *D.* are British, and cover the surface of stagnant ponds with green vegetation. Their flowers and fruit are rarely to be seen, but they spread rapidly by new fronds budding from their margins.

**DUCTILITY** is that property of bodies by which they are capable of being drawn out in length, while diminishing in breadth, without fracture or separation of their parts. Ductility is peculiarly noticeable in the case of metals. It is possessed also by gums, ghes, resins, and some other bodies, which, when softened by water or heat, may be drawn into threads. Clays, when moistened, become ductile. Metals are ductile, generally speaking, at any temperature, but their ductility is much influenced by temperature; some—brass, for example—are more ductile at ordinary temperatures than when hot. Metals are ductile nearly in the order of their Malleability (q. v.), the order of their ductility being as follows, beginning with the highest: gold, silver, platinum, iron, copper, zinc, tin, lead, nickel, palladium, cadmium. Some, however, as iron, are more ductile than malleable. The ductility of gold and glass is surprising; see article **DIVISIBILITY** for an account of the fineness to which gold-gilt silver wire and glass tubes have been drawn. The ductility of glass at red heat seems to have no limit; at high temperatures, this brittle substance may be drawn into threads finer than any hair, and of the highest flexibility. Its flexibility, indeed, according to some, increases in proportion to the fineness to which its threads are drawn, and it is conceived to be possible that we may yet convert glass into cloths for wearing apparel.

**DU DEFFAND, MARIE DE VICHY CHAMBROND, MARQUISE**, a celebrated Frenchwoman, was born of a noble family of Burgundy in 1697, and educated at the convent of La Madeleine de Trenchelle, in Paris. Here she manifested that boldness of opinion and vivacity of intellect which obtained for her so many distinguished admirers in after-years. Her parents, alarmed at her scepticism, sent the eloquent Massillon to converse with her, who was, however, more struck with the wit and beauty of the young lady, than she was with the force of his arguments. In 1718, she married the Marquis Du Deffand. The union was unhappy, and a separation took place, whereupon the Marquise threw herself into all the excesses of gallantry which characterised French society in the 18th c., and had the name of being, for a time, the mistress of the Regent. Subsequently, a reconciliation took place between her and her husband, but it lasted only a short period. She then set up an establishment of her own, and gathered round her all

the wits, philosophers, and men of fashion in her day. Among her friends and correspondents may be mentioned D'Alembert, Voltaire, President Hénault, Montesquieu, Marmontel, and Walpole. Her evening-parties at her residence in the Rue St Dominique were famous. They formed a rendezvous for all the notabilities of Paris, and were much relished by distinguished foreigners visiting the city. In 1753, she became blind, and in the following year chose as companion and reader a young lady, Mademoiselle de l'Espinasse, of whom, however, she became very jealous, on account of the attentions paid to her by the friends of the marquise. In 1764, the two ladies separated, Mademoiselle de l'Espinasse carrying with her a large number of enthusiastic partisans, who deserted the saloon in the Rue St Dominique, at the head of whom was D'Alembert. The Marquise Du D. died 24th September 1780. Her correspondence with D'Alembert, President Hénault, Montesquieu, and the Duchesse du Maine was published in 1809; and in the following year appeared at London her correspondence with Horace Walpole (written between 1766 and 1780), to which were added her letters to Voltaire.

**DUDEVANT, AMANTINE LUCILE AURORE, MADAME**, a French authoress, who has attained an extraordinary celebrity under the name of **GEORGE SAND**. She was born at Paris in 1804, and is descended by the father's side from the famous Marshal de Saxe. Her maiden name was Dupin. After having received a strict conventual education (1817—1820), she married M. Dudevant in 1822; but in the course of a few years, finding the lack of congeniality of sentiment intolerable, she arranged a separation with her husband in 1831, and repaired to Paris, where at first she was hard pushed to secure a livelihood. Her first literary efforts made their appearance in the *Figaro*. In conjunction with her friend and companion for the time, Jules Sandeau, from whose name she formed her *nom de plume*, she wrote a romance, entitled *Rose et Blanche* (1832), which only occasionally rises above mediocrity, and gave no hint of the splendid ability first fully developed in *Indiana*, published in the same year. This romance, in which a glowing heart, deeply wounded by the pressure of social relations, gives vent to its feelings, excited considerable interest. This was increased to the utmost by the succeeding romances—*Valentine* (1832), *Léon* (1833), *Jacques* (1834), *André* (1835), *Leone Leoni* (1835), and *Simon* (1836). During the next two years, she published a great variety of works, in which she shewed herself to be deeply influenced by the age in which she was living. In addition to her purely imaginative productions, Madame D. found time to contribute miscellaneous essays and political articles to the journal entitled *Le Monde*, so long as it was edited by Lammenais. She was much occupied at this time with philosophical and theological speculations, and their influence may be traced in the *Spiritism* (1839), and the extraordinary piece of prose poetry, entitled *Les Sept Cordes de la Lyre* (1840). She cherished, moreover, republican ideas of the wildest nature, which appeared conspicuously in the *Compagnon du Tour de France* (1840), and in *Pauline*. Her brilliant literary success having now placed her in comfortable circumstances, she obtained a legal divorce from her husband, and thus secured possession of a portion of the property which she had brought to him as her dowry. She now occupied herself with the education of her two children, and spent her time, sometimes in Paris, sometimes at her estate in Berri, where she had passed her childhood, or in journeys into Switzerland and Italy. A dispute with

the editors of the *Revue des Deux Mondes*, which, from 1833 to 1841, had regularly published her works in chapters before they appeared in a separate form, induced her to start the *Revue Indépendante*, in conjunction with P. Leroux and Viardot. For this new review, she wrote *Horace, Consuelo*—her best known, and probably her finest work—and *La Comtesse de Rudolstadt* (1842—1843), three romances deeply imbued with democratic feelings and sentiments, which are apparent likewise in *Jeanne* (1844), and which in the *Ménier d'Angibault* (1845), becomes altogether socialistic. It would be impossible to enumerate the works which flowed from her rapid pen between this period and the revolution of 1848. It is sufficient to say that her socialistic sympathies predominate in all of them; but if the logic is not convincing, the vigour and purity of her imagination are undeniable. This is always the case with Madame Dudevant. Even those who disapprove of her exaggerated and one-sided ideas and views of life, must admire the perfect form, the captivating style, the plastic finish, and the great affluence of thought and sentiment displayed in all her productions. Her finest romances are *Valentine*, *André*, and, in particular parts, *Consuelo*. Of her smaller pieces, *La Mare au Diable* is a master-piece of its kind, and indeed, considered from an æsthetic point of view, is, with respect to plan and execution, the most complete production of her pen. After the revolution of February, Madame D. for a short time wasted her talents on the barren politics of the day; since then, she has devoted herself chiefly to the stage, without achieving any great success, mainly, however, on account of the excess of the lyrical over the dramatic in her genius. In 1854, she commenced in the *Presse*, *Histoire de Ma Vie*, which is not yet finished.

DUDLEY, a parliamentary borough in a detached part of Worcestershire, in the south of Staffordshire, 26 miles north-north-east of Worcester, and 8½ miles west-north-west of Birmingham. It is a well-built town, and a chief seat of the iron trade. On the north-east of the town are the beautiful ruins of an old castle, founded in 760 by Dodo, a Saxon prince. It was demolished in the time of the civil wars of Charles I., was rebuilt, but was afterwards burned down in 1750. In the vicinity are iron and coal mines, and limestone quarries. The limestone is Silurian and full of organic remains; it is wrought out of caverns, and brought to the kilns through a tunnel one mile and three-quarters long, which is carried through the basalt of the Castle Hill. Saline springs occur near. The chief manufactures are fire-irons, grates, nails, vices, chain-cables, other iron utensils, and glass. Pop. (1861) 44,975. D. sends one member to parliament. The living is a vicarage in the gift of the Earl of Dudley, and valued at £1000 per annum. (1871—pop. parl. b. 82,247.)

DUDLEY LIMESTONE, a highly fossiliferous Silurian limestone belonging to the Wenlock Series (q. v.), which forms some of the most picturesque eminences around the town of Dudley. The masses of corals, shells, and trilobites which abound in this rock, form, when weathered, extremely beautiful cabinet specimens.

DUDLEY LOCUST, the popular name for a trilobite (*Calyptina Blumenbachii*, q. v.), which is very abundant in the Dudley limestone.

DUEL (Fr. *duel*, Lat. *duellum* or *duellum*, which, as Cicero remarks [*Orat.* 45], was the old form of *bellum*, war), a combat between two persons, at a time and place indicated in the challenge, cartel, or defiance borne by one party to the other. A duel generally takes place in the presence of witnesses, called seconds, who regulate the mode

of fighting, place the weapons in the hands of the combatants, and enforce compliance with the rules which they have laid down.

No trace of the duel, as an institution, is to be found in the history of the classical nations of antiquity, the Latin word from which ours is derived having been used to signify a war between two nations. So long as men continued to be barbarians, their personal quarrels were no doubt decided in the ancient, as national quarrels still are in the modern world, by an appeal to physical force. But though war has been in all times the practical solution of strife, it was not till the middle ages that it came to be regarded as a means, in any sense judicial, of settling disputes. Hitherto, it had determined who was able to prevail, justice being set aside, but it was a new view that it would determine who ought to prevail on the principles of justice. The rationale of the *judicial combat* or wager of battle was probably twofold. On the one hand, and generally amongst the people, it depended on a belief that God would interfere directly and miraculously in the conflict to protect the innocent, and to punish the guilty, and that thus the weakest combatant who had God on his side would prove more than a match for the strongest, when destitute of His aid. But there was a view of the matter which was not so directly superstitious, and which rested rather on a confusion between the principle of the original constitution and the principle of the transmission of rights. All human rights originate in the powers and faculties which God has given to man, and it was supposed that as the right originated in power, its continued existence in the individual could be ascertained by ascertaining whether the power still existed in him. The error consisted, as we have said, in confounding the principle of the constitution with the principle of the transmission of rights. If a field which was claimed by two competitors had as yet been appropriated to nobody, or had been abandoned, and was, as lawyers say, *res nullius*, the fact of which of the two claimants ought to become the possessor might be ascertained by judicial combat. But if it was already the property of one of them on a title which was to be held sacred, and the question was which of the two had this sacred title, that fact could never be determined by ascertaining which would have been in a condition to constitute it for the first time, had it been non-existent. The principle of the private duel, in so far as it had any principle at all, and was not merely a piece of barbarous and irrational foppery, was precisely the same as that of the judicial combat. But the latter had been applied to a class of cases which admitted of legal investigation and decision, and it was consequently abandoned in the days of Queen Elizabeth; whereas the former was supposed to be a means of redressing wrongs which hardly can come within the cognizance of a human tribunal, and the consequence was that it continued in green observance in this country until recently, and is still in vigour in many continental countries.

Like the other peculiarities of medieval life, the duel probably originated with the Germanic nations. It is said to have been introduced into legal proceedings in lieu of an oath by Gundebald, king of the Burgundians, in 501. Louis le Débonnaire was the first of the French kings who permitted litigants to appeal to arms. The practice was prohibited by Henry II., in consequence of a noted duel which took place in his presence between his friend, Francis de la Chastaignerie, and Guy Chabot de Jarnac, in which the latter was slain. The royal edict, however, was totally ineffectual, and the

practice of private duelling has generally prevailed more extensively in France than in any other country. Francis I. patronised it by declaring that a lie could be borne without satisfaction only by a base-born churl, and still more by the example which he set in challenging his own great rival Charles V. In 1599, the parliament of Paris declared all persons who were either principals or seconds in duels to be rebels to the king. But its efforts were unavailing; and it is said that during the first 18 years of Henry IV., no fewer than 4000 gentlemen perished in this foolish manner. In 1609, Henry added to the existing penalties, introducing even punishment by death in extreme cases. But these regulations were forced upon him by popular feeling; he had himself no aversion to the practice, and when he gave permission to Crequi to fight Don Philip of Savoy, he added: 'If I were not the king, I would be your second.' The consequence of this feeling was, that he readily granted pardons to those who had violated the laws which he had been forced to enact, and these laws not unreasonably produced an effect the very reverse of their ostensible object. Duelling acquired the charm of what the French call 'forbidden fruit,' and thus became a fashionable and favourite vice. In the reign of Louis XIII., the custom was so prevalent, that Lord Herbert, the English ambassador, wrote home to his court that there was scarcely a Frenchman worth looking on who had not killed his man. It would not seem, however, that it was from negligence in enforcing the royal edicts that duelling then reached to so alarming a height; for it was during this reign that two noblemen, the greatest duellists of the day, the Comte de Bonteville and the Marquis de Beuron, were tried and beheaded for persisting to fight. In the commencement of the reign of Louis XIV., duels with four or five sides began to be fought; and two very sanguinary affairs of this description having taken place, in which several persons of the highest rank were slain, the king determined to put an end to the practice. He published an edict in 1679, forbidding it under the highest penalties, which, unlike most of his predecessors, he had the firmness to inflict; and this measure, together with a solemn agreement which was entered into amongst the nobility themselves, led at that time to its almost total abolition.

The duel does not seem to have existed in England in Anglo-Saxon times, and was probably introduced at the Conquest. In its judicial form, it was not entirely obsolete in the reign of Queen Elizabeth; and Sir Henry Spelman gives an account of a trial by battle, which terminated, however, without actual combat, in the year 1571. See **BATTEL, TRIAL BY**. Private duelling was common, however, both in Elizabeth's reign and in that of her successor, by whom a severe statute against it was enacted in Scotland (1600 c. 12). During the Civil Wars, men's minds were too much occupied with questions of grave importance to leave time for questions of etiquette, and the duel consequently declined; but it became exceedingly prevalent during the dissolute reign of Charles II. Some attempts were made to suppress it in the reign of William III., both in England and Scotland, and, in 1712, the subject was recommended to the attention of parliament in the Queen's speech. But the bill which was brought in by the government was thrown out, and the practice continued to prevail. When the custom of wearing the sword was abandoned, the number of duels diminished, though it was then that their irrational character may be said to have attained its maximum. The pistol was substituted for the sword, and the doctrine of chance—which was reduced to an absurdity by the medical duel of a couple of pills, one

composed of bread and the other of poison—was inaugurated. Since this period, the practice has fallen into disrepute, by the gradual operation of public opinion, and in this country it may probably be now regarded as finally abolished. By the law of this country, the act of killing in a duel has always been regarded as murder, however fair the duel may have been; but whilst the practice was countenanced by public opinion, it was generally found impossible to induce a jury to convict. That a verdict of acquittal could not be looked for with the same security in the present day, is probably a pretty good guarantee for the practice not again making its appearance even in exceptional instances. In France it still prevails to a certain extent.

The duels of the students at the German universities, of which so much used to be said and written in this country, were nothing more than fencing-matches with sharp weapons. They were foolish, but not deadly affairs, as the seconds, who were also armed, always interfered to prevent serious bloodshed.

In 1844, several new Articles of War were issued by the Commander of the Forces, with a view to the abatement of duelling in the army.

1. Every officer who shall send a challenge, or who shall accept a challenge to fight a duel with another officer, or who, being privy to an intention to fight a duel, shall not take active measures to prevent such duel, or who shall upbraid another for refusing or not giving a challenge, or who shall reject or advise the rejection of a reasonable proposition made for the honourable adjustment of a difference, shall be liable, if convicted before a general court-martial, to be cashiered, or suffer such other punishment as the court may award.

2. In the event of an officer being brought to a court-martial for having acted as a second in a duel, if it appear that such officer exerted himself strenuously to bring about an honourable adjustment of the difference, but failed through the unwillingness of the adverse parties, then such officer is to suffer such punishment as the court shall award.

3. Approbation is expressed of the conduct of those who, having had the misfortune to give offence to, or injure or insult others, shall frankly explain, apologise, or offer redress for the same, or who, having received offence, shall cordially accept frank explanations or apologies for the same; or, if such apologies are refused to be made or accepted, shall submit the matter to the commanding officer; and, lastly, all officers and soldiers are acquitted of disgrace or disadvantage, who, being willing to make or accept such redress, refuse to accept challenges, as they will only have acted as is suitable to the character of honourable men, and have done their duty as good soldiers who subject themselves to discipline.

Partly in consequence of these regulations, but still more as a result of the increasing reason and humanity of English society, the practice of duelling has become almost as entirely obsolete in the British army as it has in the country generally. See **ORDEAL**.

**DUËT**, in Music, a composition for two voices or instruments.

**DUFF, ALEXANDER, D.D.**, who has so thoroughly identified himself with the cause of Indian missions, was born in 1808 at Pitlochry, a village in Perthshire. He studied at the university of St Andrews with great success. In 1829 he resolved to go out to India as a missionary from the Church of Scotland; and in October of that year, having been previously ordained, he set sail from Portsmouth for India. On the passage out, he was wrecked

on a barren island to the north of the Cape of Good Hope, and at length reached his destination after a disastrous voyage of eight months. At the Disruption in 1843, the missionaries in India being obliged to declare with which party they would connect themselves, D. resolved to cast in his lot with the Free Church, and since that date he has carried on with great energy the missionary work at Calcutta under the auspices of that body. In the year 1837, he received the degree of D.D., in acknowledgment of his distinguished services. D. has been twice in his native land since his departure in 1829; on the occasion of his last visit to Scotland, he was appointed Moderator of the General Assembly of the Free Church which met in Edinburgh in May 1851. He is the author of numerous works bearing upon the subject of missions; of these the principal are *New Era of the English Language and Literature* (Edin. 1837); *Missions the Chief End of the Christian Church* (Edin. 1839), *India and Indian Missions* (1839); *The Jesuits, their Origin, &c.* (second edition, 1845); *Missionary Addresses* (1850); *The Indian Rebellion, its Causes and Results* (1858). *The Calcutta Review*, a periodical of great ability, was established mainly through the exertions of Dr Duff.

DUFRESNE, CHARLES, SEIGNEUR DU CANGE, hence generally styled merely DUCANGE, a French author, distinguished by his historical and linguistic writings, belonged to an ancient family of Picardy, and was born at Amiens, 18th December 1610. After having received the rudiments of a scientific education at the Jesuits' College in his native town, he studied law at Orleans, and in 1631 became parliamentary advocate at Paris, where he continued to reside till his death, 23d October 1688. There was scarcely any branch of science with which he was unacquainted, but his favourite studies were classical philology and history. Among his historical works may be mentioned the *Histoire de l'Empire de Constantinople sous les Empereurs François* (Paris, 1657). He also edited, along with other scholars, the *Corpus Historiæ Byzantinæ* (Paris, 1650), and Joinville's *Histoire de Saint Louis, Roi de France*. His two principal works, however, are the *Glossarium ad Scriptores Mediæ et Infimæ Latinitatis* (3 vols. fol., Paris, 1678; much enlarged by the Benedictines of St Maur, 6 vols. fol., Paris, 1733—1736, to which four supplementary volumes were afterwards added by Carpentier, a Benedictine), and the *Glossarium ad Scriptores Mediæ et Infimæ Græcitatatis* (Paris, 1688). Both works display great learning, good judgment, and admirable industry, and are extremely valuable contributions to the study of the history and antiquities of the middle ages. A new edition of the Latin Glossary, incorporating all the previous supplements, together with additions of his own, was published by G. A. Henschel (7 vols. 4to, Paris, 1842—1853); and a supplementary volume (*Latino-Germanicum*) has since been added by Diefenbach (Francf. 1857). D. left a large quantity of valuable manuscripts, which have been collected in the Imperial Library at Paris.

DUGDALE, SIR WILLIAM, a celebrated antiquary and historian, was born in 1605 at Shustoke, near Coleshill, Warwickshire. He was educated for some time at the free school of Coventry, but left it at the age of 15, and continued his studies under the care of his father, who, having a decided predilection for the branches of civil law and history, seems to have encouraged similar tastes in his son. His antiquarian pursuits led to his being created (1638) a pursuivant-at-arms extraordinary by the name of Blanche Lyon; and shortly

afterwards, he was made Rouge Croix pursuivant-in-ordinary. During the civil war, D. adhered to the royal cause, and lived for several years in Oxford, employed in researches for his great works. On the restoration, D. was made Norroy King of Arms, and in 1677 Garter King of Arms; at the same time, the king, much against the wishes of D., whose estate was but a poor one, conferred upon him the honour of knighthood. He died at his estate of Blythe Hall, February 10, 1686. His chief works are *Monasticon Anglicanum* (Lond. 1655—1661—1673), (which, though for the most part written by another antiquary, named Dodsworth, was concluded, arranged, indexed, and corrected by D.); a new and greatly enlarged edition of the *Monasticon* by Bandinel, Caley, and Ellis, was published in 1817—1830, and re-issued in 1846; *The Antiquities of Warwickshire* (1656; second edition revised and continued, 1730); *The Baronage of England* (1675—1676); *Origines Juridicæ, or Historical Memoirs of the English Laws, &c.* (1666; 3d edit. 1680); *Short View of the Late Troubles in England* (Oxford, 1681); *The Ancient Usage in Bearing Arms* (1682; new edition, 1811). D. bequeathed upwards of 27 folio MS. volumes, written in his own hand, to the university of Oxford. They are now in the Bodleian Library, the Herald's College, and the Ashmolean Museum.

DUGONG (*Halicore*), a genus of mammalia, of the family *Manatide* (q. v.), or Herbivorous Cetacea, distinguished by molar teeth with flat summits, and composed of two cones laterally united, the incisors of the upper jaw elongated almost into tusks; the tail forked or crescent-shaped; and the swimming paws destitute of any vestiges of nails. One species alone has been thoroughly ascertained and accurately described. The D. (*H. Indicus*, or *H. Dugong*) of the

Dugong (*Halicore Indicus*).

Indian Archipelago is said to attain a length of 20 feet when full grown, although it is more frequently seen of only 8 to 12 feet long. In general form, it much resembles the manatee. The skull is remarkable for the sudden bending downwards of the upper jaw almost at a right angle. The upper lip is large, thick, and fleshy, covering the prominent incisors, and forming a kind of snout, 'something like the trunk of the elephant cut short across.' The eyes are very small, and are furnished with a third eyelid or *nictitating membrane*. The skin is smooth and thick, but yields no oil. The anatomy of the D. has been very carefully examined. It exhibits a very remarkable peculiarity, in the ventricles of the heart being completely detached from one another. Its osteology has been found to exhibit interesting points of correspondence with that of the *Pachydermata*, as in the numerous ribs, &c.; its dentition resembles in some particulars that of the elephant; its digestive apparatus is adapted to vegetable food,

differing very much from that of the whales, dolphins, and other ordinary cetaceans. It feeds on the algae which grow on submarine rocks in shallow seas. Its lips are of much use in gathering together its food. It often comes to the surface to breathe, and is said to utter a peculiar cry. It is gregarious. The female produces one young one at a birth, and shews an affection for it which is proverbial among the Malays. When the young one is taken, the mother is easily secured. The D. is generally pursued in boats, and killed by spearing. The flesh is highly esteemed even by Europeans, and is described as resembling young beef. That of full-grown animals is, however, comparatively coarse, on which account, and the greater facility of capture, the younger ones are more frequently killed. According to Ruppell, it was with the skin of the D. of the Red Sea that the Jews were directed to veil the tabernacle.

**DUGUAY TROUIN, RENÉ**, one of the most celebrated naval officers of France, was born 10th June 1673, at St Malo, left the school at Caen, where he was to have studied theology, with the reputation of a good-for-nothing fellow, and betook himself to the sea. His career, which was very brilliant, may be divided into two parts, the first extending from 1689 to 1697, and the second from 1697 to the close of his life. During the former, he cruised about as a sort of privateer, inflicting immense damage on the enemies of France. The English merchantmen suffered severely from his attacks. In the Channel, on the coasts of Ireland and Holland, in the Spanish Main, everywhere fortune followed Duguay. Louis XIV., as a reward for his daring exploits, admitted him into the state navy, and gave him the command of a frigate. The second part of his career was as brilliant as the first. In 1707, he engaged a part of the English fleet at the entrance of the Channel, burned one ship, captured three others, and about 60 transports; but the most glorious of his triumphs was the attack and capture of Rio Janeiro in 1711, after hostilities had lasted for eleven days. The city was ransomed for 610,000 cruzades. The South American expedition of D. T., which cost Portugal in all about 30,000,000 francs, put the seal to the celebrity of the French commander. He was successively named *chef d'escadre*, member of the council of the Indies, lieutenant-general, and naval commandant at Brest. In 1731, Louis XV. sent D. T. into the Levant, to chastise the barbarians inhabiting the neighbouring coasts, and to obtain reparation for the damages done to French commerce. In this also D. T. was successful. He died 27th September 1736. His *Mémoires* were published by Beauchamps (4 vols., Paris, 1740).

**DUIDA**, a mountain of Venezuela, in South America, stands in lat. 3° 30' N., and long. 66° 10' W. It is of conspicuous form, being perpendicular on two sides, and bare at the summit. Rising, moreover, to the height of 8500 feet, it forms a safe landmark for the voyager on the Orinoco.

**DUISBURG**, a town of Rhenish Prussia, about 15 miles north of Düsseldorf, is situated in a fertile district, between the Ruhr and the Rhine, which unite about three miles below this town. It is surrounded partly by walls, flanked with towers, which are now somewhat decayed, and partly by a rampart and ditches. D. contains a gymnasium founded in 1599, a monastery of Minorites, and five churches, two of which—that of St John the Baptist, dating from 1187, and St Salvador's, a handsome specimen of the architecture of the 15th c.—are worthy of notice. The manufactures of D. consist chiefly of cotton cloths, hosiery, glue, soap, starch, and leather; there is also a large trade in wine and

colonial produce, grain, and cattle. In the neighbourhood are ironworks. Pop. 11,629. D. is an ancient town. In the 13th c., it was a member of the Hansatic League, and afterwards a free town of the German empire, but at the close of the war in 1815 it was handed over to Prussia.

**DUKE** (Fr. *duc*, Lat. *dux*, from *ducere*, to lead), a term applied originally to any military leader. Gibbon informs us that the title came first into use when Constantine separated the civil and the military commands in the provinces, which had been exercised in common by such men as Agricola. From that time forth, the military governors of provinces were either counts or dukes. But these titles originally stood to each other in an opposite relation to that which they afterwards assumed. 'It should be recollected,' says Gibbon (iii. 57, cap. xvii.), 'that the second of these appellations—that of duke—is only a corruption of the Latin word, which was indiscriminately applied to any military chief. All provincial generals were therefore *dukes*, but no more than ten among them were dignified with the rank of *counts*, or companions, a title of honour, or rather of favour, which had been recently invented in the court of Constantine.' See COUNT. 'A gold belt,' continues Gibbon, 'was the ensign which distinguished the office of the counts and dukes; and, besides their pay, they received a liberal allowance, sufficient to maintain 100 servants and 150 horses. They were strictly prohibited from interfering in any matter which related to the administration of justice or the revenue; and the command which they exercised over the troops of their department, was independent of the authority of the magistrates.' When the Goths, and Franks, and other barbarians successfully invaded the provinces of the empire, they preserved the titles of count and duke, if they had not already borrowed them from the Romans. But amongst races who owed their supremacy to the sword, no dignity could prevail over that of the commander of an army; and the dukes, as military chiefs, acquired a marked pre-eminence over the counts, whose lofty functions under the empire had been partly of a civil, and partly of a military nature. The only exception under the first Merovingians was in the case of the Count of the Palace. See COUNT. In the hierarchy observed by the Franks and other Teutonic races, the ordinary count became the lieutenant of the duke, and the government of the latter extended to several provinces; whereas that of the former was confined to one province, or even to a single locality. The power of the dukes grew so rapidly, in consequence of the dissensions of the Merovingians, that, towards the end of the sixth c. (582), they arrogated to themselves the right to dispose of the crown. Amongst the causes which tended to raise the power of the dukes, was the immense wealth which had been acquired by the great provincial families. The chiefs who had attached themselves to the fortunes of Clovis had been richly endowed with conquered lands. After the close of the 7th c., they overshadowed the crown, and the title of prince and chief (*chef*) began to be attributed to them. It has been said that the *ducs-maires* of the palace sometimes assumed the title of Archduke (q.v.). Under the second dynasty, the title of duke retained all its dignity and importance, and it was to the successive invasions of local upon central power, that feudality owed its origin. The concession, tacit or express, of hereditary power and independent jurisdiction, first to the central province known as the Isle of France, and then to Aquitaine, extended itself, under the Carolingians, to Burgundy, Normandy, and Gascony; and on the accession of Hugo Capet, to all the other subaltern tenures. Once

become unlimited masters of their respective legations, the dukes did not long delay to proclaim their title to be as good as that of the king. They assumed the crown and the sceptre, promulgated laws for their subjects, struck money with their own image, and made war in their own name against the crown, with whom they balanced and several times divided the supreme authority. The confederation of the feudal lords had assumed such dimensions, that about the period of the Norman invasion of England nothing remained directly under the crown except a few towns, of which Rheims and Laon were the chief. The rest of the kingdom was divided amongst the dukes and the counts, under an obligation, which they almost always evaded, of service and fidelity to the crown. But the Capetians had been enlightened by the fall of two dynasties, and were careful to delegate to no other hands the duchy of the Isle of France, which had so often been a stepping-stone to the throne. When it became extinct in 887, it was not re-established, and that event was the signal for the restoration of a national character to France. The duchy of Gascony was joined to Aquitaine in 1052; and both provinces, along with Normandy, were finally re-united to the crown, in 1204, by confiscation. This latter duchy was sometimes given to princes of the blood, but without any separation of its fiscal arrangements from those of the kingdom. A part of Aquitaine was given up to England in 1259, and again ceded to France in 1453. The ducal sovereignty of Burgundy was extinguished in 1477, that of Brittany in 1514, of Narbonne in 1229, and of Toulouse in 1361.

The duchies which were subsequently granted to members of the royal family—that of Bourbon, erected in 1327; of Orleans, in 1344; of Auvergne, Berri, Touraine, Valois, and Alençon, at subsequent periods—enjoyed none of the privileges of independent sovereignty which had belonged to the ancient duchies. The subordination of these fiefs was absolute, and the princes who governed them, though placed on the steps of the throne, were only the first subjects of the realm. The tendency to diminish the actual power which anciently had attached to the ducal title, was still more apparent in the case of those dukedoms which were conferred on the representatives of illustrious noble families. The Montmorencies were created dukes in 1551, but they enjoyed no other privileges than those of titled nobles, and their position had no analogy whatever to that of the old provincial dukes. The duke-peers, as they were called, were simply the first class of nobles in France, just as dukes are with us in England; but they differed from English dukes, in that, after the extinction of the Comté pairie d'Eu, in 1775, the duke-peers alone sat in parliament. Several prelates enjoyed this rank—as, for example, the Archbishop-duke of Rheims, the Bishop-duke of Laon, and the Bishop-duke of Langres. The Archbishop of Paris took the same rank after the erection of St Cloud into a ducal peerage in 1674. There were still two other sorts of dukes in France—the dukes who were not hereditary peers, and the dukes for life, or patent dukes, who date only from the reign of Louis XIV. Swept away by the Revolution, the title was restored by Napoleon, who conferred it, with rich endowments, on his marshals. Several ducal peers were created by Louis XVIII. and Charles X.

In Germany, the dukedom passed through phases very similar to those which it exhibited in the earlier history of France. What is special to the position of the nobility of that country, will be stated under Graf (q. v.).

Dukes, in the older European sense, do not appear

ever to have existed in England. The title seems not to have been known earlier than the reign of Edward III., and from the first it was a mere honorary distinction. The Black Prince, who was created Duke of Cornwall (see below) in 1335, was the first English duke. In 1350, Henry, the king's cousin, was created Duke of Lancaster; and when he died, and his daughter was married to John of Gaunt, the king's son, the title was transferred to him—his elder brother, Lionel, being made Duke of Clarence. In the succeeding reign—that of Richard II.—the two younger sons of Edward III. were created, the one Duke of York, and the other Duke of Gloucester. The dignity was thus, in the first instance, confined to the royal house. But the families of Holland and Mowbray very soon received the same title; and one of the Beauforts, an illegitimate son of John of Gaunt, was raised to the peerage by the title of Duke of Exeter. In the reign of Henry VI., the title was granted more widely, and there were at one time ten duchesses in his court. The Staffords, Beauchamps, and De la Poles, belong to this period. King Henry VIII. created only two dukes—the one was his illegitimate son, whom he made Duke of Richmond; and the other Charles Brandon, who married his sister, the French queen, and was made Duke of Suffolk. Queen Elizabeth found only one duke when she came to the throne—Thomas Howard, Duke of Norfolk—attainder or failure of male issue having extinguished the rest of them. After the attainder and execution of the Duke of Norfolk, there was no duke in England, except the king's sons, till Ludovic Stuart, a relative of the king's, was made Duke of Richmond in 1623. In 1623, Villiers was made Duke of Buckingham. On the Restoration, Charles II. restored the Seymours to the rank of Dukes of Somerset, and created Monk Duke of Albemarle. But the habit of conferring this dignity on the illegitimate sons of the monarch was still adhered to, as in the case of the Duke of Monmouth, who was the illegitimate son of Charles II.; and the Duke of Berwick, of James II. Of the existing dukes besides the descendants of Charles II., there are only three families which date their dukedoms before the Revolution—viz., the Howards, the Seymours, and the Somersets. It was William and Anne who, by advancing a very considerable number of the first families of peers to the rank of duke, altogether changed its character. There are now 21 English dukes, 7 Scottish, and 1 Irish. The limitation in the patents of dukes is generally to heirs-male of the body.

The DUCAL CORONET is composed of a circle of gold, with eight strawberry or parsley leaves, of equal height above the rim.

DUKE OF CORNWALL. The duchy of Cornwall was by royal charter of Edward III. conferred on his son Edward the Black Prince. King Henry IV. subsequently included the D. of C. in a patent in favour of his son Henry Prince of Wales. But since that time, the duchy has belonged of right, without any special grant, to the king's heir-apparent from the time of his birth. On the death of the king's eldest son without issue, during the life of his father, the duchy descends to the next brother. In the event of the death of the heir-apparent without issue, and without leaving a younger brother, or in case of the heir-apparent succeeding to the crown, the duchy of Cornwall merges in the crown until the birth of a son calls it again into existence. The uncertainty thus arising in regard to the duchy has produced much confusion in regard to leases held of the duke, and

various acts of parliament have been passed, from the 21 James I. to the reign of the present Queen, to regulate this matter. The D. of C. formerly possessed 'royal jurisdiction and crown rights, giving liberty to send burgesses to parliament, and appointing the sheriffs, admirals, and other officers.'—Carew's *Cornwall*. At the present day, there is a separate chancellor, and attorney and solicitor general for the D. of Cornwall. The revenues of the duchy are considerable, arising partly from the rents, &c., of the different manors, and partly from the dues on tin, which is produced in large quantities from the Cornish mines. There is a special court for the settlement of questions arising among the miners, called the Stannaries Court (q. v.).

**DUKE OF EXETER'S DAUGHTER**, an instrument of torture resembling a rack, said to have been invented by the Dukes of Exeter and Suffolk during the reign of Henry VI. This curious instrument was for some time preserved in the Tower of London. Blackstone avers that it was never put into use.—*Blackstone*, iv. 326.

**DUKE OF YORK'S SCHOOL** is the popular designation for the *Royal Military Asylum* at Chelsea. In the French army, there have long been *civans de troupe* borne on the books of each company or battalion of soldiers; that is, children of deceased soldiers, unprovided with other homes. In England, no such system prevails. The late Duke of York, about the year 1800, used his influence to obtain the formation of a soldiers' orphan asylum. Accommodation was obtained at Chelsea; and in 1803, schools were opened for 700 boys and 300 girls, children of deceased soldiers. The institution has been maintained ever since, under certain alterations of plan. The boys are wholly supported as well as educated. They are not bound to serve the state after they leave the asylum; but most of them nevertheless enter the army. A soldier's son has not a *right* of admission; a selection is made according as vacancies may occur. When the boys leave the school, those who do not enter the army are apprenticed to trades. The asylum is under a board of commissioners, who make the necessary rules and regulations. The chief officers are the commandant, secretary, quarter-master, head-master, chaplain, surgeon, and dispenser.

The current expenses are defrayed by an annual parliamentary grant, included in the Army Estimates.

It may here be stated that no provision is now made by the state for the *daughters* of deceased soldiers. The girls admitted into the asylum in the early years of its history, brought discredit to it by their after-life; and this part of the system was abandoned. There is only a private institution, situated near Hampstead, unaided by the state, for receiving soldiers' orphan daughters; it originated during the Crimean war.

**DUKINFIELD**, a township in the north-east of Cheshire, 42 miles from Chester, and separated from Ashton-under-Line in Lancashire by the river Tame. It has extensive cotton-factories, iron-foundries, fire-brick and tile works, and collieries. Astley's New Pit in this township is the deepest coal-mine in the world, being 690 yards from the surface. Pop. (1861) 29,949.

**DULCIGNO**, a town and seaport of European Turkey, province of Albania, is situated on the shore of the Adriatic, 15 miles west-south-west of Scutari. The inhabitants were long notorious for piracy, but are now more creditably engaged in the oil and coasting trade. D. is the seat of a Catholic bishop. Pop. about 7000.

**DULCIMER**, a musical instrument somewhat resembling a flat box, with sounding-board and bridges, strung with thin wire, and played on by striking the wires with a small piece of wood in each hand.

**DULCOSE**, or **DULCINE**, is a substance closely allied to manna-sugar or mannite, and imported from Madagascar. It consists of  $C_6H_7O_6$ , or  $C_{12}H_{14}O_{12}$ , is insoluble in boiling alcohol, and does not undergo fermentation.

**DULSE** (*Rhodomenia palmata*), a sea-weed, one of the **CERAMIACEÆ** (q. v.), growing on rocks in the sea, and used as food by the poor on the coasts of Scotland, Ireland, and other northern countries, and of the Grecian Archipelago, occasionally also as a luxury by some of the wealthier classes who have acquired a taste for it. It has a purple, leathery, or somewhat membranous, veinless, sessile frond, irregularly cut, with repeatedly forked segments, which are either entire at the edges, or furnished with lateral leaflets, the spores distributed in cloud-like spots over the whole frond. Its smell somewhat resembles that of violets. It is eaten raw or roasted, and with vinegar. In Iceland, it is sometimes boiled in milk. It is an important plant to the Icelanders, and after being washed and dried, is stored in casks, to be eaten with fish. In Kamtschatka, a fermented liquor is made from it. It is extremely common on all parts of the British coasts. Sheep are fond of it, and seek it eagerly at low water.—The cry 'Dulse and tangle' was once common in Edinburgh.—The name Dulse is also given in the south-west of England to another seaweed, *Iridaea edulis*, also one of the *Ceramiaceæ*, which has an undivided, obovate or wedge-shaped, flat, expanded frond, very succulent, tapering to a short stalk, and of a dull purple colour. It is occasionally employed as food both in the south-west of England and in Scotland, and is either eaten raw or pinched between hot irons.—**PEPPER DULSE** (*Laurentia pinnatifida*), another of the *Ceramiaceæ*, has a compressed cartilaginous frond, twice or thrice pinnatifid. It has a pungent taste, and is used as a condiment when other sea-weeds are eaten.

**DULWICH**, a suburb of London, in the north-east of Surrey, four and a half miles south-south-east of St Paul's Cathedral, and near Sydenham. Pop. (1861) 1723. It is a fine rural spot, has many genteel residences, and is noted for its college and picture-gallery.

**DULWICH COLLEGE**, or God's Gift, was founded in 1619 by Edward Alleyne, a tragic actor. The building consists of three sides of a quadrangle, and has attached a manor of 1400 acres. Its revenue in 1860 amounted to £12,000, and it maintains a head-master, several under-masters, a chaplain, six poor brethren, six poor sisters, twelve poor scholars, and thirty out-members. The picture-gallery, of choice old Italian, Flemish, and other paintings, was left to the college in 1811 by Sir F. Bourgeois, and is much visited.

**DUMANGAS**, a town in the province of Iloilo, island of Panay, one of the Philippines. It is situated not far from the sea-coast, near the river Jalaur. The vast plain of D. produces abundance of rice. Pop. of town, 25,000. See Sir J. Bowring's *Visit to the Philippine Islands* (Lond. 1859).

**DUMAS, ALEXANDRE**, a French novelist, is the son of the republican general, Alexandre Davy-Dumas, who was himself the offspring of the Marquis Davy de la Pailleterie and a negress. The crisp hair and thick lips of D. bear testimony to his African origin, a testimony which is confirmed by the savage voluptuousness and barbaric taste of his partial innumerable compositions. D. was born at Villers-Cotterets, 24th July 1803.

His father died when he was quite a child, and he received in consequence a very imperfect education. At the age of twenty, he came to Paris to seek his fortune, and after a short time received an appointment in the household of the Duc d'Orleans. In 1826, he first appeared as an author in a volume of *Nouvelles*; but it was not till 1829, when his historical drama, *Henri III. et sa Cour*, was brought upon the stage, that France fairly mistook him for a genius. This work appeared at the time when *Romanticism* was beginning to triumph over *Classicism* in French poetic literature, and was hailed by the advocates of the former as a crowning victory. The Duc d'Orleans, who was delighted with the production, led the applause, on the first night of its representation, in honour of the author. Next morning, D. was made librarian to his Highness. From this period, he became more and more a noted character in Paris, dexterously contriving at once to feast the appetites of the mob, and to continue the companion of princes. In 1846, he accompanied the Duc de Montpensier to Spain, as the historiographer of his marriage. Afterwards, he visited Africa; and on his return to Paris, finding his income inadequate to meet the expenses of his costly mode of life, he opened a theatre of his own. The revolution induced him to attempt a political career; but France, in spite of its discreditable admiration of this literary Cagliostro, had sufficient good sense to turn the cold shoulder to him. In 1853, 'financial considerations' compelled him to seek refuge in Belgium. Subsequently, his pecuniary star being once more in the ascendant, D. visited the East. After the conquest of Sicily by Garibaldi in 1860, he followed in the wake of the great Liberator, who does not seem, however, to have been imposed upon by his mountebank worship and bombastic enthusiasm.

It would require pages to enumerate all the productions which have been issued under the name of D.; but for two reasons, this is unnecessary: first, they are for the most part worthless, and second, they are for the most part not his. M. Alphonse Karr, in his *Mercantilisme Litteraire* (1845), and M. Eugène de Mircourt, in his *Fabrique de Romans, Maison A. Dumas et Cie* (1845), have exposed the astounding quackery of this writer. It would seem that D. has introduced the *sweating-system* into literature, for he has, or rather had, in his employment a large number of poor authors and literary hacks, whose circumstances or position hindered them from demanding a legitimate emolument for their labour. To these persons, D. was in the habit of giving a few brief outlines of a novel or drama, and then paid them for composing the work, which appeared as the production of D.'s miraculous pen. Thus it happened that D. sometimes contrived to issue more volumes in a year than it was possible for a human being to transcribe in the same period. His best known works are *Les Trois Mousquetaires* (8 vols., 1844), *Le Comte de Monte-Cristo* (12 vols., 1841—1845), *La Reine Margot* (6 vols., 1845). His *Mémoires*, commenced in 1852, only confirm the impression of his character which one derives from the perusal of his books. Altogether, it may be said that the appearance in literature of a writer like D. is a portentous phenomenon; and the avidity with which his immoral fictions are devoured, is the most severe condemnation of modern, and especially French, society that could well be pronounced. (He died 5th Dec. 1870.)—DUMAS, ALEXANDRE, or Dumas the Younger, son of the preceding, who has unhappily followed in the footsteps of his father, was born at Paris, 28th July 1824. His principal work is *La Dame aux Camélias* (2 vols., 1848), a novel on which is founded the notorious opera of

*La Traviata*. It is perhaps the most audaciously immoral work in existence. The heroine is a prostitute, who, while following her avocation, contrives (in a manner known only to French novelists) to keep up a pure and unsullied affection for a young gentleman, who is a compound of sentimentalism, imbecility, and lust. Among D.'s other works may be mentioned *Le Roman d'une Femme* (1849), *Diane de Lys* (1851), *La Dame aux Perles* (1854), and *La Vie à l'ingt Ans* (1856).

DUMAS, JEAN BAPTISTE, a distinguished French chemist, was born at Alais, in the department of Gard, in 1800. He was at first apprentice to an apothecary in Geneva, and engaged in some scientific investigations that attracted the attention of Decandolle and Prévost. In 1821, he came to Paris, and was appointed chemical *répétiteur* (tutor) in the Polytechnic School, and then professor of chemistry in the Athenæum. He was afterwards removed to the Sorbonne, and made a member of the Institute. His researches in organic chemistry, on atomic weights, sulphuric ether, and the law of 'substitutions,' attracted attention over all Europe. D. is not merely an expert chemist, but an able and bold thinker, and eloquent expounder, who has the art of making science attractive, and of captivating his hearers. During the July monarchy, he was a member of the Council of Education. After the revolution of February, he was chosen a member of the Legislative Assembly; and from 1849 to 1851, he held the portfolio of Agriculture and Commerce. After the *coup d'état*, he was made a member of the Senate and of the Superior Council of Public Instruction, of which he is at present vice-president. Numerous contributions from his pen are contained in the *Annales de l'Industrie* and other scientific journals, and in the *Mémoires de l'Académie*. His chief work is *Traité de Chimie appliquée aux Arts* (8 vols., Paris, 1828—1845). He has also published *Leçons sur la Philosophie Chimique* (Paris, 1837); *Essai sur la Statique Chimique des Êtres Organisés* (Paris, 1841; 2d ed., 1843), &c.

DUMB. See DEAF AND DUMB.

DUMB CANE (*Dieffenbachia seguina*, formerly called *Arum seguinum* and *Caladium seguinum*), a plant of the natural order *Araceæ*, remarkably differing from the plants of that order generally in its almost arborescent character, but agreeing with them in its acidity, which is in none of them more highly developed. It has a cylindrical stem, with ringed scars and oblongo-ovate leaves. It is a native of the West Indies, and has received its English name from the property which it has of producing dumbness when chewed, its acrid poisonous juice causing an immediate swelling of the tongue, accompanied with excruciating pain. The juice is, however, sometimes used to effect the granulation of sugar. A decoction of the stem is used as a bath and fomentation in dropsy, and the root-stock is used in obstinate constipation.

DUMBAR'TON, a royal, parliamentary, and municipal burgh, seaport, and chief town of Dumbarton county, is situated on the left bank of the Leven, near its junction with the Clyde, and 15 miles west-north-west of Glasgow. It is well built, and chiefly consists of a long irregular and semicircular street, parallel to the river. The chief branches of industry carried on in the town of D. are ship-building, machine-making, and rope-works, print and bleach works, and salmon-fisheries. It has regular steam-communication with Glasgow, Greenock, and Loch Long. Pop. (1861) 8253. It unites with Kilmarnock, Renfrew, Rutherglen, and Port Glasgow in sending one member

to parliament. D. is supposed to have been the Roman station Theodosia, and the capital of the kingdom of the Britons, on the vale of the Clyde. Alexander II., in 1222, made it a royal burgh. To the east of the alluvial plain at the mouth of the Leven stands the famous and picturesque castle of Dumbarton, on a steep, rugged, basaltic rock, rising to the height of 560 feet, a mile in circuit at the base, and forming nearly an island at high water. The rock almost hides the town of D. from the Clyde. The fortress, composed of houses and batteries, studded over the rock, is of considerable historical interest. The rock is accessible only at one part, which is fortified by a rampart. The castle has been often besieged. A huge two-handed sword, said to be that of Wallace, is shewn here. D. gave the title of Earl of Dumbarton to a cadet of the house of Douglas, and commander of a regiment in the royal cause during the troubles in Scotland in the reigns of Charles II. and James II.; the popular song, *Dumbarton's Drums beat bonny, O*, has reference to this personage, who died in exile after the revolution. (1871—pop. of p. b. 11,404.)

**DUMBA'RTONSHIRE** (anciently, Lennox, Levenax, or Leven's Field), a sickle-shaped county in the west of Scotland, bounded E. by Loch Lomond, Stirling, and Lanark; S., by Renfrew and the Clyde estuary; W., by Loch Long and Argyre, and N., by Perth. It is 35 miles long, and 15 (average  $7\frac{1}{2}$ ) broad, with 35 miles of coast; area, 297 square miles. On the east, it has a detached part of 12 square miles, enclosed by Stirling and Lanark. The south coast on the Clyde is mostly low and sandy. Loch Long forms twenty miles of the west border. The Gare Loch, one mile broad and six long, forms, with Loch Long, the Roseneath peninsula in the south-west, studded with beautiful villas. Loch Lomond for 24 miles bounds the east side of the county, the hills rising from a low, narrow, and wooded shore. Here is the romantic scenery of part of Rob Roy's country described by Scott. The north of the county is mountainous or hilly, rising in Ben Voirich 3300 feet. The scenery of D. is very romantic, and the county forms the route to the West Highlands of Argyre and Perth. The ancient ferry from the Lowlands to the Highlands was between Port Glasgow and Cardross. There are many streams, and nine freshwater lakes, the largest being Loch Lomond. The chief rivers are the Clyde, along the south border; and the Leven, the outlet of Loch Lomond, and running six miles into the Clyde, at the foot of Dumbarton Rock. The rocks are mica-slate, tale-slate, clay-slate, trap, coal-measures, and carboniferous limestone. The mineral products are coal, freestone, limestone, ironstone, and slates. The climate is mild and humid. The arable lands lie chiefly south of Loch Lomond, and along the Clyde east and west of Dumbarton Castle. On the hills are reared Highland cattle and black-faced sheep, and on the plains Ayrshire cattle and Cheviot sheep. In 1857, a fourth of the county was in crop, the chief crops being oats, turnips, barley, wheat, and potatoes. D. has extensive and valuable woods. The chief branches of industry are the manufactures of cottons and linens, ship-building, bleaching, calico-printing, and dyeing. D. is divided into twelve parishes. Pop. (1861) 52,035. In 1851, D. had 46,995 inhabitants; 75 schools, with 4778 scholars; and 55 churches (16 Established, 15 Free, and 10 United Presbyterian). D. sends one member to parliament. A portion of the Roman Wall of Antoninus runs through the south-east corner of the county, and ends at Kilpatrick. At Luss is the cairn of St Kessock, a martyr in 520. There are remains of Roman forts, and of a Roman bridge at Duntocher.

Stone coffins and Roman vases and coins have been found. (1871—pop. 58,857.)

**DUMBNESS.** See DEAF AND DUMB.

**DUM'DUM**, the name of a town and of a valley in India.—1. The town is well known in the military history of the country, standing in lat.  $22^{\circ} 38' N.$ , and long.  $88^{\circ} 30' E.$  It is ten miles to the south-east of Barrackpore, and eight to the north-east of Calcutta, having extensive accommodations for troops, and a cannon-foundry. The place is famous in connection with the mutiny of 1857, as the scene of the first open manifestation on the part of the sepoy's against the greased cartridges.—2. The valley leads into Cashmere from the south, over what is called the Pir Panjal Pass, whose crest is 11,800 feet above the level of the sea. It is about lat.  $33^{\circ} 45' N.$ , and long.  $75^{\circ} E.$

**DUMFRIES**, a royal, parliamentary, and municipal burgh, river-port, and county-town of Dumfriesshire, on the left bank of the Nith, nine miles from its mouth in the Solway Firth, 73 miles south-by-west of Edinburgh, and 33 west-north-west of Carlisle. It stands on a rising-ground, surrounded, except towards the sea, by fine undulating hills, many of which are green to the top. It is an irregular but well-built town of red freestone, and is reckoned the capital of the south of Scotland. Two bridges cross the Nith to Maxwelltown, a suburb in Kirkcudbright. One of the bridges is usually stated to have been begun by the mother of John Bahol, king of Scotland; but is in reality a structure of the 17th c.: it had 13 arches, with a central gate; only six arches now remain, and it is limited to foot-passengers. Inigo Jones erected the mid-steeple of the town-house. The very high tides of the Solway Firth bring vessels of sixty tons up to the town, and larger ones to the river quays below the town. D. has two large manufactories of woollen cloths (Tweeds); it also manufactures hats, hosiery, leather, baskets, and wooden shoes. The chief exports are woollen cloths, wool, freestone, hosiery, shoes, sheep, grain, wood, and bark. D. is noted for its markets, livestock being here transferred from Scotch to English dealers. Pop. (1861) 14,024. It unites with Annan, Sanquhar, Lochmaben, and Kirkcudbright, in sending one member to parliament. D. arose in a castle, of which nothing now remains. The early Scotch and English kings had frequent contests for its possession. About 1200, a monastery was founded here, in the chapel of which Comyn (q. v.) was stabbed by Robert Bruce in 1305. The town was often plundered and burned in the border wars. The Highlanders, under Prince Charles, in 1745, fined D. £4000, and plundered and burned it. Burns was for some years an exciseman here, and his tomb is one of the notable objects of the place. In 1860, 1312 vessels, of 75,345 tons, entered and cleared the port. (1871—pop. of p. b. 15,435.)

**DUMFRIESSHIRE**, a border county of Scotland, on the Solway Firth, having Kirkcudbright on the west. It forms an irregular ellipse 55 miles by 32, with 22 miles of coast-line on the Solway Firth, to which its surface slopes; area, 1129 square miles. The north half is mountainous, rising in Hart Fell 2635 feet; Lowther Hills, 2522; Black Lark, 2890; Ettrick Pen, 2258; and Queensberry, 2259. The south part is undulating. The country on the Solway Firth (q. v.) for ten miles inland is flat, sandy, and gravelly, with some clay, and tracts of 'cobbles' or large stones. D. is drained principally by three rivers—the Nith, 40 miles long; the Annan, 30; and the Esk, 30; which run south-east and south into the Solway Firth from the north border of the

county, and divide it into three districts or dales, called after the rivers. There are many small lochs, some of which contain vendace. D. consists of Silurian, Permian, and Carboniferous strata, with eruptions of trap. Tortoise footprints were found in the new red sandstone of Annandale. The mineral products are coal, limestone, marl, ironstone, lead, and silver. There are extensive lead-mines at Wanlockhead, two miles from Leadhills, in Lanarkshire. Gold was formerly obtained in quartz veins in the hills near Wanlockhead; a mass of five ounces found there is now in the British Museum. There are noted sulphureous springs at Moffat, and chalybeate ones at Hart Fell. The climate is moist and mild, and most of the land has a southern exposure. The soil in the lower parts is a light, gravelly, or sandy loam, or clay. There are rich alluvial tracts along the rivers and on the Solway Firth. The Lochar peat tract, on the Solway Firth, is 13 by 2 to 3 miles, and contains shells, trees, and fragments of ships. The chief occupations are agriculture, and the rearing of cattle, sheep, and pigs. In 1857, nearly a fourth of the county was in crop, the principal crops being oats and turnips. Sheep-farms occupy the hills, of which a third of the county consists. The chief exports are cattle, sheep, grain, freestone, wool, hams, and bacon. There are fisheries of salmon in the rivers, and of cod, cockles, and mussels in the Solway Firth. Two railways cross the county from Carlisle to Edinburgh and Glasgow. Pop. in 1861, 75,877. In 1851, D. had 78,123 inhabitants; 176 schools, with 11,349 scholars; 92 churches (36 being Established, 20 Free, and 20 United Presbyterian). The chief towns are Dumfries, Annan, Sanquhar, Lochmaben, and Moffat. D. sends one member to parliament. A third of the county belongs to the Duke of Buccleuch. There are numerous antiquities. D. formed part of Valentia in Roman times. It afterwards belonged to the Saxon Northumbrian kings. (1871—pop. 74,808.)

**DUMMOW**, a town in the territory of Sangor and Nerbudda, stands in lat. 23° 50' N., and long. 79° 30' E., being 775 miles to the westward of Calcutta. It has a large bazaar, and is abundantly provided with wells. Its district, a pergunnah of the same name, contains 1,554,058 acres, and 363,554 inhabitants.

**DUMONT, PIERRE ETIENNE LOUIS**, an able propagator of the Benthamite philosophy, was born at Geneva, 18th July 1759, studied theology, and after officiating as a minister for a short time in his native town, proceeded to St Petersburg in 1783, where he accepted the charge of the French Protestant Church. In 1785, he left Russia, went to England, and became tutor to the sons of Lord Shelburne, afterwards Marquis of Lansdowne. His superior talents, liberal sentiments, and fine character, soon recommended him to the illustrious Whigs of that period; with Sir Samuel Romilly, in particular, he formed a close friendship. During the early years of the French Revolution, D. was at Paris, where he became greatly attached to Mirabeau, regarding whom he has given the world much important information in his *Souvenirs sur Mirabeau et sur les deux Premières Assemblées Législatives* (which were not published till 1832, seven years after the author's death). From this work, it appears that D. wrote many of the best articles and speeches attributed to Mirabeau. In 1791, D. returned to England, and formed an intimacy with Bentham. This was certainly the most important event in his life. Deeply convinced of the value of that philosopher's views of legislation, he requested his friend to allow him to arrange and edit his

unpublished writings on this subject. Bentham gave him his manuscripts. D. laboured earnestly to abridge, elucidate, correct, and simplify what he had received. The results appeared in his *Traité de Législation Civile et Pénale* (Geneva, 1802), *Théorie des Peines et des Récompenses* (Geneva, 1810), *Tactique des Assemblées Législatives* (Geneva, 1815), *Preuves Judiciaires* (Geneva, 1823), and the *Organisation Judiciaire et Codification* (1828, a posthumous work). D. returned to Geneva in 1814, and became a member of the representative council. In this office he found many opportunities of putting the principles of Bentham into practice, and thus greatly benefited his native city. He died in 1825, at Milan.

**DUMOURIEZ, CHARLES FRANÇOIS**, a French general, was born at Cambrai, 25th January 1739, entered the army in 1757, and served in Germany during the Seven Years' War. On the conclusion of hostilities in 1763, D., who possessed a restless, adventurous genius, went from one country to another, seeking active employment. Under Louis XVI., he held the office of commandant of Cherbourg, where he commenced the formation of a great naval establishment. As the Revolution drew on, D. began to attach himself more closely to the popular party. In 1790, he became connected with the Jacobin Club, and during the same year was appointed military commandant of Lower Normandy. After holding for a short time the office of Minister of Foreign Affairs, he became Lieutenant-general in the army of the North, commanded by Maréchal Luckner. The allies were advancing in great force. By a series of bold and rapid manœuvres, D. prevented his enemies from sweeping over the plains of Champagne, and finally took up his position at Grand-Pré. Succours quickly arrived, and the victory of Kellermann at Valmy compelled the invaders to retreat. It is generally admitted that by his admirable strategic movements at this critical period D. saved France. A winter campaign in Belgium followed, and on the 5th and 6th November 1792, D. overthrew the Austrians under the Duke of Sachsen-Teschen and Clairfait at Jemappes. The campaign of 1793, which aimed at the complete conquest of the Netherlands, was opened with the siege of Maestricht; Breda and other places were taken by the French; but at Neerwinde, D. sustained a severe defeat from the Austrians under Coburg. D.'s Jacobinism had been cooling for some time, on account of the anarchy prevailing at Paris, and when commissioners were sent to remonstrate with him on account of his monarchical leanings, he told them nothing could save France from the horrors of anarchy but a constitutional monarchy; D. then entered into secret negotiations with Coburg, evacuated Belgium, and promised to exert himself on behalf of the Bourbon family. He was now accused of being a traitor, by the authorities at Paris; but when requested by the commissioners to proceed to the capital, and stand his trial, he answered by handing over the representatives of the people to the Austrians. He next endeavoured, but in vain, to win the army over to his plan of marching upon Paris, and re-establishing the royal authority, and D. had to take refuge, accompanied by the Duc de Chartes, in the ranks of the enemies of France. The Convention set a price of 300,000 francs upon his head. After wandering through many countries of Europe, he finally settled in England, where he died an exile at Turville Park, near Henley-upon-Thames, 14th March 1823. Besides a multitude of pamphlets, D. has written *Mémoires du Général Dumouriez* (Hamburg, 1796), and *La Vie et les Mémoires du Général Dumouriez* (3d edit., Paris, 1822—1824).

**DUN**, a root common to the Celtic and Gothic languages, signifying a hill or height. Besides giving rise to the Fr. *dunes*, Ger. *dünen*, Eng. *downs* (q. v.), it enters extensively into the names of places (becoming often *dun*, *don*), as *Dunkirk*, *Dumbarton*, *Donegal*. It is allied to the Ang.-Sax. *tun*, *ton*, whence *town* (q. v.).

**DÜ'NA**, **DW'NA**, or **DVI'NA**, the name of a river of Russia, which rises in the government of Tver, in the neighbourhood of the source of the Volga, and flows west-south-west in a course almost parallel to that of the Dnieper. At Vitebsk, the D. turns to the west, then to the north-west, and advances in that direction toward its debouchure in the Gulf of Riga, passing the towns of Disna, Drissa, Düna, Jacobstadt, and Riga. The entire length of the D. is about 650 miles. It is navigable from Düna-münde, at its mouth, to Veliĭ, on the border of the government of Smolensk—a distance of 400 miles; but the navigation, owing to its shallows, its rock-obstructions, and sand-banks, is extremely difficult and dangerous, except during the spring and autumn floods. The basin of the D. is estimated at 28,350 square miles; at Riga, its breadth is 2400 feet. In the spring, the surface of the D. is covered with rafts and planks, which are floated down from the forests of the provinces through which it flows. Its waters, which abound in fish, are connected with those of the Dnieper by means of the Beresina Canal, and there is thus a water-communication between the Black Sea and the Baltic.

**DÜ'NABURG**, a strongly fortified town of Western Russia, is situated on the Düna, in lat. 55° 53' N., long. 26° 24' E. It is of great military importance, owing to the strength of its fortifications. It has three fairs in the course of the year, and considerable trade. Pop. (1855) 11,511. D. was formerly the capital of Polish Livonia.

**DUNBA'R**, a royal, parliamentary, and municipal burgh, and very ancient seaport and town in the north-east of Haddingtonshire, on an eminence at the mouth of the Firth of Forth, 29 miles east-north-east of Edinburgh. The coast near D. consists of basaltic rocks and islets, and gives fine views of the Bass Rock, the Isle of May, and Fifeshire. D. is a fine old town with broad streets. It has a sailcloth and cordage manufactory, and extensive tile-work, breweries, &c., but the chief industry is the fisheries, in connection with which there are large curing establishments. The old harbour is impeded at the entrance by craggy islets and sunken rocks, but is accessible to vessels of 300 tons. About the year 1840, an additional harbour, called the Victoria Harbour, was erected at D., at the expense of the Fishery Board and town; with recent important repairs and improvements, it has cost altogether upwards of £50,000. It has four feet at low water, and is considered one of the best suited for fishery purposes in the country. From 4000 to 5000 tons of herrings are annually exported from D., besides what are used for local consumption. The other exports are chiefly corn and potatoes. Pop. (1861) 3791. D. unites with North Berwick, Jedburgh, Haddington, and Lander in sending a member to parliament. On the high rocks at the entrance to the new harbour are a few fragments of the ruins of a castle, which, from the end of the 11th c., was the chief seat of the ancient Earls of March. It was once very strong, and an important security against English invasions: Edward I. took it, and Edward II. fled thither after the battle of Bannockburn; it was demolished in 1333, and rebuilt in 1336; it was successfully defended in a siege of six weeks against the Earl of Salisbury by Black Agnes, Countess of Dunbar, in 1338; it sheltered Queen Mary and

Bothwell in 1567; and in the same year it was destroyed by the Regent Murray. In 1650, Cromwell, at the 'Race of Dunbar,' defeated the Scottish army under Leslie. (1871—pop. 3311.)

**DUNBAR**, **WILLIAM**, the greatest of the old Scottish poets, is supposed to have been born about 1460. In 1475, he went to St Andrews, where, in 1477, he took the degree of B.A., and in 1479 that of M.A. Considerable obscurity rests upon his career for about twenty years after he left the university. From his own writings, we learn that he entered the order of St Francis, and was employed for some time as an itinerant or preaching friar. In that capacity, he 'ascended the pulpit at Dernton and Canterbury, and crossed the sea at Dover, and instructed the inhabitants of Picardy.' He appears to have entered the king's service, and to have been retained as 'clerk' or secretary to some of James's numerous embassies to foreign courts. In 1500, he obtained from the king a yearly pension of £10. In 1501, he visited England, in the train, as his biographers suppose, of the ambassadors sent thither to conclude the negotiations for the king's marriage. On the 9th May 1503, three months before the queen's arrival, he composed in honour of the event his most famous poem, the *Thryssil and the Rois*. He seems now to have lived chiefly about court, writing poems, and sustaining himself with hope of preferment in the church. On the 17th March 1504, he received a gift for saying mass for the first time in the royal presence. At Martinmas 1507, his pension was doubled, and three years afterwards, it again received augmentation. He is supposed to have visited the northern parts of Scotland in May 1511, in the train of Queen Margaret. After the ruinous defeat at Flodden, and the confusion consequent on the king's death and a prolonged regency, D.'s name disappears altogether. He is supposed to have died about 1520.

As a poet, he possessed a wonderful variety of gifts; his genius comprised the excellences of many masters. He is at times as rich in fancy and colour as Spenser in the *Faery Queen*; as homely, and shrewd, and coarse as Chaucer in the *Miller's Tale*; as pious and devotional as Cowper in his *Hymns*; and as wildly grotesque in satire as Burns in his *Death and Doctor Hornbook*. When Scott read portions of his works to Crabbe, in Edinburgh, the latter remarked that, 'before the Ayrshire ploughman, Scotland possessed at least one great poet.' A complete and carefully elaborated edition of D.'s works, by Mr David Laing, was published at Edinburgh in 1834.

**DUNBLANE**, a city and burgh of barony in the south of Perthshire, picturesquely situated on the left bank of the Allan, on the Scottish Central Railway, 28 miles south-west of Perth, and 5 north of Stirling. It takes its name from St Blane, a bishop of the 7th or 8th c., said to have been born in Bute. It mainly consists of one street of old-fashioned houses. Pop. (1861) 1709. The cathedral of Dunblane, chiefly in the First-pointed or Early English style, about the year 1240, is now in ruins, except the choir, used as the parish church, 80 by 30 feet, with a tower 128 feet high, the first four stages of which are Romanesque work of about the year 1140. The prebendary stalls of richly carved oak still remain. Of the bishops of Dunblane, by far the most celebrated was Robert Leighton, who held the see from 1661 till 1672, when he was translated to Glasgow. A path near the river, which he is said to have frequented, still bears the name of 'The Bishop's Walk;' and the library which he bequeathed to his diocese, is still kept in the town. Two miles

from D. was fought, in 1715, the indecisive battle of Sheriffmuir, between the royal forces, under the Duke of Argyle, and the troops of the Pretender, under the Earl of Mar. D. once had an ancient Culdee monastery. (1871—pop. 1042.)

DUNCAN, ADAM, VISCOUNT, a celebrated British admiral, was born in 1731 at Dundee, entered the navy as midshipman in 1746, became lieutenant in 1755, and in 1761, commander of the *Valiant*, of 74 guns, which took part in the expedition to Havana under Admiral Keppel. In 1789, he was appointed Rear-admiral of the Blue, and in 1793, Vice-admiral of the Blue, but had little opportunity of distinguishing himself, and was even meditating, it is said, retiring altogether from the service, when he was appointed to the command of the united English and Russian squadron in the North Sea, with the special design of watching the movements of the Dutch fleet—Holland and France being then both at war with England. D.'s blockade of the Texel was one of the most effective ever made, and the Dutch trade was almost ruined. During the blockade, a mutiny took place among the seamen, and D.'s position was for some time very critical, but the insubordination was ultimately quelled. Although weakened by the recall of the Russians, he gained a brilliant victory over the Dutch near Camperdown, 11th October 1797, where he took the Dutch admiral, De Winter, prisoner. D. was rewarded with a pension of £2000, and raised to the peerage, with the title of Viscount. In 1799, he was promoted to the rank of Admiral of the White, and died 4th August 1804, after having inherited the family estates in Perthshire, on the death of his brother.

DUNCAN, THOMAS, R.S.A., and A.R.A., was born at Kinclaven, Perthshire, May 24, 1807; and died at Edinburgh, 25th May 1845. He studied in the Trustees' Academy, under Sir William Allan; was his successor as head-master of that school, and one of the most distinguished members of the Royal Scottish Academy. His portraits, and historical and fancy subjects, evince delicate feeling for female beauty, and keen appreciation of the humorous in Scottish character. The drawing is always careful and correct, and the colouring remarkable for clearness and delicacy. Though he exhibited but few pictures in the Royal Academy of London, they at once attracted marked attention, and he was elected an Associate of that body in 1843. The principal works he exhibited there were: 'Anne Page and Slender,' an illustration from the ballad of *Auld Robin Gray*, now in the Sheepshanks Gallery, South Kensington; 'Prince Charles's Entry into Edinburgh after the Battle of Prestonpans'—and the same Prince, when a fugitive, concealed in a cave. He had now entered on a most successful career, and was engaged on the studies for two important works: 'Wishart Dispensing the Sacrament on the Day of his Martyrdom,' and a large picture for the Marquis of Breadalbane, 'Queen Victoria at Taymouth,' when he was seized with an illness which terminated fatally. One of his latest works was a portrait of himself; it is now in the National Gallery of Scotland, and is an excellent specimen of careful drawing, united to great power of colour and effect. That D. was remarkable for energy and industry, is proved by the number and high quality of the works he executed, though he died at the early age of thirty-eight. His portraits, especially those of ladies and children, will always hold a high place. Though constantly engaged on fancy subjects, he every year exhibited a very considerable number of portraits. In addition to the works above referred to, the following is a list

of the principal historical and fancy subjects exhibited by him in the Royal Scottish Academy—1829: 'The Death of Old Mortality,' and 'A Milk-girl.' 1830: 'The Braw Wooer,' and 'Children and Rabbit.' 1831: 'Lucy Ashton,' and finished sketch of 'Jeanie Deans and the Robbers.' 1832: 'Girl with Flowers.' 1834: 'Cuddie Headrig Visiting Jenny Dennison.' 1835: 'Mary Queen of Scots compelled to Sign her Abdication.' 1836: 'A Covenanter,' and 'Old Mortality Renewing the Inscription on a Tombstone.' 1838: 'The Secret Chamber—Isaac of York Visiting his Treasure,' 'The Lily of St Leonards,' and 'The Friends.' 1839: 'Study of 'A Highland Stag, with Dead Game and Fruit.' 1845: 'The Martyrdom of John Brown of Priesthill, 1685.' 1846: The finished sketch of 'Wishart Dispensing the Sacrament on the Day of his Martyrdom, March 1, 1546,' was exhibited after the artist's death.

DUNCANSBY HEAD (the *Berubium* of Ptolemy), a promontory forming the north-east extremity of Caithness, in lat. 58° 39' N., and long. 3° 1' W., and one mile and a half east of John o' Groat's House. In the vicinity are deep long chasms or *ghoos*, in the Devonian strata, and curious detached sandstone columns in the sea called *stacks*. One of the chasms is 300 yards long, 12 to 15 wide, and 100 feet deep, and communicates with the sea by three openings, one of which is arched. The horizontal beds of the sides of the perpendicular gullies look like ruined walls.

DUNCIAD, THE, by Alexander Pope, was published in 1728, in three books; and to these, in 1742, a fourth book was added. Pope had been, during the greater part of his career, afflicted by a host of critics and detractors. His own genius had not been spared; the worst motives, personal and literary, had been imputed to him; and he resolved to mete unto his enemies the measure which had been meted unto himself. Hence the origin of *The Dunciad*. Never was chastisement more complete. On its publication, a universal howl of rage and pain arose. The satire conferred immortality on his opponents. Pope was a good hater, and his hatred and contempt defy the tooth of Time more completely than all the balsams of the Pharaohs.

DUNCOMBE, THOMAS SLINGSBY, an English politician, nephew of first Lord Feversham, was born 1796. He was elected M.P. for Hertford in 1824, assisted in carrying the Reform Bill, and became a prominent member of the extreme Liberal party. In 1832, he was rejected at Hertford; but in 1834 he was returned for Finsbury, which seat he retained in the parliament which assembled in 1859. In 1842, he presented the Chartist petition, signed by 3,000,000 of the lower classes in favour of universal suffrage, vote by ballot, short parliaments, &c. In 1842, the then Home Secretary, Sir James Graham, having sanctioned the opening of the letters of Mazzini, D. stood up in the House of Commons and denounced, with bitter and scathing invective, the adoption of the post-office spy-system on English soil. He was an earnest advocate of Jewish emancipation; and his motion in 1858 for placing Baron Lionel Rothschild on a committee of the House of Commons, which was to hold a conference with the House of Lords, was soon followed by the concession, by the latter chamber, of the right of Jewish members to sit in the House of Commons.

DUNDALK, a parliamentary and municipal burgh and seaport, the capital of the county of Louth, Ireland, is beautifully situated at the mouth of the Castleton, on a flat at the head of Dundalk Bay, 50 miles north of Dublin. It is backed on the north-east by the Mourne Mountains, 2000 feet

high. Vessels drawing 16 feet can enter the harbour. D. has manufactures of tobacco, soap, leather, pins, starch, and salt; steam flour-mills; important fisheries; distilleries, and flax-spinning-mills. The chief exports, especially to Liverpool, are timber, coal, iron, slates, flax, linen, and all sorts of agricultural and dairy products and livestock. D. is the chief outlet for the produce of the counties of Louth, Monaghan, and Cavan. Pop. (1861) 10,075. It sends one member to parliament. It has the remains of a Franciscan friary and a Druid's circle. The last king of all Ireland was crowned and resided here. Edward Bruce took D. in 1315, and crowned himself and held his court here till killed in battle by the English in the vicinity in 1318. D. was captured by the Irish in 1641, by Cromwell in 1649, and by Schomberg in 1689.—DUNDALK BAY is a shallow inlet of the Irish Sea, in the east of Louth county, eight miles broad by seven deep, and with four to six fathoms water in the middle. It contains oyster beds, and receives the rivers Fane, Dee, and Castleton. In 1860, 1167 vessels, of 232,923 tons, entered and cleared the port.

DUNDA'S, a term of various application, indicates a castle and manor, a town, an island, a group, a river, and a strait.—1. The castle and manor, from which all the others take name, are on the south bank of the Firth of Forth, near south Queensferry; the castle is a square tower of the 15th c., with modern additions; the manor was the original seat of the distinguished family of Dundas, to whose progenitor it was granted by the Earl of March about the year 1150.—2. The town is in Upper or West Canada, being at the head of Burlington Bay, at the western extremity of Lake Ontario.—3. The island, which belongs to Great Britain, is situated on the north-west coast of America, 40 miles north-east of Queen Charlotte Island. It has Dixon's Entrance (q. v.) on the west, and is separated by Chatham Sound from the most southerly of the Russian islands.—4. The group lies off the east coast of Africa, being about lat. 1° S. It comprises nearly 500 islets, all of coral-line formation. There is only one secure harbour.—5. The river is a tributary of Delagoa Bay (q. v.).—6. The strait, in North Australia, separates Melville Island from Coburg Peninsula, being 18 miles across.

DUNDAS (of Arniston), the name of a Scottish family singularly distinguished for legal and political talent. Sir James Dundas, the first of Arniston, received the honour of knighthood from James VI., and was governor of Berwick. His son, Sir James Dundas, was appointed a judge of the Court of Session in 1662, and took his seat on the bench under the title of Lord Arniston, but was soon after deprived of his office for refusing to abjure the 'National and Solemn League and Covenant.' He died in 1679. His eldest son, Sir Robert Dundas, who also rose to the bench, died in 1727.—DUNDAS, ROBERT, the son of the preceding, was born 9th December 1685; became a member of the Faculty of Advocates in 1709; and in 1717 was appointed Solicitor-general for Scotland, an office which he filled with great ability in a period of much political confusion. In 1720 he was made Lord Advocate; and in 1722 was chosen to represent the county of Edinburgh in the British parliament, where he honourably distinguished himself by his attention to Scottish affairs. When Sir Robert Walpole came into power in 1725, D. resigned his office, when he was elected Dean of the Faculty of Advocates. In 1737, he was raised to the bench, when, like his father and grandfather, he took the title of Lord Arniston. On the death of Lord President Forbes

of Culloden, in 1748, he was appointed his successor. He died in 1753. As an advocate, D. was a powerful and ingenious reasoner, and though somewhat disliked on the bench, his ability was universally admitted.—DUNDAS, ROBERT, the eldest son of the preceding, was born 18th July 1713, studied at Edinburgh and Utrecht, was admitted to the Scottish bar in 1738, and rose to be Lord Advocate (1754) and President of the Court of Session (1760). D. died at Edinburgh, 13th December 1787.

DUNDAS, the RIGHT HONOURABLE HENRY, VISCOUNT MELVILLE, and BARON DUNIRA, brother of the preceding, was born in 1741, and educated at the university of Edinburgh. He was admitted a member of the Scottish bar in 1763. As a younger son of a pretty numerous family, his circumstances were rather straitened; but his assiduity, his large share of the family talent, and no doubt of the family influence, soon procured him advancement in his profession. He was successively appointed Depute-advocate and Solicitor-general. In 1774, he was returned to parliament for the county of Edinburgh, and in the following year was appointed Lord Advocate for Scotland. Two years after, he was made keeper of the King's Signet for Scotland. D.'s career in parliament was highly successful, though not very creditable to his political consistency. Elected in opposition to ministerial influence, he soon allied himself with the party in power, and became a strenuous supporter of Lord North's administration, being one of the most obstinate defenders of the war with the American colonists. When Lord North resigned in 1781, D. continued to hold the office of Lord Advocate under the Rockingham ministry. On the question of the war with America, D. had been opposed to Pitt; but when the Coalition Ministry was formed by Fox and Lord North, he passed over to the side of his old opponent, and became Pitt's ablest coadjutor. When Pitt returned to the helm of the state in 1784, D. was appointed President of the Board of Control. In 1784 he introduced a bill for restoring the estates in Scotland forfeited on account of the rebellion of 1745. In 1791, he was appointed principal Secretary of State for the Home Department. He also held a great number of other offices, one of which, the treasurership of the navy, involved him some years after in much trouble. D.'s aptitude for business was undeniable. Many of the most important public measures originated with, or were directly promoted by him. Among such were the formation of the fencible regiments, the supplementary militia, the volunteer corps, and the provisional cavalry; in short, the whole of that domestic military force raised during the war consequent on the French Revolution. When Pitt resigned in 1801, D. did the same. In 1802, under the administration of Mr Addington, he was elevated to the peerage by the titles of Viscount Melville and Baron Dunira. In 1805, his lordship was accused of 'gross malversation and breach of duty,' while acting as treasurer of the navy. The trial commenced 29th April 1806; but in spite of the splendid array of Whig talent against him, D. was acquitted on all the charges. After this, however, he took little part in public affairs, spending the most of his time in retirement in Scotland. He died at Edinburgh, 27th May 1811.

DUNDEE' (Lat. *Taodunum*, the 'hill or fort on the Tay'), a royal parliamentary and municipal burgh and seaport, in the south of Forfarshire, on the left bank of the estuary of the Tay, here two miles broad, 10 miles from the entrance of that river into the sea, 50 miles north-north-east of Edinburgh, 20 east-north-east of Perth, and 14 south-east of Forfar. In population, it is the third town in Scotland.

It stands mostly on the slope between Dundee Law (525 feet high, composed of trap, and with traces of ancient vitrification) and Balgay Hill and the Tay. The new streets are wide and well laid out. The most striking architectural features of the town are—the Town Hall, in the Roman Ionic style, with a spire 140 feet high, erected by the 'Elder Adams,' in 1734; the Albert Institute and Free Library, in 15th-century Gothic, from designs by Sir Gilbert Scott, recently erected at a cost of £30,000; the Royal Exchange, built in the Flemish pointed style of the 15th c., at a cost of upwards of £12,000, and opened in 1856; the Eastern Club House; the Corn Exchange, capable of containing 2000 people; the Infirmary; the Judiciary and Sheriff Court Buildings; the Post-office; the High School; the Town's Churches, with the old tower, 156 feet high, just restored (1873) under the charge of Sir Gilbert Scott, at a cost of £7000; St Paul's Episcopal Church, with a tower and spire 217 feet high; St Paul's Free Church, with a tower and spire 167 feet high; and St Enoch's Free Church, with two handsome towers; the Morgan Hospital (opened 1868), erected and endowed at a cost of nearly £80,000, under the will of John Morgan, a native of Dundee, for the maintenance and education of 100 boys; and the new Orphan Hospital. D. has several public parks, one of which, the Baxter Park, on a beautiful slope to the eastward of the town, is 37 acres in extent, and was presented by the late Sir David Baxter, at a cost of £50,000; another, to the westward of the town, occupies the hill of Balgay, and is finely wooded and beautifully laid out, its extent being about 60 acres. D. is the chief seat in Great Britain of the manufacture of coarse linen fabrics (Osnaburgs, sheetings, ducks, dowlas, drills, canvas, and cordage). Manufactures of jute are almost exclusively carried on here. The consumption in D. of this material, which is grown in India, amounts to fully 120,000 tons annually. The raw material costs in D. a little over 2d. per lb.; and the cloth made from it, reckoned by weight, is the cheapest textile fabric made in Great Britain. Of jute many varieties of fabric are made, from the coarsest nail-bagging to carpets of great beauty. This range includes pack-sheets for every species of merchandise, sacks for wool, coffee, guano, &c. The annual value of the flax, hemp, and jute manufactures in D. is upwards of £5,500,000. D. is also famous for its manufacture of confectionary, which is exported to all parts of the world. One firm uses 150 tons of bitter oranges annually in the manufacture of marmalade. Ship-building (both wood and iron) and machine-making are carried on to some extent. D. has magnificent harbours, in addition to the tide harbour. Its wet docks cover 35 acres, one of them admitting vessels drawing, at spring-tides, 25 feet; and at neap-tides, 19 feet. The docks have been erected at a cost of upwards of £600,000; and plans for extending them gradually, so as to include an area of 122 acres, are under consideration. In 1872, 2518 vessels, of 421,285 tons, entered and cleared the port. At the north end of the mid quay stands the Royal Arch, in commemoration of Her Majesty's landing here in 1844. Dundee is at present well supplied with water from Monikie, 10 miles distant; and an act has been obtained to bring in a very abundant supply from the Loch of Lintlathen, about 24 miles distant. Pop. (1871) 118,977. D. sends two members to parliament. It was an important place in the 12th century. Edward I. was here in 1296 and 1303. Wallace is said to have taken the castle in 1297, and Bruce demolished it in 1313. The Duke of Lancaster burned D. in 1385, and the Marquis of Montrose pillaged it in 1645. Charles II. lived

here, after his coronation at Scone, in 1650. On the refusal of D. to submit to Cromwell, General Monk, in 1651, sacked and burned it, massacring 1000 citizens and soldiers, and filling 60 vessels with booty, which were totally wrecked on their voyage to England. D. was one of the first Scotch towns which publicly adopted the Reformation. Wishart the martyr preached here during the plague of 1541.

**DUNDO'NALD, THOMAS COCHRANE, EARL OF,** son of the ninth Earl of Dundonald, was born December 14, 1775. He, while still a boy, entered the 104th Regiment. At the age of 17, he joined the *Hind* corvette, commanded by his uncle, Captain Sir Alexander Cochrane. In 1800, he became master and commander of the *Speedy* sloop-of-war, of 14 guns and 54 men; and in ten months he took 33 vessels, carrying together 128 guns and 533 men, besides assisting in the capture of many others. D. received his post-rank, 1801, for the capture, by boarding, of *El Gamo*, a Spanish frigate of 32 guns, off Barcelona. In 1803, he was appointed to the *Arab*, 22, and served at the blockade of Boulogne. In 1804, he removed to the *Pallas* frigate, 32, and was sent out to assist his uncle, then employed in the blockade of Ferrol. He made several valuable prizes while cruising off the Spanish coast, among others the *Fortuna*, with specie to the amount of £150,000, besides merchandise, but generously returned 10,000 crowns to the Spanish captain and supercargo. In 1806, he cut out the *Tapageuse* corvette, which lay in the Gironde, under the protection of two heavy batteries. He destroyed the semaphores along the French coast, and carried by storm the battery at Pointe l'Equilon, which he blew up. Being now transferred to *L'Impérieuse*, he took and destroyed, in the month ending January 7, 1807, 15 of the enemy's ships, chiefly laden with wine and provisions. He was next sent to co-operate with the patriots on the coast of Catalonia, and contributed to the surrender of the castle of Mongat. After harassing the French coast, and destroying the semaphores on the coast of Languedoc, he volunteered for the defence of Fort Trinidad, at Rosas, on the coast of Catalonia. At the head of 80 of his own men, and the same number of Spaniards, he repelled 1000 of the enemy in an assault made by them upon the castle. He protracted the siege for 12 days, then blew up the magazine, and returned to his ship. In April 1809, he was selected by the Admiralty for the daring and hazardous service of burning the French fleet then lying at anchor, and blockaded by Lord Gambier, in the Basque Roads. At night he went on board one of the fireships, containing 1500 barrels of gunpowder, and performed the service intrusted to him with characteristic intrepidity. He was rewarded with the knighthood of the Bath. He had been chosen M.P. for Westminster in 1807; and his charges of incompetency against Lord Gambier led to a court-martial upon that nobleman. Lord Gambier, after a partial trial, was acquitted, and the professional prospects of his assailant were ruined. During the rest of the war, the country lost the incalculable benefit of his services at sea, the navy gaining, on the other hand, such small advantage as could in those days be derived from D.'s protests in parliament against naval abuses. Early in 1814, he was accused of complicity in fraudulent stock-jobbing transactions. A rumour of the downfall of Napoleon having caused a sudden rise in the funds, D. and his friends were charged with having fraudulently propagated the rumour, and with having 'sold out' to a large amount. He was found guilty of fraud, and was sentenced to pay a fine of £1000, to suffer a year's imprisonment, and to stand in the pillory. The latter part of the punishment

was remitted, but he was deprived of the order of the Bath, of his rank in the navy, and expelled from the House of Commons. A new writ was issued for Westminster; but his constituents immediately re-elected him, notwithstanding his expulsion from the House; and his daring was shewn by his escape from prison, and his re-appearance in the House. He represented Westminster until 1818, when, panting for a more active and eventful career, he drew his sword in defence of the independence of the South American colonies of Spain. The command of the fleet of the republic of Chili was offered to him, and the terror of his name materially contributed to the success of the national cause. Valdivia, the last stronghold of the Spaniards, was captured by him. Another daring exploit was the cutting out of a large 40-gun frigate from under the guns of the castle of Callao, 5th November 1820. The Emperor of Brazil, Dom Pedro, afterwards gave him the command of the Brazilian fleet, and created him a marquis. In 1827 and 1828, he assisted in the Greek war of independence. In 1830, the Whig administration of Earl Grey came into office, and, believing him to have been the victim of a cruel and unjust persecution, hastened to restore him to his naval rank. In 1831, he succeeded to the earldom. In 1847, Queen Victoria conferred on him the Grand Cross of the Bath. He was also appointed commander-in-chief on the North American and West India station. In 1851, he was Vice-admiral of the White, and in 1854, Rear-admiral of the United Kingdom, a distinction which he held until his death. On his retirement from active service, he devoted himself to scientific inventions. He made improvements in poop and signal lights, and especially turned his attention to naval projectiles. He declared himself to be in possession of a means of annihilating an enemy's fleet, and during the Russian war offered to destroy Sebastopol in a few hours with perfect security to the assailants. His plans were, however, rejected. When upwards of 80 years of age, he published his *Autobiography*—the record of a career almost unequalled even by British seamen for desperate service and dauntless exploit. He died October 31, 1860, and was interred in Westminster Abbey. In his naval expeditions, it was his fate to be constantly opposed to forces greatly superior to his own in numbers and metal. His inventiveness and fertility of resource under such circumstances have perhaps never been equalled. His daring would have been, in a man of less genius, the height of rashness, yet the almost unvarying success of his manoeuvres and exploits attests his forethought, and his happy adaptation of slender means to the achievement of great ends and noble enterprises. In person, he was tall and broad built; and a slight stoop, contracted by service in the small sloops and corvettes of his early days, scarcely impaired a height of stature that might be described as commanding. His features were Scottish in character, and strongly marked, bearing in deep lines the traces of struggle, sorrow, and the wear and tear of an unusually long, active, and eventful life. His life at sea was a constant romance, and the story of his ubiquitous and incessant actions against the enemy will remain the wonder and delight of sailors of every age and nation.

**DUNDRUM BAY**, an inlet of the Irish Sea, on the east coast of Ireland, in the county of Down, 5 miles to the south of Downpatrick, is about 10 miles wide at its entrance, and forms a long curve into the shore, with a uniform breadth of about 2½ miles. Here, in 1846, the steam-ship *Great Britain* was stranded, but was got off in the following year without having suffered any very serious damage.

**DUNEDIN**, the capital of the province of Otago, in New Zealand, is situated in lat. 45° 50' S., long. 170° 36' E., on the east side of Middle Island, towards its southern extremity. It is 200 miles by sea from Lyttleton, and 150 miles from Invercargill, which is the only other seaport of its section of the colony. Since its foundation by the New Zealand Company, in 1848, the city has rapidly increased in importance; chiefly after the year 1861, when the discovery of extensive gold-fields in the neighbourhood caused a sudden increase of population. For three years, the city, as well as the province, made great strides in wealth and prosperity; and although subsequently the excessive increase of population was checked by a decrease in the yield of gold, D. has ever since made steady progress. The population of the city proper is now 14,851; and inclusive of the suburbs of Roslyn and Caversham, it is 21,511. Within the last few years, the population has been increased by emigration from the colony of Victoria. D. is divided into four wards. It is as well laid out as the hilly nature of its site will allow; it is well paved, and lighted with gas. There are many handsome buildings—about a dozen of them churches; the First Presbyterian Church, lately built, being one of the finest in the colony. Other public buildings are the post-office, hospital, government buildings, mechanics' institute, &c.; and the inhabitants of the city possess places of recreation in the Vauxhall Gardens, Botanical Gardens, and the grounds of the Acclimatisation Society. Steamers sail regularly between D. and Melbourne; and a railway is being made to Clutha. Several daily and weekly newspapers are published. The principal articles of export are grain, potatoes, and wool—the last being by far the most important. The rapid extension of the wool-traffic has indeed been marvellous. Between 1853 and 1859, the quantity exported had risen from 5000 lbs. to 900,000, so that in six years the proportion had become as 180 to 1. For the year ending June 1871, the exports of wool were 12,928,007 lbs., valued at £523,243.

**DUNES**, from the same root as Dun (q. v.), a hill, the name given to the sand-hills or mounds which stretch less or more along the sea-coast of the Netherlands and north of France. These dunes are a natural curiosity. 'As if anxious to save the low countries from tidal inundation, Nature has for centuries been energetically working to increase the magnitude of the mounds on the coast. At low water, when the beach is exposed to the action of the winds from the German Ocean, clouds of sand are raised into the air, and showered down upon the country for at least a mile inland; and this constantly going on, the result is, that along the whole line, from Haarlem to about Dunkirk or Calais, the coast consists of sandy mounds of great breadth, partially covered with grass and heath, but unfit for pasturage or any other purpose, and these are the bulwarks which protect the coast. In some places, these dunes look like a series of irregular hills; and when seen from the tops of the steeples, they are so huge as to shut out the view of the sea. The traveller, in visiting them from the fertile plains, all at once ascends into a region of desert barrenness. He walks on and on for miles in a wilderness such as might be expected to be seen in Africa, and at last emerges on the sea-shore, where the mode of creation of this singular kind of territory is at once conspicuous. Loose particles of sand are blown in his face; and as he descends to the shore, he sinks to the ankle in the drifted heaps. In some parts of these dreary solitudes, the sandy soil has been prevented from rising with the wind and injuring the fertile country, by

being sown with the seeds of a kind of bent-grass, and in a few spots fir-trees have been successfully planted.—*Tour in Holland*, by W. Chambers. The English term *down* (q. v.) has a similar meaning.

**DUNFERMLINE**, a royal burgh in Fife, of the western district of which it is the chief town, under the jurisdiction of a sheriff-substitute, who holds courts twice a week during the session. The town is situated on a long swelling ridge, 3 miles from the Firth of Forth, and 16 miles west-north-west from Edinburgh, 300 feet above the mean level of the firth, and seen from the south, has an imposing appearance. The date of the origin of the town is not known, but it was a place of note before the end of the 11th century. Here, King Malcolm Canmore and his queen, St Margaret, between the years 1070 and 1093, founded an abbey for Benedictines brought from Canterbury. In 1303—1304, Edward I. of England wintered here, the buildings being then described as capable of accommodating three kings and their suites. In 1588, D. was created a royal burgh by James VI. David II., James I. of Scotland, and Charles I., were born here; and Malcolm Canmore, his queen Margaret, Edgar, Alexander I., David I., Malcolm the Maiden, Alexander III., Robert Bruce, his queen Elizabeth, and nephew Randolph, Annabella, queen of Robert III., Robert Duke of Albany, governor of Scotland, were buried in the abbey and its precincts. The tomb of Robert the Bruce was discovered at the building of the new church, which was opened in 1821. The skeleton of the king was disinterred, and a cast was taken of the cranium. Some interesting fragments of the ancient regal and ecclesiastical magnificence of D. still remain. What is called Malcolm Canmore's Tower is a mass of shapeless ruins, but the south wall of the palace of the Stuarts still exists, overhanging the romantic glen of Pittencriell, a noble wreck, with massive flying buttresses. Of the abbey, the Frater Hall or refectory, and a tower and arched gateway, still remain. The nave of the abbey church, consecrated in 1150, is in the Romanesque style, 106 feet long, and 55 wide. The choir, built about 1250, a fine example of the First Pointed style, was taken down in 1818—1821, when it was replaced by what is now the parish church, surmounted by a square tower 100 feet high, round which is the inscription, in open hewn capital letters, 'King Robert the Bruce.' The modern history of D. is chiefly remarkable in connection with the rise of Scottish dissent, Ralph Erskine and Thomas Gillespie having respectively been founders of the Seceder and Relief bodies, now joined under the name of United Presbyterians. The staple trade of the town is damask linen-weaving, which took its rise about the beginning of last century; there are likewise large collieries and lime-works, iron foundries, breweries, dye-works, a soap-work, a flax spinning-mill, bleach-works, four power-weaving, besides several hand-loom factories. See article DAMASK. The public buildings are—town-house and county buildings, each having a spire, and the prison, poors-house, and music hall. There are eight fairs, a monthly cattle-market, and two weekly markets for grain and country produce. Pop. of parish (1861), 20,952, of which the town contains 13,504. It joins with Stirling, Inverkeithing, Queensferry, and Culross in returning a member to parliament. (1871—pop. of town, 14,958.)

**DUNGANNON**, a parliamentary and municipal burgh in the east of Tyrone, near a tributary of the Blackwater, eleven miles north-north-west of Armagh, and eight west of Lough Neagh. It lies on a hill-slope, in a densely peopled district, with high mountains to the west. It is well built, and

consists of a square with diverging streets. In the vicinity are the largest lime-quarries and collieries in Ulster. The chief manufactures are linen, coarse earthen-ware, and firebrick. Pop. (1861) 3586. It sends one member to parliament. It was the chief seat of the O'Neils, the kings of Ulster, till 1607. Its castle was destroyed by the parliamentary forces in 1641.

**DUNGARVAN**, a parliamentary and municipal burgh, seaport, and bathing-place, in the south of Waterford county, 25 miles west-south-west of Waterford. Pop. of parliamentary burgh (1861) 8614, chiefly engaged in hake, cod, herring, &c. fisheries. The chief exports are grain, butter, cattle, and fish. Vessels of more than 250 tons cannot discharge at the quay. D. has the remains of an Augustinian abbey, founded in the 7th c. by St Garvan. It has besides the remains of walls built by King John, who also built the castle, now a barracks.—Dungarvan Bay is three miles across and three deep, with one to five fathoms of water.

**DUNG BEETLE**, the common name of many coleopterous insects of the tribe *Scarabæides*, which feed upon the dung of animals, and for the most part live in it. They are found in all parts of the world. Many of them belong to the section of *Scarabæides* called *Coprophagi* (Gr. dung-eaters); but others, as the *DOR*, or *SHARD-BORN BEETLE* (*Geotrupes stercorarius*), to the section called *Arenicoli* (Lat. sand-dwelling), distinguished by peculiarities in the antennæ, mandibles, &c. Neither section, however, consists exclusively of insects entitled from their habits to be called dung beetles, some of the *Coprophagi* feeding chiefly on marine vegetables in a state of putrescence, and some of the *Arenicoli* on the roots of plants. The *DOR* is one of the most common British beetles; it is of a stout form, less than an inch long; black, with brilliant metallic and blue

Dung Beetle (*Geotrupes stercorarius*).

reflections on the under surface; it may often be heard droning through the air towards the close of the summer twilight, and finds its way with rapidity and certainty to cow-dung, on which it feeds, and under which it burrows, making a large cylindrical hole, often of considerable depth, and depositing therein its eggs, enveloped in a mass of dung. These habits—more or less modified—are shared by many other species, which thus not only hasten the removal of what would otherwise become offensive on the surface of the ground, but even distribute it in the soil, where it affords nourishment to plants.—The sacred beetle or *Scarabæus* (q. v.) of the Egyptians (*Scarabæus sacer*, or *Ateuchus sacer* of modern entomologists) is a true D. B., one of the *Coprophagi*, in size and colour much resembling the dor. It is found not only in Egypt, but in the south of Europe and west of Asia, and deposits its eggs in dung, which it rolls into little balls for the purpose. A nearly allied insect (*Gymnopleurus pilularius*), a native of North America, is known as the **TUMBLE-DUNG BEETLE**, from its habit of rolling globular pellets of dung to the place where they are to be buried in the earth. Several individuals sometimes combine their strength in this curious operation, which is performed by the hind-feet pushing backwards.—The dor, and some other dung beetles, simulate death to deceive their enemies when they apprehend danger, not, like many insects,

by contracting their bodies as much as possible, and drawing in their legs, but by stretching every part out to the utmost, and rigidly fixing themselves in that position. Crows and other birds are supposed to prefer them in a living state.

DUNGEON. See DONJON.

DUNKE'LD, a city and burgh of barony in the east of Perthshire, 15 miles north-north-west of Perth. It lies in a deep romantic hollow, on the great east pass (of Birnam) to the Highlands, on the left bank of the Tay, across which it communicates with the south by a handsome bridge, built in 1809 by the Duke of Athole. It is environed by dark-wooded and craggy mountains. Pop. (1861) 929. D. is a place of great antiquity, dating probably from the 7th or 8th century. About the year 1130, King David I. made it the seat of a bishopric, of which the Culdees of the ancient abbey were the chapter. The choir of the cathedral, chiefly in the First Pointed style, was built between 1318 and 1337; the nave, in the Second Pointed style, was built between 1406 and 1464; and the tower and chapter-house, also in the Second Pointed style, were built between 1470 and 1477. The choir is now the parish church. The nave, which is in ruins, contains one or two ancient monuments. The monument of the Wolf of Eadenoch (Alexander Stuart, Earl of Buchan, who died in 1384) lies in the vestibule. The Duke of Athole's grounds, unsurpassed in Scotland for extent and beauty, lie on the west and north of D., and include the cathedral; Craiginvean and Craig-y-Barns; 50 miles of walks, and 30 miles of drives; falls of the Bran (upper one, 50 feet), near Ossian's Hall at the Rumbling Bridge; and 20 square miles of larch-wood, including the first two larches planted in Britain (in 1737). D., in ancient times, is said to have been the seat of the Pictish kings. It was the seat of a diocese from 1127 to 1658. Three miles south of D. stood Birnam Wood, so famous in connection with the fate of Macbeth.

DUNKIRK, or DUNKERQUE, the most northerly seaport and fortified town of France, stands on the eastern shore of the Strait of Dover, in the department of Nord, its distance from Paris being in a direct line about 155 miles north, and from Lille about 43 miles north-west. The town, which is connected by railway and canal with the principal manufacturing centres of Belgium and France, is surrounded by ramparts and ditches, and is defended by a citadel. It is well built, the streets spacious and well paved, the houses chiefly of brick. Its quay and pier, its church of St Eloi—a Gothic structure, having a handsome though rather incongruous frontispiece in its Corinthian portico—its town-hall, barracks, college, and theatre, are the principal architectural features. The harbour of D. is shallow, and the entrance difficult, but the roadstead is large and safe. D. has manufactures of soap, starch, beer, beetroot-sugar, cordage, and leather; also metal foundries, distilleries, salt-refineries, and ship-building yards. Forming as it does the outlet for the great manufacturing department of Nord, its trade by sea is very considerable. Since becoming a free port, it has also carried on a good trade in wine and liqueurs. Its cod and herring fisheries are actively prosecuted. The immediate vicinity of D. has a dreary and uninteresting appearance. Pop. 26,132.

D. is a place of considerable historic interest. It owes its origin, it is said, to the church built by St Eloi in the 7th c., in the midst of a waste of sand-hills or dunes, and hence its name, 'Church of the Dunes.' D. was burned by the English in 1588, taken by them under Oliver Cromwell in

1658, but sold to Louis XIV. by Charles II. for a sum of money in 1662. By the treaty of Utrecht in 1715, the French were compelled to destroy the fortifications of D., which were again restored, however, in 1783. In 1793, the allies under the Duke of York laid siege to D., but were compelled by the French to retire, after having suffered severely. D. was made a free port in 1826.

DUNLIN, or PURRE (*Tringa alpina*, *T. cinclus*, or *T. variabilis*), a bird of the family *Scolopacidae* (Snipes, &c.), and of the large group to which the names Sandpiper and Stint are variously given. It is not quite nine inches in length from the extremity of the bill to that of the tail. The plumage undergoes great variations in summer and winter. It is a

Dunlin (*Tringa alpina*):  
Summer and winter plumage.

very widely diffused bird. In summer, it frequents even the desolate shores of Melville Island. It is to be seen in autumn and winter on the shores of Britain and of most parts of Europe; often in very great numbers on sandy or muddy sea-shores; and is equally common on those of America from the Gulf of St Lawrence to the Gulf of Mexico. It exhibits great restlessness and activity in running about, searching and probing for its food. When flying in great autumnal flocks, its aerial movements are extremely beautiful, each individual of the vast assemblage yielding so instantaneously to the same impulsion as to exhibit alternately the upper and the under surface of the body, so that we have for a time a living moving cloud of dusky brown, and then a brilliant flash of snowy whiteness.

DUNMOW FLITCH OF BACON, a prize instituted at Dunmow, in Essex, in 1244, by Robert de Fitzwalter, on the following conditions: 'That whatever married couple will go to the priory, and kneeling on two sharp-pointed stones, will swear that they have not quarrelled nor repented of their marriage within a year and a day after its celebration, shall receive a flitch of bacon.' The prize was first claimed in 1445, two hundred years after the prize had been instituted, and since that time it has been awarded only on eight occasions, of which the last two were in 1855 and in 1860. Endeavours are being made to perpetuate the custom.

DUNNAGE, on shipboard, is a name applied to miscellaneous fagots, boughs, bamboos, old mats or sails, and loose wood of any kind, laid in the bottom of the hold to rest the cargo upon; either to keep the ship in trim, or to preserve the cargo from damage by leakage.

DUNNET HEAD, a rocky peninsula, 100 to 600 feet high, the most northerly point of Scotland, on the north coast of Caithness, in lat. 58° 40' N., and long. 3° 21' W. It consists of upper old red

sandstone, resting on the middle flagstone of the same system. It is frequented by various species of sea-fowl, among which is the puffin.

**DUNNOCK.** See **HEDGE-SPARROW.**

**DUNNOTTAR CASTLE**, the ancient seat, now in ruins, of the Keiths, the Earls Marischal of Scotland, on the Kincardineshire coast, a mile and a half south of Stonehaven. It occupies the top of a rock 3 acres in extent, and 160 feet high, overhanging the

sea, with a deep though dry chasm between it and the mainland, and it is approached by a steep winding path. In 1296, Wallace is said to have taken the rock and the kirk of Dunnottar from the English. During the Commonwealth, the Regalia of Scotland were hid in the castle from the republican army, and before the garrison surrendered to Cromwell's troops in 1651, the Regalia were removed and secreted in the church of Kinnelf, by Mrs Grainger, the minister's wife. In the times

Dunnottar Castle.

of James II. and Charles II., D. C. was one of the state prisons, where the Covenanters were confined. It was dismantled after the rebellion of 1715, on the attainder of the last Earl Marischal.

**DUNOIS, JEAN**, called the Bastard of Orleans, Count of Dunois and Longueville, one of the most brilliant soldiers that France ever produced, was born about the year 1403. He was the natural son of Louis Duke of Orleans, brother of Charles VI., and was brought up in the house of that prince along with his legitimate children. D. is said to have been intended for the church, but this is doubted. His first important military achievement was the overthrow of the English at Montargis (1427). He next threw himself into Orleans with a small body of men, and bravely defended the place till the arrival of the famous Joan of Arc, whose religious enthusiasm combined with the valour of the Bastard raised the drooping spirits of the French, and the English were obliged to raise the siege. This was the turning-point in the fortunes of the French nation. In 1429, D. and the Maid of Orleans won the battle of Patay, after which he marched, with a small body of men, through the provinces then overrun by the English, and took the fortified towns. The capture and death of Joan of Arc arrested for a moment the progress of the French arms, but the heroism of D. was irresistible. He took Chartres, the key of Paris, forced Bedford to raise the siege of Lagny, chased the enemy from Paris, and within a very short period deprived them of all their French conquests except Normandy and Guienne. The next grand series of successes on the part of D. was the expulsion of the English

from Normandy. Town after town yielded—Rouen, Harfleur, Honfleur, Caen, Falaise, Cherbourg. This splendid campaign lasted only a year and six days. Not less triumphant was his career immediately after in Guienne; Montguyon, Blaye, Fronsac, Bordeaux, and lastly Bayonne, fell into his hands. The English, in fact, were swept out of the country, and the freedom of France from all external pressure permanently secured. Louis XI., on his accession to the throne in 1462, despatched D. as governor to Genoa, which had yielded itself to France, but soon after, in a fit of jealousy and suspicion, deprived him of all his offices. D. now placed himself at the head of the alliance *Pour le Bien Public*, and by the treaty of Conflans, 1465, recovered all his confiscated estates. He died 24th November 1468. There is no name so popular in France as that of D.; there is no hero so national; he laboured 25 years for the deliverance of his country, and this *alone*—his sword was never unsheathed, except against the English. He never had a force under him which could enable him to win a victory that might balance Agincourt or Crécy, but the multitude and constancy of his petty successes served the cause of France more effectively than great and sanguinary contests would have done.

**DUNOON**, one of the most frequented sea-bathing places and summer residences in the west of Scotland, is situated in the south-east of Argyleshire, on the west side of the Firth of Clyde, nine miles west of Greenock. A village existed here from a very early date, but a new well-built town, with fine villas around, has of late years sprung up. The population fluctuates from 1500 to 2500.

Dunoon Castle, of which only a small part now remains, stood on a conical hill near the pier, and was once a royal palace and strong fortress. The Argyle family once lived here, but the building became a ruin about 1700. (1871—pop. 3756.)

DUNSE, a burgh of barony in the Merse, in the middle of Berwickshire, the largest town in the county, on an eminence on the Whitadder, 44 miles south-east of Edinburgh, and 13 west of Berwick-on-Tweed. Pop. (1861) 2556. To the north of the town is Dunse Law, 630 feet high.

DUNSINNANE, one of the Sidlaw Hills, in the east of Perthshire, 1114 feet high, 7 miles north-east of Perth, and looking towards Birnam Hill (q. v.). On the top are the remains of the rampart and fosse of an ancient fortification, popularly called Macbeth's Castle.

DUNS SCOTUS, one of the most famous and influential of the scholastics of the 14th century. His history is involved in considerable obscurity. England, Scotland, and Ireland all contend for the honour of having given him birth, but without anything to offer in support of their respective claims beyond inference from his name. As to the date of his birth, all that can be said is, that it was in the last half of the 13th century. Whatever was the history of his youth, he entered early the order of Franciscans, studied at Oxford, and soon became professor of theology. His prelections were attended by crowds of auditors, the number of students at Oxford then exceeding 30,000. About 1304, he removed to Paris, then the chief seat of scholastic philosophy, where he taught theology with great applause. He was especially distinguished for the zeal and ability with which he defended the immaculate conception of the Virgin against Thomas Aquinas. He is said to have demolished 200 objections to the doctrine, and established it by a cloud of proofs. It continued long a point of dispute between the Scotists and Thomists; and it was only in 1854 that the dogma was by papal authority declared a necessary doctrine of the Catholic faith, which it is now heresy to deny. In 1308, D. S. was called to Cologne to oppose the heresies of the Beguin brethren, and there he suddenly died, in the 34th or 43d year of his life. D. S. was mostly opposed to Thomas Aquinas in theological opinions, and held very tenaciously the doctrine of the absolute freedom of the human will, from whose spontaneous exercise he derives all morality. He was a realist in philosophy, and his followers are on that ground opposed to the Occamists, who were nominalists. See NOMINALISTS AND REALISTS. He defended his opinions in the style of dialectic then in vogue, and with an acuteness that got him from his contemporaries the name of Doctor Subtilis. When, however, at the revival of learning, the followers of Duns, or *Dunsmen*, saw that the hair-splitting style of reasoning was going out of fashion, they 'raged,' as old Tyndal says, 'in every pulpit' against the new classic studies, so that the name gradually came to signify not only one opposed to learning, but one slow at learning; hence our word *dunce*, a blockhead. It would be difficult to indicate the nature of his speculative opinions without entering into particulars, nor are his writings as yet sufficiently known and explored for the formation of a decided judgment. The most famous of his works, besides his commentaries on the Bible and on Aristotle, is his Commentary on the Sentences of Peter Lombard, called the *Opus Oxoniense*, of which the *Opus Parisiense* is an abridgment. The chief edition of his works is that of Luke Wadding (12 vols., Lyon, 1639), but it is by no means complete. The controversies

carried on so long between the Scotists and Thomists owed their bitterness not so much to zeal for science and religion, as to the jealousy existing between the Franciscans and Dominicans.

DUNSTABLE, a town in the south of Bedfordshire, at the east base of the Chiltern chalk-hills or Dunstable Downs, 18 miles south-south-west of Bedford. It chiefly consists of one main street crossed by another. The houses are mostly of brick, some of them very old. Pop. (1861) 4467. D. is the chief seat of the British straw-plait manufacture, which employs many women. Whiting is also made. In winter, many large larks are caught in the neighbourhood, and sold chiefly in London as an article of luxury. Henry I. founded here a priory of Black Canons, of which the present parish church is a part. D. was in 1110 the scene of some of the earliest theatricals, the subject being the miracles of Catherine, by Abbot Geoffry of St Albans.

DUNSTAN, Sr, was born at or near Glastonbury, in Somersetshire, 925 A. D. He was of noble birth, and even remotely related to the royal family, as well as connected with the church through two uncles, one of whom, Adelm, was Archbishop of Canterbury. His early studies were pursued with extraordinary assiduity; but besides his professional learning, D. possessed a variety of accomplishments. He was an excellent composer in music; he played skilfully upon various instruments; he was a painter, a worker in design, and a calligrapher; a jeweller, and a blacksmith. After he had taken the clerical habit, he was introduced by his uncle Adelm to King Athelstane, who seems to have been delighted with his music; but the courtiers envying the favour of the sovereign, denounced him as a dealer in sorcery, and procured his expulsion from court. D. now began to figure in a new character. Contiguous to the church of Glastonbury, he erected a cell, five feet in length by two in breadth, the floor of which was sunk beneath the surface, while the roof, on the outside, was only breast-high, so that he could stand upright in it, though unable to lie at full length. This was at once his bed-chamber, his oratory, and his workshop. It was here that (according to the monkish legends) he had his most celebrated contest with the devil. One evening, while the saint was employed at his forge, the devil thrust his head in at the window, and began to tempt him with some immoral propositions. D. patiently endured the annoyance until his tongs were red hot in the fire, when, snatching them suddenly up, he seized the foul fiend by the nose, and held him till the whole neighbourhood resounded with the clamour of his agony. Gradually, D. acquired a great reputation for sanctity; and on the accession of Edmund to the throne in 940, he was recalled to court; but in spite of the exploits and penances which had made his banishment illustrious, he was still opposed by the courtiers, who saw his ambition, and dreaded his talents. A second time D. was dismissed, but the king made him Abbot of Glastonbury, and increased the privileges of that monastery. Edred, nicknamed *debilis pedibus* (weak in the feet), who succeeded Edmund in 946, shewed D. great favour. The saint now began to distinguish himself as a statesman, and the vigorous policy of Edred's reign is affirmed to have proceeded from the inspiration of Dunstan. If such was the case, then to D. was owing the complete subjugation of the Northumbrian Danes. Edred was succeeded by Edwy in 955, who detested D., and not without reason, for the saint, on the day of Edwy's coronation, had grossly insulted his wife and her mother. Besides, Edwy had long suspected D. of pecculation in his charge, and this outrage made his wrath overflow.

D. was deprived of his clerical office, his places at court were taken from him, his so-called reform—viz., of compelling the clergy to become celibates—was frustrated, the monks were driven out of their monasteries, their functions handed over to the secular clergy, and D. himself was banished. He fled to Flanders, narrowly escaping having his eyes put out by the messengers whom the infuriated king had sent after him. After D.'s flight, a rising took place among the Northumbrian Danes, instigated by Odo, Archbishop of Canterbury, himself a Dane, and a friend of the expatriated saint. Edgar, the brother of Edwy, was chosen king of the whole of the island north of the Thames, and D. returned in triumph from his brief exile. Meanwhile, Edwy's beautiful wife, Elgiva, had been seized and murdered, under circumstances of horrid cruelty, by the Mercians, who were armed in the cause of D. and Odo, or, as others say, by the immediate retainers of these churchmen themselves. Edwy himself died of a broken heart, or (according to an old MS. in the Cottonian Library) was assassinated, in 958, and was succeeded by his brother Edgar. The latter, as a boy of 15, could exercise little authority: he was long a passive instrument in the hands of D. and his party, who used their power in establishing their cause over the whole island, in enforcing the celibacy of the clergy, and in driving out by main force from all abbeys, cathedrals, and churches, all such married clergymen as would not separate from their wives. At the same time, it cannot be denied that D. and the monks ruled the kingdom with vigour and success, and consolidated the detached states into compact integrity and union than had ever been known before. The Danish districts of Anglia and Northumbria were divided into earldoms or governments; the fleet of the king was increased to 360 sail, which acted as a most efficient coast-guard, preventing the Norse rovers from making their usual destructive descents on the country. In 960, D. was made Archbishop of Canterbury on the death of his friend Odo, when, according to custom, he went to Rome to receive the pall at the hands of the pope. He also induced Edgar to visit in person every part of his dominions annually, when courts of justice were held in the various districts, audiences and feasts given, and appeals heard. The many other beneficial measures of Edgar's reign, such as the reform of the coinage, and the endeavour to extirpate wild animals in the mountainous districts, are generally, and with good reason, attributed to Dunstan. The king, who was zealous for the celibacy of the clergy, was himself one of the most viciously profligate of the Saxon kings; yet D. could wink at his crimes, so long as he himself was allowed to carry out his 'religious' schemes. On the death of Edgar, a fierce struggle took place between the partisans of Edward the Martyr and his half-brother Ethelred. The cause of the former was espoused by D., who succeeded in placing his favourite on the throne; but the mother of Ethelred, named Elfrida, a beautiful but ferocious woman, caused Edward to be murdered in 979, and D. was compelled to place the crown on the head of Ethelred. The credit and influence of the great monk now declined; his threatenings of divine vengeance were treated with contempt; and soured and exasperated at the triumph of his enemies, he retired to his archiepiscopal city, where he died of grief and vexation, May 19, 988. D. was a man of extraordinary abilities. His vigour, his persistency of purpose, and his stern and unscrupulous disposition, would have elevated him to power in any age; but he possessed, in addition to these qualities, a deep knowledge of the weaknesses of human nature, and a clear

and penetrating understanding, which enabled him to see what it was necessary and prudent for a ruler to do. Hence, though despotic to the last degree, he was not blindly so, like a common-place despot. His ambition was ever under the control of his wisdom and his fixed ideas. But the grand designs of his life—viz., the complete subjection and conformity of the Anglo-Saxon church to that of Rome, and the extension and multiplication of ecclesiastical interests—are not such as excite the admiration of modern times, and all discerning people will regret the success that attended the unpatriotic labours of the saint. That he was successful, there can be no manner of doubt. Though personally out of favour at court in the latter years of his life, his efforts to spread his official influence were unceasing. At an early period in his career, he had introduced a new order of monks into the land, the Benedictines, whose strict discipline had changed the character and condition of ecclesiastical affairs, and in spite of the confusion and even opposition thus caused, he persevered to the end. Monasteries continued to be founded or endowed in every part of the kingdom; and such were the multitudes who devoted themselves to the cloister, that the foreboding of the wise Bede was at length accomplished—above a third of the property of the land was in possession of the church, and exempted from taxes and military service. D.'s *Concord of Monastic Rules* will be found in Reyner's *Apostolatus Benedictinorum in Anglia*, fol., Duac. 1626, page 77 of the Appendix. Other writings have been attributed to him. See Wright, *Biog. Brit. Lit., Ang.-Sar. Period*. For further information, consult William of Malmesbury, Lingard's *History of England*, and Kemble's *Saxons in England*, book ii.

**DUODECIMAL SCALE** (Lat. *duodecim*, twelve) is the name given to the division of unity into twelve equal parts, as when the foot is divided into 12 inches, and the inch into 12 lines; or the pound is divided into 12 ounces. This plan of counting by dozens has some advantages, as 12 admits of so many divisions into equal parts—viz., by 2, 3, 4, and 6. But the decimal scale, or division into ten equal parts, is now universally recognised as preferable, from its coinciding with our decimal system of notation.—**DUODECIMALS** is a term applied to a method of calculating the area of a rectangular surface when the length and breadth are stated in feet and inches.

**DUODECIMO** (Lat. *duodecim*, twelve) is that form of volume whose leaf is equal to the twelfth part of a folio—the folio being the large sheet called the *broadside*, folded once. A book is said to be *quarto*, *octavo*, *duodecimo*, &c., because the sheet of which the pages of the book are made up has been folded into four, eight, twelve leaves, &c. Quarto, octavo, and duodecimo, are almost always written 4to, 8vo, and 12mo.

**DUODENUM.** See **DIGESTION.**

**DUPIN, ANDRÉ-MARIE-JEAN-JACQUES**, a French statesman and lawyer, was born, 1st February 1783, at Varzy, in the department of Nièvre, and studied in Paris. In 1815, he was elected a member of the Chamber of Representatives, when he opposed the motion for proclaiming Napoleon II. successor to the throne. During the same year, he published his treatise, *Sur la Libre Défense des Accusés*. The attention excited by this work procured him the honour of defending Marshal Ney, and afterwards the English officers, Wilson, Bruce, and Hutchinson, accused of having favoured Lavalette's escape. He had also the honour to defend the poet Béranger in 1821. From 1825 to 1829, he was the advocate of the liberal party. In his pamphlet, *La Révolution*

de 1830, he endeavoured to prove the legal character of this revolution; and on the question being mooted whether the new king should assume the title of Philippe VII., D. declared 'that the Duke of Orleans was called to the throne not because he was a Bourbon, but although he was a Bourbon, and on the condition that he should not follow in the footsteps of his predecessors.' After having been appointed to various important offices by the new government, D. found it necessary to pass over to the opposition, and was eight times chosen president of the Chamber of Deputies. On the revolution of 1848, he urged (but unsuccessfully) the Chamber to proclaim the Comte de Paris king of the French, with the Duchess of Orleans regent during his minority. In consequence of the confiscation of the Orleans estates in 1852, D. resigned his place, and retired for a time from public life; but in 1857 he consented to resume his previous office of *Procureur-Général* of the Court of Cassation. He has written many important works, mostly on legal questions, among which may be mentioned his *Manuel du Droit Ecclésiastique Français*, which had the high honour of being censured by the congregation of the *Index* at Rome. In 1853 appeared his *Le Morvan; Topographie, Agriculture, Mœurs des Habitants, Etat Ancien, Etat Actuel*; and in 1857, *Règles Générales de Droit et de Morale tirées de l'Écriture Sainte*.

DUPIN, FRANÇOIS-PIERRE-CHARLES, BARON, a French economist, brother to the preceding, was born at Varzy, in the department of Nièvre, 6th October 1784, and educated at the Polytechnic School, Paris. During the Empire, he was actively employed as an engineer. Between 1816—1819, he made several visits to England and Ireland, to study the great works of construction in those countries. The results of his investigations appeared in his *Voyages dans la Grande Bretagne* (6 vols., Paris, 1820—1824, with atlas)—a comprehensive statement of the advantages and defects of British internal administration, exhibiting in a popular form a complete view of the roads, canals, aqueducts, bridges, ports, &c., of this country. D. was about this time appointed member of the Académie des Sciences, and in 1824 was raised to the rank of baron. In 1828, he was elected deputy for the department of Tarn, and he took part with the liberal opposition. After the February revolution of 1848, D. was elected member of the Constituent Assembly by the department of Seine-Inférieure. After the *coup d'état*, he became a senator of the Empire. D. has published a multitude of works on geometry, naval affairs, commerce, &c.

DUPLICATE RATIO. See PROPORTION.

DUPLICATION OF THE CUBE. See DOUBLING THE CUBE.

DUPONT, JACQUES CHARLES, styled DE L'EURE, a leader of the French liberal party, born 27th February 1767 at Neubourg, in Normandy. During the periods of the Revolution and the Empire, he filled several important offices. In 1813, he became a member of the legislative body, and acted as vice-president when this assembly was convoked by Louis XVIII. on the fall of Napoleon. During the Hundred Days he was elected to represent the department of Eure, and, after the battle of Waterloo, became vice-president of the Chamber of Representatives. After the revolution of 1830, he was appointed Minister of Justice, but at the end of six months sent in his resignation, and took his place in the ranks of the opposition. After the revolution of 1848, during the session of the 24th February, D. took the president's chair, and so far

silenced the tumult of the populace, as to render it possible to appoint a provisional government, of which he was proclaimed president. He died in 1855. His political friends styled him the most virtuous among the virtuous, the Aristides of French liberalism. His disinterestedness was not denied even by his enemies; but he manifested fidelity to his convictions rather than energy of character.

DUPUIS, CHARLES FRANÇOIS, a distinguished French *savant*, was the son of a poor schoolmaster, and was born at Trie-Chateau, near Chaumont, 16th October 1742. He obtained admission into the college of Harcourt, where he so soon acquired such extensive knowledge that at the age of 24 he was made Professor of Rhetoric in the college of Lisieux. At the same time he went through a course of law-studies, and was admitted an advocate of the parliament. His acquaintance with Lalande introduced him to the study of mathematics and astronomy, and he was led to the thought of explaining mythology by means of astronomy. After several communications in the *Journal des Savans*, appeared his *Mémoire sur l'Origine des Constellations et sur l'Explication de la Fable par l'Astronomie* (Par. 1781). He was now appointed Professor of Eloquence in the Collège de France, member of the Académie des Inscriptions, and shortly after a member of the commission of public instruction. Although he rather shunned the storms of the Revolution, his reputation necessitated his becoming a member of the Convention, next of the Council of 500, and after the 18th Brumaire, of the legislative body. He was also one of the 48 individuals who formed the nucleus of the Institut National. His great work, *Origine de tous les Cultes, ou Religion Universelle* (12 vols., Par. 1794), which he had long withheld from fear of offending the religious world, was at last published at the instigation of the Cordeliers' Club. This circumstance rendered the book more an object of party bitterness than its own purely scientific character would probably have called forth. It made a considerable impression on France at the time, and no doubt originated the famous commission afterwards appointed by Napoleon to explore Upper Egypt, which D. had pointed out as the general source of southern mythology. No less attention was awakened by his memoirs on the origin and spread of the Pelasgi, and on the zodiac of Denderah (q. v.). In his last work, *Mémoire Explicatif du Zodiac Chronologique et Mythologique* (Par. 1806), he attempts to demonstrate the unity of the astronomical and religious myths of all nations. He died 29th September 1809.

DUPUYTREN, GUILLAUME, LE BARON, an illustrious French surgeon and anatomist, was born at Pierre-Buffière, in Limousin, 6th October 1777; educated at the Collège de la Marche in Paris; and on the formation of a new school of medicine there in 1794, was appointed to the office of *prosecteur*. In 1801, he was appointed *chef des travaux anatomiques*, and applied himself with intense ardour to pathological anatomy. In 1803, he was appointed assistant-surgeon, and later, in 1815, first surgeon at the Hôtel-Dieu. In 1813, he became professor of surgery to the medical faculty, an office which he exchanged, in 1818, for the professorship of clinical surgery at the Hôtel-Dieu. In 1820, Louis XVIII. conferred on him the title of baron, and in 1823, appointed him royal surgeon. He died at Paris, 8th February 1835. D. possessed extraordinary penetration in diagnosis, a penetration that was generally justified by his bold and skilful operations, and an immovable firmness of nerve. He is the inventor of many ingenious modes of surgical operation and of various surgical instruments. He has likewise made several

important discoveries in pathological anatomy; and although he wrote very little, almost nothing indeed, he formed a large school of enlightened surgeons in his native country. Among his works may be mentioned *Leçons Orales de Clinique Chirurgicale faites à l'Hôtel-Dieu* (4 vols., Par. 1830—1834), published by some of his students; and his *Traité Théorique et Pratique des Blessures par Armes de Guerre*, edited by Paillard and Marx (2 vols., Par. 1834).

DUQUESNE, ABRAHAM, MARQUIS, one of the most eminent naval officers of France, was born at Dieppe in 1610, and trained under his father, the captain of a ship, for the naval service. In the war between France and Spain, he brilliantly distinguished himself at Corunna, Tarragona, Barcelona, and other places. During the minority of Louis XIV., when the navy of France was inactive, he entered the service of Sweden, which was then at war with Denmark. D. defeated the Danish fleet near Gothenburg in 1643, was elevated to the rank of vice-admiral, and by a succession of victories over the united fleets of Denmark and Holland, forced Denmark to conclude peace. He then returned to France, where he found the Spaniards prepared to support Bordeaux, which had declared itself for the party of the *Fronde* in 1650. D. immediately collected a squadron at his own expense, and compelled Bordeaux to submit. He was next employed in punishing the pirates of Algiers and Morocco who infested the Mediterranean. On the revolt of Messina against the Spanish government, France sent him to support the insurgents in the Mediterranean. With a small force, D. gallantly opposed the united fleets of Spain and Holland, commanded by De Ruyter, and in April 1676, completely defeated his enemies off the coast of Sicily, in the vicinity of Mount Etna. De Ruyter died a few days after. France thus obtained possession of the island of Sicily. Louis XIV. rewarded D. with the title of marquis and a considerable estate. On the revocation of the Edict of Nantes, D. was made the only exception to the general decree of banishment issued against all Protestants. His last achievement was the humiliation of Genoa. D. died at Paris, 2d February 1688.

DUR' A DEN, between Cupar and St Andrews, in Fifeshire, a small glen through which runs a tributary of the Eden, has become famous on account of the numerous and beautifully preserved fossil fish entombed in its yellow sandstone. This sandstone is one of the upper beds of the Old Red Sandstone. It is developed in D. D. to a thickness of 300 or 400 feet, and is rich in the remains of ganoid fishes. They occur in clusters and detached groups, sometimes crowded together in an extraordinary manner, so that nearly a hundred specimens have been counted on a single slab about five feet square. They are found only in one thin layer, no fragment of skeleton or scale having been obtained in any other portion of the sandstone. The specimens are beautifully preserved; they often exhibit the rounded plump form of the living animal, in some instances not a scale being displaced; the scales retain their original glistening enamel, very different from the white chalky appearance they present in other localities. The specimens consist of two species of *Holoptychius*, viz., *Andersoni* and *Flemingii*; also of *Dipterus*, *Platygnaeus*, *Phaneropteron Andersoni*, *Glyptolemus*, *Glyptopomus*, and *Pamphractus*. For further information on this interesting locality of fossiliferous remains, see *Dura Den*, by J. Anderson, D.D. Edin., Edmonston and Douglas.

DURA MATER. See MEMBRANES OF THE BRAIN.

DURAMEN, or HEART-WOOD, in Botany, the inner and fully ripened wood of exogenous trees. The division is often very marked between the D. and the *Albumen* (q. v.) or sap-wood, the D. being more dense and compact, and its tubes thickened and filled with the peculiar secretions of the plant, so that juices no longer freely flow through them. It is also very frequently of a darker colour than the albumen: in ebony, it is black; and some other trees are remarkable for the peculiar colour of their wood, which appears, however, only in the D., and not in the albumen. As timber, it is much more valuable and durable than the albumen; and the distinction is as well known to the carpenter or cabinet-maker as to the botanist.

DURANCE, a river in the south-east of France, rises in the department of the Hautes-Alpes, near the base of Mont Genève, one of the peaks of the Cottian Alps. It flows through the department of the Basses-Alpes in a southerly direction; then curving westward, it proceeds towards the Rhone, forming the boundary between the departments of Vaucluse and Bouches-du-Rhone, and joins that river about three miles below Avignon. Its principal affluents are the Buech and the Calavon from the right; and the Ubaye, the Eleone, the Asse, and the Verdon from the left. Its total length is about 180 miles—no part of its course is navigable. Its current is swift and impetuous, and carries down with it great quantities of sand and pebbles. Large quantities of timber are floated down from the forest districts upon its banks to Arles, and thence to the Mediterranean. An aqueduct 51 miles long has been recently constructed from the D. to Marseille. This great work not only supplies Marseille with water, but affords water-power for driving machinery, and irrigates an otherwise parched area of 25,000 acres.

DURANGO, or GUADIANA, and also recently named CIUDA'D DE VICTORIA, in honour of the first president of the Mexican Confederation, is a city in Mexico, and stands in the Sierra Madre, at the elevation of 6348 feet—almost a mile and a quarter—above the level of the sea. Lat. 24° 2' N., long. 104° 3' W. It is near the Culiacan (q. v.), being 150 miles to the north-west of Zacatecas. It is regularly built, with a cathedral and other churches, and with convents, a theatre, and a mint; and the inhabitants, 22,000 in number, carry on manufactures in iron, wood, wool, and leather. The city gives name to a department containing 54,500 square miles, nearly the area of England, and 150,000 inhabitants—less than the population of Edinburgh.

DURAZZO (called by the Turks *Dratsch*, and by the Slaves *Durtz*), a maritime town of Albania, European Turkey, is built on the rocky peninsula of Peli, in the Adriatic. Lat. 41° 19' N., long. 19° 27' E. It is fortified, and is a place of considerable antiquity. Its situation in a fertile district gives it an export trade in grain, oil, &c.; but in recent years, owing to partial failures in crops, and disease in olives, the exports have been small. D. has large imports of British manufactured goods; and also of sugar, coffee, rice, soap, and iron. Pop. between 9000 and 10,000.

D. is the ancient *Epidamnus*, which was founded about 627 B.C. by a conjoined band of Coreyreans and Corinthians under one Phalcos, a Heraclidean. It became a great and populous city, but was much harassed by the internal strifes of party, which ultimately led to the Peloponnesian War (q. v.). Under the Romans it was called *Dyrrachium* (whence its modern name), and became the seat of a Roman colony, and an important landing-place for those sailing from Brundisium in Italy to Greece.

Here Pompey was for some time beleaguered by Cæsar. Dyrrachium attained its highest consequence about the end of the 4th c., when it became the capital of the Byzantine eparchy of New Epirus. In the 5th c. it was besieged by Theodoric the Ostro-Goth; in the 10th and 11th, by the Bulgarians; and in 1081 it was captured, after a severe battle, by the Norman, Robert Guiscard of Apulia. In 1205 it fell into the hands of the Venetians; in 1273, it was wholly destroyed by an earthquake, but was soon after rebuilt; and after several other changes, it was finally conquered by the Turks in 1502, in whose possession it still remains.

DÜREN (the Roman *Marcodurum*, whence its former name, *Mark-Düren*), an ancient town of Rhenish Prussia, situated on the Roer, 18 miles east of Aix-la-Chapelle. It is surrounded with walls, and has several churches remarkable for their fine architecture. D. has important manufactures of woollen cloths, iron and steel ware, paper, soap, leather, oil, &c. In the vicinity are iron foundries and other factories worked by water-power, obtained from the Roer. Pop. 8500. Here Charlemagne, on his way to attack the Saxons, held diets in 775 and 779 A. D. After an obstinate resistance, D. was taken and burned by Charles V. in 1543. In 1794, the French made it the capital of the department of Roer; but in 1814 it was handed over to Prussia.

DÜRER, ALBERT, the father of the German school of painting, 'the prince of artists,' as his countrymen loved to call him, was born at Nürnberg in 1471, according to an entry in his father's day-book, 'on the day of St Prudentius, on a Friday of the holy week.' His father was a humble pious goldsmith, of whom the great painter said: 'His daily speech to us was, that we should abound in love to God, and act faithfully towards our neighbour.' D. was carefully educated and instructed by his father in the goldsmith trade, and at 15 executed a piece of work in chased silver representing the seven 'falls of Christ'—in reference to the tradition that Christ fell seven times while bearing his cross to Mount Calvary. Even as a child, drawing was his delight, and he was wont to astonish by the exactness with which he drew parts of the human body, and even whole figures, also lines and circles at the first stroke, without ruler or compass. His father therefore bound him apprentice, in 1486, to Michael Wohlgemuth, the chief Nürnberg artist, with whom he served three years. From 1490 to 1494 he travelled in Germany and the Venetian States; and on his return, his father 'bargained' with Hans Frei, a skilful mechanic of Nürnberg, to give him to wife his daughter Agnes, who turned out a perfect Nantippe, with nothing to recommend her but beauty and 200 florins, who embittered the whole course of his life, and, as his life-long friend Pirckheimer asserts, hastened his death. After receiving his diploma with all the honours and rights of a master, obtained for his famous drawing of Orpheus, he went to Venice in 1505, where he painted a picture of the martyrdom of St Bartholomew, and one of Adam and Eve, afterwards bought for the gallery at Prague. He also visited Bologna, where it is said that he met with Raphael, who esteemed him highly, and that each painted for the other his portrait. After this journey, his fame spread widely; and the Emperor Maximilian appointed him court painter, with an annuity of 100 florins; and Charles V. confirmed the same in a document still to be seen in the Nürnberg archives. In 1520, he visited the Netherlands with his wife and their maid-servant; and they were splendidly entertained at Antwerp and

Bruges by the painters, a costly dinner being served on vessels of silver, the whole party conducting them home late in the night by the light of many torches. His expenses were often defrayed at the inns, and he was escorted free from city to city. He says in his journal: 'The people did obeisance unto me as if they were leading some great lord.' D. warmly embraced the doctrines of the Reformation; and his journal contains a long lamentation and prayer on hearing that Luther had been carried off to the castle of Wartburg. At Antwerp he records: 'I was now overcome by a strange sickness, of which I never yet heard from any man.' This was in 1521, and the 'strange sickness'—no other than consumption—took yet seven years to consume his strong frame; he died in his native city, 6th April 1528, in his 57th year.

D.'s facility was almost incredible. He *thought out* his works, and then executed them without sketch, and never altered a line. Of his colouring, Fuseli says: 'Dürer excelled Raphael in juice and breadth of colouring as much as Raphael excelled him in every other quality.' His drawing was perfect. So quaint were the presentments of his genius, he may be called the Chaucer of painting. In his portraits, he not only caught the expression, but delineated character and passion. D. was the inventor of the art of etching. He found wood-engraving in its infancy, and raised it to be a pattern for all times; he also discovered the method of bringing out wood-cuts in two colours. Historical and other paintings by D. are to be seen at Vienna, Munich, Prague, Dresden, and Nürnberg. The oldest of his pictures extant is the portrait of himself of the year 1498, in the Florentine Gallery. His engravings and wood-cuts are so numerous, that with all his surpassing diligence it is known that for many of them he only gave the designs: 262 wood-cuts are known marked with his name, the most famous of which are the 'Great Passion,' the 'Little Passion,' his favourite work, the 'Revelation of St John,' and the series called the 'Triumph of Maximilian,' a copy of which is in the Advocates' Library in Edinburgh. In the British Museum, there is a volume with more than 200 original drawings by D., formerly in the collection of Sir Hans Sloane, also an exquisite carving in hone-stone, of the Birth of St John, and a number of engravings, bequeathed by Mr Nollekens. His own list of his works enumerates 1254 pieces.

In the last three years of his life he published works on perspective and measurement, on fortification, and on human proportion, of which last he only lived to correct the first volume. His life has been written by Heller, Roth, Campe, and others. Deeply religious and reverent, he was also of a cheerful temperament, and was long chief magistrate of his native town, where there is a brass statue of him, designed by the famous sculptor Rauch, and his house is still to be seen at the corner of a street called by his name.

DÜRESS, in English Law, is the plea of a man who has obliged himself to pay or perform, or who has committed a misdemeanour, that he was constrained to do so, and therefore ought to be free from the consequences. There is both *duress of imprisonment* and *duress per minas*.—*Tomlins' Dict.*

D'URFEY, THOMAS, a writer of plays and poems in the reign of Charles II., by whom he was a favourite for his wit, liveliness, and songs. In literature, he is best remembered for his sonnets, entitled *Pills to Purge Melancholy*, a work found only among the rarities of private libraries. Tom D., as he was usually called, lived to entertain

Queen Anne by singing his catches and glees; but being without any settled means of support, he concluded his career in poor circumstances. Addison, who was his friend, pleaded in his behalf—'He has made the world merry, and I hope they will make him easy, as long as he stays among us. This I will take upon me to say, they cannot do a kindness to a more diverting companion, or a more cheerful, honest, good-natured man.' He died at an advanced age in 1723.

DURGA PUJA. See UMA.

DURHAM, a parliamentary and municipal borough, and ancient episcopal city of England, near the middle of Durham county, built around a steep rocky hill 86 feet high, nearly encircled by the Wear. On the top of the hill are the cathedral and castle. Ancient walls partly enclose the hill, from which are fine views of the fertile wooded country around, and of the suburbs across the river. The chief manufactures of D. are carpets and paper. In the vicinity are coal-mines, and saline, chalybeate, and sulphurous springs. Pop. (1861) 13,743. It sends two members to parliament. D. arose about the year 995, when Bishop Aldune brought here St Cuthbert's bones from Ripon, and built a church to enshrine them. On the site of this church, Bishop William de Carlepho, about 1093, began the present magnificent cathedral, a Romanesque structure in the form of a Latin cross, to which additions continued to be made till about 1500. It thus exhibits the gradual changes of style between these periods. It was restored during last century. It is 507 by 200 feet, with a central tower 214 feet high, and two west towers 138 feet high. A plan of it is given in illustration of the article CHURCH. The cathedral contains many old monuments. Here lie St Cuthbert's (q. v.) remains, discovered in 1827, and immediately reinterred. Here, also, are Bede's tomb and some manuscripts said to be in his handwriting. Cardinal Wolsey was a prelate here. The bishop's income is now £8000. The castle, formerly the residence of the bishops of D., but now the seat of the university of D., was founded about 1072, by William the Conqueror, in the Romanesque style, but it has since been much altered. The dormitory, now the new library of the cathedral, which belonged to the monastery of D., is one of the finest in England. Two of the bridges over the Wear were erected in the 12th century. D. was often attacked by the Scots.

A college was founded here in 1290 by the prior and convent of Durham. It was abolished, however, at the dissolution of monastic houses in the reign of Henry VIII., and its endowments given to the dean and chapter of Durham. Under the Commonwealth, Cromwell instituted a college here, and endowed it with the sequestrated revenues of the dean and chapter, to whom, however, these revenues again reverted at the Restoration, when the college was suppressed. The present university of D. was opened for students in 1833, under the provisions of an act of parliament, obtained by the dean and chapter during the previous year. A royal charter in 1837 empowered the university to bestow degrees. The D. university comprises professorships in Divinity, Ecclesiastical History, Classical Literature, Mathematics, and Astronomy, with readers in Law, Hebrew, History and Polite Literature, and Natural Philosophy, and a lecturer in Chemistry and Mineralogy. (1871—pop. 14,406.)

DURHAM, a maritime county of the north-east of England, between the Tyne and Tees, bounded N. by Northumberland, E. by the German Ocean, S. by Yorkshire, W. by Cumberland and Westmoreland. It is 48 miles long, by 39 broad, with 32

miles of coast, generally low, but with some cliffs; area 973 square miles,  $\frac{2}{5}$  being arable. The surface is hilly, and slopes to the east. In the west, which is waste but rich in minerals, are branches of the Pennine chain, rising in Killhope Law, 2196 feet; Collier Law, 1678; and Pontop Pike, 1618. The two chief branches enclose the valley of the Wear, and send forth several parallel ranges, declining toward the coast, and enclosing many fertile tracts and sheltered valleys. The chief rivers are the Wear, Tyne, and Tees, navigable respectively for 20, 15, and 10 miles. The rocks are new red sandstone, magnesian limestone, millstone grit, carboniferous limestone, rich in lead; and coal-measures, forming the valuable D. coal-field, 25 by 10 miles, with many faults, and with about 40 beds of coal, three to ten feet thick, some of the mines being 1800 feet deep. Basalt and greenstone trap dikes intersect the west part of D., one being 20 miles long, and another 24. The mineral products are coal, limestone, black marble, freestone, ironstone, firestone, slate, millstone, grindstone, and lead. D. is one of the chief counties in England for the production and export of coal: 500 ships are employed at Sunderland for this export alone. Five of the coal-seams, three to eight feet thick, and at the depth of 20 to 100 fathoms, are worked horizontally for many miles. Above 160 miles of railway are connected with the mines and ports. The soil is a clayey or dry loam. The chief crops are oats, barley, wheat, turnips, beans, and pease. The Teeswater or Holderness breed of cattle is famed for fattening, quantity of milk, and early maturity. The D. horses are famed for draught and the saddle. Many sheep are pastured on the hills. There are manufactures of iron, pottery, glass, alkalis and chemicals, and salt, and much ship-building at Sunderland and South Shields. Coal is the chief export. It is divided into 4 wards, 14 poor-law unions, and 60 parishes. In 1861, the population amounted to 509,018. In 1851, there were 390,997 inhabitants, 837 schools, with 49,231 scholars; 621 churches (169 Church of England, 351 Wesleyan Methodists). The chief towns are Durham, the county town, Sunderland, Darlington, Gateshead, South Shields, Stockton, and Hartlepool. The county sends four members to parliament. D. has some ancient barrows, and has afforded many Roman antiquities, as altars, urns, and coins. There are the remains of a fine Roman station at Lanchester. D. formed part of the Saxon kingdom of Northumbria (547 to 827). Subsequently, it suffered severely from the incursions of the Scots.

DURHAM COUNTY PALATINE, one of the three counties palatine of England, the other two being Lancaster and Chester. For the privileges of a county palatine, see PALATINE. The county palatine of Durham existed by prescription. It was the only county palatine in the hands of a subject, and belonged to the Bishop of Durham. By 6 and 7 Will. IV. c. 19, the county palatine of Durham is separated from the bishopric, and vested in the crown. (1871—pop. 685,045.)

DURHAM, JOHN GEORGE LAMETON, EARL OF, an English statesman, was the son of William Henry Lambton, Esq., of Lambton Hall, county of Durham, and was born at the family seat, 12th April 1792. The Lambton estate was not very large, but had been in the possession of the family since the 12th c., the male issue having never once failed during all that period. The antiquity of the family, however, exercised no narrowing influence on his opinions, which were markedly radical. He was educated at Eton; and when only twenty years of age, married at Gretna Green a Miss Harriet Cholmondeley, who died in the course

of a few years. In 1814, he was returned for his native county, and though he did not speak on many questions, he took part in all the more important debates, opposing the Corn-law Bill of 1815, the additions made to the incomes of the royal dukes, the Indemnity Bill of 1818, the six repressive bills brought in by government to coerce the people after the great reform meeting at Manchester in 1819, &c. Two years after, he submitted to the House of Commons a scheme of parliamentary reform, which of course was not accepted. In 1828, he was raised to the peerage, with the title of Baron Durham of the city of Durham. He was one of the four persons who drew up the Reform Bill, and supported it in the House of Lords. In 1833, Lord D. was despatched on a mission to Russia. On his return to this country, his 'advanced liberalism' was proclaimed at a dinner given to Lord Grey at Edinburgh, in 1834, and in various other parts of the country. After a second mission to Russia, he was appointed governor-general of Canada, where he arrived in May 1839; but on account of a misunderstanding with the home government, he took the extraordinary step of returning to England in the course of half a year, without either being recalled or obtaining the royal consent. D. died at Cowes, Isle of Wight, 28th July 1840. He left a son, the present Earl of Durham, and three daughters.

**DURIAN**, or **DURION** (*Durio zibethinus*), a fruit-tree of the Malayan Archipelago, of the natural order *Sterculiaceae*, of the same tribe or sub-order (*Bombacae*) with the silk-cotton tree. It is a lofty tree, with leaves resembling those of the cherry, and large bunches of pale-yellow flowers. The fruit is of the size of a man's head, roundish oblong, with a hard thick rind, covered with soft spines, so that it somewhat resembles a hedgehog rolled up. The pulp of the fruit is of a sort of creamy substance and delicious taste, but has a smell which is at first very repulsive to Europeans. Persons accustomed to it, however, universally regard the D. as one of the very finest fruits of the East. It brings a higher price than any other fruit in the market in India. It contains ten or twelve seeds, as large as pigeons' eggs, which, when roasted, are not inferior to chestnuts. One tree yields about 200 durians in a year.—The cultivation of the D. has not yet been successfully attempted in our hot-houses, the great size of the tree forming one principal obstacle to it. The D. is not a native of India, nor of Ceylon, but is now successfully cultivated in the latter country.

**DURLACH**, an old town of Germany, in the grand-duchy of Baden, is situated on the river Pfalz, at the base of the Thurmberg, a highly cultivated hill, three miles east of Carlsruhe. D. has manufactures of linen, tobacco, chicory, vinegar, as also important fruit and grain markets. The environs are covered with orchards. On the summit of the Thurmberg are the ruins of an old castle. D. is a station on the Mannheim and Basel Railway. Pop. 5000.

**DURRA**, **DOURA**, **DURRA MILLET**, **INDIAN MILLET**, or **SORGHO GRASS** (*Sorghum*), a genus of grasses, distinguished from *Andropogon*—in which many botanists prefer to include it—only by the ovate or oblongo-ovate hermaphrodite spikelets, with glumes that have three small teeth at the extremity. The species are generally annual, tall, broad-leaved grasses, having strong culms filled with a juicy and saccharine pith, and large panicles. Several of them are cultivated as corn-plants, chiefly in Asia and Africa, particularly the common D. (*S. vulgare*, or *Andropogon Sorghum*,

*Holcus Sorghum* of the older botanists), also called *Joar* and *Jowaree* in India. It grows 4—8 feet high, with thickly crowded panicles. It is a coarse, strong grass; its grain is round, a little larger than mustard seed. It is a native of the East Indies, is extensively cultivated in Asia, and may perhaps be described as the principal corn-plant of Africa. It is also cultivated to a considerable extent in the south of Europe. It is sometimes cultivated in Germany, but the summer is not sufficiently long and warm to secure its greatest perfection. The climate of Britain is still less suitable. D. yields a very abundant produce, in this respect even rivalling maize, but the meal does not make good bread; it is excellent, however, instead of rice for puddings, and is prepared in various ways for food. The culms and leaves, although coarse, are excellent food for horses and cattle, as is also the grain.—The seeds of the **SHALOO** or **SUGAR-GRASS** (*S. saccharatum*) are more pleasant to the taste than those of the common durra. It is cultivated in the warm parts of Asia and in Africa, and has a diffuse and very spreading panicle. The sweet pith of the culm is eaten, and is also of value as a source of sugar. This plant has been cultivated to some extent in the Veronese, and its cultivation has been recently introduced into North America—where it is called **CHINESE SUGAR-CANE**—in order to the production of sugar. It seems likely to form an important new feature in American agriculture, succeeding well at least as far north as Maine, and yielding sugar in large quantity. In Britain, it succeeds only in the warmest parts. As a forage plant, it is very nutritious when young.—**KAFIR CORN** (*S. Caffrorum*) has a very diffuse umbel-like panicle, with branches bending down all around. The culm is more than the height of a man, and has a sweet pith. This species is largely cultivated in South Africa, both by Kafirs and by the colonists. By the latter, the grain is chiefly used for feeding horses.—*S. Halpense* is a troublesome weed in the fields of the north of Italy, like couch-grass. The sweet runners of the roots are kept by the apothecaries of that country as a substitute for sarsaparilla, under the name of *Garnigione*, or *Smilace dolce*.

**DURRENBERG**, a small town of Prussian Saxony, five miles south-east of Merseburg, deserves mention only for its salt springs, which produce about 250,000 bushels of salt annually. Pop. upwards of 300.

**DURRENSTEIN**, a village of Lower Austria, is situated in a highly picturesque locality, on the left bank of the Danube, about 45 miles west-north-west of Vienna. It is chiefly notable for the ruins of a castle, which stand upon a ridge of bare rock overlooking the town. A peculiar interest attaches to this grand but desolate and shattered fortress, from its having been the prison in which Richard Cœur-de-Lion was confined by Leopold of Austria, for fifteen months. Pop. 500.

**DURSLEY**, a town in the west of Gloucestershire, amid picturesque scenery, at the base of a steep beech-covered hill, and near the Cotswold hills, 15 miles south-south-west of Gloucester. It is irregularly built, and chiefly consists of three streets, diverging in different directions from the market-place. Pop. (1861) about 2500. In the oolitic and lias formation in the vicinity is a quarry of topics or puffstone, which is a soft and easily worked stone, but hardens on exposure to the air.

**DUSICYON**, a genus of *Canida*, or sub-genus of *Canis* (Dog), consisting of a number of South American species or varieties, sometimes called *Aguara Dogs*. They have the body rather long in proportion to their height, and of considerable

bulk, the muzzle rather sharp, eyes somewhat oblique, and aspect somewhat foxlike, tho tail also has a more or less perfect foxlike brush. They are more diurnal than nocturnal in their habits, live in burrows, and feed on birds and small quadrupeds. Some of them have been domesticated by the Indians.—Akiu to the Aguara Dogs, but more foxlike, are the Aguara Foxes (CERDOCYON, q. v.).

**DUSKY BAY**, a large inlet on the south-west coast of Middle Isle, in New Zealand, is in lat. 45° 40' S., and long. 166° 20' E. It was entered by Cook in 1769, who here found good anchorage.

**DÜSSELDORF**, the chief town of the district of Düsseldorf, in Rhenish Prussia, and the capital of the former duchy of Berg, is situated in the centre of a fertile district, on the right bank of the Rhine, at the confluence of the Düsseldorf with that river, in lat. 51° 13' N., long. 6° 45' E. It was formerly fortified, but its ramparts were converted into gardens and promenades at the treaty of Luneville, 1802. It is seated in the midst of extensive garden-grounds, and is well built. The streets, the houses of which are built of brick, are regular and spacious; while the rows of trees with which many of them are planted, greatly enhance their appearance. D. is divided into the *Allstadt*, on the right bank of the Düsseldorf; the *Karlstadt*, the handsomest quarter of the town, founded in 1786, by the Elector Karl Theodore, on the left side of the same stream; and the *Neustadt*, on the Rhine. A colossal equestrian statue of the Elector Johann Wilhelm, who founded a famous picture-gallery here in 1710—the pictures of which, however, were removed to Munich in 1808—stands in one of the five squares of Düsseldorf. The Düsseldorf Academy was founded in 1767, reorganised in 1822, and attained great eminence during the years 1822—1826, under the management of Cornelius and Schadow. The Art-Union for the Rhine Provinces and Westphalia was founded here in 1828. The principal buildings of D. are the old electoral palace; the present palace, the residence of the governor of the province; the government house, the observatory, town-hall (built in 1567), theatre, gymnasium, and public library. Of the ecclesiastical edifices, the most remarkable are the churches of St Andrew and St Lambert, and the church of the Jesuits, a handsome and highly ornate structure, having two steeples. The Hofgarten, one of the finest public gardens in Germany, is a very agreeable promenade. D. has manufactures of woollens, cottons, leather, hats, tobacco, jewellery, mirrors, &c.; but it may be said to derive its chief importance from its position on the Rhine, as on this account great quantities of goods are sent to D. from the surrounding districts for exportation. Its principal trade is in its manufactures, and in wines, spirits, iron-ware, &c. Pop. 46,849, most of whom are Catholics. Along with the duchy of Berg, D. came into the possession of Prussia in 1815. It was made a free port in 1829, and since that time it has prospered. It has daily communication with Mayence and Rotterdam by the Rhine steamers. Industry and commerce have likewise received a new impulse since D. became the central point of several lines of railway. (1871—pop. 69,351.)

**DUST-BRAND.** See SMUT.

**DUSTEE**, the largest river of Beloochistan, enters the Arabian Sea, in lat. 25° 3' N., and long. 61° 45' E. In proportion to length, it is certainly the least considerable stream in existence. It is about 1000 miles long; and yet it has been found to be, at its mouth, 20 inches deep, and 20 yards wide. During its entire course, it is, in its permanent character, remarkably shallow; and,

in fact, the water-courses of the country depend, without exception, almost exclusively on the rainy season.

**DUSTY-FOOT**, a court of summary jurisdiction established in fairs in England for the speedy determination of questions arising between those who resort to the fair. See *PREN-POUDRE*, COURT OF.

**DUTCH GOLD** is an alloy of copper and zinc, in the proportion of three or four ounces of zinc to one pound of copper. It can be beaten out into thin leaves resembling gold-leaf, when it receives the name of *Dutch gold-leaf*, and almost rivals gold in appearance. It is very liable to be tarnished by gases, such as hydrosulphuric acid (sulphuretted hydrogen), which are constantly present in the air, especially in town districts, and it may be distinguished from true gold-leaf by the action of strong nitric acid, which instantly dissolves Dutch gold, and leaves true gold unaffected.

**DUTCH LIQUID** is an oily substance obtained by mixing chlorine and olefiant gases, which combine together and yield D. L., with the formula C<sub>4</sub>H<sub>2</sub>Cl<sub>2</sub>. It has a specific gravity of 1250 (water = 1000), boils at 184° F., is not miscible with water, but readily dissolves in ether and alcohol. It possesses the power of producing Anæsthesia (q. v.), just as Chloroform (q. v.) does; but the great difficulty of preparing D. L. in commercial quantities must retard its employment as an anæsthetic.

**DUTCH RUSHES.** See *EQUISETUM*.

**DUTENS, LOUIS**, a French writer, was born at Tours, 16th January 1730. Being a Protestant, he sought to make his way in England, and occupied himself at first in teaching and in self-improvement. At last, he accompanied the English ambassador to the court of Turin as his secretary, and afterwards remained as *chargé-d'affaires*, a position which he occupied twice subsequently. He held a pension, and was presented to the rich living of Elsdon, in Northumberland; and was likewise made Historiographer Royal of Great Britain. He died in 1812. His numerous works display great versatility and knowledge of the world. He undertook the first comprehensive, though not complete, edition of Leibnitz's works (6 vols., Geneva, 1769). In his *Recherches sur l'Origine des Découvertes attribuées aux Modernes* (2 vols., 1766), he rates the knowledge and invention of the ancients by far too high. The *Tocsin* (Rome, 1769), which afterwards appeared under the title of *Appel au Bon Sens* (Lond. 1777), contains some sharp attacks on Voltaire and Rousseau. There is considerable historical interest in his *Histoire de ce qui s'est passé pour le Rétablissement d'une Régence en Angleterre* (Lond. 1789). He also wrote several able treatises on numismatics and other subjects. In the *Considerations Théologiques sur les Moyens de réunir toutes les Eglises Chrétiennes* (Par. 1798), he proposed that a council should compose a confession of faith grounded on the decrees of the councils of the first six centuries. His *Mémoires d'un Voyageur qui se repose* (Par. 1806) met with general favour.

**DUTROCHET, RENÉ JOACHIM HENRI**, an eminent French physiologist and physician, was born at the Château de Néon (Poitou), 14th November 1776, and came to Paris in 1802, to study medicine. His career as a student was brilliant, and in 1808 he was appointed military physician to Joseph Bonaparte, king of Spain. Soon after, he became physician-in-chief of the hospital of Burgos, then devastated by typhus fever. Returning to France in 1809, he gave himself up exclusively to the study of nature, and published a series of works on physics and physiology, full of new ideas. In 1819, ho

became a correspondent of the Royal Academy of Science; in 1823, of the Royal Academy of Medicine; and in 1831, a member of the former. He died 4th February 1847. The substance of all D.'s investigations and discoveries is contained in his *Mémoires pour servir à l'Histoire Anatomique et Physiologique des Végétaux et des Animaux* (Paris, 1837). He is best known by his researches on the passages of fluids through animal and vegetable substances. The passage of a fluid from without, inwards, he calls *endosmosis*; and from within, outwards, *exosmosis*. These terms have since been widely adopted by physiologists. See DIFFUSION OF LIQUIDS AND GASES.

DUTTEEAH, a city of Bundelcund, in Central India, lies between Agra and Saugor, being 125 miles to the south-east of the former, and 148 to the north-west of the latter. With a population of about 50,000, the place has many good houses, the residences of the principal zemindars or landholders of the neighbourhood. Like most towns in Bundelcund (q. v.), D. has a rocky site; and it is surrounded by a stone-wall 30 feet high. The lat. and long. are 25° 40' N., and 78° 31' E.

DUTTEEAH, the principality or raj of which the above-mentioned city is the capital, is a protected but not tributary state, extending in N. lat. from 25° 32' to 26° 18', and in E. long. from 78° 15' to 78° 54'. It contains 850 square miles, and 120,000 inhabitants. The revenue is fully £100,000; and the armed force numbers 6000 men.

DUTY. See ETHICS.

DUYSE, PRUDENS VAN, a Belgian writer, was born in Dendermonde, in Belgium, September 28, 1804. After completing his academical career, he was appointed Archivist of his native town, from which he was removed to the same office in Ghent. He soon afterwards received the office of Professor of National History in the Athenæum, and was made a member of various learned societies both in Belgium and France. He died November 13, 1859. D. was one of the chief contributors to the revival of Flemish literature. As a poet, he was less remarkable for genius than for prodigious fertility; his pieces all bear the stamp of improvisation, of which he was a great master. Several of his productions, both poetical and prose, obtained prizes from literary societies. Of 47 poetical publications issued by D. between 1836 and 1859, we may mention *Vaderlandsche Poëzij*, *Natalia*, *Elegien*, *Gedichtjes voor Kinderen*, *Het Klaverblad*, and *Nieuwe Kindergedichtjes*.

DWALE. See BELLADONNA.

DWARF. See GIANTS AND DWARFS.

DWARFED TREES, growing in flower-pots, are a characteristic ornament of Chinese and Japanese houses and gardens, and the production of them is an art which has been carried to great perfection. It depends on the prevention of an abundant flow of sap, so that whilst the tree is kept living and healthful, vegetation does not go on with its natural activity. The trees are planted in shallow and narrow flower-pots; care is taken that their roots never pass into the ground beneath; they are very sparingly supplied with water; their strongest and leading shoots are pinched off, and their branches are bent and twisted in various ways. A very extraordinary dwarfing is the result of these and other such processes; and the dwarfed trees not unfrequently abound in flowers and fruit.

DWARKA, a maritime town of the province of Guzerat, in India, stands on the west side of the peninsula of Kattywar, being in lat. 22° 15' N., and long. 69° 1' E. It is one of the most sacred places

in this part of Hindustan. On an eminence overhanging the sea-shore, which was once an islet, stands a great temple of Krishna, presenting to the mariner a conspicuous landmark; while, connected therewith by a colonnade, is a smaller edifice dedicated to Deoki, the mother of Krishna. The Gunti, a bordering rivulet which barely reaches the ankle, is, notwithstanding its insignificance, an object of profound veneration.

DWIGHT, DR TIMOTHY, a well-known American theologian, was born at Northampton, in Massachusetts, May 14, 1752; studied at Yale College, Newhaven; and was licensed to preach in 1777. During the War of Independence, he was for some time a chaplain in the American army. In 1783, he was ordained minister of Greenfield in Connecticut, where he also conducted an academy for twelve years with distinguished success. In 1787, the College of Princeton, New Jersey, conferred on him the degree of D.D.; and in 1795, he was elected President of Yale College and Professor of Divinity. He died January 11, 1817. D.'s principal work is his *Theology Explained and Defended in a series of 173 Sermons* (5 vols., Middletown, Conn. 1818, &c.). It has been frequently reprinted in England; and used to be—as probably it still is in quiet country quarters—very popular among elderly persons of a serious turn of mind. D. was not a great or original thinker; but his mind was fertile in the production of respectable ideas, which, though sufficiently commonplace, were yet pleasing both in themselves, and from the important nature of the subjects to which they referred. Among his other writings may be mentioned, *The Conquest of Canaan, an Epic Poem* (1785); *Travels in New England and New York* (1821), reckoned by Southey the most important of his writings; and two volumes of *Sermons* (Edin. 1828).

DWINA, NORTHERN—as distinguished from the Western Dwina or Dïna (q. v.)—an important river of Russia, has its origin in the confluence of the Suchona and the Jug, two streams, the latter more than 200 miles, and the former nearly 300 miles in length, rising in the south of the province of Vologda, and uniting in lat. 60° 45' N., long. 46° 30' E. The D., from the union of these streams, flows north for about 50 miles, and receives the Vytchegda from the east, a river 500 miles long. At this point, the D. becomes navigable, and here it alters its direction, and proceeds north-west toward the Gulf of Archangel, into which it flows, having been joined on the right by the Pinga, and on the left by the Waga, and having traversed a course of about 700 miles. The basin of the D. comprehends an area of 123,900 square miles. Its average width is from 500 to 600 feet; before debouching into the White Sea, however, its surface, which is there marked by many islands, increases in width to about four miles. The waters of the D., the largest river that falls into the White Sea, are abundantly supplied with fish. Vessels of more than 14 feet draught cannot enter the D., on account of the shoals at its mouth.

DYCE, ALEXANDER, an English literary historian, was born at Edinburgh, 30th June 1798. He was educated at the High School of that city, and afterwards at Oxford. After officiating for some time as curate, he settled in London in 1827. His literary reputation is chiefly based on his editions of the older English poets and authors—George Peele, Robert Greene, John Webster, Shirley, Thomas Middleton, John Skelton (an author of the beginning of the 16th c., previously little known), Beaumont and Fletcher, and Marlowe, with biographies of the authors, and instructive notices. He also edited the poems of Shakspeare, Pope,

Akenside, and Beattie, for Pickering's Aldine Edition of the Poets. An old play discovered by him, called *Timon*, and which may possibly have first suggested to the great poet the idea of his drama of the same name, was besides published for the Shakspeare Society, as well as another entitled *Sir Thomas More*. In conjunction with Collier, Halliwell, and Wright, he founded the Percy Society for the publication of old English ballads, plays, and poems. His ability as a commentator on Shakspeare is proved by his *Complete Edition of the Works of Shakspeare; the Text revised; with Account of the Life, Plays, and Editions of Shakspeare, Notes, &c.* (1858).

DYCE, WILLIAM, R.A., a distinguished painter, was born at Aberdeen. He was educated at the university there, and at the age of 16 obtained the degree of Master of Arts. After acquiring the rudiments of his art-education he went to Rome, where he studied for some years. His tendency at first was very strongly, and continued so under certain modifications, towards early Italian, or pre-Raphaelite art, and his productions attracted the marked attention of Overbeck, the head of the modern German school. On his return to this country, he settled in Edinburgh, where, besides painting portraits, he contributed largely to the Exhibitions. The first picture he exhibited in Edinburgh was in the Perugin style, and though evincing great power, was at that period, 1829, but little felt or appreciated; his 'Puck,' however, exhibited at the same time, was very successful, and most of his after-contributions to the Exhibitions of the Royal Scottish Academy, of which he was a member, were deservedly popular, particularly his picture of 'Francisca da Rimini,' exhibited in 1837. After this he went to London, having been nominated to the head-mastership of the New School of Design at Somerset House, an office which he obtained on account of his general acquirements and knowledge of art, and which he held for three years. Soon after this he was appointed Professor of Painting in the London University. He distinguished himself at the Westminster competition by his frescoes, and in consequence was one of the artists selected to decorate the Palace of Westminster and the House of Lords, and at Osborne House several works in fresco have been executed by him. D. was elected an Associate of the Royal Academy in 1844, and Academician in 1848. The following are some of the works he exhibited in the Royal Academy: 'King Joash Shooting the Arrow of Deliverance,' a 'Madonna and Child' (1846), a 'Meeting of Jacob and Rachel' (1850), 'Christabel' (1855), 'The Good Shepherd' (1856), 'Titan Preparing to make his Essay in Colouring,' 'Neptune Assigning to Britannia the Empire of the Sea,' a study for a fresco at Osborne (1857), 'St John Leading Home his Adopted Mother,' 'The Man of Sorrows' (1860), and 'George Herbert at Bemerton' (1861). (Died Feb. 14, 1864.)

DYCK, SIR ANTHONY VAN. The history of this celebrated painter is of great interest, not only from the high position he held as an artist, but from his having settled in England, where he executed numerous works, which enable us to realise most of the personages whose actions form prominent points in the history of this country. He was born at Antwerp, 22d March 1599. His father, according to Houbraken, was a glass-painter; and it is said that his talent was fostered by his mother, who painted landscapes, and was skilful in embroidery. After making very considerable progress under Van Balen, he was, in 1615, admitted as a pupil of Rubens, who was not slow to appreciate his great talents. In a letter, dated 17th July 1620, addressed to the Earl

of Arundel, known historically for his patronage of art, the writer states, 'Van Dyck lives with Rubens, and his works are beginning to be esteemed little less than those of his master. He is a young man of one-and-twenty, whose parents are persons of considerable property, and it will be difficult, therefore, to induce him to remove.' Soon after this—namely, in 1621—by advice of Rubens, he visited Italy. The works of the great Venetians were the first to attract his attention. After leaving Venice, Genoa was the next city he resided in, then Rome, and he went a second time to Genoa, from whence he made a short visit to Palermo. Van Dyck was five years in Italy, and from the number of portraits painted by him in Genoa—many of the best of his works in his Italian manner are still there—he must have lived a considerable portion of the time in that city. On his return to Antwerp in 1626, he executed various pictures for churches, and the portraits classed among those painted in his Flemish style; the series of cabinet portraits of the painters of his day, engraved by Vostermans, &c., and most of which are now in the possession of the Duke of Buccleuch, were also painted at this time. It is stated, that about 1630—1631, Van Dyck visited England, and, meeting with no encouragement, remained only a short time; however, there is no satisfactory proof of this. But in 1632, he came to England, by invitation of the Earl of Arundel, at the command of Charles I. He was lodged at Blackfriars, was soon afterwards knighted, and had a pension of £200 a year settled on him. His commissions were now numerous, he was enabled to live in great style, entertained people of high rank, and had a country-house at Eltham, in Kent. His wife, Marie Ruthven, by whom he had one daughter, was the daughter of Patrick Ruthven, physician, fifth son of Lord Gowrie. Van Dyck died in London in 1641, leaving property to the amount, it is said, of about £20,000. Only twenty years are included within the time when Van Dyck left the studio of Rubens till the period of his death; and during that short career, the number of pictures executed by him, on what is thought to be good authority, seems almost incredible, for in Smith's Catalogue Raisonné of the Works of the Dutch and Flemish Painters, there are descriptions and interesting particulars of upwards of 950. This artist's works may be classed as executed in three distinctly marked styles—1. Those painted in Italy during his residence of five years, from 1621 till 1626; these are distinguished by deep tone and colour, and dignity of character and expression. The portraits of the Lomellini Family and an Italian Nobleman, in the Scottish National Gallery, are good examples of his style at this period. 2. His productions between 1626 and 1631, when he lived in Flanders, are known as done in his Flemish style; these works are executed with much *impasto* or body of colour in the lights, and transparency in the shadows. Perhaps it was during this period of his career that he executed his finest works, among which the best are the portrait of Snyders the painter, now the property of the Earl of Carlisle; the companion-picture of Snyders's wife, now belonging to the Earl of Warwick; and the portraits of Philip le Roy and of his wife Madame le Roy, purchased by the Marquis of Hertford at the sale of the king of Holland's pictures. 3. The portraits he painted in England between 1631 and 1641; these are noted for grace and elegance, but many of them were often slight in execution, or done partly by assistants. Van Dyck's biographers and critics generally dwell at great length on his Scripture subjects, and express regret that he devoted so much of his time to portrait-painting; but different notions seem to be now gaining ground. No Scripture

subjects by Rubens or Van Dyck, or produced in any of the later schools, will stand comparison, for purity of feeling and appropriate technical execution, with the works of the earlier masters; and the allegorical pieces so much in vogue in the 17th c., are little in accordance with the ideas of the present time. But the portraits by Van Dyck are all interesting and valuable histories, recorded with marvellous truth and vividness, of characters who played important parts in an era noted for great events—and as works of art will rank with the productions of the best schools.

Van Dyck's etchings are admirable. Several of the portraits in the collection of portraits of artists, are etched by him. The impressions of those that were thrown off, when the heads merely were etched, are of great value; indeed, in expression and spirit, they have never been equalled.

DYEING is the art of staining or colouring yarn or cloth. It has been practised among eastern nations from time immemorial; and in the sacred writings, we read of the vestments of the high-priest being dyed purple, of linen cloths being dyed blue, purple, and scarlet, and of rams' skins being dyed red. The famous Tyrian purple is believed to have been discovered by an inhabitant of Tyre fifteen hundred years B.C.; and immediately afterwards the Tyrian purple became the badge of royalty, and cloth dyed with it commanded a princely price. The Egyptians, Greeks, and Romans practised the art of dyeing; and gradually it became more and more wide-spread as civilisation advanced, the discovery of America and other lands materially increasing the number of dye-stuffs. In earlier times, dyeing was much more extensively followed as a domestic art than it is at the present time. In the Highlands of Scotland, however, females are still in the habit of dyeing cloth *brown* by immersing it in a solution of copperas (sulphate of iron), and then treating it with a decoction of sumach, logwood, and crottel (*Parmelia omphalodes*), a lichen which covers many rocks and trees in moist situations; *black*, by immersing the cloth or yarn in an infusion of the bark of the alder-tree (*Alnus glutinosa*), along with copperas and a little sumach; *yellow*, by the common heather (*Calluna vulgaris*) and alum; *red*, by the roots of bed-straw (*Galium verum*) and alum, &c.

The Dye-stuffs (q. v.) employed in the various processes of dyeing are numerous, and when two or more are associated together, many different shades and colours are produced besides the original colour yielded by each. The dyeing materials are procured from the mineral, vegetable, and animal kingdoms, and are often very costly. The arrangements connected with dyeing operations are at times simple, whilst at other times they are complex, and require the greatest care and skill on the part of the dyer. In communicating the deep indigo blue to woollen cloth and yarn, a vat is taken, about 6 or 7 feet in diameter, and 8 to 9 feet in depth, and nearly filled with water, along with 18 to 22 lbs. of indigo, 10 to 20 lbs. of madder, 7 to 9 lbs. of bran, and generally 7 to 9 lbs. of woad. After the requisite boiling, and the addition of 7 or 8 lbs. of lime, to form an alkaline liquid in which the indigo can be held in solution, the whole is well closed over with tightly fitting wooden covers; and in a day, the putrid fermentation of the woad and bran proceeds, the result of which is to abstract the oxygen from the blue indigo, the colour of which is gradually reduced till it assumes a yellowish colour, and the solution then contains indigo white. If woollen yarn or cloth is now dipped in this liquid, it comes out of a yellow tint, from the attachment of the white indigo solution; but when exposed

to the air, the oxygen immediately begins to act upon the white indigo, combining with it, so as to form oxidised or blue indigo, and as the process of oxidation proceeds, the yarn or cloth becomes first of a greenish and then of a blue colour. If the cloth be again soaked in the yellowish solution, and subsequently exposed to the air, the depth of the blue colour may be increased step by step, till it arrives at that deep shade of blue so well known, especially in the coarser qualities of woollen cloth. In the dyeing of cotton with indigo, the vat is prepared differently. The indigo is first ground into a thin paste with water, and afterwards placed in a vat with protosulphate of iron and milk of lime. The lime (CaO) takes the sulphuric acid (SO<sub>3</sub>) from the sulphate of iron (FeOSO<sub>3</sub>), forming sulphate of lime (CaOSO<sub>3</sub>), and liberating protoxide of iron (FeO), which immediately abstracts the oxygen from the blue indigo, reducing it to white indigo, and the latter dissolves in the excess of lime present in the vat, yielding a colourless solution. When cotton cloth or yarn is dipped in this, it comes out of the vat almost colourless; but on exposure to the air, the indigo becomes reoxidised, and the cloth passes to a green, and ultimately to a deep-blue shade. The cloth or yarn is then washed in water, and afterwards soaked in very dilute sulphuric acid, to remove any oxide of iron remaining attached, and re-washed in water, when the blue colour becomes more bright and clear.

In the fixation of colour upon cloth, recourse is often had to a mordant (see CALICO-PRINTING), which acts as a middle agent, and attaches the colour to the cloth. The principal mordants are alum, cream of tartar, and salts of tin. Previous to the application of any colour, the cloth or yarn must be well cleansed from grease, oil, &c., by scouring in soda or in soap, and except where the material is to be dyed of a dark colour, the goods are also subjected to the process of bleaching. In the case of fabrics which require a smooth surface, the preliminary operation of singeing off the loose hairs is resorted to. See CALICO-PRINTING.

DYEING OF COTTON.—The following receipts for the dyeing of cotton apply to 10 lbs. weight of cotton yarn or cloth, which is found to be the smallest quantity capable of being well dyed at one time. The proportions of each ingredient may be altered, however, so as to correspond with the quantity of cloth or yarn to be operated upon.

1. *Common Black*.—Take 3 lbs. sumach, and treat with hot water; steep the goods in the hot decoction for some hours; wring out; wash for 10 minutes in lime-water, and for 30 minutes in a solution of 2 lbs. copperas. Wash the goods well in cold water, sometimes repeating the treatment with lime, and re-washing; then work the goods for 30 minutes in a warm solution of 3 lbs. of logwood, and afterwards with 2 oz. copperas; work again for 10 minutes; wash, and dry.

2. *Jet Black*.—Proceed as at 1, adding 1 lb. of fustic with the logwood; and when 3 pints of iron liquor are used instead of the 2 oz. copperas, a more brilliant black is obtained.

3. *Blue Black*.—Use the indigo blue vat, and then proceed as at 1.

4. *Brown*.—Treat the goods with a yellow dye; then work for 30 minutes in a decoction of 2 lbs. lima wood and 8 oz. logwood; lift and work with 2 oz. alum for 15 minutes; then wash, and dry.

5. *Catechu Brown*.—Immerse the goods at a boiling temperature in a decoction of catechu; then work for 30 minutes in a hot solution of 6 oz. bichromate of potash. Wash in hot water, and if the latter contain a little soap, the colour will be improved.

6. *Chocolate or French Brown*.—Dye the goods with a spirit yellow; then treat for half an hour with a solution of 3 lbs. of logwood; raise with a little red liquor; work for 10 minutes; wash, and dry.

7. *Red*.—Make a hot solution of 3 lbs. of sumach; introduce the goods, and let stand till the liquor is cold; then wring out, and work in water containing in each gallon a gill of red spirits (prepared by adding 2 oz. of feathered tin by degrees to a mixture of three parts of hydrochloric acid, one part of nitric acid, and one of water in the cold) for 30 minutes; wring and wash well; then work the goods for 30 minutes in a lukewarm decoction of 3 lbs. of lima wood, and 1 lb. of fustic; add a gill of red spirits; work the goods longer; wash, and dry. The famous Turkey-red is imparted to the cloth by first impregnating it with an oily or fatty substance, and then subjecting it to a decoction of madder. It is one of the most durable of all colours.

8. *Yellow or Straw*.—Work the goods in a weak solution of acetate of lead; then wring out, and work in a dilute solution of bichromate of potash; wring out, and work again in the lead solution; wash, and dry.

9. *Leghorn Yellow*.—Proceed as at 8, but add a little annatto liquor with the solution of bichromate of potash.

10. *Spirit Yellow*.—Work the goods through a weak solution of protochloride of tin for 30 minutes; then work in a solution of quercitron bark for 15 minutes; lift out, and work again in tin solution, and wash in cold water.

11. *Orange*.—Proceed as at 8, and afterwards pass through lime-water at the boiling-point, ultimately washing in cold water.

12. *Blue*.—The goods are worked in various strengths of solutions of salts of iron, such as nitrate of iron; wring out; wash in water, and then work in solution of yellow prussiate of potash; wring out, and wash in water containing a little alum. The various shades of blue may be obtained by using stronger or weaker solutions.

13. *Green*.—Dye the cloth blue; then work in red liquor (acetate of alumina); wash in water; work in decoction of fustic or bark; raise with solution of alum; wash in cold water, and dry. The darker shades of green, as olive or bottle green, are brought out by the use of sumach and logwood along with the fustic.

14. *Puce or Lilac*.—Work the cloth or yarn in red spirits (see 7), then in logwood solution at a temperature of 140° F., adding a little red spirits, red liquor, or alum; wash, and dry; or dye the cloth blue (12); then work in solution of logwood; add alum; work again; wash, and dry.

15. *Purple*.—Soak the goods in a warm decoction of sumach till cold; work for an hour in red spirits; wash; work in hot solution of logwood; then add a little red spirits, and work again; wash, and dry. The various shades of purple may be obtained by altering the strength of the chemicals; the more sumach, the browner the hue, and the more logwood, the bluer the purple becomes.

16. *Lavender or Peach*.—Work the goods for 20 minutes in spirit-plumb (a strong solution of logwood, treated with about one-sixth of its volume of a solution of tin, made by dissolving tin in six or seven parts of hydrochloric acid, one part of nitric acid, and one of water); wring out, and wash well in cold water.

17. *Safflower Lavender* is obtained by dyeing the goods a light-blue, then working in decoction of safflower, which places a pink on the top of the blue.

18. *Drab*.—Work the goods in a decoction of sumach; lift, add copperas; rework; wash in

water; then work in a mixed decoction of fustic, lima wood, and logwood; raise with a little alum; wash, and dry. Catechu is occasionally employed.

**DYEING OF WOOL**.—In the dyeing of woollen yarn and cloth, the various steeps are used warm, but the washings in water are done cold. Care must be taken to remove every particle of grease from the wool by washing with soda and soap, before it is subjected to the process of dyeing, else the colouring matters will not adhere. The more common and important colours are obtained as follows:

19. *Black*—by working the cloth in a bath of camwood, then of copperas; after which wash out; then treat with decoction of logwood and copperas; or work in a bath of bichromate of potash, alum, and fustic; lift, and expose to the air; then immerse in decoction of logwood, barwood, and fustic; thereafter of copperas.

20. *Brown*.—The goods are worked in a bath of fustic, madder, peachwood, and logwood; then introduce into dilute solution of copperas; or the goods are treated with a bath of bichromate of potash, argol, and alum, washed, and then introduced into a bath of fustic, madder, peachwood, and logwood.

21. *Red*—by working in a decoction of bichromate of potash and alum, and subsequently in a bath of peach or lima wood, with a little alum. Scarlet is obtained from cream of tartar, cochineal, sumach, and fustic.

22. *Crimson*—from cochineal, cream of tartar, and chloride of tin. Cudbear gives a wine tint.

23. *Pink*.—Work the goods in a bath of tartar, alum, cochineal, and red spirits.

24. *Orange*—from a bath of sumach, cochineal, fustic, tartar, and red spirits.

25. *Yellow*—from a bath of tartar and alum; then a decoction of bark, sumach, fustic, and red spirits.

26. *Blue*.—Various shades may be obtained from immersion in salts of iron, and then in solutions of yellow prussiate of potash (see 12). Also work the wool in a bath of argol, alum, and indigo extract.

27. *Green*.—Work the goods in a bath of fustic, argol, and alum, and thereafter in a solution of indigo. The dark shades of green, such as olive, are brought out by a bath of fustic, logwood, madder, and peachwood, and afterwards of copperas.

28. *Violet*—from eudbear, logwood, barwood, or camwood, and peachwood; as also alum. The addition of copperas brings out a puce tint.

29. *Drab*.—The manifold shades of this colour are procured from variable strengths of decoctions of madder, peachwood, logwood, fustic, associated with alum and copperas.

**DYEING OF SILK**.—The operations connected with the dyeing of silk are similar to those already sketched out, but a more thorough scouring of the raw material requires to be made, so as to remove all the gum and wax belonging naturally to the fibre.

30. *Black* is obtained by working the silken material in copperas (sulphate of iron), then in logwood containing some chamber liquid, and repeating the treatment with copperas and logwood till the requisite shade is procured. A little nitrate of iron tends to give a more full, deep black; and alum and white soap are also used with advantage. Acetate of copper is occasionally used.

31. *Blue Black*.—Dye a blue as at 12, and then proceed as at 30.

32. *Brown*.—Obtain an orange by immersion in a solution of annatto, then treat with copperas; and introduce into a bath of fustic, logwood, archil, and a little alum. If a more yellow tint is required, add more fustic; redness is obtained by adding peachwood, and blueness by the addition of logwood.

33. *Reds* are obtained from peachwood and fustic, and thereafter red spirits. Annotta is used in getting up the scarlet shades, and cochineal and safflower in the more expensive red dyes. Rubies and maroons require cudbear.

34. *Pink*—from safflower, associated with sulphuric acid and cream of tartar.

35. *Orange and Yellow*—by treating the goods with more or less strong solutions of annotta, associated with alum and white soap.

36. *Blue*—from salts of iron and yellow prussiate of potash; or from solutions of sulphate of indigo, assisted with a little alum.

37. *Green*—from steeping in decoctions of fustic and sulphate of indigo, along with a little alum. The darker shades have copperas added and logwood.

38. *French and Pearl White*.—Work the silk in a lather of white soap, to which archil or cudbear has been added, to give the required shade.

39. *Drab*—from decoctions of sumach, fustic, logwood, and more or less copperas, according to the depth of shade required.

**DYEING OF MIXED FABRICS.**—The coloration of textile fabrics composed of more than one kind of material, generally requires two or more processes, as the plan pursued in dyeing wool is seldom capable of fixing the colour upon cotton. The customary plan followed is to immerse the fabric in the requisite baths, to dye the wool, and then to treat the partially dyed material in the manner found suitable for cotton. Occasionally, the woollen thread of the cloth is dyed of one colour, and thereafter the cotton is treated so as to acquire a different shade or colour. The producing of a coloured pattern on cloth has already been considered under CALICO-PRINTING.

DYER, GEORGE, an antiquary and scholar of some eminence, was born in London, March 15, 1755, and was educated first at Christ's Hospital, and afterwards at Emanuel College, Cambridge, which he entered in 1774, and where, after four years' study, he took his degree of B.A. During the next fourteen years, he was variously engaged, chiefly at Cambridge, as usher, tutor, and as minister (in the Baptist denomination), but he finally settled in London in 1792. Here he devoted himself principally to literature, and produced, among many works of less note, the *History of the University and Colleges of Cambridge* (Lond. 2 vols., 1814), and *Privileges of the University of Cambridge* (Lond. 2 vols., 1824). He also contributed largely to magazines. He died in London in 1841. D. was a man of remarkable straightforwardness and honesty of character, qualities which are everywhere discernible in his works. He was also a poet, although now forgotten, and never famous.

DYER, REV. JOHN, an English poet, was born at Aberglasney, in Caermarthenshire, in the year 1700, and educated at Westminster School. He was intended for the law, but, however, abandoned that study for painting. In 1727, he published his poem of *Groggar Hill*, remarkable for simplicity, warmth of feeling, and exquisite descriptions of nature. He then made the tour of Italy, and returning home in bad health, took orders, and obtained some respectable ecclesiastical preferment. In his didactic poem, entitled *The Fleeco* (1754), the difficult subject is treated with great success; but the unpretending tone of the poem made no impression upon his contemporaries. Another poem, *The Ruins of Rome* (1740), abounds in isolated beauties. D. died in 1758. A collected edition of his poems appeared in 1761.

**DYE-STUFFS.** The substances used in dyeing as the sources of colouring matter, are mostly

derived from the vegetable and animal kingdoms, the far greater number of them from the former. To the animal kingdom, and to the class of Insects, we are indebted for *Cochineal*—and consequently for *Carmine*—*Kermes*, and *Lac*, and less directly for *Galls*. The *Tyrian purple* of the ancients is also said to have been a product of the animal kingdom, obtained from a mollusc.—The dye-stuffs obtained from the vegetable kingdom are numerous, and in every part of the world there are some in domestic use, which have not become articles of commerce. Such are those dye-stuffs of the Highlands of Scotland, mentioned in the article DYEING. Dye-stuffs are procured from plants of widely different natural families: there are some indeed in which certain colouring matters appear to be extensively prevalent, as in *Rubiaceæ* (madder, &c.), and the genus *Casalpinia* (q. v.). They are also obtained from almost all different parts of plants, as the heart-wood (*duramen*) of the stem (Logwood, Brazil-wood, Camwood, Fustic, &c.); the bark (Alder, &c.), the root or its bark (Barberry root, &c.); the leaves and other herbaceous parts (Indigo, &c.); the corolla (*Safflower*); the fruit (*French Berries*, Annotta, &c.). The principal dye-stuffs are the following: *Alkanet* (q. v.), useful in dyeing various shades of lilac, lavender, and violet, which are, however, liable to fade on exposure to light. *Aloes*, obtained by evaporating the juice of the aloe, which is grown in the East and West Indies, Sicily, Italy, and Malta. It contains a brown colouring matter named *Aloetin*, which may be employed in the production of a brown tint. *Annatto* (q. v.), employed in imparting the various shades of yellow, orange, and scarlet, to silk, wool, and cotton. *Archil*, yielding, when infused in water, a crimson dye of great beauty, though fugitive, and used in giving a finish to wool and silk which have been previously dyed. *Barberry root*, imported from the East Indies, and containing a yellow colouring matter called *berberin*. *Brazil-wood*, often called *peach-wood*, containing *brazilin*, which, in contact with the air, yields a rich red colour. *Camwood* (q. v.) or *Barwood*, has a red colour similar to that of Brazil-wood, is generally employed in the form of a coarse powder, and readily imparts its colour to water. *Catechu*, yields a reddish-brown solution in water, and performs an important office in the dyeing of many shades of brown, black, and green. *Chicu* (q. v.), employed in the dyeing of wool and cotton of an orange-yellow colour. *Cochineal*, employed directly, or indirectly in the form of carmine (extracted from the cochineal), in imparting the most beautiful red and crimson colours. *French*, *Persian*, *Turkey*, or *Spanish berries*, obtained from several species of *Rhamnus* (see BUCKTHORN), yield a powerful yellow dye. *Fustic*, the finely divided wood of *Rhus cotinus* (see SUMACH), a yellow dye. *Fustic* or *yellow wood*, used for dyeing cloth yellow, and for communicating a good green tint to cloth already rendered blue; as also, in conjunction with other dyes, in imparting various shades of drabs, olives, fawns, &c. *Galls* or *gall-nuts* are employed in dyeing cloth of a dark or black colour. *Indigo* (q. v.), very extensively used in the dyeing of yarn and cloth of a deep blue colour, which may be afterwards rendered green by a yellow dye. *Kermes*, *Kermes grains*, or *Alkermes*, an excellent material for dyeing many shades of red, and one of the most ancient dye-stuffs employed in the colouring of silk. *Lac* (q. v.), *Shell-lac*, or *Stick-lac*, is used in the preparation of red dyes. *Logwood* (q. v.), broken up into small chips, or reduced to powder, is employed in the dyeing of reds, and, when associated with other substances, yields purples, violets, and blues. *Madder* (q. v.), one of the most important of dye-stuffs,

is extensively used in the dyeing of cloth and yarn red, purple, brown, &c. *Munjeet* or *Indian madder* is used in India instead of madder. *Quercitron* yields a rich orange-yellow, or yellow-red dye, capable of being afterwards made a brown; and when used after a blue dye, it changes the latter to a bright green. *Safflower* yields a rich yellow dye. *Sandal-wood*, *Santal* or *Saunders wood*, yields a red colour, which, along with other substances, may be altered to violet, reddish brown, and scarlet. *Sumach*, occasionally called *young fustic*, is employed as a yellow dye, and also for the tannin and gallic acid it contains, which enables decoctions of sumach to be used with great effect for imparting depth or solidity to other colours. *Turmeric*, or *Indian saffron*, is employed as a yellow dye, but is very fugitive. *Weld*, or *Wald*, produces a rich but fugitive yellow. *Wood* is employed as a blue dye for woollen and silk yarn and cloth, either with or without indigo. *Wongshy* is a new yellow dye-stuff procured from the seed-vessels of a plant belonging to the family of *Geraniaceae*, and imported from Batavia.

The above list of dye-stuffs comprehends those which are obtained, directly or indirectly, from the vegetable and animal kingdoms; and a more lengthened notice of the substances will be found under their respective names. Other dye-stuffs less generally used are also noticed in the articles devoted to different orders and genera of plants. The metallic salts and compounds employed in dyeing will be specially noticed under the various metals; thus for acetate of lead, see **LEAD**; sulphate of iron, see **IRON**; &c.

**COAL-TAR COLOURS.**—The most recent discovery of importance in dyeing, is the extraction of coloured substances of great beauty from coal-tar, and the application of these to the colouring of cloth. At the present time (1861), these dyes of coal-tar origin are most extensively employed, and give rise to the fashionable colours named Aniline purple, Tyrian purple or Mauve, Violine, Roseine, Fuchsine or Magenta, Solferina, Bleu de Paris, Aniline green or Emeraldine, Azuline, &c. It is only, however, within the last four years that these dyes have become practically known, though the preliminary discoveries in connection with their extraction were made in 1826. The condensable product or gas liquor obtained during the destructive distillation of coal in gas-works, consists of aqueous matter holding salts of ammonia in solution, and tar with naphtha. The tar consists of a numerous class of bodies, of which aniline and benzole are two. The aniline is present in minute quantity; and for manufacturing purposes, means are generally resorted to for the conversion of the benzole of gas-tar into aniline. The process followed on the commercial scale is to act upon the benzole by nitric acid, by which it is converted into nitrobenzole, and thereafter, by the action of acetate of the protoxide of iron, it becomes aniline.

*Aniline Purple.*—In the preparation of the dye known as aniline purple, solutions of equal equivalents of sulphate of aniline and bichromate of potash are mixed together; and when the reaction is complete, a black precipitate is obtained, which is dried, and then digested several times in coal-tar naphtha, to separate all resinous matter. The residue is dissolved by successive quantities of alcohol; and the solution being placed in a retort, the alcohol is distilled off, and the aniline purple is left as a beautiful bronze-coloured substance. Aniline purple is slightly soluble in cold water, more so in hot water, and is readily dissolved by the alcohols and aniline itself. It is nearly insoluble in ether and naphtha.

*Roseine* is most readily prepared on the commercial scale by adding two equivalents of binoxide of lead to a boiling solution of one equivalent of sulphate of aniline, and boiling the whole for a short time. On filtration, a rose-coloured solution is obtained, which is evaporated down to small bulk, when some resin separates, and the roseine is precipitated by soda or potash, and being collected on a filter, can be washed and dried. This dye is readily soluble in alcohol, and yields a very intense crimson colour, which, on being evaporated to dryness, leaves a dark metallic-looking and brittle residue of roseine. It is soluble in water, but not in naphtha.

*Violine* is procured by the oxidation of aniline, and the process generally followed is to heat a mixture of two equivalents of sulphuric acid, one equivalent of aniline, and some water, to the boiling-point, then add binoxide of lead, boil for some time, and filter hot. A purple liquid is obtained, which is boiled with potash till the aniline present is volatilised, and the colouring matter is precipitated, when the latter is thrown on a filter, washed with water, and dissolved in a dilute solution of tartaric acid. On filtration, the coloured liquid is evaporated to small bulk, re-filtered, reprecipitated by potash and soda, and the precipitate being dissolved in alcohol, yields an alcoholic coloured solution, which on distilling off the alcohol, leaves the violine as a brittle bronze-coloured substance. Violine is very slightly soluble in water, is readily dissolved by alcohol, and is insoluble in ether and naphtha.

*Fuchsine* or *Magenta* is prepared by adding anhydrous bichloride of tin by degrees to aniline. The materials are constantly stirred during the operation, to keep down the intensity of the action, and the result is, that much heat is evolved, the mixture becomes pasty, then liquid and brown; and as the temperature approaches the boiling-point, it becomes a dark, almost black liquid, which in very thin layers presents a rich crimson colour. This liquid is boiled for some time, much water added, the whole reboiled, so as to volatilise any free aniline, and chloride of sodium (common salt) added till saturation, when the fuchsine or magenta is precipitated as a golden green, semi-solid, pitchy substance. Any resinous matter still remaining may be separated by digestion in benzole. This dye may also be obtained by acting upon aniline with nitrate of mercury. Fuchsine or magenta is sparingly soluble in water, dissolves to some extent in alcohol, and is insoluble in ether and naphtha.

*Bleu de Paris* is prepared by heating 9 parts by weight of bielloride of tin and 16 parts of aniline to a temperature of about 350° F., in a sealed tube, for 30 hours, when a blue product is obtained, which is soluble in alcohol, and crystallises therefrom in fine needles of a lively blue colour. Bleu de Paris is soluble in water, alcohol, wood-spirit, and acetic acid, and insoluble in ether and bisulphuret of carbon.

*Aniline Green* or *Emeraldine* is obtained by acting upon a hydrochloric acid solution of aniline by chlorate of potash, when the aniline becomes oxidised, and yields a dull green precipitate, which on drying becomes an olive-green residue. It is insoluble in water, alcohol, ether, and benzole, and in the presence of a free acid the green colour improves in appearance, though it returns to its original shade when the free acid is removed.

*Quinoline* or *Chinoline* is present in coal-tar, and may be employed to yield three colouring matters—a violet, a blue, and a green; but the processes as yet followed in their preparation belong more to the laboratory experiments of the scientific chemist than to the practical operations of the manufacturer.

*Picric Acid* is obtained by acting upon many organic substances, such as indigo, amline, carbolic acid, salicin, silk, aloes, gun-resins, &c., by nitric acid. On the commercial scale, carbolic acid is generally employed, and it is first treated with nitric acid of slightly less density than 1300 (water = 1000), and afterwards boiled with stronger acid, when it passes into picric acid, and is precipitated on dilution with water. It can be purified by recrystallisation from boiling water. Pure picric acid crystallises in lamina of a primrose yellow colour.

*Azuline* is the only other colouring matter of practical importance derived directly or indirectly from coal-tar. It is a brittle, non-crystallisable substance, with a copper-coloured metallic appearance. It is sparingly soluble in water, but is soluble in alcohol, yielding a fine blue solution with a shade of red. Treated with concentrated sulphuric acid, it becomes a fine blood-red liquid, which, on dilution with much water, gives a red precipitate of azuline.

*Pittacal* is a blue colouring matter obtained from coal-tar.

*Dyeing of Silk and Wool by the Coal-tar Colours.*—This department of the operations of the dyer is very simple, as the silk and wool fibres possess the power of taking up and fixing the majority of these colouring matters with great rapidity, whenever the yarn or textile fabric is placed in the vessel containing a solution of the colour. In the dyeing of silk with aniline purple, violine, and roseine, the alcoholic solution of the colour is diluted with eight times its volume of hot water acidulated with tartaric acid, and thereafter treated with a larger quantity of cold water. The silk is merely worked in this comparatively weak solution of the dye till the shade of colour is deep enough. The addition of a little sulphate of indigo to the dye-vat assists in bringing out a more decided blue tint. The same result is obtained by first dyeing the goods with Prussian blue before immersion in the coal-tar colour. When silk is to be dyed with fuchsine, picric acid, chinoline blue or chinoline violet, the goods require only to be worked in water-solutions of these colours. A little acetic acid added to the vat containing the fuchsine or picric acid is advantageous, and if a solution of sulphate of indigo is mixed with the solution of picric acid, the goods acquire a fine green colour.

Azuline is attached to silk with more difficulty than any of the preceding colours. The silk requires to be worked first in a solution of azuline acidulated with sulphuric acid, and thereafter the liquid is raised to the boiling-point, and the silk continued to be worked in it. The goods are then washed in water, worked in a bath of soap-lather, rinsed, and finished in a weak acid bath.

Wool is dyed with aniline purple, violine, roseine, fuchsine, and chinoline by merely working the yarn or cloth in a vat containing a water-solution of the colouring matter at a temperature ranging between 112° and 140° F.

Cotton has not the power of firmly attaching, directly, coal-tar colours to its fibre so as to resist the action of soda and of soap. When the cotton, however, is treated with a solution containing much tannin, such as a decoction of sumach, or galls, for an hour or so, then introduced into a dilute solution of alum or stannate of soda, and, lastly, passed into a dilute acid liquid, and washed in water, it acquires a great power of firmly attaching aniline purple, roseine, violine, fuchsine, and chinoline colours, whenever it is worked in a dye-vat containing these colouring matters. This principle of the attachment of these colours to cotton by means of a mordant of tannin and alum, may be applied in

printing patterns upon cloth, as in Calico-printing (q. v.). The pattern is printed on the cloth by means of tannin and alum dissolved in water and thickened with gum; and afterwards, when the prepared goods have been introduced into a hot dilute acid solution of the colouring matter, the dye becomes attached to those parts on which only the tannin has been printed, and leaves the other parts uncoloured. Another mode is to mix the dye with albumen or lacterine, print on the cloth, and then subject to the action of steam, which coagulates the albumen or lacterine, and at the same time fixes the colour on the cloth.

**DYING DECLARATION.** By the law of all nations, the declaration of a party, made in the immediate prospect of death, relative to the mode of his death, is received as evidence. The ground of this exception to the general rule of law, that hearsay evidence is inadmissible, is thus clearly stated by Lord Chief Baron Eyre: 'That they are declarations made in extremity, when the party is at the point of death, and when every hope of this world is gone; when every motive to falsehood is silenced, and the mind is induced, by the most powerful considerations, to speak the truth: a situation so solemn and so awful is considered by the law as creating an obligation equal to that which is imposed by a positive oath in a court of justice.' In Scotland, the dying declaration of a witness is admissible even though he is not himself conscious of the danger of death. In this respect, the law of Scotland differs from that of England and America. The general rules as to dying declarations are, that they cannot be received in any civil case, and in criminal cases only where the death of the deceased is the subject of the charge, and the circumstances of the death are the subject of the dying declaration. They must be made, except in Scotland, with the full knowledge of impending death; they are subject to the ordinary rules of law as to capacity to give evidence; they must relate to facts only, and not opinions, and must be freely made; they must be complete in themselves, and if it appear that the dying man intended to qualify them, they cannot be received. See Taylor on Evidence.

**DYKE, or DIKE** (Dutch, *dyk*), an artificial mound along the bank of a river or sea-shore, erected for the purpose of preventing inundation. The term is from the same root as *dig*—hence also *ditch*, or the hollow from which the dyke is formed. The French employ the term *levée* to signify this species of embankment, of which there is a notable example in the levées created along the Mississippi near New Orleans. The principle on which dykes or levées are formed is very simple. The embankment must be of sufficient breadth and height to resist the pressure of the water, and must be constructed with that easy slope which will allow the floods to rise without any particular impediment. This is quite understood in practical engineering. Flowing water must not be abruptly resisted, but suffered to rise gradually and expend itself. It is accordingly of the first consequence, in all attempts to restrain water by embanking, that the mounds should possess not only magnitude, but a very gradual rise in the side which has to resist the impact of the flood. For want of attention to this method of embanking, there has often been much ineffectual dyking of the sea and rivers liable to do damage by flooding.

In no country has the erection of dykes been carried to such a length as the Dutch Netherlands. Consisting to a large extent of low meadow-land, formed of materials brought from Switzerland and Germany by the Rhine, there is a constant liability

to be deluged by the several branches of that river previous to their entering the sea. Inspired by a sense of their perilous situation, as well as a naturally industrious and painstaking disposition, the Dutch have for ages been distinguished for their ingenious system of river-embanking; till at length the dykes of Holland are spoken of as almost one of the wonders of the world. While the country generally is guarded against sea-inundations by high mounds of sand or dunes, created by the deposit of light sand blown from the level shores (see DUNE), the interior is secured from the rivers by the system of dykes here referred to. These ramparts are in appearance long green mounds, broad at the base, graduated in their slope, and often of sufficient width to admit of a canal or road, or both, being formed along the top. To give strength to the fabric, willows are planted and also interwoven like wicker-work on the sides. Carried along the banks of rivers, and in some places along the margin of the sea, as well as crosswise in different parts of Holland, a singular net-work of embanking is presented, which answers the double purpose of a protection from inundation and a means of having canals, by which superfluous water pumped from the meadows, or *polders*, may be run off into the sea. The whole system of dyking is placed under local and general superintendence, at a considerable cost to the public. One of the most gigantic of these dykes is that along the Helder; it measures about six miles in length, 40 feet broad at the summit, along which there is a good road, and descends into the sea by a slope of 200 feet, inclined about 40 degrees. Notwithstanding the precautions taken, one or other of the lower branches of the Rhine occasionally overflows its banks and lays a wide district of country under water. One of these inundations took place in the winter of 1860—1861, and, committing immense havoc, was the cause of much loss and suffering. A good example of dyking for the purpose of drainage is shewn near Haerlem, where it has facilitated the withdrawal of the Haerlem Sea (q. v.).

**DYKES.** In volcanic districts, rents frequently occur which are filled with molten materials from below, that subsequently solidify, and form solid walls, filling the fissures, and separating the edges of the disjointed strata. To these walls, geologists apply the term *dyke*, a Scottish word for a wall or fence. Similar walls of intruded matter occur in stratified rocks of all ages, and have been connected with volcanic eruptions belonging perhaps to every geological epoch. They consist of similar materials to whatever period they belong—viz., lava, either in a granular, compact, or glassy condition. The dykes connected with Vesuvius have been minutely described. Those in the great escarpment which Somma presents to the modern crater of Vesuvius permit of a careful examination. They are chiefly vertical, and traverse at right angles the beds of lava, scorie, breccia, and sand which form the ancient cone. They project in relief several inches, or sometimes feet, from the face of the cliff, being extremely compact, and less destructible than the intersected tufts and porous lavas. In vertical extent they vary from a few yards to 500 feet, and breadth from one to 12 feet. Many of them cut all the inclined beds in the escarpment from top to bottom, others stop short before they ascend above half-way, and a few terminate at both ends, either in a point or abruptly. In mineral composition, they scarcely differ from the lavas of Somma. Their texture is different at the edges and in the middle; toward the centre, the rock is larger grained, while at the edge it is always finer grained, sometimes vitreous. This evidently arises from the rate of

cooling, it being known that molten trap or lava, when suddenly cooled, assumes a vitreous structure, while a slow cooling, as it permits the mass to remain in a condition fitted for the operation of the crystalline force, and the segregation of the separate materials, produces a more or less granular structure, in proportion to the time occupied in cooling. The rock forming the dykes is far more compact than that of ordinary lava, for the pressure of a column of melted matter in a fissure greatly exceeds that in an ordinary stream of lava; and pressure checks the expansion of those gases which form vesicles in lava. When the fissures have been openings for the egress of molten matter, the surfaces have been worn and smoothed by the current, the intense heat having melted all projections and obstructions to the passage of the incandescent fluid.

The appearances of ancient trap-dykes are very similar to those of recent volcanic dykes. Trap-dykes generally are prominent objects in the landscape, because, while the softer rocks through which they have intruded have been abraded by the sea, rivers, or rain, they, being more compact, stand out prominently in the face of precipices or on the level surface of a country. Sometimes, however, from chemical action, and chiefly from the oxidation of the iron which all trap-rocks contain to a greater or less extent, the intruded dyke decomposes more rapidly than the containing rock. It then for some feet or yards leaves the original fissure again unoccupied. A singular modification of this arrangement may sometimes be noticed, when the intruded igneous rock has so indurated the beds through which it passed as to make them less liable to weather than the unaltered portions of the beds, or than even the dyke itself. In such cases, we find two parallel walls of indurated strata rising above the general level of the country, and forming the banks of a ditch produced by the disappearance of so much of the dyke. All these appearances may be observed in the island of Arran, a locality unsurpassed for observing those remarkable geological phenomena. Some dykes have had no apparent influence on the adjoining strata, even when these consist of materials most liable to be affected by heat. Thus seams of coal sometimes remain unaltered, though in contact with the supposed injected molten matter. Considerable doubt is thus cast upon the generally received opinion, that in all cases dykes were intrusions of lava. The effects that have been produced in numerous instances can, however, only be accounted for by supposing that the adjacent rocks have been affected by heat. The writer has observed in Arran, at a place where a dyke cut at right angles an older one, that the edges of the older dyke, which had been acted upon by the current of liquid lava, were converted into true obsidian to the depth of nearly half an inch. In Anglesea, shale at the edge of a dyke 134 feet wide has been converted into hard porcellanous jasper; and argillaceous limestone loses its earthy texture, and becomes granular and crystalline. The chalk, in Antrim, is converted, by basaltic dykes, into granular marble. Coal, as might have been expected, is often altered in an extraordinary degree. Witham describes the effects of the Cockfield Fell dyke on a seam of coal through which it passes. It is a nearly vertical wall of trap, 18 or 20 yards thick, and is traceable to a distance of 70 miles running in a south-east direction. The coal is about 6 or 8 feet thick, and is affected about 50 yards from the dyke. It first loses the calcareous spar, which occurs in the joints and faces, begins to look dull, and loses its quality for burning. As it comes nearer, it assumes the appearance of a half-burnt cinder; and approaching still nearer the dyke, it grows less

and less in thickness, becoming a pretty hard cinder only two feet and a half in thickness. Eight yards further, it is converted into real cinder; and more immediately in contact with the dyke, it becomes a black substance resembling soot caked together, the seam being reduced to nine inches in thickness. The coal thus deteriorated is 25 yards of bad short coal, half reduced to cinder; 16 yards of cinder; and 10 of sooty substance.

**DYNACTINOMETER**, an instrument employed for measuring the actinic force of light, and for comparing the degrees of rapidity with which photographic lenses act. It is too complex in use, and too expensive, to admit of being generally adopted. For a detailed description, the reader is referred to Hunt's *Photography*.

**DYNAMICS** is that division of Mechanics (q. v.) which contains the doctrine of the motion of bodies produced by forces. It is essentially a science of deduction from the laws of motion (see MOTION, LAWS OF), under which head will also be found a brief sketch of the growth of the science. The branches of dynamics capable of being treated in the present work will be found discussed under separate heads. We shall here confine ourselves to giving a view of the main branches and their correlation. I. The first branch of dynamics deals with the fundamental conceptions of the science, their names and definitions, such as velocity (q. v.) and the different kinds of motion (q. v.), and accelerated motion (q. v.); force, accelerating force, and moving force (see FORCE). Under this branch also falls the composition of motions (see COMPOSITION OF FORCES AND MOTIONS). II. The second main branch of dynamics treats of the motion, free or constrained, of points. Here two problems are solved in each case—i. e., whether the motion be free or constrained—viz., a direct and an inverse problem; as, for example: 1. To determine the path of a point when the forces are given which act upon it; 2. To determine the forces or force acting on a point when its path is given. This division of dynamical problems into direct and inverse, obtains in all the branches. It may be mentioned that it was by solving the inverse problem that Newton and Huygens effected their greatest glories in connection with dynamics. The method of treating the case of a free point now generally employed, is due to Euler. See, under this head, CENTRAL FORCES; FALLING BODIES, and PROJECTILES. III. The third main branch of dynamics is concerned with the motion of a rigid system of points, or of a solid body. Few of the sub-branches of this part of dynamics are capable of exposition in this work, but see CENTRE OF GYRATION, CENTRE OF OSCILLATION, CENTRE OF PERCUSSION, and PENDULUM. The honour belongs to D'Alembert of establishing a general method of treating problems in rigid dynamics. Previous to his time, each set of such problems was treated on some principle peculiarly applicable to itself. D'Alembert invented one (which goes by his name) applicable to all such problems. For a statement of this principle, see RIGID DYNAMICS. IV. The fourth main branch of dynamics is concerned with motions of rotation. A system of rigid points may be subject to two independent kinds of motion. It may suffer a motion of translation in space, or a motion of rotation about some point or axis within itself, or it may suffer at once a motion of translation and a rotatory motion. These may clearly be treated conjunctly or independently; they are now uniformly treated independently, by investigating, 1. The velocity and direction of the centre of gravity of the system; and, 2. The direction at each instant of the spon-

aneous axis of rotation passing through the centre of gravity (see ROTATION), and the velocity of the rotation of the system round that axis. To effect the second task, Poinsot proposed his theory of Couples (q. v.). Several general theorems in dynamics, not above mentioned, will be found discussed under various heads, to which the reader is now referred. For the conservation of areas, see CENTRAL FORCES. For the conservation of living forces (*virium vivarum*), and the principle of least action, see FORCES. See also MOMENTS OF INERTIA, and IMPACT.

**DY'SART**, a royal parliamentary and municipal burgh and seaport in the south of Fifeshire, on the rocky shore of the Firth of Forth, 12 miles north-north-east of Edinburgh. It chiefly consists of three streets, with a small square. In the High Street are many antique houses, with inscriptions and dates. It has ship-building, flax-spinning, and manufactures of damasks and ticks. In the vicinity are coal and ironstone mines. Pop. (1861) 8067. It unites with Kirkcaldy, Burntisland, and Kinghorn, in sending a member to parliament.

**DYSCRA'SIA** (Gr. *dys*, difficult, and *krâsis*, a mixture), a pathological term much used in Germany by certain authorities, to indicate an altered condition of the blood and fluids of the system, leading to constitutional diseases, as dropsy, cancer, delirium tremens, lead-poisoning, &c. See CACHEXIA and DIATHESIS.

**DYSENTERY** (Gr. *dys*, difficult, and *enteron*, the intestine), a form of disease attended by discharges from the bowels, and differing from Diarrhœa (q. v.) chiefly in being attended by marked fever and pain, as also by the presence of blood and inflammatory products in the discharges. Dysentery is, in fact, a disease of the mucous membrane of the Colon (q. v.) or great intestine, and when severe, it is followed by the destruction of that mucous membrane to a great extent, the intestine becoming much contracted at intervals, especially in its lower part, and the evacuations being therefore apt to be retained, especially the solid portions. The most distinctive symptoms are excessive pain in evacuating the bowels, and frequent ineffectual attempts at evacuation (*tenesmus*), tenderness on pressure in the left side of the abdomen, discharges of blood mixed with mucus, and comparatively little fecal matter; these symptoms being accompanied or followed by intense fever, passing into early depression of strength. Dysentery is a disease of extreme danger in many cases, and should always be placed early under medical treatment. The best domestic plan, when medical advice cannot be at once procured, is to give a moderate dose of castor oil, guarded by twenty or thirty drops of laudanum, and then either Dover's powder in ten-grain doses every hour or two, or ipecacuanha wine in two or three successive teaspoonful doses at similar intervals, each with ten or twenty drops of laudanum, according to the effect on the system. If vomiting is repeatedly produced, the dose of ipecacuanha wine should be lessened. If the pain and irritation of the bowels are extreme, the opium had better be given by a small injection (see CLYSTER) with starch, after the lower bowel has been well cleansed by a larger warm-water injection; and it will be well to repeat the simple warm-water injection at intervals throughout the treatment. Dysentery, in its most severe forms, is commonly a disease of the tropical zone. It is often found in connection with inflammation of the liver.

**DY'SLYSINE** is an organic substance ( $C_4H_{13}O_2$ ) obtained by boiling choloidic acid with hydrochloric acid for some time. It is a

neutral resinous body, which is difficultly soluble in naphtha, turpentine, and other common solvents.

**DY'SODII**, a yellow or grayish laminated bituminous mineral, often found with lignite. It burns vividly, and diffuses an odour of assafetida.

**DYSPE'PSIA** (Gr. *dys*, difficult, and *pepsis*, digestion), a scientific term for indigestion (q. v.).

**DYSPNŒ'A** (Gr. *dys*, difficult, and *pnœa*, breathing), a word the meaning of which is sufficiently indicated by its etymology. See **ASTHMA**; **RESPIRATION**; **LUNGS**, **DISEASES OF**, &c.

**DYSUR'IA** (Gr. *dys*, difficult, and *ouros*, urine), a difficulty of passing urine. It may depend on a variety of causes, as regards which, see **BLADDER**; and **URETHRA**, **DISEASES OF**.

**DYTI'SCUS** (Gr. *dytes*, a diver), a Linnæan genus of aquatic coleopterous insects or water-beetles, now forming the tribe or family *Dytiscideæ*. They are *pentamerous* coleoptera; that is, have all the *tarsi* five-jointed. Their general form is oval, the outline little broken, and the surface very smooth. The respiratory organs of the perfect insect are not adapted to the extraction of air from water, and it must occasionally come to the surface to breathe, where it rests for a short time back downward, and with the extremity of the abdomen exposed to the air, the openings of the air-tubes being in the last segment. The *Dytiscideæ* are

1488, and Christian became acquainted with her in 1507 in Bergen, where her mother, Sigbrit Wynlus, had settled as an innkeeper. She followed him to Opslow, and, when he mounted the throne, to Copenhagen. Notwithstanding the marriage of Christian with Isabella, the sister of the Emperor Charles V., his relation with D. was continued, and her mother acquired unbounded influence in the affairs of the country. Though D. herself never interfered, she was naturally hated by the party of the nobles; and her death, which happened suddenly in 1516, was attributed, with almost certainty, to poison. The poison was understood to have been administered to her in cherries by the noble and proud relations of the governor of the palace, Torben Oxé, who was a suitor for the affections of Dyveké. On her death, the character of Christian broke out in all its savageness. He first ordered the treasurer Faabrg to be executed for having said that Torben Oxé had enjoyed the favour of D.; and then at the instigation, as was given out, of a nightly vision, Torben Oxé himself. Samsøe, a Danish poet, wrote, about the end of the 18th c., a tragedy called *Dyveké*, often represented in Copenhagen. The story has since been made the subject of several novels and tragedies; e.g., *Wilhelm Zabern*, by J. C. Hauch, a Dane; and Rieckhoff's tragedy, *Dyveke* (Berl. 1843).

**DY'VOUR** AND **DYVOUR'S HABIT** (from the Fr. *devoir*, to owe; a debtor). In the old legal language of Scotland, a dyvour seems to have been synonymous with a bankrupt. Skene speaks of a dyvour, or 'bairman' (bare-man), as one who, 'being involved and drowned in debts, and not able to pay or satisfy the same, for eschewing of prison and other pains, makes cession and assignation of all his goods and gear in favour of his creditors, and dons his devour and duty to them, proclaiming himself bairman and indigent, and becoming debt-bound to them of all he has.' It was ordained by act of Sederunt (q. v.) of 17th May 1606, that a pillory be erected near the Market Cross of Edinburgh, with a seat upon it, upon which dyvours shall be exposed once on a market-day; and before their liberation from jail, they are required to provide themselves with a hat or bonnet of yellow colour, to be worn by them while thus exposed, and constantly thereafter, while they continue dyvours, under pain of three months' imprisonment if they be found without it. By subsequent acts (26th February 1669, and 23d January 1673), the dyvour's habit is appointed to be a coat or upper garment, half yellow and half brown, with a party-coloured cap or hood, to be worn on the head; any of his creditors being entitled to imprison him if he be found without it. The act of sederunt of 18th July 1688 prescribes as the dyvour's habit, 'a bonnet, partly of a brown and partly of a yellow colour, with uppermost hose, or stockings, on his legs, half brown and half yellow coloured, conform to a pattern delivered to the magistrates of Edinburgh, to be kept in their tolbooth;' and declares that the Lords will not hereafter dispense with it, unless in the case of innocent misfortunes. Finally, by statute (1696 c. 5), the Lords of Session are prohibited from dispensing with the dyvour's habit unless, in the process of Cessio Bonorum (q. v.), the bankrupt's failure be alleged and proved to have been by misfortune. This statute is repealed, and the dyvour's habit abolished, by 6 and 7 Will. IV. c. 56—previous to which time the barbaric practice of wearing the habit had, by sufferance of the court, been departed from.

A, *Dytiscus Marginalis*, or great Water-beetle; B, larva.

excessively voracious, feeding upon any kind of animal food, and boldly attacking creatures larger than themselves. They are very amusing inmates of the fresh-water aquarium, and sometimes live in it for a year or two, getting tame, and readily coming to be fed with small earthworms, bits of beef, &c. The species are numerous, and vary much in size, some being very small, and some almost two inches in length. A very common British species is *D. marginalis*, about an inch and a quarter in length, of a dark olive colour, the thorax and outer sides of the elytra margined with yellow. All the species are found in lakes, ditches, marshes, and the still parts of rivers. They often leave the water by night, and can fly well. Their larvæ have the body long and tapering, composed of eleven rings or segments, besides the head. They hide themselves in the earth, in chambers which they make for themselves, before changing into pupæ.

**DY'VEKÉ** (i. e., *dove*), called by the Latin chroniclers *Columbula*, the mistress of Christian II. of Denmark, has been often celebrated in works of poetry and fiction. She was born in Amsterdam in

**DZEREN**. See **ANTELOPE**.

DZIGGETHAI, DJIGGETAI, KĪ'ANG, KHUR, or GOOR (*Equus Hemionus*), a quadruped nearly allied to the ass, and believed to be the *hemionus* of Herodotus and Pliny. See Ass. It inhabits the elevated steppes of Tartary, extending into the south of Siberia and to the borders of India. In appearance and characters, it is intermediate between the horse and the ass, whence the ancient Greek name *hemionus* (half-ass). In size it approaches the horse, which it resembles also in gracefulness of action, and in its neighing, which is even more deep and sonorous. Its general shape is

much like that of a mule. The D. lives in small herds, sometimes of several males and several females, sometimes of a single male with about twenty females and foals. It is an animal of great fleetness and shyness, or watchfulness, and possesses also great powers of endurance in flight, so that it is with difficulty killed by the hunter. The Mongols and Tunguse, however, hunt it very eagerly on account of its flesh. It has been domesticated and reduced to the service of man, but there does not seem to be any evidence of its ever breeding in a state of domestication.

# E

**E** THE fifth letter in the Græco-Roman alphabets. Its original and fundamental sound is that heard in Eng. *tent*. The sound heard in *me* is not given to it in any language but English. In the series of vowels it stands intermediate between *i* and *a*. See LETTERS AND ARTICULATE SOUNDS, where the various vowel-sounds represented by the character *e* in English will be noticed.

E, in Music, is the third note or sound of the natural diatonic scale, and is a third above the tonic C, to which it stands in proportion as 5 to 4. As a major third, that is, when the tonic C vibrates 4 times, the E above vibrates 5 times. E is the third harmonic which arises naturally from C as a fundamental note. E major, as a key, has four sharps at its signature, viz., F, C, G, and D sharp. E minor, as a key, has only one sharp, F, same as G major, of which E is the relative minor.

**EADMER OF CANTERBURY**, a man of considerable mark in the beginning of the 12th c., would seem, from his name, to have been the child of English parents. At an early age, he entered the Benedictine monastery of Canterbury; and when St Anselm, in 1093, was made archbishop of that see, E. became one of his most devoted friends, sharing his exile, watching his death-bed, ordering his burial, and writing the chronicle of his life. E. continued at Canterbury, in high esteem with St Anselm's successor, Archbishop Ralph, until 1120, when, at the request of King Alexander I., he went to Scotland, and was there chosen Bishop of St Andrews. The question of lay investiture of ecclesiastical benefices was then in its crisis; there was a controversy between Canterbury and York for jurisdiction over the see of St Andrews; that see, again, asserted its independence of either of the English metropolitans; and E. seems to have added to all these perplexities a difficulty as to his monastic allegiance. 'Not for all Scotland,' he said to the Scottish king, 'will I renounce being a monk of Canterbury.' The king, on his side, was equally unyielding; and the issue was the return of E. to his English monastery, unconsecrated, indeed, but still claiming to be Bishop of St Andrews. He was made precentor of Canterbury, and died, it is supposed, in January 1124. He tells us that, from his childhood, he was a diligent observer of contemporary events, especially in church affairs; and this habit has given more than usual interest to his writings. The most valuable are his *Historia Novorum*, or History of his Own Times, first printed by Selden in 1623, and his *Vita Anselmi*, or Life of St Anselm, first published at Antwerp in 1551. Both these works are included in the selection of his writings published by the Benedictines of St Maur (as a supplement to their edition of the works of St Anselm), in 1 vol. fol. (Paris, 1721). His lives of St Odo, St

Dunstan, and St Bregwyn, of Canterbury, and of St Wilfrid and St Oswald, of York, were printed, some of them, by Wharton, in the second part of his *Anglia Sacra* (Lond. 1691), and others by Gerberon in his *Anselmi Opera* (Paris, 1675). The history of E., in relation to the bishopric of St Andrews, is given at considerable length by Lord Hailes, in his *Annals of Scotland*, vol. i. pp. 59—71; and, still better, in Mr Grub's *Ecclesiastical History of Scotland*, vol. i. pp. 209—217 (Edin. 1861).

**EA'GLE** (*Aquila*), a genus of birds of prey, by some naturalists subdivided into several genera, constituting a group which contains the largest and most powerful of the *Falconida*. From the most ancient times, the E. has been universally regarded as the emblem of might and courage; and, like the lion, it has been fancifully invested with other attributes of greatness, such as men thought to harmonise with these. Its extraordinary powers of vision, the vast height to which it soars in the sky, the wild grandeur of the scenery amidst which it chiefly loves to make its abode, and perhaps also its longevity, have concurred to recommend it to poetic regard. It was associated with Jupiter in the Roman mythology; its figure on the standards of the Roman legions expressed and animated their confidence of victory (see under).

The eagles have the beak not curved from the very base, like the true falcons, nor notched on the edge, neither are their wings so long in proportion to their size. Their wings are, however, very broad and expansive; their legs are very robust; their claws curved, sharp, and strong. In the most restricted use of the generic term, the true eagles, of which the Golden E. may be taken as a type, have a rather short bill, curved from the cere, with a slight festoon on the edge of the upper mandible, the tarsi are short, and feathered down to the toes. This last character distinguishes them at once from the Ernes (q. v.), often also called eagles. There are several species of true eagles well ascertained, although in this as in allied genera much confusion has arisen from the diversity of plumage at different ages.—The **GOLDEN E.** (*A. chrysaetos*)—of which what is called the Ring-tailed E. is the young—is about three feet or three feet and a half in length, and eight feet in spread of wing. The female is rather larger than the male; the colour is dark brown, in some parts almost black, the head and back of the neck in mature birds covered with pointed feathers of a golden-red colour; young birds have a considerable part of the tail white. The Golden E. is the largest of the European eagles, and is found not only throughout Europe, preferring wild and mountainous situations, but throughout almost the whole northern hemisphere: it is amongst the birds of India, of the north of Africa, and of North America; and the savage warrior of the Rocky Mountains, 'as well as the Highland chieftain, glories in his eagle plume.' Although occasionally seen in all parts of Britain, it builds its nest only in mountainous districts, carrying a few sticks and brambles to the inaccessible

shelf of a rocky precipice, where the eggs are deposited almost on the bare rock. The Golden E. is now rare even in the Highlands of Scotland. A great quantity of prey is necessary to support a pair of these birds and their two or three young ones; and not only hares, game of every kind, and lambs are carried to the eyrie, but larger animals are sometimes attacked, and almost every district where eagles build their nests has its story of children carried off to feed the eaglets, and often of their almost miraculous preservation.—The next in size to the Golden E. among the eagles of Europe, is the Imperial or Grecian E. (*A. imperialis*), but it is more common in Egypt than in Europe, and has never been seen in Britain.—The Spotted E. (*A. nevia*) has occurred in the south of Ireland.—There is an Australian E. (*A. fucosus*).

Eagles were ranked among what were called, in the language of falconry, ignoble birds of prey, as incapable of being tamed and employed to assist in the sports of man. But either the Golden E. or the Imperial E. is used by the Tartars in the chase of antelopes, wolves, foxes, hares, &c.

The White-tailed E. or Cincereous E. of Britain is the common Erne (q. v.). The White-headed E. or Bald-headed E. of America—the chosen emblematic E. of the United States—is also an erne. What particular species was the emblematic E. of the ancients, is not more certain than what is the original emblematic Scotch thistle.—Others of the E. group of *Falconidae* are known as Marsh Eagles, Harpy Eagles, Eagle-hawks, Ospreys, &c., some of which will be noticed in their places.

The head and foot of the golden eagle are figured in the article ACCIPITRES, its skeleton in the article BIRDS.

Eagle Displayed.

of the kingdom of Prussia.

EAGLE, as a military standard, was adopted by the Romans, and even by nations preceding them in history. The Persians, in the time of Cyrus the Younger, bore an eagle on a spear as a standard.

The Romans for some time used the eagle, the wolf, the boar, the horse, and the minotaur for standards, but afterwards abandoned the last four, and confined themselves to the first. The Roman eagle, sometimes of gold, but more frequently of silver, was about as large as a pigeon with extended wings, and was borne on the top of a spear, with a cross-bar or a shield to support it. Some of the eagles were represented as holding thunderbolts in their talons, and usually bore the name of the legion to which each respectively belonged. The eagle was sometime

made of steel, but rarely.

In modern times France, Russia, Prussia, Austria,

and the United States of America, have all adopted the eagle as a national military symbol. The Austrian eagle is represented double-headed.

EAGLE, a gold coin of the United States of America, of the value of ten dollars. See DOLLAR.

EAGLE, BLACK, ORDER OF THE, in Prussia, was founded by the Elector of Brandenburg, on 17th January 1701, the day of his coronation as king of Prussia. The number of knights, in addition to the princes of the royal family, was originally 30, but it is now unlimited. They must at their nomination be at least 30 years of age. They must prove their noble descent for four generations through both parents. A chapter is held twice a year.

The insignia of the order consist of an octagonal cross of blue enamel, and a black eagle, displayed

Star of the Order of the Black Eagle.

between each of the arms of the cross. The cross is suspended by a broad ribbon of orange colour across the left shoulder, and it is accompanied by an

embroidered silver star, fastened on the left breast. The centre of the star represents a black flying eagle, holding in one claw a laurel wreath, and in the other a thunderbolt, with the legend, *Suum cuique*. Fifty ducats must be paid by every new member for the support of the Orphan Asylum at Königsberg, and he then receives gratis the costume and insignia of the order, of which a full description will be found in *Burke's Orders of Knighthood*, p. 199.

As the Black Eagle is the highest order in Prussia, no member of it, with the exception of foreign princes and knights of St John, is permitted to wear any other order along with it; and as it is generally granted only to those who are expected to be about the person of the king, no one who holds it is permitted to travel from the court more than twenty German miles without giving notice. Knights of the Black Eagle are likewise knights of the Red Eagle (q. v.), first class.

EAGLE, RED, ORDER OF THE, in Prussia, founded in 1734 by the Markgraf George Frederick Charles, as a reorganisation of the 'Ordre de la Sincérité,' which had been instituted in the beginning of the century by the hereditary prince of Anspach and Baireuth. After passing through various modifications, the order of the Red Eagle was raised in 1791 by Frederick William II. to the rank of the second order in the monarchy, and it was then that the decoration of a

Ribbon and Cross of the Order of the Black Eagle.

white enamelled Maltese cross, surmounted by a royal crown, with the Brandenburg eagle in the corner, was adopted. All the knights of the Black Eagle were received into this new order; and it was latterly decreed that only those who had been decorated with the Red Eagle, in the first instance, could be received into the black. In 1810, the order of the Red Eagle was reorganised, and two more classes were added to it. In 1830, the second class was subdivided into two, one of which only was allowed to wear a square star.

**EAGLE HAWK** (*Morphuus* or *Spizacetus*), a genus or sub-genus of *Falconidae*, of the eagle group, but consisting of species of comparatively small size, and characterised by short wings, long slender legs (*tarsi*), and comparatively feeble toes and claws. Some of the species are extremely beautiful in form

Eagle-Hawk (*Morphuus cristatus*).

and colours. They are natives of warm climates, chiefly of South America, but also of Africa and the East Indies. The Crested E. (*M. cristatus*) of Guiana, and the Brazilian E., or Urubitinga (*M. Urubitinga*), may be mentioned as examples. The latter, although not so large as a goose, is sometimes called the Brazilian eagle.

Eagle Owl (*Bubo maximus*).

**EAGLE OWL** (*Bubo*), a genus of the Owl (q. v.) family (*Strigidae*), characterised by a somewhat

incomplete facial disc, two tufts of feathers (*horns* or *eyebrows*) of considerable size on the head, ears with small openings (*conchas*), legs and toes covered with feathers, short strong curved bill, and long curved sharp claws. To this genus belong the largest of the nocturnal birds of prey. The E. O. of Europe (*B. maximus*) is little inferior in size to the Golden Eagle, and preys on quadrupeds such as hares, rabbits, and young deer, and on grouse, partridges, and other kinds of game. It seizes its prey with its feet, and seldom touches it with the bill till its struggles are over. It is an inhabitant of many parts of Europe and Asia, but it is only a rare occasional visitor in Britain. The loud peculiar cry of this bird, resounding strangely through the night, has obtained for it its German name of *Uhu*, and an intimate association from time immemorial with evil omens and superstitious terrors.—The E. O. of America (*B. Virginianus*), the VIRGINIAN HORNED OWL or GREAT HORNED OWL, is very similar to the species just noticed, but of inferior size, although still a large and powerful, as it is also a bold bird. It does not scruple to attack half-grown turkeys, and often succeeds in making them its prey. It carries off with ease almost any other inhabitant of the poultry-yard. It is found in almost all parts of America.

**EAR, THE, ANATOMY AND PHYSIOLOGY OF.** The apparatus of hearing, as it exists in man and the mammalia, is composed of three parts—the external ear, the middle ear or tympanum, and the internal ear or labyrinth.

Fig. 1.

General view of the external, middle, and internal ear, shewing the interior of the auditory canal, tympanic cavity, and Eustachian tube.

*a*, the auditory canal; *b*, the tympanum; *c*, the Eustachian tube, leading to the pharynx; *d*, the cochlea; and *e*, the semicircular canals and vestibule, seen on their exterior by the removal of the surrounding bony tissue.

The *external ear* consists of two portions, the *auricle* or *pinna* (the part popularly recognised as the ear), and the *auditory canal* or *external meatus*.

The *auricle*, on its outer or more exposed surface, presents various eminences and depressions, resulting from the form of its cartilaginous framework. These have received special anatomical names, to which it is unnecessary to advert further than to mention that the deep capacious central space to which several grooves converge, is termed the *concha*, and that the lowest and pendulous portion of the ear is termed the *lobe*. The cartilage forming the basis of the external ear consists of one principal piece, in which there are several fissures, which are filled up by fibrous membrane. Several muscles are described as passing from one part of the auricle to another, but they are so little developed in man that they do not require notice; there are additionally three

muscles—the *attollens aurem* (or *superior auris*), the *atrahens aurem* (or *anterior auris*), and the *retrahens aurem* (or *posterior auris*), which pass from adjacent parts of the scalp to the ear, and which, though more developed than the previous group, are of little or no real importance in man (at least in his civilised state), but are of considerable use in many mammals. Their actions are sufficiently indicated by their names.

The auditory canal passes from the concha inwards, and a little forwards, for rather more than an inch. It is narrower at the middle than at either extremity; and on this account there is often considerable difficulty in extracting foreign bodies that have been inserted into it. The membrane of the tympanum which terminates it is placed obliquely, in consequence of the lower surface of the meatus being longer than the upper. The canal is partly cartilaginous and partly osseous; the osseous portion consisting in the fetus of a ring of bone, across which the membrane is stretched, and in many animals remaining persistently as a separate bone. The orifice of the meatus is concealed by a pointed process, which projects from the facial direction over it like a valve, and which is called the *tragus*, probably from being sometimes covered with bristly hair like that of a goat (*tragos*); and it is further defended by an abundance of ceruminous glands, which furnish an adhesive, yellow, and bitter secretion (see CERUMEN), which entangles small insects, particles of dust, and other small foreign bodies, and prevents their further passage into the meatus.

The *middle ear*, or *cavity of the tympanum*, is a space filled with air which is received from the Pharynx (q. v.) through the Eustachian tube (see fig. 1, *b*, *c*), and traversed by a chain of very small movable bones (fig. 2), which connect the membrane of the tympanum with the internal ear. It lies, as its name implies, between the external meatus and the labyrinth or internal ear, and opens posteriorly into the cells contained in the mastoid portion of the Temporal Bone, which are also filled with air, and anteriorly into the Eustachian tube. The cavity is of an irregular shape, and is lined by a very delicate ciliated epithelium, which is a prolongation of that of the pharynx through the Eustachian tube.

Its external wall is mainly formed by the membrane of the tympanum, which is nearly oval, and placed in a direction slanting inwards, so as to form an angle of about 45° with the floor of the auditory canal (see fig. 1). The handle of the malleus (or hammer), the first of the chain of ossicles (see fig. 2), is firmly attached to the inner side of this membrane in a vertical direction as far downwards as the centre, and by drawing it inwards, renders its external surface concave.

Its internal wall has two openings communicating with the internal ear, each of which is closed by a delicate membrane. These openings are termed, from their respective shapes, the *fenestra ovalis*, and the *fenestra rotunda*; the former leads to the vestibule, and is connected by its membrane with the base of the stapes (or stirrup-bone), the last of the chain of ossicles; while the latter opens into the cochlea.

The ossicles of the tympanum are three—viz., the *malleus*, the *incus* (or anvil), and the *stapes*. We have already explained how the malleus is connected with the membrane of the tympanum by means of its handle. Through this connection, the tension of that membrane may be modified by the agency of one or two muscles which are attached to this ossicle. These muscles are the *Laxator tympani*, which arises from the spinous process of the Sphenoid Bone (q. v.), and is inserted into the processus gracilis; and the *Tensor tympani*, which arises from

the under surface of the petrous portion of the temporal bone, and is inserted into the handle of the malleus immediately below the commencement of the *processus gracilis*. The existence of the former of these muscles is doubtful, many anatomists regarding

Fig. 2.

Ossicles of the left ear, as seen from the outside and below.

*m*, head of the malleus; *g*, the slender process, or *processus gracilis*; *h*, the manubrium or handle; *sc*, the short crus, and *lc* the long crus of the incus; *a*, the position of the lenticular process, through the medium of which it articulates with the head of the stapes; *s*, the base of the stapes. Magnified three diameters.

the structure in question as ligamentous rather than muscular. The mode in which this bone articulates with the incus is sufficiently explained by the figure. The *incus* much more closely resembles a molar tooth with two fangs, than the anvil from which it derives its name. Of the two processes which it gives off (see fig. 2), the short one, *sc*, runs backwards, and projects into the mastoid cells behind the tympanic cavity; while the long one, *lc*, inclines downwards, and terminates in the lenticular or orbicular process, *a*, to which the head of the stapes is attached. The *stapes* is almost sufficiently described by the figure. It has a head, neck, two branches, and a base, which, as has been already mentioned, fits into the *fenestra ovalis*. A minute muscle, the *stapedius*, takes its origin from a hollow conical eminence termed the *pyramid*, which lies behind the *fenestra ovalis*, and is inserted into the neck of the stapes; by pulling the neck backwards, it probably compresses the contents of the vestibule.

The Eustachian tube, into which the tympanic cavity opens anteriorly, is about an inch and a half in length, and passes downwards, forwards, and inwards to its opening in the pharynx. It is partly bony, but chiefly cartilaginous. Its use is to allow the free passage of air in and out of the tympanum, and to admit of the egress of the mucus secreted in that cavity.

The *internal ear* or *labyrinth* is the essential part of the organ of hearing, being the portion to which the ultimate filaments of the Auditory Nerve (q. v.) are distributed. It is composed of three parts—viz., the *vestibule*, the *semicircular canals*, and the *cochlea*, which form a series of cavities presenting a very complicated arrangement, and lying imbedded in the hardest part of the petrous portion of the temporal bone. They communicate externally with the tympanum by the two openings already described—the *fenestra ovalis*, and the *fenestra rotunda*; and internally with the internal auditory canal, which conveys the auditory nerve from the cranial cavity to the internal ear. The very dense bone immediately bounding these cavities is termed the *osseous labyrinth*, to distinguish it from the *membranous labyrinth*, which lies within a portion of it.

The *vestibule* is a common central cavity into which the semicircular canals and the cochlea open

(see fig. 3, V). It is about a fifth of an inch in height, and in length from before backwards its transverse diameter (from side to side) being somewhat less. On its posterior wall are five orifices for

Fig. 3.

## Interior of the Osseous Labyrinth :

V, vestibule; an, aqueduct of the vestibule; s, fovea semi-elliptica; p, fovea hemispherica; S, semicircular canals; s, superior; p, posterior; i, inferior; a, a, a, the ampullar extremity of each; C, the cochlea; st, osseous zone of the lamina spiralis, above which is the scala vestibuli, communicating with the vestibule; st, scala tympani, below the spiral lamina. Magnified  $3\frac{1}{2}$  diameters.

the semicircular canals, one of the orifices being common to two of the canals. Anteriorly, the cochlea enters it by a single opening, the beginning of the *scala vestibuli*. On its outer wall is the fenestra ovalis, and on its inner are the *fovea hemispherica*, containing several minute orifices for the entrance of filaments of the auditory nerve, and the fovea semi-elliptica.

The *semicircular canals* are three in number, and open at both ends into the vestibule. They vary in length, and notwithstanding their name, each is considerably more than a semicircle, the superior vertical canal being the longest. Their average diameter is about a twentieth of an inch, the extremity of each canal exhibiting a dilatation or *ampulla*. Each canal lies in a different plane, very nearly at right angles to the planes of the other two, hence their names of the *superior vertical*, the *inferior vertical*, and the *horizontal* canals.

The *cochlea*, which derives its name from its resemblance to a common snail-shell, forms the anterior portion of the labyrinth. It consists of an osseous and gradually tapering canal, about an inch and a half in length, which makes two turns and a half spirally around a central axis, termed the *modiolus*, which is perforated at its base for the entrance of the filaments of the cochlear portion of the auditory nerve. This spiral canal is about one-tenth of an inch at its commencement, and gradually diminishes towards the apex of the cochlea. At its base, it presents two important openings, one into the vestibule, and the other (closed by a membrane except in the dry bone), and communicating with the tympanum, being the *fenestra rotunda* already described. Its interior is subdivided into two passages (*scale*) by an osseo-membranous lamina, extending from the modiolus to the periphery, and taking the same spiral course as the canal itself. This is the *lamina spiralis*, which divides the cochlea into an upper passage, the *scala vestibuli*, and a lower one, the *scala tympani*. At the apex, these two passages communicate by an opening to which the term *helicotrema* has been applied. For a notice of the membranous portion of the *lamina spiralis*, we

must refer to the article AUDITORY NERVE, where it is shown that this structure must be regarded as the fundamental portion of the cochlea, being that on which the nervous filaments are spread out.

We now return to the *membranous labyrinth*, or the soft parts contained within the osseous vestibule and the semicircular canals. The membranous and osseous labyrinths have the same shape, but the former is considerably smaller than the latter, a fluid, termed the *perilymph*, intervening in some quantity between them. The vestibular portion

Fig. 4.

## Membranous Labyrinth of the Left Side, with its Nerves and Otoliths.

sw, superior semicircular canal, with the ampulla and its nerve at one end, and the other end joined by p, the posterior canal, to form a common tube; i, inferior or horizontal canal, with the ampulla and its nerve at one end, and the other entering the utricle separately; c, powdery otolith seen through the transparent wall of the utricle or common sinus; s, powdery otolith of the saccule, seen with its nerve in a similar way; n, cochlear division of the auditory nerve, cut through; d, portio dura, or facial nerve, leaving the auditory nerve, or portio mollis, to enter the aqueduct of Fallopius. Magnified.

consists of two sacs, an upper and larger one, of an oval shape, termed the *utricle*, or *common sinus*, and a lower and smaller one of a more globular shape, called the *sacculus*.

The membranous semicircular canals resemble in form and arrangement the osseous canals which enclose them, but are only one-third of the diameter of the latter. The ultimate filaments of the Auditory Nerve (q. v.) mainly go (see fig. 4) to the utricle, to the sacculus, and to the ampulla of the canals.

The membranous labyrinth is filled by a fluid which is termed the *endolymph*; and in certain spots, especially at the terminations of the vestibular nerves, we observe, both in man and the lower animals, calcareous matter either in a powdered or solid form. In man and mammals generally, and in birds and reptiles, it occurs as a powder, and is termed *otoconia* or *ear-powder*, and it always consists of carbonate of lime.

We now proceed to consider the different functions or offices of the various parts of the organ of hearing.

1. *Of the External Ear.*—A true auricle only exists in the mammalia, and in this class it varies from little more than an irregularly shaped cartilaginous disc, with little or no motion, as in man and the quadrupeds, to an elongated funnel-shaped ear-trumpet, movable in all directions by numerous large muscles, as in the horse, the ass, and the bat.

The mode in which we see it employed by those animals in which it is highly developed, sufficiently indicates that its main function is to collect and concentrate the sounds which fall upon it. But the experimental investigations of Savart, with an apparatus constructed to resemble the tympanic membrane and the external auditory apparatus, shew that these parts are also adapted to enter into vibrations in unison with those of the air; and he suggested that the human auricle, by the various directions of different parts of its surface, could always present to the air a certain number of parts whose direction is at right angles with that of the molecular movement of that fluid, and therefore is the most favourable position for entering into vibrations with it.

2. *Of the Tympanum and its Contents.*—Savart's experiments shew that the membrane of the tympanum is thrown into vibration by the air, and that it always executes vibrations equal in number to those of the sonorous body which excites the oscillations in the air. He further ascertained that the malleus participates in the oscillations of the tympanic membrane, and that these vibrations are propagated to the incus and stapes, and thus to the membrane of the fenestra ovalis. The malleus has further the office of regulating, through the *tensor tympani* muscle, the tension of the tympanic membrane; and to allow of the motion necessary for this purpose, we find movable joints between it and the incus, and again between the latter bone and the stapes. The contraction of the stapedius muscle similarly modifies the tension of the membrane of the *fenestra ovalis*; and as compression exercised on this membrane extends to the perilymph, and is propagated through it to the *fenestra rotunda*, the tension of the membrane of the latter opening is also influenced by the muscle in question. The incus is much more limited in its motions than either of the other bones, and its use seems to be to complete the chain of ossicles in such a manner as to prevent any sudden or violent tension of the membranes, such as we can easily conceive might occur, if the conductor between the membranes were a single bone. The presence of air in the tympanic cavity serves a double purpose: in the first place, it preserves a uniform temperature on the outer surfaces of the fenestral membranes, and thus supports a fixed elasticity in them, which would not be the case if they were freely exposed to ordinary atmospheric changes; and secondly, the action of the chain of ossicles as conductors of sound is materially increased by their being completely surrounded by air, as is obvious from the first principles of acoustics.

3. *Of the Labyrinth.*—Sound is conducted to the labyrinth in three ways: first, by the chain of bones; secondly, by the air in the tympanic cavity; and thirdly, through the bones of the head.

Müller has shewn, by very ingenious experiments on an apparatus constructed to resemble, on a large scale, the middle and internal ear, that while the air in the tympanum conducts sound to the cochlea, through the *fenestra rotunda*, the chain of bones forms a much better conductor of it to the vestibule, through the *fenestra ovalis* (see the chapter on Hearing in his *Physiology*). Hence, we infer that the vestibule is adapted to receive sounds from the membrane of the tympanum and the external ear, while the cochlea, on the other hand, as its structure and connections indicate, may be regarded as that part of the labyrinth which is specially affected by sounds communicated through the bones of the head.

That the vestibule is the essential or fundamental part of the organ of hearing, is sufficiently proved by its constancy, other parts gradually disappearing

as we descend the animal scale, and by its central position in the ears of the higher animals. The use of the otoconia or ear-powder is to strengthen the sonorous undulations, and to communicate to the membranous vestibule and ampulla, and to their nerves, stronger impulses than the perilymph alone could impart. The action of otoliths or ear-stones, such as occur in osseous fishes, must be still more decided, and is well illustrated by the following experiment of Camper. Fill a bladder with water, and place a pebble in it. The slightest impulse communicated to the bladder disturbs the pebble, which consequently produces a greater impression on the hand supporting the bladder than the water alone could do.

Nothing certain is known regarding the functions of the semicircular canals, but their constant existence and number\* in the vertebrated animals indicate their importance; and in most cases of congenital deafness they are more or less defective. The fact of their position corresponding with the three dimensions of a cube—namely, its length, breadth, and height—has led to the opinion that they are concerned in conveying a knowledge of the direction of sounds. This view is supported by Professor Wheatstone, who believes that we distinguish best the direction of those sounds which are sufficiently intense to affect the bones of the head, and that it is from the vibrations which are transmitted through these bones that our perception of direction is obtained. Thus, if the sound be transmitted in the plane of any one canal, the nervous matter in that canal will be more strongly acted on than in either of the other two; or if it be transmitted in a plane intermediate between the planes of this canal and the adjacent one, the relative intensity with which these two canals will be affected will depend upon, and indicate the direction of the intermediate plane.

The range of hearing, like that of vision, varies remarkably in different persons. Some persons are insensible to sounds which others can readily hear. The ordinary range of human hearing comprised between the lowest notes of the organ and the highest known sound emitted by insects includes, according to Wollaston, more than nine octaves, the whole of which are distinctly perceptible by most ears. He relates, however, several cases in which the range, in reference to the perception of high notes, was much less. In one individual, the sense of hearing terminated at a note four octaves above the middle E of the pianoforte, the F above it being inaudible, although his hearing in other respects was as perfect as that of persons in general; another case was that of a lady who could never hear the chirping of the field-cricket; and in a third case the chirping of the common house-sparrow could not be heard. See his Memoir on Sounds Inaudible by Certain Ears, *Phil. Trans.* 1820.

The sensation of sound, like that of light, frequently lasts longer than the exciting cause. We have familiar proof of this fact in the noise which remains in the ears after a long journey in a coach or railway; and it was clearly demonstrated by Savart, who found, in his experiments on toothed wheels, that the removal of one tooth did not produce any interruption of the sound.

For diseases of the ear, see DEAFNESS.

EAR, in Music, is a figurative expression, meaning the possessing of a sensitive, just, and delicate appreciation of sound and measure.

\* The only exceptions that we can call to mind are those presented by the myxine or hag and the lamprey—the former has only one, the latter two, semicircular canals. Both are fishes of very low organisation.

**EAR-COCKLES, PURPLES, or PEPPER-CORN,** a disease in wheat, owing to the presence of *Fibrio tritici*, one of the *Infusoria*. This is an animal of worm-like form, yellowish-white, slender, tapering towards the tail, and more suddenly attenuated to a point at the head. Its minute eggs are supposed to be introduced into the sap of the wheat from infected seed, and so to find their way to the flowers, where they are hatched in the germen; the infected grains become dark green, then black,

Ear-Cockles:

*a*, diseased wheat; *b*, the vibrio, greatly magnified; *c*, its egg, with embryo; *d*, diseased germen of wheat; *e*, section of diseased germen of wheat, greatly magnified, shewing vibrios and their eggs.

rounded like small pepper-corns, and furrowed on the surface; the glumes spread open, and the awns become twisted; the grains are filled with a white cottony substance, which at once dissolves in water, liberating the *Vibrio* in great numbers. Henslow calculates that 50,000 of the young *Vibrio* might exist in a grain of wheat. If the wheat is dried, the *Vibrio* becomes dormant, but retains its vitality in this state for six or seven years, and is ready to revive on the application of moisture.

**EARL** (Ang.-Sax. *eorl*—a corruption of *ealdor*). The distinctive name of the noble amongst the northern races was *eorl*, or *jarl*, as opposed to the mere freeman, the *ceorl*, or *karl*; from which latter name come the modern German word *kerl*, and the Scotch word *carl*. From indicating the whole noble class, the title of *eorl* among the Anglo-Saxons, and perhaps generally among the Teutonic nations, came at first probably to be limited to those who were *ealdors*, or *ealdormen*, by office—that is to say, to those who were appointed to be at once governors and judges over a certain district, and to whom, according to Kemble (*Saxons in England*, ii. p. 126), the titles of *dux*, *princeps*, and *comes* are indiscriminately applied by the Latin writers, the same officer being sometimes called by the one title, and sometimes by the other. Being thus limited to those who held the office of *ealdors*, the social not unnaturally came to be confounded with the official title, and hence the general error of tracing the word *earl* not to *eorl*, a noble, but to *ealdorman*, a title which Mr Kemble prefers to translate by duke. The early relation which subsisted between the duke and the count has been explained under the former title. In Europe generally, it was not till the count came to be recognised as a subordinate officer to the duke, governing a district of the province committed to the latter, that the earl assumed the position of the governor of a county, by the name of which he was commonly known. The title of duke, if it had ever existed, early disappeared in England, and was not revived till the time of

Edward III. After the Norman Conquest, the French term count was substituted for earl; but it held its place only for a very short time as the title of the officer, though it has continued ever since to give a name to the district over which he presided, and a title to his wife. William the Conqueror, after the battle of Hastings, recompensed his chief captains by granting to them the lands and offices of the Saxon nobles; but by making the title of earl hereditary, he took, unintentionally perhaps, the first step towards changing it from a title of office to a title of dignity, and thus depriving it of substantial power. Deputies, *vice-comites*, or sheriffs, came necessarily to be appointed in all cases in which the earl was a minor, or otherwise incapacitated from discharging the duties of the office, till gradually the office itself passed to the deputy; the dignity alone, with the hereditary privilege of sitting as a legislator in the House of Lords, remaining with the principal. The form of creation of an earl formerly was by the king girding on his sword, and placing his coronet on his head, and his mantle on his shoulders; but earls are now created by letters-patent; and it is not unusual for them to depart so far from the old notion of their being territorial officers, as to take as their titles their own names, with the prefix earl—e. g., Earl Grey, Earl Spencer, Earl Russell, &c. At present, the number of earls, including the peerages of Scotland and Ireland, exceeds 200. See **PEER**.

The **EARL'S CORONET** is a circle of gold, rising at intervals into eight pyramidal points, or spikes, on the tops of which are placed as many pearls, and which alternate with strawberry-leaves. See **CROWN**.

**EARL MARSHAL**, an office of great antiquity, and formerly of importance. There seems reason to believe that the Marshal of England, afterwards the earl marshal, was a distinct officer from the Marshal of the King's House, but the point is not altogether clear, and there is, consequently, some difficulty in determining which of the offices was held by the Mareschals, Earls of Pembroke. For many generations, the office has been hereditary in the family of the Dukes of Norfolk, though the earls marshal having, to an unusual extent, had the fate to die either childless or without heirs-male, the line of descent has been by no means a direct one. The last grant is by King Charles II., and bears date 19th October 1672. The earl marshal presided jointly with the constable over the Court of Chivalry (q. v.), the last proceedings of which are said to have taken place in 1631. He is the head of the College of Arms (q. v.), which has jurisdiction in descents and pedigrees; determines all rival claims to arms; and he grants armorial-bearings, through the medium of the kings-of-arms, to parties not possessed of hereditary arms. The office of the Lyon in Scotland is generally supposed to correspond to that of the earl marshal in England, but not quite correctly. The Lyon having been subordinate to the Marshal and Constable of Scotland, his office was more nearly that of the kings-of-arms in England; with this difference, that it extended to the whole kingdom.

**EARLOM, RICHARD**, an engraver, whose works in mezzotinto, published during the end of last and beginning of this century, are well known as amongst the best at the period when that kind of engraving was practised without the admixture of etching, adopted at the present time. His works after Reynolds, his plates from pictures in the Houghton Gallery and the *Liber Veritatis*, consisting

of imitations of the celebrated drawings by Claude, in the possession of the Duke of Devonshire, are standard works in their various departments. He died in 1822, having some time previously retired from his profession.

**EARL'S PENNY**, an English corruption for Arles Penny. See **EARNEST**.

**EARLSTON**, or **ER/CILDOUNE**, a village in the south-west of Berwickshire, on the Leader, a north branch of the Tweed, 30 miles west-south-west of Berwick. Pop. (1861) 1829. E. has been and still is famed for its manufacture of gingham; it has also a factory for the manufacture of blankets, tweeds, &c. On the left bank of the Leader are the ruins of a building called 'Rhymer's Tower,' as having been the residence of Thomas the Rhymer (q. v.), so famous in Scottish tradition. A mile south of E. is Cowdenknowes, which is celebrated in song for its 'bonny, bonny broom.'

**EARLY ENGLISH**, the term generally applied to the form of Gothic in which the pointed arch was first employed in this country. The early English succeeded the Norman towards the end of the 12th c., and merged into the Decorated (q. v.) at the end of the 13th. Its characteristics are beautiful and peculiar. Retaining much of the strength and solidity of the earlier style, it exhibited the graceful forms, without the redundancy of ornament which latterly degenerated into a fault in that which followed. Generally, it may be said to bear to the decorated something like the relation which an expanding rosebud bears to a full-blown rose. The windows are long and narrow, and when gathered into a group, are frequently surmounted by a large arch, which springs from the extreme moulding of the window on each side. The space between this arch and the tops of the windows is often pierced with circles, or with trefoils or quatrefoils, which constituted the earliest form of tracery. Each window, however, is generally destitute of any tracery in itself. 'The mouldings,' says Parker, 'in general consist of alternate rounds and deeply-cut hollows, with a small admixture of fillets, producing a strong effect of light and shadow.'—*Gloss. of Architecture*. From the same work we borrow the accompanying illustration of two very beautiful piers, surmounted

Early English Piers and Arch.

by a lancet-shaped arch, and decorated in the manner peculiar to the style. They are from Westminster Abbey. Circular windows, however, still continued to be used, and trifoliated archways over doors are

also to be found, as at Salisbury Cathedral. By far the most characteristic feature of the style is the Tooth-ornament (q. v.), which is often used in great profusion. Where foliage is used, it is cut with great boldness, so as to throw deep shadows, and produce a very fine effect. The under-cutting is often so deep as to leave nothing to connect the leaves with the mouldings but the stalks, and occasionally the edge or point of a leaf. The term Early English is said, by Parker, to have been introduced by Mr Millers in 1805. It corresponds to *Ojwale primitive* of French writers, and is very often known as the first pointed or lancet-arched amongst ourselves. See **GOthic ARCHITECTURE**.

**EARN**, a river and loch in the south of Perthshire, in the finely-wooded, beautiful valley of Strathearn. Loch E. lies to the north of Ben Voirrlich; its eastern extremity is 24 miles west of Perth. It is 7 miles long from east to west, 1 mile broad, and 100 fathoms deep, and is surrounded by bold and rugged hills. The river E. flows east from the loch 40 miles through the strath, past Comrie, Crieff, and Bridge of Earn, into the estuary of the Tay, 7 miles south-east of Perth. Along the river, near Abernethy, under a thick bed of clay, is a peat-bed 2 or 3 feet thick, supposed to be a continuation of the submarine forest at Fisk.—The Bridge of Earn, a much frequented village, stands on the right bank of the river, 6 miles south-south-west of Perth, and near the saline springs of Pitcaithly.

**EARNEST**, or **ARLES**, as it is called in Scotland, from the civil law word *arraha*, is a small sum of money which is given, or a simple ceremony, such as shaking hands, which is performed in proof of the existence of that mutual consent which constitutes a contract. In the first case, the earnest is said to be pecuniary; in the second, symbolical. It is not the earnest, but the consent, i. e., the agreement to a certain price, that is the root of the bargain; and the earnest thus becomes a mere admixture of evidence, which may be dispensed with even in cases in which it is exacted by custom, if the parties choose to preserve other evidence of the completion of their bargain. The contracts in which earnest has been most frequently given both in this country and elsewhere, are sale and service. In the case of sale, it usually consists of a small sum paid by the buyer, by the acceptance of which the seller is held to bind himself to the sale; in the case of service, it is a small sum given by the master, in accepting which the servant becomes bound to serve. The question as to whether the earnest shall count as part of the price or wage depends on the intention of the parties, which, in the absence of direct evidence, will be inferred from the proportion which it bears to the whole sum. 'If a shilling be given,' as Mr Erskine says, 'in the purchase of a ship or of a box of diamonds, it is presumed to be given merely in evidence of the bargain, or, in the common way of speaking, is dead earnest; but if the sum be more considerable, it is reckoned up in the price.'—*Institutes*, b. iii. tit. iii. s. 5. The original view of earnest in England was, that it was a payment of a small portion of the price or wage, in token of the conclusion of the contract (Story on *Sales*, p. 216); and as this view seems to have been adhered to, the sum, however small, would probably there be counted as a part payment. There is only one decision under the 17th section of the statute of Frauds (29 Ch. 11. c. 3), which provides that 'no contract for the sale of any goods, wares, and merchandises, for the price of £10 sterling, or upwards, shall be allowed to be good, except the buyer shall accept part of the goods so sold; and actually receive the same, or give something in earnest to bind the bargain, or in

part payment.' The case referred to 'related to the purchase of a horse, where the purchaser produced a shilling from his pocket, and drew it across the hand of the seller's servant, and then returned it to his own pocket; and it was held that this act (which is a custom in the North of England, and is called striking a bargain) was not sufficient to satisfy the requisitions of the statute.'—Story, *ut sup.* From this decision it follows that no importance is attached in England to such fictitious ceremonies as the Jew plucking off his shoe and giving it to his neighbour, the Indian smoking his pipe, or the less poetical observance of thumb-licking, which Erskine tells us was common among the lower classes in Scotland in his day.

**EARRING.** A ring suspended from the ear, which is bored for the purpose. This mode of adorning the person has always enjoyed great favour amongst Orientals. By Persians, Babylonians, Lydians, Libyans, and Carthaginians, earrings were worn by both sexes. In the classical nations of antiquity, their use was confined to women. In the *Iliad* (xiv. 182, 183), Juno is represented as adorning herself with earrings made with three drops resembling mulberries. From this period down to the latest, the practice prevailed in Greece, and we find the ears of the Venus de Medici pierced for the reception of earrings. Pliny says (xi. 50) that there was no part of dress on which greater expense was lavished amongst the Romans; and Seneca mentions an earring, of which a drawing, copied in our illustration (fig. 1), is given in Smith's *Dictionary*, which he says was worth a patrimony. It has four pearls, two above

Ancient Earrings.

and two below the precious stone in the centre. In the more valuable of the antique earrings, pearls were almost always used; and they were valued for the completeness of their form as well as for their whiteness. In place of a ring, the ornament was often attached to the ear with a hook (see fig. 2), a custom which still prevails in Italy. Many Egyptian earrings of very beautiful design have been preserved, of which fig. 3 is an example. These antique designs have been imitated in modern times, and if the use of an ornament which seems fitter for a South Sea islander than an English gentleman is to be continued, it can scarcely assume a more graceful form than was often given to it by the ancients. See NOSE-RING. During the reigns of Elizabeth and James I., earrings were worn in England by men; a custom which is still continued by many sailors. Master Matthew, in *Every Man in his Humour*, says to Brainworm: 'I will pawn this jewel in my ear;' and Hall, in his *Satires* (B. vi. Sat. 1), speaks of the 'ringed ear' of the new-come traveller; and many similar passages to the like effect might be quoted. At the present day in England, earrings are worn only by women. The ears are bored usually at about seven years of age. The boring, which produces a temporary inflammation, acts as a counter-irritant in cases of sore eyes; and this is sometimes given as a reason for putting rings in the ears.

**EARS,** a term in Organ-building, given to small projecting pieces of metal on the sides of the mouths

of metal pipes, put on for the purpose of assisting the pipes to speak promptly, especially when the organ is of small scale. The German name of 'beard' is fully more appropriate.

**EARTH, THE,** the globe on which we live, being the third planet in order from the sun, and the largest within the belt of the Planetoids. We proceed to consider briefly the points of chief interest connected with it, and which do not fall to be treated under separate heads, viz., 1. Its form and magnitude; 2. Its mass and density; 3. Its motions; 4. Its temperature.

1. *The Form and Magnitude of the Earth.*—To a spectator so placed as to have an unobstructed view all round, it appears a circular plain, on whose circumference the vault of heaven seems to rest. Accordingly, in ancient times, even philosophers long looked upon the earth as a flat disc swimming upon the water. But many appearances were soon observed to be at variance with this idea, and even in antiquity, the spherical form of the earth began to be suspected by individuals. It is only by assuming the earth to be spherical, that we can explain how our circle of vision becomes wider as our position is more elevated; and how the tops of towers, mountains, masts of ships, and the like come first into view as we approach them. There are many other proofs that the earth is a globe. Thus, as we advance from the poles towards the equator, new stars, formerly invisible, come gradually into view; the shadow of the earth upon the moon during an eclipse is always round; the same momentary appearance in the heavens is seen at different hours of the day in different places on the earth's surface; and lastly, the earth, since 1519, has been circumnavigated innumerable times. The objection to this view that readily arises from our unthinking impressions of up and down, which immediately suggest the picture of the inhabitants of the opposite side of the earth—our *antipodes*—with their heads downwards, is easily got over by considering that on all parts of the earth's surface *down* is towards the earth's centre.

It is not, however, strictly true that the earth is a sphere; it is slightly flattened or compressed at two opposite points—the poles—as has been proved by actual measurement of degrees of latitude, and by observations of the pendulum. It is found that a degree of a meridian is not everywhere of the same length (see DEGREE OF LATITUDE), as it would be if the earth were a perfect sphere, but increases from the equator to the poles; from which it is rightly inferred that the earth is flattened there. A pendulum, again, of a given length is found to move faster when carried towards the poles, and slower when carried towards the equator, which shews that the force of gravity is less at the equator than at the poles, or, in other words, that the centre, the seat of gravity, is more distant at the former than at the latter. The diminished force of gravity at the equator has, it is true, another cause, namely, the centrifugal force arising from the rotation of the earth, which acts counter to gravitation, and is necessarily greatest at the equator, and gradually lessens as we move northwards or southwards, till at the poles it is nothing. But the diminution of the force of gravity at the equator arising from the centrifugal force amounts to only  $\frac{1}{177}$  of the whole force; while the diminution indicated by the pendulum is  $\frac{1}{177}$ . The difference, or  $\frac{1}{177}$  nearly, remains assignable to the greater distance of the surface from the centre at the equator than at the poles. From the most accurate measurements of degrees that have been made, the flattening or ellipticity of the earth has been determined by Bessel as  $\frac{1}{230.7167}$ , or  $\frac{1}{230.7}$  nearly; or, the equatorial radius is to the

polar as 300 to 299. These measurements of degrees determine not only the shape but the size of the earth. Bessel's calculations give a geographical mile, or the 60th part of a mean degree of the meridian, at 951'807 toises (2029 yards, thus making the whole circumference 43,526,400 yards), and the equatorial and polar diameters at 6875'6 and 6852'4 geographical miles (7925'6 and 7899'4 English naperial miles). The surface of the earth contains nearly 150 millions of square geographical miles.

2. *The Mass and Density of the Earth.*—We have now seen that the earth is a sphere slightly flattened at its poles—what is called by geometers an elliptical spheroid—of a mean radius of somewhat less than 4000 miles. We have next to consider its mass and density. Nothing astonishes the young student more than the idea of weighing the earth; but there are several ways of doing it; and unless we could do it, we never could know its density. (1.) The first method is by observing how much the attraction of a mountain deflects a plummet from the vertical line. This being observed, if we can ascertain the actual weight of the mountain, we can calculate that of the earth. In this way, Dr Maskelyne, in the years 1774—1776, by experiments at Schellhallen, in Perthshire—a large mountain mass lying east and west, and steep on both sides—calculated the earth's mean density to be five times greater than that of water. The observed deflection of the plummet in these experiments was between 4" and 5". (2.) In the method just described, there must always be uncertainty, however accurate the observations, in regard to the mass or weight of the mountain. The method known as *Cavendish's experiment* is much freer from liability to error. This experiment was first made by Henry Cavendish on the suggestion of Michel, and has since been repeated by Reich of Freyberg, and Mr Francis Baily. The apparatus used by Mr Baily is represented in the

Baily's Apparatus.

annexed figure. Two small balls at the extremities of a fine rod AB, are suspended by a wire DE, and their position carefully observed by the aid of a telescope. Large balls of lead, G, F, placed on a turning-frame, are then brought near them in such a way that they can affect them only by the force of their attraction. On the large balls being so placed, the small ones move towards them through a small space, which is carefully measured. The position of the large balls is then reversed (they are brought into the positions K, II), and the change of position of the small balls is again observed. Many observations are made, till the exact amount of the deviation of the small balls is ascertained beyond doubt. Then by calculation the amount of attraction of the large balls to produce this deviation is easily obtained. Having reached this, the next question is, what would their attraction be if they were as large

as the earth? This is easily answered, and hence, as we know the attractive force of the earth, we can at once compare its mean density with that of lead. Mr Baily's experiments lead to the result that the earth's mean density is 5'67 times that of water. (3.) A third mode has lately been adopted by Mr Airy, astronomer-royal, by comparison of two invariable pendulums, one at the earth's surface, the other at the bottom of a pit at Harton Colliery near Newcastle, 1260 feet below the surface. The density of the earth, as ascertained by Mr Airy from this experiment, is between 6 and 7 times that of water; but for various reasons this result is not to be accepted as against that of the Cavendish experiment, and it is said that Mr Airy is himself dissatisfied with it, and means to repeat the experiment with new precautions. The density of the earth being known, its mass is easily calculated, and made a unit of mass for measuring that of the other bodies in the system. It is found that the mass of the earth compared with that of the sun is '0000028173.

3. *The Motions of the Earth.*—The earth, as a member of the solar system, moves along with the other planets round the sun from west to east. This is contrary to our sensible impressions, according to which the sun seems to move round the earth; and it was not till a few centuries ago that men were able to get over this illusion. See *COPERNICAN SYSTEM*. This journey round the sun is performed in about 365 $\frac{1}{4}$  days, which we call a year (solar year). The earth's path or orbit is not strictly a circle, but an ellipse of small eccentricity, in one of the foci of which is the sun. It follows that the earth is not equally distant from the sun at all times of the year; it is nearest, or in perihelion, at the beginning of the year, or when the northern hemisphere has winter; and at its greatest distance, or aphelion, about the middle of the year, or during the summer of the northern hemisphere. The difference of distance, however, is comparatively too small to exercise any perceptible influence on the heat derived from the sun, and the variation of the seasons has a quite different cause. The least distance of the sun from the earth is over 94 millions of miles, and the greatest over 96 millions; the mean distance is commonly stated at 95 millions of miles. If the mean distance be taken as unity, then the greatest and least are respectively represented by 1'01679, and 0'98321. It follows that the earth yearly describes a path of upwards of 596 millions of miles, so that its velocity in its orbit is about 99,000 feet, or 19 miles in a second.

Besides its annual motion round the sun, the earth has a daily motion or rotation on its axis, or shorter diameter, which is performed from west to east, and occupies exactly 23 hours, 56 minutes, 4 seconds of mean time. On this motion depend the rising and setting of the sun, or the vicissitudes of day and night. The relative lengths of day and night depend upon the angle formed by the earth's axis with the plane of its orbit. If the axis were perpendicular to the plane of the orbit, day and night would be equal during the whole year over all the earth, and there would be no change of seasons; but the axis makes with the orbit an angle of 23 $\frac{1}{2}$ °, and the consequence of this is all that variety of seasons and of climates that we find on the earth's surface; for it is only for a small strip (theoretically, for a mere line) lying under the equator that the days and nights are equal all the year; at all other places, this equality only occurs on the two days in each year when the sun seems to pass through the celestial equator, i. e., about the 21st of March and the 23d of September. From March 21, the sun departs from the equator towards the north, till, about June 21, he has reached a north

# EARTH ROUND THE SUN.

Fig 3.

## THEORY OF THE TWILIGHT

Apparent position of the Sun at different hours of the day at the time of the Equinoxes

Fig 3.

For some time after Sun set the rays still illumine the Atmosphere diffusing themselves through space and Night comes on almost insensibly, this is called twilight and the dawn is a similar Phenomenon which precedes Sun rise. The Solar rays SO which enters the Atmosphere at O instead of coming out at M will be turned aside refracted or bent more and more as it penetrates the various Strata of Air and will at last reach the Earth describing the Curve O G. The Observer at G would thus see the Sun much longer at E than he really was visible above the horizon. The effect of the dawn is the reverse at this let the Earth be represented by ABCD and G where the Sun rises the horizon at HGR receives light from all parts of the Heavens either directly or by reflection the point A at which the Sun has not actually risen has above its horizon the lenticular portion of the Atmosphere KLR indirectly illuminated the dawn is most brilliant at K the tint becoming more visible until it reaches R its utmost limit above the horizon at B it is Midnight and at D where the Sun is Rising the whole of the horizon is illuminated while at C the lenticular portions of the Heavens TX X only receive light. The extent of twilight is shown on the figure by a Zone of lighter shade than that which marks Night. Suppose M the Meridian of London & it is Noon at G 90° West Long. it is 6 A M and at Y 45° West Long. 9 o'Clock by the direct of Atmosphere attraction the Sun would appear to be at Y at Q 45° East Long. the Sun would appear at E at 3 o'Clock P M Thus as the Earth the North Pole being at P turns round Axis from West to East as is directed by the Arrows, the Sun will appear to occupy the opposite points F, J, S, E, U. This figure is drawn at the time when the Sun appears to describe the Equator

	MERCURY	VENUS
Inclination of the Orbit to the Ecliptic	70	3° 23
Mean distance from the Sun in leagues	43 567 000	24 366 000
Sideral revolution round the Sun	87 days 23	224 days 70
Diameter in leagues	1 130	2 787
Velocity per minute in leagues	653	135
Time of rotation upon its axis	24 1 40	240 21 00

declination of  $23\frac{1}{2}^{\circ}$ , when he again approaches the equator, which he reaches about September 23. He then advances southward, and about December 21 has reached a south declination of  $23\frac{1}{2}^{\circ}$ , when he turns once more towards the equator, at which he arrives, March 21. The 21st of June is the longest day in the northern hemisphere, and the shortest in the southern; with the 21st of December it is the reverse.

The velocity of the earth's rotation on its axis evidently increases gradually from the poles to the equator, where it is about equal to that of a musket-ball, being at the rate of 24,840 miles a day, or about 1440 feet in a second.

A direct proof of the rotation of the earth is furnished by its compression at the poles. There are indubitable indications that the earth was originally fluid, or at least soft; and in that condition it must have assumed the spherical shape. The only cause, then, that can be assigned for the fact that it has not done so, is its rotation on its axis. Calculation also shows that the amount of compression which the earth actually has, corresponds exactly to what its known velocity and mass must have produced. Experiments with the pendulum, too, shew a decrease of the force of gravity from the poles towards the equator; and though a part of this decrease is owing to the want of perfect sphericity, the greatest part arises from the centrifugal force caused by the motion of rotation. Another direct proof of the same hypothesis may be drawn from the observation, that bodies dropped from a considerable height deviate towards the east from the vertical line. This fact has been established by the experiments of Benzenberg and others. In former times, it was believed that if the earth actually revolved in the direction of east, a stone dropped from the top of a tower would fall, not exactly at the foot of the tower, but to the west of it. Now, as experience, it was argued, shews that this is not the case—that the stone, in fact, does fall at the bottom—we have here a proof that the pretended rotation of the earth does not take place. Even Tycho, Brahe and Riccioli held this objection to the doctrine to be unanswerable. But the facts of the case were just the reverse. Newton, with his wonted clearness of vision, saw that, in consequence of the earth's motion from west to east, bodies descending from a height must decline from the perpendicular, not westward, but eastward; since, by their greater distance from the earth's centre, they acquire at the top a greater eastward velocity than the surface of the earth has at the bottom, and retain that velocity during their descent. He therefore proposed that more exact observations should be made to ascertain the fact; but it was not till more than a century afterwards that experiments of sufficient delicacy were made to bring out the expected result satisfactorily. It is difficult to find an elevation sufficiently great for the purpose, as several hundred feet give merely a slight deviation, which it requires great accuracy to observe. If a height of 10,000 feet could be made available, the deviation would be not less than  $7\frac{1}{2}$  feet. The analogy of our earth to the other planets may also be adduced, the rotation of which, with the exception of the smallest and the most distant, is distinctly discernible. Finally, an additional proof of the earth's rotation was lately given by Léon Foucault's striking experiment with the pendulum. The principle of the experiment is this: that a pendulum once set in motion, and swinging freely, continues to swing in the same plane, while at any place at a distance from the equator the plane of the meridian continues to change its position relative to this fixed plane.—The objection taken to the doctrine

of rotation from the fact that we are unconscious of any motion, has little weight. The movement of a vessel in smooth water is not felt, though far less uniform than that of the earth; and as the atmosphere accompanies the earth in its motion, there is no feeling of cutting through it to break the illusion of rest.

If the turning of the earth on its axis is thus proved to be the cause of the apparent daily motion of the heavens, it is an easy step to consider the annual motion of the sun through the constellations of the zodiac as also apparent, and arising from a revolution of the earth about the sun in the same direction of west to east. If we consider that the mass of the sun is about 359,000 times greater than that of the earth, and that by the laws of mechanics, two bodies that revolve round each other, must revolve about their common centre of gravity, the idea of the sun revolving about the earth is seen to be simply impossible. The common centre of gravity of the two bodies being distant from the centre of each inversely as their respective masses, is calculated to be only 267 miles from the centre of the sun, and therefore far within his body, which has a diameter of 882,000 miles. But by help of a figure, it is easy to shew that the apparent motion of the sun on the ecliptic naturally arises from a motion of the earth about the sun. The motions of the planets also, that appear so complicated and irregular as seen by us, can only be satisfactorily explained by assuming that they too revolve round the sun in the same direction as the earth. See PRECESSION and NUTATION for an account of a small periodic motion of the earth's axis and its effects.

4. *The Earth's Temperature.* See METEOROLOGY and TEMPERATURE as to the phenomena of heat on the earth's surface. As we go below the surface, we reach a depth beyond which the interior of the earth seems to have no sympathy with the external causes of heat or cold, and its heat appears to be its own, and to increase according to a fixed law the deeper we descend. The average rate of observed increase is  $1^{\circ}$  F. for a descent of between 40 and 50 feet. If this law were universal—which we do not know it to be—at a depth of less than 30 miles the heat would be such as to hold in fusion all known substances, and the earth would have to be regarded as a very thin crust or shell full of molten liquid. This theory of a central heat obtained till lately extensive currency among philosophers, being endorsed with the names of Fourier and Humboldt; but it has recently been shewn by Mr W. Hopkins (see *Cambridge Essays* for 1858), that such thinness of crust is quite irreconcilable with the phenomena of Precession (q. v.). See also GEOLOGY. The fact is, that the law of temperature increasing as we descend has been inferred from far too few local observations, and most probably these may yet be explained by local causes.

EARTHEN-WARE. See POTTERY.

EARTH-HOUSES, EIRD-HOUSES, or YIRD-HOUSES, the name which seems to have been generally given throughout Scotland to the underground buildings, which in some places are called also 'PICTS' HOUSES' (q. v.), and in others, it would appear, 'Weems,' or caves. Martin, in his Description of the Western Islands, printed in 1703, when their use would appear to have been still remembered, speaks of them as 'little stone-houses, built under ground, called earth-houses, which served to hide a few people and their goods in time of war.' The earth-house, in its simplest form, is a single irregularly shaped chamber, from four to ten feet in width, from twenty to sixty feet in length, and from four to seven feet in height, built of unhewn

and uncemented stones, roofed by unhewn flags, and entered from near the top by a rude doorway, so low and narrow that only one man can slide down through it at a time. When the chamber is unusually wide, the side-walls converge, one stone overlapping another, until the space at the top can be spanned by stones of four or five feet in length. In its more advanced form, the earth-house shews two or more chambers, communicating with one another by a narrow passage. There are instances in which one of the chambers has the circular shape and dome-roof to which archaeologists have given the name of the 'BEEHIVE-HOUSE' (q. v.). Occasionally, as many as forty or fifty earth-houses are found in the same spot, as in the moor of Clova, not far from Kildrummy, in Aberdeenshire. They appear to have been almost invariably built in dry places, such as gravelly knolls, steep banks of rivers, and hill-sides. They are generally so near the surface of the ground, that the plough strikes upon the flagstones of the roof, and thus leads to their discovery. The object most frequently found in them is a stone quern, or hand-mill, not differing from that which continued to be used in remote corners of Scotland within the memory of living men. Along with the quern are generally found ashes, bones, and deers' horns; and more rarely small round plates of stone or slate, earthen vessels, cups and implements of bone, stone celts, bronze swords, gold rings, and the like. Occasionally, the surface of the ground beside the earth-house shews vestiges of what are supposed to have been rude dwelling-houses, and folds or enclosures for cattle. This, with other things, would indicate that the earth-houses of Scotland and Ireland (for they are found also in that island) were put to the same purpose as the caves which, as Tacitus (writing in the 2d c.) tells us, the Germans of his day dug in the earth, as store-houses for their corn, and as places of retreat for themselves during winter, or in time of war.

EARTH-NUT, a popular name of the tubers of certain umbelliferous plants, particularly *Bunium bulbocastanum* and *B. flexuosum*, which are common in most parts of Europe. Names of the same signification are given to them in a number of European languages. *Arnut*, *Yernut*, and *Jurnut*, Scotch and English provincial names, are corruptions of earth-nut. PIG-NUT is another common English name, pigs being very fond of these tubers, grubbing up the ground in quest of them, and soon becoming fat upon them. They are also called *earth-chestnut*, from their resemblance in taste and qualities to chestnuts, perhaps also from their resemblance in size, and their being black or very dark brown externally, and white within. By some they are preferred to chestnuts, and they are much used for food in different parts of Europe, and occasionally in some parts of England, either roasted or in soups. They are wholesome and nutritious; they form an article of trade in Sweden, and have sometimes been recommended as worthy of an attention which they have never yet received in Britain. The two species are very similar in general appearance, although *B. bulbocastanum* has by some botanists been referred to the genus *Carum* (Caraway), because its carpels have single vittæ between the ribs, whilst *B. flexuosum* has three. The former is also a plant of stouter habit. Both have umbels of small white flowers, much divided leaves with very narrow segments, and a single roundish tuber at the root of each plant. *B. flexuosum* is common in woods, pastures, waysides, &c., in most parts of Britain. *B. bulbocastanum* is found only in some of the chalk districts of England, but is abundant in many parts of Europe. *B. ferulacum* likewise affords tubers, which are used as food in Greece.—The some-

what similar tubers of another umbelliferous plant, *Oenanthe pimpinelloides*, which grows in the pastures of some parts of the south of England, are sometimes also used for food, notwithstanding the very poisonous qualities of some of its congeners. See WATER-DROPWORT.—A Himalayan umbelliferous plant (*Cherophyllum tuberosum*), a species of Chervil (q. v.), yields edible tubers or *earth-nuts*.—The name E. is sometimes extended to other small tuberous roots of similar quality, although produced by plants widely remote in the botanical system, as *Apios tuberosa* and *Lathyrus tuberosus*. See APIOS and LATHYRUS.

EARTHQUAKE, the term applied to any tremor or shaking of the solid crust of the earth. The frequent occurrence of earthquakes, their destruction of life and property, their influence upon the solid surface of the earth, and the mysteriousness of their cause, force them upon our attention. It is estimated that 12 or 13 earthquakes, destructive more or less of life and property, occur every year, and it is well known that the surface of the globe is never free from sensible evidence of the continued operation of earthquake agency—that in some quarter or another tremors or slight shakings are always taking place. When these are of a serious nature, whole cities have been destroyed; fertile districts, with all their fruits and grain, have been laid waste; and enormous masses of human beings have lost their lives. No less than 60,000 perished in the great Lisbon earthquake; while in that of Calabria, in the end of last century, 40,000 were destroyed. It is estimated that as many as 13,000,000 of the human race have thus perished! The great changes which earthquakes produce on the earth's surface deserve the careful attention of the geologist. They disclose to him an agency which seems to have been at work during every period of the earth's history, and which has altered the earth's surface to an extent that can scarcely be imagined. The observed results of earthquakes which more immediately demand his attention are such as these: the new lakes and river-courses which they form, at the same time obliterating the old ones; the new valleys which they hollow out; the fissures of various sizes they form; and the immense landslips they frequently produce. But the mysterious nature of the producing cause of earthquakes is also a strong incentive to their study. It is unfortunately true, that the most popular scientific inquiries are those in which the imagination has large play: dry inductions from observed phenomena are not suited to the genius of popular modern science. Consequently, earthquakes, where every attempt at explaining their origin is theoretical, from the impossibility of obtaining direct observation, affording as they do a wide field for the play of the poetic faculty, find plenty of students.

No portion of the earth's surface is exempt from the influence of earthquakes. Egypt has been less visited than perhaps any other country, but even here we have the record of one which took place in 1740 A. D.; and Holland, with its loose alluvial deposits, has also felt their power. Nor is the bed of the ocean exempt; records of many subaqueous earthquakes exist, taken by vessels at sea, sometimes passing over the point of greatest disturbance at the moment of the shock. In like manner earthquakes have been active at every period of the earth's existence, breaking up its solid crust, elevating or depressing its surface, and doing as much as any other single agent to bring it into its present condition. They have been probably at some periods more active than at others, just as we find that some districts are now more liable than others to their visitation. So well defined, indeed, are the

localities where earthquakes occur, that it is easy to exhibit their limits on a map. They are most frequent around the present lines or centres of volcanic action (see VOLCANO); and their frequency and violence seem to bear some relation to the activity and intensity of the associated volcanoes. Observers of volcanic phenomena have noticed that every great eruption, in whatever part of the world observed, and whether from a volcanic vent on land or beneath the ocean, is accompanied by earthquake shocks of greater or less violence and duration; while, on the other hand, those observing earthquakes speak of them as accompanied by volcanic eruptions, and of their often being stopped on the opening of volcanic vents. It is, however, an important fact that, although regions of active volcanic action are those of most frequent earthquake movements, yet the most violent earthquakes do not appear to have occurred in these regions, but, on the contrary, in districts lying some degrees away from the nearest volcanic action, as, for instance, in the famous earthquake of Lisbon. Districts in which there are extinct volcanoes are not more liable to such visitations than non-volcanic regions.

The phenomena connected with earthquakes have been variously described. Many writers refer to appearances in the heavens, or changes in the atmosphere, which to them seem to have some connection with the catastrophes they narrate. They tell of irregularities in the seasons preceding or following the shock, of sudden gusts of wind interrupted by sudden calms, of violent rains at unusual seasons, or in countries where such phenomena are almost unknown, of a reddening of the sun's disc, of a haziness in the air often continued for months, and similar phenomena. But these are so irregular in their appearance, and have been so seldom observed associated with more than a single earthquake, that, in the absence of any decided reason to the contrary, there seem good grounds for believing they have no real connection with the earthquake. It is different with underground noises, which frequently precede, accompany, or succeed the occurrence of earthquakes, or some of the shocks of them. They are undoubtedly intimately connected with the shock, yet earthquakes occur, even of the greatest violence, which are unaccompanied by any sound whatever. Different descriptions have been given of these subterranean noises. In some earthquakes, they are likened to chains pulled about, increasing to thunder; in others, the sound is like the rumbling of carriages, growing gradually louder, until it equals the loudest artillery; or like heavy wagons running away upon a road; or distant thunder; or like the hissing produced by the quenching of masses of red-hot iron in water; or like the rush of wind underground. As there have been earthquakes without subterranean noises, so there are frequently, in South America and elsewhere, underground sounds which are not followed by earthquakes.

The more intimate earthquake-phenomena are more uniform. Sometimes there is nothing else felt than a trembling or gentle motion of the surface, without producing any injury. In severe earthquakes, the almost invariable succession of phenomena is first a trembling, then a severe shock, or a succession of shocks, and then a trembling, gradually becoming insensible. The violent shocks are instantaneous, and very few in number, sometimes only one, usually not more than three or four. In the intervals between these, smaller shocks or tremblings take place. The severe shocks do the mischief. At the point or line of greatest disturbance, the shock has a distinctly vertical direction, coming from below upwards. As

we leave this point, the direction of the motion becomes more and more horizontal, gradually also decreasing in intensity until it becomes insensible. This progressive movement is produced by an earth-wave or true undulation of the solid crust of the earth. The whole mass of the area is not moved at once, but only the wave-crest. In the case of the earthquake at Lisbon, the progress of the wave was roughly calculated; it was shewn to have had a very great velocity, and to have lasted only for an instant at any one spot. The area affected on this occasion was very extensive. The shock was felt on the one side as far as the southern shores of Finland, and on the other it reached beyond the St Lawrence in Canada, and was observed in some of the West India Islands—an area of no less than 7,500,000 square miles. The force required to move this must have been enormous, for, suppose the thickness of the earth's crust moved to have been no more than 20 miles, then 150,000,000 cubic miles of solid matter was moved. The influence of this earth-wave is communicated to the sea, when the earthquake is near the shore, or on the bed of the ocean. The sea swells, and slightly retires from the beach, and then a great wave rolls in upon the shore. At the Lisbon earthquake, this wave rose to a height of 60 feet at Cadiz. It carries with it sea-spoil, scattering it over the surface of the earth, far beyond the ordinary reach of the sea.

Of the various theories as to the nature of earthquakes, we can only refer to the most important. All theorists are agreed as to the connection between volcanoes and earthquakes; that they are produced by the same subterranean agency. The existence of a molten fluid mass in the centre of the earth, is the starting-point in all except the chemical theory propounded by Davy, which, though in the end abandoned by him, still finds supporters. When he discovered the metallic bases of the earths and alkalis, he threw out the idea that those metals might abound in an unoxidised state in the subterranean regions, to which water must occasionally penetrate. When this occurred, gaseous matter would be set free, sufficient to produce the earthquake, the metals would combine with the oxygen of the water, and heat enough would be evolved to melt the surrounding rocks.

The internal molten mass being taken for granted, it is generally supposed that the generation of immense bulks of elastic gases, through the influence of this vast source of heat, would produce an explosion sufficient to account for earthquakes. Mr Mallet, in an elaborate report on the subject presented to the British Association, proposes an ingenious theory. He assumes that volcanoes, and the centres of earthquake disturbances, are near the sea, or other large supplies of water; and he says that when an eruption of igneous matter takes place beneath the sea-bottom, the first action must be to open up large fissures in its rocky material, or to lift and remove its incoherent portions, such as sand, mud, gravel, &c. The water on meeting the heated surfaces assumes the spheroidal state; while in this condition, the intestine motion may be great, but little steam is generated, and no impulses will be conveyed to a distance except only the tremblings which precede the shock; but no sooner have the surfaces cooled, than the water comes into close contact with them, and a vast volume of steam is evolved explosively, and blown off into the deep and cold water of the sea, where it is condensed, and thus a blow of the most tremendous sort is given at the volcanic focus, and being transferred outwardly in all directions, is transmitted as the earthquake shock. The surfaces of the ignited material, however, now cooled down below the point at which

steam can be generated rapidly, merely keep up a gentle ebullition, which is transmitted as the trembling after the shock. On the surfaces again becoming heated by conduction from the molten mass, the various phases are again repeated. This he considers the chief cause of earthquakes, but he supposes they may also be due to the evolution of steam through fissures, and its irregular and *per saltum* condensation under pressure of sea-water; or to great fractures and dislocations in the rocky crust, suddenly produced by pressure acting on it from beneath, or in any other direction.

The latest, and perhaps in all respects the most satisfactory theory, is that proposed by the brothers Rogers, who consider the producing cause as an actual pulsation in the fluid matter beneath the crust propagated in the manner of great waves of translation, from enormous ruptures caused by tension of elastic matter, and floating forwards on its surface the superimposed rocky crust of the earth. This theory accords with the phenomena of earthquakes, and meets with a remarkable confirmation in the structure of certain mountain masses. See APPALACHIANS.

**EARTHS**, in Chemistry, are a class of substances regarded by the alchemists and older chemists as elementary, and which are insoluble in water. The earths *proper* are now known to be compound, consisting of a metal in combination with oxygen. The list includes Alumina, Glucina, Zirconia, Thoria, Didymia, Lantana, Ceria, Yttria, Terbia, Erbä. They do not alter vegetable colours, are soluble in acids, and are precipitated from their solutions by ammonia, potash, or soda. The *Alkaline Earths* have already been noticed. See ALKALIES.

**EARTHWORKS**, in Fortification, is a general name for all military constructions, whether for attack or defence, in which the material employed is chiefly earth. The word *earthwork*, however, has lately received a new importance, in reference to a discussion among military engineers, whether earthwork defences generally are better or worse than those of masonry. The subject cannot be discussed here, but its general character may be indicated. The fracture of the Russian granite fortifications at Bomarsund, and the obstinate defence made within the earthen defences at Sebastopol, led many writers, about the year 1855, to express a preference for earthworks instead of stoneworks. Mr J. Fergusson (*Portsmouth Protected*, 1856) has especially distinguished himself by his advocacy of this view. The reasons urged are—that masses of earth can be more quickly and cheaply put up than masses of masonry; that in most places earth is more readily obtained than stone; that if an earthwork be knocked to ruin by balls and shells, it can be repaired in a very short time; and that the defenders are not exposed to so much injury as in masonry-works, where splinters of stone fly about in a perilous way. The late Sir John Burgoyne, the leading military engineer in England of his day, combated these views. He contended, among other things, that as a given amount of cannonading will make a much larger breach in earthwork than in stonework, the latter is best fitted to prevent capture by assault. He insisted that earthworks should be regarded rather as temporary expedients than as purposed and permanent constructions; and he claimed the authority of continental engineers in support of this opinion. See further under FORTIFICATION.

**EARTHWORM** (*Lumbricus*), a genus of *Annelida* (q. v.), of the order *Terricolæ*. There are many species, all of them pretty closely resembling in characters and habits the common E. or Dew-

worm (*L. terrestris*), which is everywhere plentiful in Britain and throughout Europe, and is familiar to everybody. It has no head distinct from the body, no eyes, no antennæ, nor any organs external to the rings of which its body is composed, except minute bristles pointing backwards, of which each ring bears four pair, and which are of use in its locomotion. It sometimes attains to nearly a foot in length, and more than 120 rings have been counted in its body. The end at which the mouth is situated is pointed, and the tail is flattened, whilst the general form is cylindrical. The mouth consists merely of two lips, the upper lip elongated; there are no teeth nor tentacles, and the worm subsists by swallowing fine particles of the soil, from which its digestive organs extract the digestible matter, the rest being voided often in little intestine shaped heaps, called *worm-casts*, on the surface of the ground. The locomotion of the E. is effected by means of two sets of muscles, which enable it to contract and dilate its rings; its bristles preventing motion backwards, and the whole muscular effort thus resulting in progress; whilst the expansion of the rings, as it contracts the anterior segments, and draws forward the hinder parts, widens a passage for it through earth whose particles were close together before. Earthworms are thus of very great use, their multitudes continually stirring and loosening the soil through which they work their way; and moles, pursuing them to feed on them, stir and loosen it still more; whilst worm-casts gradually accumulate on the surface to form a layer of the very finest soil, to which it is supposed that the best old pastures in a great measure owe their high value.

Earthworms do not often visit the surface of the ground, except during night, and when the ground is moist. In the evening, during or after rain, or in the morning when the dew is abundant, they may sometimes be seen travelling about in great numbers. Both drought and cold cause them to retreat more deeply into the earth.—Their respiration is effected by means of little sacs, which communicate by minute pores with the external air. They are hermaphrodite, but mutual fecundation takes place by means of the thickened knot (*clitellum*) which is situated before the middle of their body. Their eggs often contain two embryos, and the young worms escape by a sort of valvular opening at the end.

Besides their usefulness in the improvement of the soil, earthworms are of importance as food for birds, fishes, &c. Their value as bait for fishes is well known to every angler. The instinct which prompts them to hasten to the surface, when, in quest of bait, the angler shakes the soil with a spade or fork, is probably to be referred to the similar shaking on the approach of their constant enemy, the mole.

An E. of great size is common in the East Indies, wherever the climate is moist, from the Himalaya to Ceylon and Java. It is *Icthyophis glutinosus*,

Earthworm (*Lumbricus terrestris*):

a, earthworm; b, anterior extremity, shewing the mouth (the bristles are also shewn); c, egg, containing two young; d, young escaping from the egg.

and abounds very much in that viscid secretion which in the common E. also forms a kind of protecting sheath for the animal, and smooths its way.

**EAR-TRUMPET**, a contrivance for improving the hearing of the partially deaf. For this purpose, many ingenious instruments have been devised. The principle in them all is the same: to collect the sonorous vibrations, and to convey them in an intensified form to the deeper parts of the ear. In this way, the hand placed behind the external ear constitutes the simplest form of ear-trumpet. Though, in a great number of cases of impaired hearing, there can be no doubt that much assistance and comfort are obtained from the use of one or other of the varieties of the ear-trumpet, still they must not be used indiscriminately, for in unsuitable cases they often do much mischief, both by increasing the deafness, and aggravating the noises in the head from which deaf persons often suffer so much. They are of most use, perhaps, in advanced cases of nervous deafness, though injurious in the early stages of this complaint; they are hurtful also in all acute diseases of the organ, and of little or no use in those cases of great thickening of the contents of the middle ear, where the adapting power of the organ has been lost. There are many varieties of trumpet in common use. By far the most useful and comfortable are those which are worn on the head, which go by the name of ear-cornets or acoustic auricles. They can be concealed under the hair or cap, and may be adapted to one or both ears by means of a spring over the head. The apparatus most commonly in use requires to be held in the hand, and consists of a narrow portion inserted into the ear-passage, and which gradually expands into a wide mouth; or the extremity of the instrument may be turned downwards, as in that form which passes by the name of Miss Martineau's trumpet. Another variety, applicable to the more severe cases of deafness, consists of an elastic tube, one end of which is tipped with ivory, and is placed in the ear of the patient; the other is held in the hand of the speaker, who applies his mouth to the open extremity. With this instrument, only one voice can be heard at a time. With the first-mentioned variety, general conversation can be heard often quite well. Ear-trumpets are generally made of some thin metallic substance, such as tin. Gutta-percha, vulcanite, and other substances, are also frequently used.

**EARWIG** (*Forficula*), a genus of orthopterous insects, recently subdivided into a number of genera, and forming the family *Forficulidae*, which many entomologists constitute into a distinct order, *Dermaptera* (Gr. leather-winged). These insects indeed connect the true *Orthoptera* with the *Coleoptera*. Their legs are formed for running, and not for leaping; their wing-covers (*elytra*)—which are very small, and hide only a small part of the abdomen—are of firmer substance than in the other *Orthoptera*; the wings, of which there are two sets—hind and fore wings—are curiously folded under them, both longitudinally, in a fan-like manner, and transversely; the organs of the mouth resemble those of the true *Orthoptera*, with which also earwigs agree in the important character of *semi-complete* metamorphosis; the larvæ and pupæ much resembling the perfect insect, running about and feeding in the same manner, but the larvæ being destitute of wings and wing-covers, the pupæ having them only in a rudimentary state. Earwigs have the body narrow, and of nearly equal breadth throughout, the head exposed, the mandibles very strong and horny, the antennæ long and thread-shaped. The abdomen bears at its extremity a large pair of forceps, apparently of use

as an instrument of defence. Earwigs abound in moist situations, as under the decayed bark of trees, under stones, among decaying straw, &c. They feed both on animal and vegetable food; the COMMON E. (*F. urticularia*), very abundant in Britain and in most parts of Europe, is troublesome

Earwig:

1, female sitting on her eggs; 2, young just emerged from eggs.

to gardeners by eating the leaves of plants and the petals of fine flowers; but the injury which it does is probably more than compensated, particularly as to field-crops, by the destruction of multitudes of smaller insects, as *thrips*, *aphis*, &c. The appearance of this insect is by no means agreeable, and its mandibles and forceps are suggestive of unpleasant possibilities, which, however, would seem never to be realised, although it is a very frequent visitor of houses, particularly those of which the walls are covered with foliage. It is curious how extensively prevalent the notion is that earwigs creep into the ear. To this they owe their English name (E. from *ear*, and Sax. *wiega*, a worm or grub), and their names in many languages, as the French *Prece-oreille*, the German *Ohrwurm*, &c. Newman, in his *Introduction to the History of Insects*, says: 'The shape of these wings (the hind ones), when fully opened, is nearly that of the human ear; and from this circumstance it seems highly probable that the original name of this insect was *carwing*.' The hind wing is here figured.

Hind Wing of Earwig, magnified.

It is agreeable to the general habits of the E. to creep into holes, yet there is apparently no authenticated instance of an E. entering the ear of a human being. Of their habit of creeping into holes, particularly to hide during the day, gardeners take advantage to make earwig-traps of different descriptions.

An interesting peculiarity in the habits of these insects remains to be noticed. The female E. sits upon her eggs and hatches them like a hen; she also gathers her young ones around her and under her in the most affectionate manner. The observations of De Geer on this point have been confirmed by Mr Spence and others.

**EASDALE**, a small isle on the west coast of Argyleshire, in the Firth of Lorn, ten miles south-south-west of Oban. It contains one and a half square miles, and is situated in Kilbrandon parish. It is noted for its primary or metamorphic slate-quarries, belonging to the Marquis of Breadalbane, which have been wrought for more than 150 years, and supply 4 or 5 millions of slates yearly. Compact felspar and conglomerate also occur in the isle.

**EASEL.** This structure, the object of which is to support the canvas or panel of the artist at a convenient height for work, has been used for ages pretty much in its present form.

Easel :

a, easel open for use; b, easel folded up.

very important kind; they include rights of water, rights of way, rights to light and air, rights to support from a neighbouring soil or house, rights to carry on an offensive trade, &c. An easement is an incorporeal Hereditament (q. v.), and corresponds in many respects with a Servitude (q. v.) in Scotch law. But an easement is more limited than a servitude, inasmuch as it comprehends those rights only which carry no title to the profit of the soil. These latter rights are in England known as *Profits a prendre* (q. v.). An easement cannot exist apart from an estate in land, it being necessary that there should be two tenements, the one enjoying the right (dominant), the other over which it is enjoyed (servient). An easement must be constituted by deed or by Prescription (q. v.). It may be extinguished by an actual or implied release. When a party entitled to the enjoyment of an easement is disturbed in that enjoyment, he may enforce his right by action at law, or he may enter upon the servient tenement, and abate the nuisance himself. The American law on the subject of easement is regulated by the same principles that prevail in England. See *Kent's Commentaries on American Law*.

**EAST** (Ger. *Ost*; allied probably to Greek *ēōs*, the morning, and Lat. *oriens*, the rising, i. e., sun) is, vaguely speaking, that quarter of the horizon where the sun rises, or which a person with his face to the south has on his left hand. It is only at the equinoxes that the sun rises exactly in the east point. A line at right angles to the meridian of a place points exactly east and west. See **MERIDIAN** and **HORIZON**.

From very early times, the east has been invested with a certain sacred character, or at least held in respect over other points of the compass. It was the practice of the ancient pagans to fix their altar in the eastern part of their temples, so that they might sacrifice towards the rising sun, which in itself was an object of worship. The custom of venerating the east was perpetuated by the early Christian church from various circumstances mentioned in the sacred record. For example: 'The glory of the God of Israel came from the way of the east.—Ezek. xlili. 2. 'There came wise men from the east to Jerusalem.'—Matt. ii. 1. 'And, lo, the star, which they saw in the east, went before them.'—Matt. ii. 9. Tradition heightened respect for the east. It was said that Christ had been placed in

the tomb with his feet towards the east, and that at the day of judgment he should come from the eastward in the heavens. Looking towards the sun in the east in praying or repeating the creed, was thought to put worshippers in remembrance that Christ is the sun of righteousness, and such an attitude was accordingly adopted as an aid to devotion. From these various circumstances, the building of churches with the Chancel (q. v.) to the east, bowing to the east on uttering the name of Jesus, and burying with the feet to the east, were introduced as customs in the church. In recent times, there has been a general disregard to the practice of turning formally with the face to the east on repeating the creed, and, as is well known, the attempt to revive it by a party in the English church has caused considerable dispease. It is a curious instance of the inveteracy of popular custom, that in Scotland, where everything that savoured of ancient usage was set aside as popish by the reformers, the practice of burying with the feet to the east was maintained in the old churchyards, nor is it uncommon still to set down churches with a scrupulous regard to east and west. In modern cemeteries in England and Scotland, no attention appears to be paid to the old punctilio of interring with the feet to the east, the nature of the ground alone being considered in the disposition of graves.

**EAST CAPE**, the name of the most easterly headlands of the island of Madagascar, of the North Island of New Zealand, and of Siberia or Asiatic Russia. The *first* is in lat. 15° 20' S., and long. 50° 15' E.; the *second* in lat. 37° 40' S., and long. 178° 40' E., being almost precisely the antipodes of Carthagenia in Spain; and the *third* is that extremity of the Old World which is nearest to the New, being separated by Behring's Strait (q. v.) from Cape Prince of Wales in America. It is in lat. 66° 6' N., and long. 169° 38' W.; or rather, to follow the natural reckoning, 190° 22' E.

**EAST INDIA ARMY.** When the East India Company (q. v.) first sent factors or agents to India, an army was not thought of. Military forces arose out of the exigencies of the times. Some of the first troops in the Company's pay were mere adventurers; some were liberated convicts; some deserters from European armies. Gradually, organisation was introduced, and improved arms furnished. As the power of the Company increased, natives entered the battalions; until at length most of the troops were Hindus or Mohammedans, drilled by non-commissioned officers sent out from England. A few regiments were raised in England; a much larger number were raised in India; but all alike were officered by the Company's favoured English officers, largely paid, and having many opportunities for making rapid fortunes. The ranks were filled by enlistment; the Company never compelled the natives to become soldiers; the pay offered was always such as to induce a sufficient number of men to enter. Their periods of leave of absence were liberal; and after a certain number of years' service, they retired on a pension sufficient to support them for the remainder of their days.

At the period immediately preceding the outbreak of the Revolt in 1857, the army in the pay of the Company comprised about 24,000 royal troops (sent to, and paid for by, the Company); 18,000 European troops, raised and drilled by the Company in England; 180,000 native regulars; and 60,000 native irregular horse—making about 280,000 in all. This large force was irrespective of 40,000 contingents furnished by dependent native princes, and of the native armies belonging to the independent and semi-dependent princes. The Company's troops

formed three distinct armies, each under its own commander-in-chief, and each stationed in one particular presidency. In these three armies, three kinds of troops—Europeans, native regulars, and native irregulars—had their own special organisation. In order to secure unity of action when necessary, it was customary to give the commander-in-chief of the Bengal army precedence over those of Madras and Bombay; he was, in effect, commander-in-chief of the whole of the Company's forces. There were too few English officers with the native regiments, and these, in most cases, knew too little of the men under their command. This was not the cause of the Revolt in 1857, but it was one of the circumstances that led to the rapid spread of the Revolt when once begun. To what extent this fine army melted away during 1857 and the two following years, is described under INDIA. Speaking generally, it may be said that the armies of the Madras and Bombay presidencies remained faithful, especially the infantry. It was in the Bengal army that the disruption chiefly occurred. The irregulars, both cavalry and infantry, raised amongst the Sikhs and Punjabees, were in almost every case faithful.

In August 1858, the act which transferred the government of India from the Company to the crown received the royal assent. The army was transferred as well as the political power. As the Sikhs had behaved well, most of the regiments from the Punjab were retained, as well as most of the native regiments in the Bombay and Madras presidencies; but it was not deemed expedient to restore the native regiments of Bengal proper, which had proved so treacherous. In that year, at the suggestion of Earl Canning, a committee was appointed to inquire into the whole circumstances relating to the reorganisation of the army. The Company originated the inquiry, but the commissioners did not make their Report till after the transfer of the Company's powers to the crown. Although the commissioners' Report was presented in the summer of 1859, very little was effected during the remainder of that year, or in 1860, to reorganise the Indian army; matters were kept together in a provisional way. Meanwhile, when the European troops of the Company's army were turned over to the crown, a disturbance, amounting almost to a mutiny, occurred. The men claimed that, as they had enlisted into the Company's service, they ought not to be transferred without their own consent asked, or without receiving a bonus on re-enlisting. To prevent a dangerous excitement, the government allowed such as chose to retire.

In 1861, an act was passed reorganising the Indian army. The *British* portion of it now forms part of the Queen's army generally, with certain honorary distinctions, and takes its turn at home and in the colonies like the rest; but the expenses are paid out of Indian, not imperial revenues. The *native* portion is managed wholly in India. A majority of the officers educated and commissioned by the Company having suffered greatly by the Revolt, certain compensatory advantages were conceded to them. On the reorganisation of the Indian army in 1861, the 21st Hussars, with the 105th, 106th, 107th, 108th, and 109th Foot, were formed from the European troops previously in the service of the East India Company.

**EAST INDIA COMPANY.** On the 31st December 1600, a charter was granted by Queen Elizabeth to a number of London merchants, under the title of 'The Governour and Company of Merchants of London trading to the East Indies.' From the time when Vasco de Gama effected the eastern passage to India, by doubling the Cape of Good Hope, in 1497, the Portuguese carried on an

extensive trade with that country, unaffected by rivals until nearly a century afterwards, when the Dutch and the English began to compete with them. This competition became formidable when two 'East India Companies' were established, one at Amsterdam, and one in London. It is of the latter of these that we here treat. The charter was exclusive, as is usual in such cases; prohibiting the rest of the community from trading within the limits assigned to the Company. These limits were enormous, comprising the whole space, land and sea, from the Cape of Good Hope eastward to Cape Horn—i. e., the whole of the Indian and Pacific Oceans. The charter was for fifteen years. The Company speedily sent out ships to Java and Sumatra, which returned with calicoes, silk, indigo, and spices. It was then determined to make some kind of settlements on the coast of Hindustan itself; and about 1612, the Company obtained permission from the native princes to establish factories or agencies at Surat, Ahmedabad, Cambay, and Gogo.

The Company's charter was renewed from time to time, with various modifications, but not without much contention and difficulty. Gradually establishments were formed in Java, Sumatra, Borneo, Celebes, Malacca, Siam, the Banda Islands, and other places in the East; as well as on the Coromandel and Malabar coasts of India itself. The first beginning of Madras dates in 1640, of Calcutta in 1645, and of Bombay in 1665, as chief establishments of the Company. In 1662, Charles II. gave them permission 'to make war and peace on the native princes'—a privilege of which they largely availed themselves for nearly 200 years.

In 1698, the crown granted a charter to a *new* E. I. C., who offered a loan of £2,000,000 to the state; but this naturally led to wranglings, and the two companies were united into one by an act of parliament passed in 1702. The constitution then established was maintained with little alteration as long as the Company existed. Every shareholder who held £500 of the Company's stock became a member of the Court of Proprietors; and this court had legislative functions in all that related to the Company's affairs. The proprietors annually chose 24 to form a Court of Directors, from those of their number who held not less than £2000 of stock. Six of the directors went out of office every year; they retired in rotation, so that each had four years of office. It was a general custom with the proprietors to elect the same persons as directors over and over again. The Court of Proprietors was to meet once a year, or oftener if necessary; the Court of Directors as often as the directors chose, provided 13 were present. Theoretically, the constitution of the Company was very democratic; but practically the affairs were in the hands of the directors; for the proprietors took little other interest than in receiving their half-yearly dividends. The proprietors had from one to four votes each, according to the amount of stock held by them. The Board of Control, of later formation, bore relation to the governmental affairs of India.

Properly speaking, the Company were only merchants: sending out bullion, lead, quicksilver, wools, hardware, and other goods to India; and bringing home calicoes, silk, diamonds, tea, porcelain, pepper, drugs, saltpetre, &c. from thence. Not merely with India, but with China and other parts of the East, the trade was monopolised by the Company; and hence arose their great trade in China tea, porcelain, and silk. By degrees, avarice and ambition led the Company, or their agents in India, to take part in the quarrels among the native princes; this course gave them power and influence at the native courts, from whence arose the acquisition of

sovereign powers over vast regions. India thus became valued by the Company, not only as commercially profitable, but as affording to the friends and relations of the directors opportunities of making vast fortunes by political or military enterprises. It is not the purpose of the present article to trace the political affairs of the Company, or the rise of a British empire in India; that will be done under INDIA, BRITISH; it will suffice here merely to state, that no national or patriotic motive marked the beginning of this course.

In 1744, the Company obtained a renewal of their charter till 1780, but not without a loan of £1,000,000 to government; for the monopoly was distasteful to the nation at large. France, too, had an E. I. C., and the struggles between the two companies for power in the southern part of India, led to constant warfare between them during the remainder of the century. Other loans to government were the means of obtaining further renewals of the charter in later years. In 1833, the legislature took away all the trading privileges of the Company. The dividends to proprietors of East India stock were thenceforward to be paid out of taxes imposed by the Company on the people of India, in such provinces as were under British dominion. From that year the Company's powers became anomalous; the Company could not trade, and could not govern without the sanction and continued interference of the imperial government. The wars in India, since that year, have been waged by England as a nation, rather than by the Company; and England practically, though not nominally, became responsible for the enormous cost of those wars. In 1853, the charter was again renewed, with a further lessening of the power of the Company, and an increase of that of the Crown.

Had not the Indian Revolt occurred in 1857, the last charter would have remained in force until 1873; but that gigantic calamity led to the resolution—a resolution the wisdom of which was disputed by many of the best judges of Indian affairs—of concentrating the power in the hands of the imperial government. In spite of a strenuous resistance, in 1858, the Company were forced to cede their powers, by an act which received the royal assent on the 2d of August. The charter of 1853 had provided that £6,000,000 of India stock should have 10½ per cent. dividend guaranteed by England out of the revenues of India; and that parliament should redeem this stock at cent. per cent. premium any time after the year 1873. The act of 1858, therefore, contained due clauses for carrying out these provisions, and transferred the whole of the Company's powers to the Crown.

The Company continued to exist, but for little other purpose than that of receiving and distributing dividends. Most of the distinguished men, military and political, till then in the Company's service, accepted office under the Crown, to assist the government by their general knowledge of Indian affairs. These affairs are now managed by a Secretary in Council at the new India Office. The valuable Library and Museum of the Company have passed over to the Crown; and an Act of Parliament (1873) provides for the paying off of the India stock, and the final extinction of the once-famous East India Company.

EAST INDIES, as distinguished from *West Indies*, include not merely the two great peninsulas of Southern Asia, but likewise all the adjacent islands from the delta of the Indus to the northern extremity of the Philippines. They thus extend, to use round numbers, in latitude from 35° N. to 10° S., and in E. long. from 65° to 130°. At one time, the name of India had, towards the east,

a still wider application, occasionally comprising Japan, nay, everything in that direction except China alone. See INDIA.

EAST MAIN, formerly a portion of the Hudson Bay Territories, now incorporated in the Dominion of Canada, is bounded north by Hudson's Strait, and west by Hudson's Bay down to its southern extremity, meeting Labrador on the east, and Canada on the south. This immense region, thrice as large as Great Britain, is generally bleak and sterile, yielding little to commerce but fish-oil and a few furs.—A river of the same name, otherwise called the *Stade*, crosses its southern section, entering Hudson's Bay, here known as James's Bay, about lat. 52° 15' N., after a course of 400 miles.

EAST RIVER, the strait between Long Island Sound and New York Harbour. It is 20 miles long, separating New York City on the west from its suburbs, Williamsburg and Brooklyn, on the east. Its narrowest part is the Hurlgate or Hellgate, which is about the middle of its course. Here the rocks, which once obstructed the passage, have been removed by blasting. The name—clearly a misnomer for an arm of the sea—is convenient as contrasted with the North River, or Hudson, and may have arisen from the river-like action of the tides—an action so powerful as to have here and there materially deepened the channel.

EASTBOURNE, a rising watering-place in the south-east of Sussex. It lies in a chasm between two cliffs, one of which, 3 miles to the south-south-east, forms Beachy Head. In the vicinity are fine drives and walks. It has a martello tower and a fort. Pop. of parish (1871), 10,361. E. is supposed to have been of Roman origin, and remains of a Roman villa, bath, and tessellated pavements have been found here.

EASTER (Ger. *ostern*, Fr. *paque*, Scot. *pasch*, from Gr. *pascha*, the passover), the festival of the resurrection of Jesus Christ, derives probably its Teutonic name from the festival of the goddess Ostara, in Ang.-Sax. *Eastre*, which the Saxons of old were wont to celebrate about the same season at which the Christian festival of Easter occurs. In the ancient church, the celebration of Easter lasted eight days. After the 11th c., however, it was limited to three, and in later times, generally to two days. It was formerly the favourite time for performing the rite of baptism. The courts of justice were closed, and alms dispensed to the poor and needy, who were even feasted in the churches—a custom which led to much disorder. Slaves also received their freedom at that season; and as the austerities of Lent were over, the people gave themselves up to enjoyment; hence the day was called the 'Sunday of joy' (*Dominica gaudii*). To the popular sports and dances were added farcical exhibitions, in which even the clergy joined in some places, reciting from the pulpits stories and legends, with a view to stir the hearers to laughter (*risus paschalis*). Against this indecency, the Reformers of the 16th c. loudly and successfully raised their voices. During the whole week before Easter—that is, in the interval between Palm Sunday and the beginning of the Easter festival—daily services were held. See PASSION WEEK and GOOD FRIDAY.

On Easter day, the people saluted each other with the Easter kiss, and the exclamation *Surrexit* (He is risen); to which the reply was *Vere surrexit* (He is risen indeed). The chief solemnity always consisted of the celebration of the Lord's Supper.

The proper time for the celebration of Easter has occasioned no little controversy. In the 2d c., a dispute arose on this point between the Eastern and Western Churches. The great mass of the Eastern

EASTER.

Christians celebrated Easter on the 14th day of the first Jewish month or moon, considering it to be equivalent to the Jewish Passover. The Western churches celebrated it on the Sunday after the fourteenth day, holding that it was the commemoration of the resurrection of Jesus. The Council of Nice (325 A.D.) decided in favour of the Western usage, branding the Eastern usage with the name of the 'quartadeciman' heresy. This, however, only settled the point that Easter was to be held, not upon a certain day of the month or moon, but on a Sunday. The proper astronomical cycle for calculating the occurrence of the Easter moon was not determined by this council. It appears, however, that the Metonic Cycle (q. v.) was already in use in the West for this purpose; and it was on this cycle that the Gregorian Calendar, introduced in 1582, was arranged. The method on which this calendar is constructed is too complex for description here. An elaborate account of the whole matter was published by Professor De Morgan in the *Companion to the British Almanac* in 1845, and to this the reader is referred. The time of Easter being the most ancient and important of all the movable feasts of the Christian Church, determines all the rest. It was debated, at the time of the introduction of the Gregorian Calendar, whether Easter should continue to be movable, or whether a fixed Sunday, after the 21st of March, should not be adopted. It was deference to ancient custom that led the ecclesiastical authorities to adhere to the method of determination by the moon. It must be remembered, however, that it is not the actual moon in the heavens, nor even the mean moon of astronomers, that regulates the time of Easter, but an altogether imaginary moon, whose periods are so contrived that the new (calendar) moon always follows the real new moon (sometimes by two, or even three days). The effect of this is, that the 14th of the calendar moon—which had, from the times of Moses, been considered 'full moon' for ecclesiastical purposes—falls generally on the 15th or 16th of the real moon, and thus after the real full moon, which is generally on the 14th or 15th day. With this explanation, then, of what is meant by 'full moon,' viz., that it is the 14th day of the calendar moon, the rule is, that Easter Day is always the first Sunday after the paschal full moon, i. e., the full moon which happens upon or next after the 21st of March (the beginning of the ecclesiastical year); and if the full moon happens upon a Sunday, Easter Day is the Sunday after. For any given year, the day on which the paschal full moon falls, and then Easter Day, are found by the following table and rule—

taking the second, where there are two—and the Golden Number (see ERECT); look for the golden number in the third column of the table, and opposite to it stands the day of the full moon; then look for the dominical letter, next after the day of full moon, and the day standing opposite the dominical letter is Easter Day. It sometimes happens that Easter Day, as thus determined, is different from what it would be if by 'full moon' were understood the astronomical full moon. Thus, in 1818, Easter Day, by the calendar, fell, and was celebrated on the 22d of March, the earliest possible day, although the full moon was on that day; and in 1845, it again fell on the day of the actual full moon (the 23d March).

One object in arranging the calendar moon was, that Easter might never fall on the same day as the Jewish Passover. They did occur together, however, in 1805, on the 14th of April; and in 1825, on the 3d April; and will do so again in 1903, on the 12th April; in 1923, on the 1st April; in 1927, on the 17th April; and in 1981, on the 19th April. The Jewish festival usually occurs in Passion week, and never before the 26th of March, or after the 25th of April (new style). On the other hand, the Christian festival is never before the 22d of March, or after the 25th of April. In 1761 and 1818, Easter fell on the 22d of March; but neither in this nor the following century will such be the case again. In 1913, it will fall on the 23d of March, as it did in 1845 and 1856. The latest Easters in this century and the following, occur in 1886 and 1943, on the 25th of April. In 1848, Easter fell on the 23d of April; and in 1859, on the 24th of April.

*Popular Observances.*—Many of the popular observances connected with Easter are clearly of pagan origin. The goddess Ostara or Eastre seems to have been the personification of the morning or east (q. v.), and also of the opening year or spring. The Anglo-Saxon name of April was *Estermonath*; and it is still known in Germany as *Ostermonath*. The worship of this being seems to have struck deep root in Northern Germany, and was brought into England by the Saxons. It continued to be celebrated in many parts in the north of Germany down to the beginning of the present century, by the kindling of bonfires and numerous other rites. See BELTEIN. Like the May observances of England, it was especially a festival of joy. With her usual policy, the Church endeavoured to give a Christian significance to such of the rites as could not be rooted out; and in this case, the conversion was particularly easy. Joy at the rising of the natural sun, and at the awaking of nature from the death of winter, became joy at the rising of the Sun of Righteousness—at the resurrection of Christ from the grave. The bonfires can be traced in the great 'paschal tapers,' sometimes weighing 300 lbs., with which the churches were lighted on Easter Eve. In the ancient church disbursements of St Mary-at-Hill, in the city of London, there is even an entry 'For a quarter of coles for the hallowed fire on Easter Eve, 6d.'

The most characteristic Easter rite, and the one most widely diffused, is the use of *Pasch* (i. e., Easter) eggs. They are usually stained of various colours with dye-woods or herbs, and people mutually make presents of them; sometimes they are kept as amulets, sometimes eaten; games are also played by striking them against one another. In some moorland parts of Scotland, it used to be the custom for young people to go out early on 'Pasch Sunday' and search for wild-fowls' eggs for breakfast, and it was thought lucky to find them.

First ascertain the Dominical Letter (q. v.)—

There can be little doubt that the use of eggs at this season was originally symbolical of the revivification of nature—the springing forth of life in spring. The practice is not confined to Christians; the Jews used eggs in the feast of the Passover; and we are told that the Persians, when they keep the festival of the solar new year (in March), mutually present each other with coloured eggs.

From the Christian point of view, this 'Feast of Eggs' has been usually considered as emblematic of the resurrection and of a future life.

**EASTER ISLAND**, originally **DAVIS'S LAND**, is a detached spot on the Pacific, in lat. 27° 20' S., and long. 109° 30' W. It is of volcanic origin, rising 1200 feet above the sea; and it is moderately fertile, but almost destitute of water. It belongs to the Polynesian archipelago, of which it forms the south-easterly extremity. On this island, of thirty miles' circumference, and inhabited by less than 2000 wretched savages, there exist multitudes of rude stone statues, some of them of colossal size, and standing on long platforms of Cyclopean masonry. The present inhabitants, whose language is radically the same as that of Tahiti, have no tradition of the race that made them. The existence of these sculptures is thought to strengthen the conclusion, arrived at on other grounds, that the Polynesian islands are relics of a submerged continent.

**EASTER OFFERINGS**, or **EASTER DUES**, small sums paid to the parochial clergy in England by their parishioners at Easter, as a compensation for personal tithes, or the tithe for personal labour.

**EASTER TERM, LEGAL**. For a general history of the law terms in England, see **LAW TERMS**. Easter Term was formerly dependent upon the movable feast of Easter, and was hence called a movable term. It commenced on the Wednesday fortnight after Easter Sunday, and lasted till the following Monday three weeks. But by 11 Geo. IV. and 1 Wil. IV. c. 70, amended by 1 Wil. IV. c. 3, Easter Term now begins on 15th April and ends on 8th May. If any of the days between the Thursday before and the Wednesday after Easter fall within term, no sittings in Banc (q. v.) are held on those days, and the term is prolonged a corresponding number of days.

**EASTLAKE**, **SIR CHARLES LOCK**, President of the Royal Academy of London, was born at Plymouth in 1795, educated at the Charter-house in London, and entered as a student at the Royal Academy. Subsequently, he went to Paris, where he studied and copied the great paintings then collected in the Louvre. The return of Napoleon from Elba compelled him to leave France. He went back to his native town, and supported himself by portrait-painting. When the *Bellerophon*, with Napoleon on board, appeared in the port of Plymouth, E. profited by the opportunity, and produced his first important picture, 'Napoleon at the Gangway of the *Bellerophon*,' attended by some of his Officers.' In 1817, Sir Charles visited Italy and Greece, sketching assiduously in both countries. During a residence of several years in Rome, he executed his 'Girl of Albano leading a Blind Woman to Mass,' 'Isidas the Spartan,' 'Pilgrims arriving in Sight of Rome,' and many others, illustrative of Italian customs and scenery. In 1827 he was elected an Associate, and in 1830 a full member of the Royal Academy. His 'Greek Fugitives Prisoners to Banditti,' &c., added to his already great reputation; and in 1841 appeared what many conceive to be his master-piece, 'Christ lamenting over Jerusalem.' It was immensely admired, the duplicate painted for Mr Vernon being reckoned one of the most valuable pictures in the Vernon Gallery. 'Hagar and

Ishmael' was exhibited in 1844; 'Heloise' in 1845; 'The Escape of Francesco Novello di Carrara with Taddea d'Este, his Wife, from the Duke of Milan,' in 1850; 'Beatrice' in 1855, &c. In 1850, he was elected President of the Royal Academy, when he received the honour of knighthood. Subsequently, he was appointed Director of the National Gallery, in which capacity his services were of the highest importance; for besides its improved arrangement, many of the most valuable specimens of the best schools were added to the collection. Sir Charles also acquired a high reputation as a writer on art. In 1847, he published *Materials for the History of Oil Painting*, a work of great learning and research. He contributed several articles to the *Penny Cyclopædia* on subjects belonging to his profession, and executed a translation of Goethe's *Farbenlehre*. In 1853, he received the title of D.C.L. from the university of Oxford. He died December 1865.—**LADY EASTLAKE** (born Elizabeth Rigby) is an artist of no mean power, and also has distinguished herself as an authoress by her *Letters from the Baltic, Livonian Tales*, and her articles on subjects connected with art in the *Quarterly Review*.

**EASTON**, a flourishing town of Pennsylvania, in the United States, stands in the fork between the rivers Delaware on the east and Lehigh on the west, about 20 miles above the head of navigation on the united streams. Though the place is thus far cut off from the sea, yet, for internal trade, it clearly occupies a commanding position. Its natural advantages, too, have been largely improved. To say nothing of railways, E. is the common terminus of three canals—one of 60 miles, down on the right side of the Delaware as far as Bristol; another of 84 miles, along the Lehigh, into the great coal-field of the state; and the third of 102 miles, leading across the country to Jersey City. Within the immediate neighbourhood, likewise, iron ore and limestone abound. Having an unlimited supply of water-power, the town is the seat of extensive manufactories. Pop. in 1870, 10,987.

**EASTPORT**, a garrison-town of Maine, in the United States, is situated on one of the small islands of Passamaquoddy Bay, which receives the St Croix, the international boundary during its whole course between the United States and British America. On the coast, therefore, E. may be said to be the frontier town of the Union towards the north-east. Its harbour is deep enough for the largest vessels. The tide rises within it to a height of 25 feet—a height far exceeded in many other parts of the Bay of Fundy, of which Passamaquoddy Bay is an inlet. The place is largely engaged in the fisheries and in ship-building. Pop. (1870) 3738.

**EAU CRÉOLE**, a very fine liqueur, made in Martinique, by distilling the flowers of the Mammee Apple (*Mammea Americana*) with spirit of wine.

**EAU DE COLOGNE**, a celebrated perfume, invented long ago by the Farina family in Cologne, and since manufactured chiefly by members of the same family. It is also made in France. It consists principally of spirits of wine, along with numerous essential oils harmoniously mingled together, so as to produce a refreshing and grateful scent. The recipe said to be followed in the manufactories at Cologne is twelve drops of each of the essential oils neroli, citron, bergamot, orange, and rosemary, along with one drachm of Malabar cardamoms, and one gallon rectified spirit. The whole is distilled together, and the condensed liquid constitutes Eau de Cologne.

**EAU DE JAVELLE** is a solution of hypochlorite of potash, which, when administered to man,

is stated to act powerfully on the nervous system, and to give rise to general rigidity, and even to cause tetanic spasms.

EAU DE VIE. See BRANDY.

EAUX BONNES, a fashionable watering-place of France, in the department of Basses-Pyrénées, is situated 20 miles south-south-east of Oloron. It stands in a narrow gorge surrounded with rocks, and consists of a street of about 30 large and well-built hotels and lodging-houses. On the opposite side of the street there is an open space laid out as a shrubbery, and planted with trees; it is called the Jardin Anglais. E. B. is much frequented on account of its hot sulphureous springs, which are four in number, and are used for bathing purposes. Their temperature does not exceed 91° F. There is also a cold spring here, which is used for drinking. The springs are said to be very valuable, on account of their power of checking the progress of incipient consumption, and of curing various affections of the lungs and chest. The season of the E. B. lasts from June to October, and during that time it is crowded with visitors and patients.

EAUX CHAUDES, LES, three miles south-west of the preceding, is a similar place of resort. Its springs have the same properties as those of the Eaux Bonnes.

EAVES, in Architecture, the edge of a sloping roof which overhangs the wall, for the purpose of throwing off the water. When there is no concealed gutter at the margin to conduct the water to spouts or pipes, but the water is allowed to run from the roof to the ground, they are called *Dripping Eaves*.

EAVESDRIP, or EAVESDROP (Ang.-Sax. *yfesdryspe*). 'The owner of a private estate,' says Kemble (*Saxons in England*, vol. i. p. 45), 'was not allowed to build or cultivate to the extremity of his own possession, but must leave a space for eaves. The name for this custom was *yfesdryspe*.' The space was regulated by the charter by which the property was held. In a charter of SÖS A. D., it is limited to two feet. This Saxon custom corresponded to the well-known urban servitude of the Romans called *stillicidium*. The eavesdrop was the water which dropped from the projecting roof, and in this sense is opposed to the water collected in a spout, to which the Romans gave the name of *stumen*. Similar regulations existed in Greece, and have probably existed in all countries.

EAVES-DROPPERS 'are such as listen under walls or windows, or the eaves of houses, to hearken after discourse, and thereupon to frame slanderous or mischievous tales.'—Blackstone's *Comm.* iv. 168. Such persons are, by the law of England, regarded as common nuisances; they may be indicted at the sessions, and on conviction, are punishable by fine. Persons who by their conduct expose themselves to suspicion of an intention to commit this offence, may be brought before a magistrate, and required to give security for their good behaviour; 34 Edw. III. c. 1. See Hawk., P. C., I. 62, sec. 4.

EBB AND FLOW. See TIDES.

EBENACEÆ, a natural order of exogenous plants, consisting of trees and shrubs, with alternate leathery leaves, and axillary flowers, which are monopetalous, somewhat leathery, and generally unisexual; the fruit fleshy. They have not a milky juice. They are regarded as allied to *Aquifoliaceæ* (Holly, &c.), *Apocynaceæ*, and *Oleaceæ*. About 160 species are known, mostly tropical, but a few are natives of Europe, and other temperate countries.

The wood is in general remarkable for its hardness, as the different kinds of Ebony (q. v.) and other species of *Diospyros*; and on account of this quality, even that of species which never attain the ordinary size of timber trees is sometimes accounted valuable, as of *Toyena lucida*, the African Bladder-nut or Zwart-bast, at the Cape of Good Hope; where also that of *Euclea undulata*, a hard brown wood, is esteemed for cabinet-work. The fruit of many species is eatable. See DATE PLUM. The fruit of *Embryopteris gelatinifera* contains a viscid juice, and is used in all parts of India for paying boats.

EBERHARD, AUG. GOTTLÖB, a well-known German author, was born at Belzig in 1769, studied at Leipsic and Halle, and first attracted attention by his contributions to a periodical devoted to *belles-lettres*, entitled *Ida's Blumenkörbchen* (Ida's Flower-basket). Among his numerous works may be mentioned *List um List, oder was ein Kuss nicht vermag* (Trick for Trick, or what could not a Kiss do); *Ysop Lafayette's Sämmtliche Werke* (Ysop Lafayette's Collected Works); *Ferdinand Werner, der arme Flötenspieler* (Ferdinand Werner, the poor Flute-player); and *Ischariot Krall's Lehren und Thaten* (Ischariot Krall's Doctrines and Doings); *Hanichen und die Küchlein* (Jenny and the Chickens), a narrative poem in ten parts, which has gone through many editions, and been often translated into other languages; and *Der erste Mensch und die Erde* (The First Man and the Earth), a poem marked by simple dignity and lively representation. E., after a life of hard literary work, died at Dresden, 13th May 1845.

EBERHARD, JOHANN AUGUST, a philosophical writer of Germany, was born at Halberstadt, 31st August 1739; studied theology at Halle, 1756—1759; and after spending several years as a preacher in Berlin and Charlottenburg, became Professor of Philosophy at Halle in 1778, and Doctor of Theology in 1808. He died 6th January 1809. E.'s first work was his *Neue Apologie des Socrates* (New Apology of Socrates), 2 vols., Berlin, 1772; a work in which the rights of common sense are vindicated against the accusations of a narrow theology. It was received with much applause both in Germany and in other countries. Among his other writings may be mentioned, *Sittenlehre der Vernunft* (Ethics of the Reason), Berlin, 1781; *Theorie der schönen Künste und Wissenschaften* (Theory of the Fine Arts and Sciences), Halle, 1783; *Allgemeine Geschichte der Philosophie* (Universal History of Philosophy), Halle, 1788; *Handbuch der Aesthetik* (Manual of Aesthetics), 4 vols., Halle, 1803—1805; and *Versuch einer allgemeinen Deutschen Synonymik* (An Attempt towards a Complete Work on German Synonyms), 6 vols., Halle, 1795—1802, a work which was enriched and improved by Maas, 1818—1821, and again by Gruber, 1826—1830, but which was, at the time of its appearance, the best thing of the kind in the German language. Towards the close of his life, E. struggled, but without success, against the speculative excesses of the new schools of philosophy headed by Kant and Fichte. E. was a clear and sensible thinker, as well as an agreeable and interesting writer.

EBERNBURG, a small town in the Bavarian Palatinate, is situated about 20 miles south-west of Mayence, at the junction of the Alsenz with the Nahe. It is notable on account of the ruins of its castle, which formerly belonged to the famous knight Franz of Sickingen, who was a devoted friend of the early reformers. His stronghold, which was once considered almost impregnable, afforded a secure retreat from danger and persecution to Melancthon, Bucer, Ecolampadius, and Ulrich von Hutten, the

last of whom composed several of his works here. After the death of Sickingen, the castle of Ebernurg was besieged and dismantled by the Electors of Hesse and of Treves. Pop. about 500.

EBERT, KARL EGON, a Bohemian poet, was born at Prague, 5th June 1801; educated there and at Vienna; and after filling several situations, finally settled in Prague, where he still resides. His chief works are his *Dichtungen* (Poems), 2 vols., Prague, 1824; 3d edition, Stutt. 1845; *Wlasta, ein Böhmischnationales Heldengedicht in drei Büchern* (Wlasta, a Bohemian National Heroic Poem, in three Books), Prag, 1829; and *Das Kloster, idyllische Erzählung in fünf Gesängen* (The Cloister, a Narrative Idyll, in five cantos), Stutt. 1833. These poems, especially the last two, are marked by lyrical vehemence, and elegance of language. They were received with applause, particularly in Bohemia, whose national traditions form their groundwork. E.'s compositions shew a happy union of the German and Czech characteristics. He has also written a large number of dramas, of which *Das Gelübde* (The Vow) (1864) was received with public favour at Prague. He has also published some meritorious lyrical poetry.

EBIONITES (Heb. *ebion*, poor), a name probably given originally by the hierarchical or influential party among the Jews, to those of their countrymen who professed the Christian faith, and who generally belonged to the poorer and more ignorant class (John, chap. vii., verses 48, 49). Subsequently, it would seem, the Gentile Christians, who were ignorant of Hebrew, employed it in a distinctive sense to designate their Jewish co-religionists, who, in addition to their belief of Christianity, observed the Mosaic law. Irenæus is the first writer who makes use of the name. It is highly probable that the E. first became an organised body or sect at Pella, a city in Peræa, on the eastern side of the Jordan, whither they had betaken themselves on the breaking out of the Roman-Jewish war in the time of Hadrian. Here, indeed, a strictly Jewish-Christian church continued to exist down to the 5th century. Among the E., however, there was by no means a unanimity of religious feeling, or uniformity of opinion. Two great divergent parties are clearly recognisable—the E. proper, and the Ebionitic Nazarenes. The former were little different from Jews; their conceptions of the Saviour were meagre and unspiritual. They believed that Jesus was simply a man distinguished above all others for legal piety—pre-eminently a Jew, and selected as the Messiah because of his superior Judaism. Of course they denied his supernatural birth, yet not his resurrection; for 'they lived in expectation of his speedy return to restore this city of God (Jerusalem), and to re-establish the theocracy there in surpassing splendour.'—Neander. They were the genuine descendants of these Judaizers who plagued the church in the time of the Apostle Paul. The Ebionitic Nazarenes, on the other hand (who at the close of the 4th c. seem to have dwelt chiefly about Peræa in Lower Syria, but at an earlier period may have been more widely diffused), were Jewish Christians, in the better sense of the term. They conceived it to be their *own* duty still to circumcise, keep the Sabbath, &c., but they had no wish to impose the peculiarities of Judaism on the Gentile Christians. They did not believe that Christianity was merely a glorification of Judaism, but a new life come into the world, in which the Gentile might at once participate, without undergoing a Mosaic ordeal. Like the stricter E., they used a *Gospel of Matthew*; but it contained what the other did not—an account of the supernatural conception and birth of the Saviour. According to Neander, who has

very thoroughly investigated this question, there were a great many varieties of opinion among the E., springing out of the differences above spoken of, which it would be tedious to record. It is sufficient to say that *Essenism* (q. v.) modified Ebionism greatly, through the introduction of a Jewish mysticism, which recognised in Moses and Christ an inward identity of doctrine, and regarded them as revealers of the 'primal religion,' whose teaching, however, had been sadly corrupted. It is extremely probable that an Essenic Ebionite wrote the *Clementine Homilies*. See CLEMENS.

EBOLI (ancient *Eburæ*), a small town of Southern Italy, in the Principato Citeriore, about 16 miles east-south-east from Salerno, is picturesquely situated at a considerable elevation above sea-level. The climate, which does not become too cold in winter, notwithstanding the position of the town, is very unhealthy in summer, owing to the number of streams in the neighbourhood. There is an annual fair at E., which lasts 12 days. Pop. 7300.

EBONY (Lat. *Ebenum*; but originally from the Eastern name), a wood remarkable for its hardness, heaviness, and deep black colour, is the heart-wood of different species of *Diospyros*, of the natural order *Ebenaceæ*, the same genus which produces the Date Plum (q. v.), Kaki, and other fruits. The best E., excelling in uniformity and intensity of colour, is the produce of *D. Ebenum*, which grows in great abundance in some of the flat parts of Ceylon, and is a tree of such magnitude, that logs of its heart-wood, two feet in diameter, and varying from ten

Ebony (*Diospyros Ebenum*).

to fifteen feet in length, are easily procured. *D. melanocylon*, the E. tree of Ceromandel, yields E. of good quality; *D. tomentosa*, *D. Roylei*, and other Indian species, also yield it. In Mauritius and Madagascar, E. of very good quality is produced by *D. reticulata*. Other species of *Diospyros* are much valued for their beautiful timber, very different in colour from E., as Calamander Wood (q. v.) and Cadoberia (*Diospyros Ebenaster*). The last-named species is found in India and Ceylon. The prevailing black of the wood is beautifully striped with a rich yellowish-brown; but in density and durability it is far inferior to ebony.—E. is chiefly used by cabinet-makers for veneering. The ancient Greeks and Romans were acquainted with it; and it is supposed that they obtained it either from India or Madagascar. They frequently inlaid it with ivory, for contrast of colour. It is mentioned by Ezekiel (xxvii. 15) as an article of Tyrian commerce. It was at one time used in medicine, as a

laxative and sudorific; it has a somewhat pungent taste.—The name *E.* is sometimes given to the black wood of trees very different from those of the genus *Diospyros*. An Abyssinian tree called *Mozzangha* (*Fornasinia*), of the order *Leguminosæ*, produces a black heavy wood, much resembling ebony.—WEST INDIAN *E.* or AMERICAN *E.*, is produced by *Brya ebenus*, also of the natural order *Leguminosæ*, but the wood is of a greenish-brown rather than a black colour. It receives a good polish, is very hard and durable, and much sought after by musical instrument-makers. It is one of the articles of export from the West Indies to Britain. But the tree is of small size, seldom more than 12 feet high, and the trunk only a few inches in diameter.

**EBRO** (Lat. *Iberus*), an important river of Spain, rises in the province of Santander, at a point greatly elevated above the level of the sea, about 12 miles north-west of Reynosa, flows south-east for about 25 miles; then east past Frias, after which it maintains a general south-east course, passing Miranda, Haro, Logroño, Tudela, and Zaragoza, when it turns north, passes Mequinenza, flows south-east to Mora, south to Tortosa, and finally east to the Mediterranean, into which it falls after a course of about 350 miles. Its mouth is choked up with sand, and, to render it navigable, a canal called the San Carlos has been carried through the delta. Its principal affluents are the Najerilla, Jiloca, and Guadalupe from the right, and the Aragon, Gallego, and Segre from the left. The course of the *E.* is chiefly through narrow, and sometimes rocky valleys; and its bed is characterised by many shoals and rapids which interrupt the navigation. This is partly remedied, however, by means of the Imperial Canal, which extends from the vicinity of Tudela to a point 40 miles below Zaragoza.

**ECBATANA** (*Agbatana*, *Achmëta*, *Hagmatana*), the ancient capital of Media, situated at a distance of 12 stadia (about  $1\frac{1}{2}$  mile) from Mount Orontes, the modern Elwend. Its foundation was attributed by popular belief to Solomon or Semiramis, while the book of Judith ascribes it to Arphaxad (*Phraortes?*), and Herodotus to Deioeces (728 B. C.). It lay upon a conical hill, crowned by a temple of the Sun, and was enclosed by seven concentric walls, the innermost of which was gilded, and the next plated with silver; while the rest, in their order outwards, were painted orange, blue, scarlet, black, and white, respectively. As they rose in gradation towards the centre, all the battlements with their gorgeous hues—probably representing, in Sabrean fashion, the seven planetary spheres or the seven climes—were visible at once. The city is reported to have been 250 stadia in circumference. Its principal buildings were the citadel—a stronghold of enormous dimensions, where also the archives were kept, in which Darius found the edict of Cyrus the Great concerning the rebuilding of the temple in Jerusalem—and the royal palace. Cedar and cypress only were used for the woodwork, and the ceilings, beams, and rafters were overlaid with gold and silver. The mild climate and the magnificence of its structure singled out *E.* as the favourite summer residence, first of the Median, then of the Persian, and, lastly, of the Parthian monarchs. After the battle of Arbela (331 B. C.), Alexander followed Darius thither, and secured an immense booty. It was again pillaged by the Selencidæ; but such were the riches of this place, that Antiochus the Great still found 4000 talents' worth of silver to carry away. *E.* subsequently fell into the hands of the Parthians; and it has since so utterly sunk into decay, that notwithstanding the frequent mention

that is made of it both in the Bible and in classical writings, its very site can no longer be fixed with certainty. Gibbon and Jones tried to identify it with Tahriz or Tauriz; Williams, with Isphahan; while recent explorers, such as Kennell, Mannert, Kinnair, Morier, and Ker Porter, generally agree that the present Hamadan, with the supposed tombs of Mordechai and Esther (see **HAMADAN**), occupies the site of ancient Ecbatana. Sir Henry Rawlinson assumes two Ecbatanas, one the present Hamadan, the other the present Takhti-Suleiman, 36° 25' N. lat., 47° 10' W. long. Both the orthography of the scriptural *Achmëta*, and the cuneiform *Hagmatana* in the Behistun Inscriptions, which, by changing the *m* into *b*, became *Agbatana* in Greek, seem to point to Hamadan. Broken columns, a few cuneiform inscriptions, coins, medals, and a fragmentary stone lion, placed there, according to the Eastern legend, by the sorcerer Apollonius of Thyane, at the command of Nebuchadnezzar, in order to guard the town from excessive cold and snow—all dug out near Hamadan—are all that now remains of that once most royal of cities.—There was another **ECBATANA** in Persis, which was given to the Magi; and a third in Syria, at the foot of Carmel, the present Kaiffa, where Cambyses, the son of Cyrus, suddenly died, 520 B. C.

**ECCE HOMO** (Lat. 'Behold the man'), the name usually given by artists to paintings representing Christ bound and crowned with thorns previous to his being led forth to crucifixion. On this exalted

Ecce Homo.

subject the highest efforts of art have been employed. The finest 'Ecce Homo' is that of Correggio, in the National Gallery, London; the whole conception of this remarkable picture being of the first order of genius. Other conceptions have been painted, such as that of Gnido, a copy of which is given in the annexed illustration. See Dr Waagen's *Art and Artists in England*.

**ECCENTRIC**, or **ECCENTRIC CIRCLE** (in the Ptolemaic Astronomy). It was a fundamental doctrine of the ancient astronomers, that every heavenly body moved in a circle (the perfect figure), and at a uniform rate. To move otherwise than uniformly and in the perfect figure, would have

been unbecoming a heavenly body! But some of them appeared to misbehave by moving unsteadily, and in other figures than circles. Of course this was a mere deceptive appearance; but then, to save the fundamental doctrine, it must be explained. To explain it, they invented the *eccentric circle*. Suppose a body, such as the sun, to move in a circle ADB at a uniform rate, and a spectator to observe it, not from C, the centre of the circle, but from E. Then, if the sun's movement in a

Eccentric Circle.

given time be from D to F, and in an equal interval thereafter be from F to G, a spectator at C would observe these movements as being circular and made in equal times, because at C, DF and FG, being equal, subtend equal angles. But if the spectator, instead of being at C, be at E, then, as the angles DEF, FEG are unequal, the sun's motion will not appear to be uniform, nor will his path appear quite circular. If, then, the earth, instead of being at the centre of the sun's orbit, be in a position away from it, the want of regularity in his movements will be explained. He will appear to describe unequal spaces in equal times. Accordingly, to reconcile the observed fact with the fundamental doctrine, the ancients placed the earth at E, a point away from the centre of the sun's supposed orbit. Hence this orbit was called the *Eccentric*, in respect that its centre did not coincide with that of the earth, which was considered as the centre of the universe.

**ECCENTRIC**, in Machinery, is a contrivance for taking an alternating rectilinear motion from a revolving shaft. It consists of a circular disc or pulley, fixed on a shaft or axis which does *not* pass through the centre of the disc. The right-hand figure of the cut represents a side-plan of an eccen-

tric; *aa* the disc, the centre of which is at *b*; the inner circle is the shaft, with its centre at *c*; *ee* is a section along the axis of the shaft *d*; and *a'a'* an edge-view. A hoop, *gf*, embraces the groove *a'a'*, allowing the disc to turn within it. As the eccentric revolves with the axis, the hoop is alternately raised and lowered, and with it the rod *l*, which is keyed into it at *h*. The extent of the rise and fall of the rod is equal to twice *cb*, the distance between the centres. The eccentric is chiefly used where a subsidiary motion of small power is required; as for working the force-pump that supplies the boiler of a steam-engine (q. v.).

**ECCENTRICITY**. See fig. to art. **ECCENTRIC**

**CIRCLE**. In such a figure as the eccentric circle, the eccentricity is the ratio of EC to the radius. In the ellipse and Hyperbola (q. v.), the eccentricity is the ratio of half the distance between the foci to the semi-major axis. In older mathematical works, eccentricity is sometimes used as the name of half the distance between the foci of an ellipse or hyperbola.

**ECCHYMO'SIS** (Gr. from *ek*, out of, and *chymos*, juice), a discoloration of the surface, produced by blood effused below, or in the texture of, the skin. It is usually attended by swelling to a greater or less extent, and is the result of injury. The presence of ecchymosis is sometimes adduced in courts of law as a proof of violent injuries having been inflicted during life, or very shortly after death. A question with respect to this was raised in the celebrated case of Burke and Hare, the West Port murderers in Edinburgh. Ecchymosis may sometimes be diminished by applying cold cloths or a bladder of ice to the surface, in the case of injuries quite recently inflicted.

**ECCLESFIELD**, a township in the West Riding of Yorkshire, five miles north of Sheffield. Pop. (1871) 15,171. The chief manufacture is cutlery, but flax, linen, and nails are also branches of industry. There are coal and iron mines in the vicinity.

**ECCLESIASTES** (Eng. the Preacher), the title (taken from the Septuagint) of a canonical book of the Old Testament; its Hebrew name is *Koheloth*, which signifies nearly the same. The inscription with which it commences is: 'The words of Koheloth, the son of David, king in Jerusalem.' Its authorship is commonly ascribed to Solomon. In support of this opinion, however, there is not a vestige of internal evidence except what arises from the dramatic use of his name, an expedient in all probability resorted to by the writer to give force and emphasis to his own reflections, inasmuch as Solomon was held by the Jews to be the perfection of human wisdom. The first who doubted the Solomonian authorship of the book was Grotius. Later critics have advanced further than Grotius. The actual writer probably flourished, according to Dr Davidson, in the later period of the Persian government, not long after the time of Malachi, i. e., 350—340 B. C. Such is also substantially

the opinion of Rosenmüller, Knobel, Ewald, and De Wette. Hengstenberg, unquestionably the ablest critic of the orthodox German school, considers that the contents of the book may best be explained by supposing the author to have lived in a period like that of Malachi, in which there prevailed a pharisaical self-righteousness, and melancholy murmurings against the providence of God. The dates assigned to it by Hartmann (viz., the period of the Maccabees) and by Hitzig (204 B. C.) cannot well be sustained, as there is no trace in the

book either of Grecian philosophy or language.

The chief arguments against the Solomonian authorship are *three*. 1. The writer indicates unconsciously his own posteriority in point of time by making Solomon say: 'I was king over Israel in Jerusalem' (chap. i. verse 12); a thing which Solomon could *not* have said during his life, for he was king to the end of it. 2. The condition of the country in the time of the writer, the oppression, judicial injustice, the elevation of fools and slaves to high offices, &c., do not fit the reign of Solomon at all, nor any preceding period. 3. The language is post-exilian. Ewald, the greatest Orientalist living, asserts that 'the Hebrew is so strongly

penetrated with Aramæan, that not only single often-recurring words are entirely Aramæan, but the foreign influence is infused into the finest veins of the language.'—(Dr Davidson in vol. ii. of Horne's *Introduction to the Holy Scripture*.)

It is extremely difficult to ascertain the standpoint of the author. He is deeply convinced that 'all is vanity and vexation of spirit,' but whether this conviction springs wholly from a religious view of life, or is in part caused by personal disappointments, we have not sufficient internal evidence to determine. There is much in E. that, if it stood by itself, might be thought to be a mere product of cynical epicureanism, but it is mixed up with so much that is nobler, with a faith in God that rises high above the crushing considerations of the vanity of all mortal life, and the book terminates so grandly, that it seems more reasonable to believe that the aim or intention of the writer was moral and religious, and not cynical; that he painted the folly, weakness, and helplessness of men in such strong colours, only that he might destroy their self-righteousness, and cure them of that inability to read the laws of God, which self-righteousness always produces. For what is the conclusion of the whole matter? 'Fear God, and keep his commandments: for this is the whole duty of man.'

**ECCLESIASTICAL COMMISSIONERS FOR ENGLAND**, 'are a corporation with perpetual succession and a common seal, and with power to take, purchase, and hold real estate, notwithstanding the statutes of mortmain.'—Burns's *Eccles. Law by Phillimore*. The Ecclesiastical Commissioners consist of all the Bishops of England and Wales, the Deans of Canterbury, St Paul's, and Westminster, the two Chief Justices, the Master of the Rolls, the Chief Baron, and the judges of the Prerogative and Admiralty Courts; and also nine lay members, seven to be appointed by the Crown and two by the Archbishop of Canterbury. The lay commissioners, including all the judges, to be members of the United Church of England and Ireland. 6 and 7 Wil. IV. c. 77, and 3 and 4 Vict. c. 113, down to 29 and 30 Vict. c. 111. The Queen is empowered, by 13 and 14 Vict. c. 94, to appoint two, and the Archbishop of Canterbury one (lay members of the Church of England), by the title of Church Estates Commissioners. The Ecclesiastical Commission thus constituted is the result of certain reports made by commissioners previously appointed by the Crown. The object of the existing Commission is best explained by a reference to the instructions given to the original commissioners. 'To consider the state of the several dioceses of England and Wales, with reference to the amount of their revenues and the more equal distribution of episcopal duties, and the prevention of the necessity of attaching by commendam to bishoprics benefices with cure of souls; to consider also the state of the several cathedral and collegiate churches in England and Wales, with a view to the suggestion of such measures as may render them more conducive to the efficiency of the Established Church; and to devise the best mode of providing for the cure of souls, with special reference to the residence of the clergy on their respective benefices.' The Ecclesiastical Commission was permanently established in the year 1835. In order that it should be provided with a fund to enable it to carry out such schemes as should appear to it desirable, the seven best endowed sees were laid under a contribution amounting in all to the annual sum of £22,800. In addition to the income thus provided, several canonic in the various cathedrals are abolished, and other ecclesiastical preferments are extinguished, and the emoluments of the whole are vested in the commissioners. The Ecclesiastical

Commissioners are required to lay before her Majesty in council such schemes as appear to them best adapted for carrying out the purposes of the act. It is provided that no proceeding which requires the common seal of the corporation is to be finally concluded, nor is the seal to be affixed to any deed, unless two at least of the episcopal commissioners are present, and consenting. Notice of every scheme is to be given to any corporation, aggregate or sole, affected thereby; and the objections, if any, are to be laid before her Majesty in council, together with the scheme. The scheme, if it receive the royal assent, is to be gazetted, and thereupon acquires the power of an act of parliament. By 19 and 20 Vic. c. 55, the duties of the Church Building Commissioners have been transferred to the Ecclesiastical Commissioners. The latter body have now, therefore, in addition to their previous powers, authority to divide or to unite existing parishes, and to create new districts. Such are, very briefly, the powers of the Ecclesiastical Commissioners. The policy which led to the appointment of that Commission is not a subject for our consideration. But it is easy to see that the influence for good and evil of so powerful an institution, over the Church of England, is enormous; and it cannot be matter of surprise that its proceedings are watched with scrupulous jealousy. As a result of its deliberations during twenty-five years of its existence, two new bishoprics had been created and endowed, and a considerable number of small livings had been augmented.

On the other hand, it must be observed that much indignation has been excited by the expenditure of very large sums on the purchase and improvement of episcopal residences. It is, no doubt, fitting that the episcopal office should be furnished with appliances suitable to the position and dignity of a bishop; but the peculiar character of the revenues of the Ecclesiastical Commissioners must be borne in mind in applying those revenues. The funds of which they are composed have been violently diverted from the original purpose of the donors. Public necessity only can justify such an act. The plea put forward is the inequality of the revenues of the clergy, and the insufficient amount of the incomes of many benefices. But it may fairly be questioned whether it is a proper application of those funds to promote the convenience and luxury of those who are already liberally endowed.

**ECCLESIASTICAL CORPORATION**. The holder of an ecclesiastical benefice is, by the law of England, regarded as a corporation. Ecclesiastical corporations are divided into aggregate and sole. The former consist of several persons, as the head and fellows of a college, the dean and chapter of a cathedral, and are kept up by a continual succession of members. An ecclesiastical corporation sole consists of a single person and his successors in the benefice, as a bishop, a rector, a parson, or a vicar. The object of the common law, in thus regarding the incumbent of the benefice as a corporation sole, is to preserve the temporalities which are vested in him, and which would otherwise descend to his right heirs. The right of a rector or other corporation sole to the church and glebe, though said to be a freehold, is in fact little more than a tenancy for life. He is entitled to the full enjoyment of the benefice during his life, but he cannot sell it, and he is even punishable for waste. He may work mines or pits which he finds in use, but he is not entitled to open fresh mines. His right to timber is confined to felling it for repairs, but he is not entitled to sell it. See CORPORATION.

**ECCLESIASTICAL COURTS** are courts specially devoted to the consideration of matters

relating to the clergy and to religion. For the origin of these courts we must go back to the first days of Christianity, when the early Christians, acting upon the injunction of St Paul—'Dare any of you having a matter against another go to law before the unbelievers and not before the saints'—had established courts, apart from those provided by the heathen governors, for the settlement of their own disputes. These courts were presided over by the bishops, who took cognizance of all matters, temporal as well as spiritual, arising among the brethren. As Christianity advanced, and was acknowledged as the revelation of the Almighty, these bishops' courts acquired an independent position, and were suffered to exist concurrently with courts of civil jurisdiction (Code lib. i. tit. 4, *de episc. aul.*), and gradually special matters were assigned as the subjects of their peculiar jurisdiction—viz., questions of tithes, and matrimonial and testamentary causes.

All writers on the early constitution of England are agreed in the opinion that, in this kingdom, there existed no separate ecclesiastical courts before the Norman Conquest. Previous to that time, all matters, civil and spiritual, were in use to be heard before the county court, in which the bishop and the earl sat together. But by a charter of William I. a distinction was made for the first time between courts civil and ecclesiastical. By this charter, authority was given to the bishops to hear causes ecclesiastical according to the canon law. The bishops' courts having been thus established in England, they became a fruitful source of dispute between the crown and the see of Rome, the latter claiming supreme jurisdiction in appeal in all causes ecclesiastical. This claim was from time to time conceded by the weakness or necessity of individual sovereigns, to be as frequently retracted when the emergency was past; in particular, by 27 Ed. III. c. 1, and 16 Rich. II. c. 5, all persons were prohibited, under penalty of *Premunire* (q. v.), from resorting to the court of Rome or elsewhere. At the Reformation, by 24 Hen. VIII. c. 12, on the recital that the king is, under God, the head of the church, and again, by 25 Hen. VIII. c. 21, the authority of the pope in matters ecclesiastical was finally excluded. In Bacon's Abridgment of the Law, there are enumerated ten ecclesiastical courts—viz., Convocation, the Court of Arches, the Prerogative Court, the Court of Audience, the Court of Faculties, the Court of Peculiars, the Consistory Court, the Archdeacon's Court, the Court of Delegates, and the Court of Commissioners of Review. (For a full account of these courts, reference is made to the several heads, and also to the article DOCTORS' COMMONS.) It is to be observed that convocation, though a purely ecclesiastical assembly, is, in its nature and its duties, distinct from the courts of which we are now treating.

The chief ecclesiastical courts which have at various times existed in Scotland are the General Assembly, the Commissary Court, and the Court of Teinds. The former is the tribunal for the consideration of questions of doctrine and discipline according to the Presbyterian usage, and has existed since the Reformation. See ASSEMBLY, GENERAL; COMMISSARY; TEIND COURT.

ECCLESIASTICAL LAW. See CANON LAW.

ECCLESIASTICAL TITLES ASSUMPTION ACT (14 and 15 Vict. c. 60). In 1850, a ferment of Protestant zeal was awakened in this country by an edict issued by the court of Rome dividing Great Britain into territorial bishoprics, under an Archbishop of Westminster. The brief was immediately followed by a Pastoral by the newly appointed archbishop (Cardinal Wiseman) 'given out of the

Flaminian Gate.' At the commencement of the parliamentary session of 1851, the subject of 'papal aggression,' and of the measures to be adopted to counteract it, superseded all other topics of interest. It was in these circumstances that Lord John Russell introduced the Ecclesiastical Titles Bill. By the Act 10 Geo. IV. c. 7, it had been provided that the right and title of archbishops to their respective provinces, of bishops to their sees, and of deans to their deaneries, as well in England as in Ireland, having been settled and established by law, any person other than the person thereto entitled who should assume or use the name, style, or title of archbishop of any province, bishop of any bishopric, or dean of any deanery, in England or Ireland, should for every such offence forfeit £100. By the Roman Catholic party it was alleged that this enactment struck only at the titles to existing provinces and dioceses, and that though the pope could not create an Archbishop of Canterbury, nor could his nominee assume that title without violating the law, there was no prohibition against the creation of an Archbishop of Westminster. To meet this allegation, and remove the doubt which existed, the Ecclesiastical Titles Act was passed, its object being to prohibit the assumption of such titles 'in respect of any places within the United Kingdom.' The penalty of £100 for every contravention of the act is to be recovered in accordance with the provisions of the former act, or at the suit of any person in one of her Majesty's superior courts of law, with the consent of the Attorney-general in England, or of the Lord Advocate in Scotland. The third section saves the episcopal bishops in Scotland from the operation of the act, providing, however, that 'nothing herein contained shall be taken to give any right to any such bishop to assume or use any name, style, or title which he is not now by law entitled to assume or use.' The passing of the act allayed the fears of the country on the subject of papal aggression; and though its provisions were not very steadily complied with in Ireland, no prosecution under it took place.

The Roman Catholic party having always considered the penal clauses of this act as a grievance, an arrangement was made for the repeal of the act. This was accomplished by the Act 34 and 35 Vict. c. 53, which, after declaring that 'no ecclesiastical title of honour or dignity derived from any see, province, diocese, or deanery recognised by law, or from any city, town, place, or territory within this realm, can be validly created,' and that no 'pre-eminence or coercive power can be conferred otherwise than under the authority of her Majesty,' repeals the Ecclesiastical Titles Assumption Act (14 and 15 Vict. c. 60) as inexpedient. The result is, that while no prosecution can now take place for assuming such titles, their assumption is still treated by the law as an illegal act.

ECCLESIASTICAL YEAR. See YEAR; also DATE.

ECCLESIASTICUS, the title of an apocryphal work, called in the Septuagint *The Wisdom of Jesus, the Son of Sirach*. It obtained the title of E., not because the writer was a priest (for regarding his profession nothing is known), but because it was, in the opinion of the fathers, the chief of those apocryphal works which they designated *ecclesiastici libri* (i. e., books not inspired, but which might be read in church for the edification of the people), to distinguish them from the canonical scriptures of the Old Testament. E. was originally composed in Aramaic; and the original text was apparently extant in the time of Jerome, who states that he

had seen the Hebrew, but it is now lost. The author calls himself Jesus, the son of Sirach of Jerusalem; but when he flourished is not known. His book was translated into Greek, with an introduction by his grandson, who is usually, but not correctly, supposed to have had the same name as his grandfather. The date of the translation has been fixed as low as 130 B.C., and as high as 230 B.C. The former is the more probable. The contents of the work are not systematically arranged, so that we can only guess at what may be called the method and purpose of the thinking. The view taken of the mercy of God as extending to all mankind, indicates that the Jewish notions were breaking up; but still there is little to shew that any great spirituality was taking its place. Its tone resembles that of the book of Proverbs. Exhortations to cheerfulness are constant; medicine, agriculture, &c., are highly praised; life is regarded from an ethical rather than from a religious point of view, and consequently 'wisdom' is represented as the source of human happiness. The style of the writer is at times noble, and even sublime; and, to use the language of Addison, 'it would be regarded by our modern wits as one of the most shining tracts of morality that are extant, if it appeared under the name of Confucius or of any celebrated Grecian philosopher.'

**ECCLESIOLOGY**, a word of recent use, is the name which has been given in the British Islands to the study of church architecture and decoration. Besides discriminating the various styles of ecclesiastical architecture, ecclesiology takes account of the ground-plan and dimensions of a church; of its orientation, or the deviation of its line from the true east; of its apse, or circular or polygonal east end; of its altar or communion table, whether fixed or movable, stone or wood; of its reredos, dossal, or altar-screen; of its piscina, or basin and drain for pouring away the water in which the chalice was rinsed, or the priest washed his hands; of the sedilia, or seats for the priest, deacon, and subdeacon, during the celebration of the eucharist; of the aumbry, or locker, for the preservation of the communion vessels and elements; of the 'Easter sepulchre,' or recess for the reception of the host from Good Friday till Easter Day; of the altar-candlesticks; of the altar-steps; of the altar-rails; of the credence table, or shelf on which to place the communion elements before they were put upon the altar; of the 'misereres,' or elbowed stalls; of seats within and without the chancel walls; of the height of the chancel as compared with the nave; of the chancel arch; of the rood-screen, rood-staircase, rood-door, and rood-loft; of the piers or columns; of the triforium or blindstory; of the clerestory; of the windows; of the parvise-turret, or outside turret leading to the parvise; of the roof or groining; of the eagle-desks and letterns; of the pulpit; of the hour-glass stand, by which the preacher was warned not to weary the patience of the flock; of the reading pew; of the benches, pews, and galleries; of the aisles; of the shrine, fount, or reliquary; of the benatura, or holy-water stoup; of the corbels, with special reference to the head-dress figured on them; of the pavement; of the belfry; of the baptismal font, with its accessories, the baptistery, the steps, the kneeling-stone, the chrismatory, the cover, and the desk; of the tower, with its lantern, parapet, pinnacles, louvres, windows, buttresses, and bells; of the porch and doors, with their niches and seats; of the parvise, or priest's chamber above the porch; of the mouldings; of the pinnacle crosses; of the gurgoyles, or rain-spouts; of the churchyard or village cross; of the church-yard yew; of the lych-gate, or corpse-gate, where the corpse was met by the priest; of the crypt; of

the confessional; of the hagioscope, or opening in the chancel arch through which the elevation of the host might be seen; of the lychnoscope, or low window in the side-wall of the chancel, the use of which is uncertain; of the chest for alms; of the table of the ten commandments; of the church-plate; of the faldstool, or litany stool; of the embroidered work; of the images of saints; of the church well; of the sepulchral monuments and brasses, with their inscriptions; of the chapels or sacristies; of the vestry; of the dedication crosses. Ecclesiology has a literature of its own, including a monthly journal, called *The Ecclesiologist*. There are societies for promoting its study, one of which, 'The Ecclesiological late Cambridge Camden Society,' has published *A Handbook of English Ecclesiology* (Lond. 1847).

**ÉCHELON** (from the French *échelle*, ladder) is such a formation or arrangement of troops that, if viewed from a height, they would present some analogy to the successive steps of a ladder or staircase. The several divisions of the force, although parallel, are no two on the same alignment. Each has its front clear of that in advance, so that, by marching directly forward, it can form line with it. There are two kinds of echelon, *direct* and *oblique*. *Direct* echelon is adapted for attack and retreat; while *oblique* echelon (oblique in reference to the original front of the line) is adapted for changing position, or for getting on the enemy's flank.

The word echelon is also used in reference to nautical manœuvres. A fleet is sometimes said to be arranged *en échelon*; at which time it is compared by Sir Howard Douglas to a body of infantry in a square having its diagonal parallel with the front. In other words, it presents a wedge-form towards the enemy. Under this arrangement, the bow-guns and broadsides of the several ships can mutually defend each other; the stronger parts of one ship defending the weaker parts of some other.

**ECHIDNA**, a genus of quadrupeds peculiar to Australia, and belonging to the order *Monotremata*. Two species have been described, differing in the scantiness and abundance of the hair, but it seems not improbable that they are mere states of the same species, perhaps depending on the seasons or

Echidna Hystrix.

on age. The E. is about the size of a hedgehog, and, like that animal, is covered with spines; which, however, are much larger and stronger, and are placed among soft silky chestnut-coloured hair. Its head is small, the muzzle much elongated and slender, terminating in a small mouth, which is destitute of teeth, but furnished with several rows of small spines upon the palate, directed backwards. The tongue is extensile, and is used, like that of

ant-eaters, for catching ants, the ordinary food of the animal. The tail is very short. The legs are also very short, each foot furnished with five large broad claws, fit for digging and burrowing, the claws of the hind feet being concave, and directed backwards and outwards, so as to form very efficient shovels for throwing out the earth. The *E.* burrows with great rapidity, being possessed of strength perhaps greater in proportion to its size than that of any other quadruped. When it cannot more completely disappear under the earth, it inters itself so far as to present only its spiny back to an assailant. The *E.* is capable of very long abstinence, and confines itself to its burrow during droughts. In confinement, it may be fed on milk, hard-boiled eggs, &c.

**ECHIMYD** (*Echimyis*), a genus of rodent quadrupeds, in some of their characters agreeing with dormice, but differing from them in having the tail scaly, and the fur coarse and mingled with flattened spines. They are all South American. Some of them are known as spiny rats. They display considerable beauty of colour. One species excavates long burrows in the ground.

**ECHINEIS.** See REMORA.

**ECHINIDÆ**, a family of *Echinodermata*, the species of which are popularly known as Sea-urchins, Sea-eggs, &c. They have the body covered with a calcareous crust or shell, of an extremely porous structure (and thus differing very widely from the shells of molluscs), in polygonal plates nicely adapted to each other, and increasing by additions to the edges of each plate, so that the shell may enlarge with the enlargement of the animal, whilst new plates are also added around the superior orifice. The shell is pierced with rows of holes for the Ambulacra (q. v.), and is externally covered in a living state with a membrane—sometimes very delicate, sometimes thick and spongy—which communicates by many delicate processes with the interior, and unites the bases of all the spines. The spines differ very much in the different genera and species, in their length, strength, number, and arrangement; they are attached to tubercles on the surface of the shell, by cup-like bases capable of working upon the tubercles, in the manner of a ball-and-socket joint; and they are moved by means of the connecting membrane so as to be employed in locomotion. In some species, they seem to be the

a, *Echinus Esculentus*; b, portion with spines removed; c, mouth.

principal organs of locomotion; in others, the ambulacra are so. By means of the spines, some, in which they are few and strong, can walk even on dry ground; others, in which they are minute and very numerous, employ them in burying themselves in the sand. The mouth of the *E.* is situated at the lower orifice of the shell, and is generally furnished with five flat calcareous teeth, moved by a very complex apparatus of bony sockets and muscles—

'a very powerful mill' for grinding down their food, which is supposed to consist of small crustaceans and molluscs. The intestine is long and spiral; the vent, in the *E.* of most regular form, is at the upper end of the shell, exactly opposite the mouth; in others, in which there is a departure from the characteristic orbicular form, it is more or less lateral. The *E.* abound in all seas, and seem to have abounded still more in former geological periods. 'Of all the *Radiata*, they are most perfectly preserved in a fossil state,' and the knowledge of their habits and organisation is necessary to the geologist, 'in order to understand the relations and associations of the numerous species which abound in many of the earth's strata.'—Forbes.

**ECHINOCOCCUS.** See TAPE-WORM.

**ECHINODERMATA** (Gr. spiny-skinned), a class of radiate animals, the highest in organisation of that great division of the animal kingdom. They have a digestive and a vascular system; for the former, however, there is in many of them only a single orifice; a circular and radiating nervous system has been observed in many; they are especially characterised by their well-organised skin,

a, *Asterias Tessellata* (*Asteriadae*); b, *Spatangus* (*Echinida*), or sea-egg.

which in many is strengthened by calcareous plates, and in some also has the additional protection of numerous long spines. *Echinida* (Sea-urchins) exhibit these characteristics in greatest perfection. *Asteriadae* (Star-fishes), *Ophiurida* (Brittle-stars),

a, *Euryale Palmifera* (*Ophiurida*), front view; b, disc and part of arm, front view; c, disc and part of arm, back view.

*Crinoidea*, *Holothuriadae* (Sea-slugs, Sea-cucumbers, &c.), and *Sipunculida*, are also ranked among the *E.*, and have been variously arranged in orders by different naturalists. Spines are wanting in most

of them; in some (*Holothuridae* and *Sipunculidae*), there are not even calcareous plates, and there is no inconsiderable departure from the ordinary and perfect radiate form, an approach being made to the forms of molluscs and worms, whilst yet the accordance with the other E. is very perfect in other parts of the organisation. Almost all the E. are free, moving about at the bottom of the sea; some of them—at least in an immature state—are stalked and fixed. They are provided with ‘an apparatus for water circulation,’ a peculiar characteristic of radiate animals, and which ‘can scarcely be said to exist in any of the other types.’ By means of this it is that they fill and fit for use the suckers or *Ambulacra* (q. v.) with which most of them are provided, but of which the *Sipunculidae* are destitute. The spines as well as the ambulacra of the E. are used by those which possess them (*Echinidae* and *Ophiuridae*) as organs of locomotion.—The British E. are described by Dr Edward Forbes in a most interesting work, entitled *A History of British Star-fishes and other Animals of the Class Echinodermata* (Lond. 1841).

**ECHYNUS**, of Vitruvius, is a classical moulding in the form of a series of eggs, whence it is also called the ovolo or egg-moulding. The eggs are sometimes divided by an anchor or dart, as in the accompanying example. The type of

Echynus, or Egg and Anchor Moulding.

this ornament is sometimes said to have been the chestnut and shell.

**E'CHIUM.** See VIPER'S BUGLOSS.

**E'CHO** (Gr. *sound*). Sound is produced by waves or pulses of the air; when such a wave comes against a wall or other opposing surface, it is reflected like light, and proceeds in another direction, and the sound so heard is an echo. Even the surface of a cloud suffices to reflect sound, as may be observed during thunder and the discharge of cannon. That the echo of a sound may return to the point where the sound originated, the reflecting surface must be at right angles to a line drawn to it from that point. Oblique walls send the echoes of a person's voice off in another direction, so that they may be heard by others, though not by him. In order to echo words distinctly, the reflecting surface must on the whole be even, or so curved as to resemble a concave mirror. This last form is necessary for returning a distinct sound when the distance is considerable. A great degree of evenness, however, is not essential, as it is no uncommon thing for the edge of a wood to return an echo. The distance of the reflecting surface must also be such as to allow a sufficient time to elapse between the sound and the return of the echo for the ear to distinguish them; when they succeed too closely, they merge into one. An interval of about  $\frac{1}{3}$  of a second is necessary to discriminate two successive sounds; so that if we assume 1125 feet as the distance traversed by sound in a second,  $\frac{1}{3}$  of 1125, or 62 feet, will be the least distance at which an echo can be heard, as the sound will go that distance and return in  $\frac{1}{3}$  of a second. If the distance is less, the echo only clouds the original sound, but is not heard distinct. It is these indistinct echoes that interfere with hearing in churches and other large buildings (see ACOUSTICS); hence anything that breaks the evenness and continuity of the reflecting surfaces is an improvement in this respect. The number of syllables that any particular echo will repeat, depends upon how many can be uttered in the time that the sound takes to go and return from the reflecting surface. The echo at the tomb of Metella, in the Campagna, near

Rome, of which Gassendi speaks as repeating a hexameter line requiring  $2\frac{1}{2}$  seconds to utter it, must therefore come from a distance of about 1500 feet. Such echoes are rare, as the various conditions are seldom all fulfilled. When there happen to be several reflecting surfaces at different distances in the direction of the sound, with a sufficient interval between them, each gives a separate and distinct echo. A similar effect is produced when two surfaces are inclined to each other in such a way as to give repeated reflections of the sound from the one to the other like the mirrors of a kaleidoscope, thus multiplying echoes of echoes. To this multiple and repeating class belong the famous echoes of Killarney, and that produced between the wings of the castle of Simonetta, near Milan, which repeats the report of a pistol 60 times.

**ECHO**, in Music, is the repetition of a melodic phrase, frequently written for the organ, on account of the facility with which it can be produced by the stops.

**ECIJA**, a city of Spain, Andalusia, in the province of Seville, and 45 miles east-north-east of the town of that name, is situated on the left bank of the Jénil, in lat. 37° 33' N., long. 5° 8' W. It is surrounded by gardens, and stands in the centre of a district fertile in corn and oil. E. is a well-built and prosperous town. On account of the heat of the climate, this town is called by the Spaniards the Oven of Andalusia. E. has many pleasant alamedas (public promenades), shaded by trees, and adorned with statues and fountains; the principal promenade is that which stretches along the banks of the river. Pop. 24,000. E. was called in ancient times *Astigis*, and was one of the chief cities of the Roman province of Hispania Bœtica; its origin is unknown. It is said to have been visited by the Apostle Paul, a gilt statue of whom may be seen in the city. E. was called *Colonia Augusta Firma* by the Romans, and abounds in Roman antiquities. It also presents several specimens of Moorish architecture in the shape of gates and massive towers.

**ECK**, JOHANN MAYR VON, the well-known adversary of Luther, was born in 1486 at Eck, a village in Swabia, where his father, Michael Mayr, was a peasant, and afterwards a bailiff. Endowed with considerable ability, young Eck commenced at an early period the study of the Church Fathers and the Scholastics, and acquired a great skill in theological disputation. In 1518, when his *Obelisci* appeared in opposition to Luther's *Theses*, he was Doctor of Theology, Canon of Eichstädt, and pro-chancellor of the university of Ingolstadt. The publication of his *Obelisci* involved him in a disputation with Karlstadt, which lasted from the 27th June to the 16th July 1519. The only effect of the disputation on the people was to make them wonder at E.'s volubility; but having impugned some of Luther's views in the course of his disputation, he was assailed by the great Reformer, and by Melancthon. Eck nicknamed his opponents *Lutherans*, and instigated partly by personal hatred, and partly by Fugger (q. v.), went to Rome in 1520, to induce the pope to take strong measures against Luther. He returned with a papal bull of condemnation in his pocket, but the people in many places stood by Luther; and at Leipsic, in particular, Eck was so roughly received, that he had to take refuge in the monastery of St Paul's. Later we find him at the Augsburg Diet of 1530, where he let slip out the memorable statement, that 'with the Church Fathers, he would venture to oppose the Augsburg Confession, but not with the Scriptures.' In the religious convocations held at Worms in 1540, and at Ratisbon in 1541, he also took part. He died in

1543. A desire to shine and to play an important part in the affairs of men, coupled with a strong love of lucre, were the leading features of his character. Though an extremely learned ecclesiastic, he had no great talent, but was loud, boisterous, and full of assurance.

ECKERMANN, JOHANN PETER, well known to the literary world through his intercourse with Goethe, was born in 1792, at Winsen on the Luhe, in Hanover, studied, 1821—1823, at Göttingen, and afterwards went to Weimar, where he took part in the *réduction* of the last volume of Goethe's *Sämmtlichen Werke*. At the same time, he commenced to contribute articles to the *Morgenblatt*, on Art and Antiquity. In 1827, the university of Jena conferred on him the degree of Ph. D. Two years later, he was appointed to superintend the studies of the heir to the grand duchy of Weimar, in the German and English languages and literature. In 1830, he travelled with Goethe's son in Italy, and on the death of the patriarch of German literature, he edited his posthumous writings. During the years 1839—1840, he edited a new edition of Goethe's *Sämmtlichen Werke*, in 40 vols. But E. is most widely and favourably known by his *Gespräche mit Goethe* (Conversations with Goethe). The greater part of these *Gespräche* appeared at Leipsic in 1836, the remainder at Magdeburg in 1848. It cannot be said with truth that E. has done for Goethe what Boswell did for Johnson, because Goethe did not require this. Johnson's writings give us but a faint idea of the man; hence Boswell's *Life* looks like a revelation; whereas there was the most perfect harmony in Goethe between the man and the author. Still, E.'s book is of immense value, just because it shews us this harmony, giving us, as it does, a picture of Goethe in his manifold social and literary relations, and exhibiting to us the simple, natural, and noble principles on which he studied and wrote. The *Gespräche* have been translated into all European languages, even into Turkish. The best English translation is that by John Oxenford (Lond. 1850). E. died at Weimar, 3d December 1854.

ECKHUNG CHOO, a river of Tibet, is supposed to be the head stream of the Indus. It rises on the north side of the Himalaya, near the sources of the Sutlej. The actual locality of its sources has been assigned to the Kailas Mountains, in lat. 31° 25' N., and long. 81° 40' E. Flowing to the northwest, E. C. reaches long. 79° E. before it assumes the name of Indus.

ECKMÜHL, a village on the Lauer, in Bavaria, notable for the battle fought there, on the 22d April 1809, between 75,000 French and 40,000 Austrians. The Archduke Charles had taken up his position on the right bank of the Danube, near Eckmühl. From this point, at the head of four divisions of the Austrian army, he threatened Napoleon, and hoped to gain possession of the road to Donauwerth, the occupation of which would have decided the fate of Bavaria. This was prevented by Davout, who, moreover, by repeated attacks, contrived to keep the archduke in ignorance of Napoleon's designs. The plan of the latter was to cut off the Austrians from their whole remaining communications with the Iser and Inn, and by throwing them back upon Ratisbon and Bohemia, as their only line of retreat, to sever them entirely from the support and protection of Vienna. On the 22d, Napoleon suddenly appeared, with his army, opposite the village of Eckmühl. The action, on the side of the French, was commenced by Lannes, who drove back the Austrian left, while, at the same time, the village of E. was stormed by the

Württembergers. Shortly after, the high grounds between E. and Laiching, also occupied by the Austrians, were abandoned after a heroic struggle, and the archduke ordered a retreat on Ratisbon, which was admirably executed, though the defeated army was harassed by sixteen cavalry regiments. During the retreat, a magnificent and thrilling encounter took place at Eglofshelm between the French and Austrian cuirassiers, which, though it ended fatally for the latter, was largely instrumental in securing the retreat of the main body of the Austrian army. The Austrians had 5000 men killed and wounded, and 7000 taken prisoners, besides losing 12 standards and 16 pieces of cannon. The French loss was considerably less.

ECLAMPSIA (Gr. *ek*, and *lampas*—future, *lampas*—I seize hold of), a somewhat pedantic and unnecessary technical term for Convulsion (q. v.).

ECCLECTICS, ECCLECTICISM. Eclectics was the name given in ancient times to those philosophers who had no determinate system of their own, but who professed to choose (*eklegein*) from all systems the parts that they considered true. The systems from which the selections were originally made were those of Pythagoras, Plato, and Aristotle, but ultimately eclecticism lapsed into an attempt to reconcile Platonism and Christianity. The chief representatives of this school were Plotinus and Proclus, who, however, did not so much make up a compound of doctrines gathered from without, as set up a view that endeavoured to unite the results of previous systems into a consistent whole. Many of the early Fathers of the Christian Church who had been educated in the pagan schools of philosophy and rhetoric, and retained a fondness for their early studies, were eclectics, such as Clemens Alexandrinus and Synesius of Cyrene. Modern eclecticism is conceived by some to have originated with Bacon and Descartes, but Hegel may be more properly considered its founder. In his *Philosophy of History* and other works, he endeavours, among other things, to point out the true and false tendencies of philosophic speculation in the various ages of the world; but it is to the lucid and brilliant eloquence of Victor Cousin (q. v.) that modern eclecticism owes its popularity. This system, if it can be so called, may best be defined as an effort to expound, in a critical and sympathetic spirit, the previous systems of philosophy. Its aim is to apprehend the speculative thinking of past ages in its historical development, and it is the opinion of some that such a method is the only one possible in our day in the region of metaphysics.

ECLIPSA'REON, the name given by Ferguson, the astronomer, to a contrivance which he invented for exhibiting the time, quantity, duration, and progress of solar eclipses.

ECLIPSES. An eclipse is an obscuration of one of the heavenly bodies by the interposition of another, either between it and the spectator, or between it and the sun. The causes of eclipses, as suggested in this definition, are so simple and familiar, that it is difficult for us to imagine how deeply eclipses affected men's minds before the dawn of astronomical science. To the ancients, they were without the order of nature—terrible presages of dire events; and at Rome, at one time, it was blasphemy, and punished by law, to talk publicly of their being due to natural causes. So strong a hold had this superstition on the popular mind, that even after it came to be generally believed that eclipses of the sun were caused by the moon coming betwixt us and that orb, eclipses of the moon were still referred to supernatural agency. When the moon was in eclipse, the people turned out and made a

great noise with brazen instruments—the idea being, that by doing so they gave her ease in her affliction. According to some, Luna, when in eclipse, was in the pains of labour; according to others, she was suffering from the arts of wicked magicians. Similar notions have prevailed among all barbarian tribes. The Chinese, it is well known, imagine eclipses to be caused by great dragons trying to devour the sun and moon, and accordingly they beat drums and brass kettles to terrify the monsters into letting go their prey. Several stories are told of these popular superstitions being turned to good account by knowing persons; among which are those which represent Thales as bringing about peace between the Medes and Lydians; and Columbus, when in a great strait, procuring provisions from the natives of Jamaica through the prediction of eclipses.

Stars, planets, and the satellites of planets, may suffer eclipse. The principal eclipses, however, are those of the sun and moon, called the solar and lunar eclipses. The transits of the lower planets over the face of the sun are partial solar eclipses; but solar eclipses, properly so called, are those caused by the interposition of the moon between the sun and earth. Regarding solar eclipses, it is observed that they happen always at the time of new moon, when the sun and moon are in conjunction, i. e., on the same side of the earth. In a partial eclipse, the sun's disc suddenly loses its circular form; it becomes indented on one side, the indentation slowly increasing for some time, and then diminishing until it disappears altogether. In a total eclipse, the indentation goes on increasing till the whole orb for a time disappears; after a short interval, the sun reappears again, passing through the same phases of obscuration in an inverse order. In an annular eclipse, the whole orb is obscured except a ring or annulus. Lunar eclipses, again, it is observed, happen always at full moon, or when the sun and moon are in opposition, or on opposite sides of the earth, and are caused by the moon passing through the earth's shadow. Such eclipses are sometimes partial, and sometimes total, but never annular, and in their general phases they resemble those of the sun.

In speaking of eclipses, we shall have occasion to use certain terms, which we shall now define. The *duration* of an eclipse is the time of its continuance, or the interval between immersion and emersion. *Immersion* or incidence of an eclipse is the moment when part of the luminary begins to be obscured; *emersion* or *expurgation* is the time when the luminary begins to reappear or emerge from the shadow. When the quantity of an eclipse is mentioned, the part of the luminary obscured is intended. To determine this part, it is usual to divide the diameter of the orb into twelve *digits*; and the eclipse is said to be of so many digits, according to the number of them contained in that part of the diameter which is obscured.

Having given this general explanation of the facts of observation on which the theory of eclipses turns, and of the language employed in speaking of them, we now proceed briefly to explain the theory itself, and how it is possible to predict the time of occurrence, and the duration and quantity of eclipses.

1. *Eclipses of the Moon*.—It has been said that these are caused by the moon passing through the earth's shadow. Before this explanation can be accepted, it must be shewn that that shadow extends as far as the moon. This is easily done. Supposing the earth to have no atmosphere, then the shadow is the cone marked in shade in fig. 1, whose apex is at O; and the question is, whether the distance

OT from the apex to the earth's centre exceeds the moon's average distance from the earth. Drawing TB, SA, from the centres of the earth and sun respectively, perpendicular to the line OBA, touching both spheres, and the line TC parallel to the line OBA,

Fig. 1.

we have from the similar triangles OTB, TSC, the proportion  $OT : TB :: TS : SC$ . Now, we know that TS, the (mean) distance of the sun, is equal to about 24,000 times TB; also, from the construction,  $AC = TB$ ; and we know that  $SA = 112$  times TB, whence it follows that  $SC = 111$  times TB. The above proportion, then, gives  $OT = 216$  times TB, since  $\frac{24000}{111} = 216$  nearly. But the moon's average distance is only 60 times TB (the earth's radius). Hence it appears that the length of the earth's shadow is almost four times the average distance of the moon, and that the moon can enter it. Further, it is clear that, should it do so, it may be totally obscured; for it must enter at a point much nearer T than half the distance OT, which is 108 times TB; and everywhere within that distance it might be shewn the breadth of the shadow is much greater than the moon's disc. But one consideration now remains to be stated to complete the proof of the theory of lunar eclipses. It was mentioned that they only occur at full moon, and we know that to be the only time when the earth is between the sun and moon, and so has a chance of throwing her shadow upon it. Why they do not occur every full moon, will be explained in treating of the prediction of eclipses.

In the foregoing explanation, we proceeded on the assumption that the earth has no atmosphere. If the assumption were correct, the earth's shadow would be darker and narrower than it is, and the phenomena of eclipses shorter in duration, but more striking. The effect of the atmospheric refraction (see REFRACTION) is to bend the rays which are incident on the atmosphere in towards the axis of the cone of the earth's shadow, those which pass through the lowest strata of the air being most refracted, and converging to a point in the line OT (see fig. 1), at a distance equal 42 radii of the earth from the earth's centre. Accordingly, the moon, which, as we have seen, crosses the shadow at a distance of about 60 radii, never enters that part of it which is completely dark; thus, she never loses her light entirely, but appears of a distinct reddish colour resembling tarnished copper—an appearance caused by the atmospheric refraction, in the same way as the ruddy colour of the clouds at sunset. There is another reason why the phenomena of a lunar eclipse are less striking than, from the explanation given relative to fig. 1, might be expected. Every shadow cast by the sun's rays necessarily has a penumbra, or envelope, on both sides of the half-shadow. In the case before us (fig. 2), suppose a cone having its apex O' between the sun and earth, and enveloping each of them respectively in its opposite halves, CO'C and AO'A' (fig. 2). It is clear that from every point in the shaded part of the cone CO'C, and without the shadow BOB', a portion of the sun will be visible—and a portion only—the portion increasing as the point approaches either of the lines CB, C'B; and diminishing as it approaches the lines BO, B'O. In other words, the illumination from the

sun's rays is only partial within the space referred to, and diminishes from its extreme boundary lines towards the lines BO, B'O. When, then, the moon

Fig. 2.

is about to suffer eclipse, it first loses brightness on entering this penumbra; so that when it enters the real shadow, the contrast is not between one part of it in shade and the other in full brilliancy, but between a part in shade and a part in partial shade. On its emersion, the same contrast is presented between the part in the umbra and the part in the penumbra. What we should expect on this geometric view of the earth's shadow, actually happens. From the breadth of the penumbra, it happens that the moon may fall wholly within it before immersion in the umbra commences; and so softly do the degrees of light shade into one another, that it is impossible to tell when any remarkable point on the moon's surface leaves the penumbra to pass into the umbra, or the reverse.

2. *Prediction of Lunar Eclipses.*—We said that lunar eclipses only happen at full moon. They do not happen every full moon, because the moon's orbit is inclined to the ecliptic, on which the centre of the earth's shadow moves at an angle of  $5^{\circ} 9'$  nearly. Of course, if the moon moved on the ecliptic, there would be an eclipse every full moon; but from the magnitude of the angle of inclination of her orbit to the ecliptic, an eclipse can only occur on a full moon happening when the moon is at or near one of her nodes, or the points where her orbit intersects the ecliptic. An eclipse clearly can happen only when the centres of the circle of the earth's shadow and of the moon's disc approach within a distance less than the sum of their apparent semi-diameters; and this sum is very small; so that except when near the nodes, the moon, on whichever side of the ecliptic she may be, may pass above or below the shadow without entering it in the least. The moon's average diameter is known to be  $31' 25'' \cdot 7$ , and from the *Nautical Almanac* we may ascertain its exact amount for any hour—its variations all taking place between the values  $29' 22''$  and  $33' 28''$ . As for the diameter of the circle of the shadow, it is easily found by geometric construction and calculation, and is shewn to vary between  $1^{\circ} 15' 32''$  and  $1^{\circ} 31' 36''$ ; and its value for any time may be found from the *Nautical Almanac*, to which value astronomers usually add  $1'$  as a correction for its calculation proceeding on the assumption that the earth has no atmosphere. Starting from these elements, it is a simple problem in spherical trigonometry—which may be solved approximately by plane trigonometry by supposing the moon and the earth's shadow to move for a short time near the node in straight lines—to fix the limits within which the shadow and moon must concur to allow of an eclipse. Recollecting that the earth's shadow on the ecliptic is at the opposite end of the diameter from the sun, and that therefore as it nears one node the sun must approach the other—the sun and shadow being always equidistant from the opposite nodes—we find, from the solution of the above problem: 1. That if, at the time of full moon, the distance of the sun's centre from the nearest node be greater than  $12^{\circ} 3'$ , there cannot be an eclipse. 2. If at that time the distance of the sun's centre from the nearest node be less than  $9^{\circ} 31'$ , there will certainly be an eclipse.

3. If the distance of the sun's centre from a node be between these values, it is doubtful whether there will be an eclipse, and a detailed calculation must be resorted to, to ascertain whether there will be one or not. Into the nature of that calculation we shall not attempt here to enter; suffice it to say that, knowing from the *Nautical Almanac* the true time of the sun and moon being in opposition, the true distance of the moon from the node at the time of mean opposition, with the true place of the sun at that time, as well as the moon's latitude, we may, by means of these elements, combined with the obliquity of the moon's path and her motion relative to that of the sun, not only fix whether there shall be an eclipse or not, but predict its exact magnitude, duration, and phases. It may here be mentioned, that before the laws of the solar and lunar motions were discovered with anything like accuracy, the ancients were able to predict lunar eclipses with tolerable correctness by means of the lunar cycle (see SOLAR CYCLE) of 18 Julian years and 11 days. Their power of doing so turned on this, that in 223 lunations the moon returns almost exactly to the same position in the heavens. If she did return to exactly the same position, then, by simply observing the eclipses which occurred during the 223 lunations, we should know the order in which they would recur in all time coming.

All lunar eclipses are universal or visible in all parts of the earth which have the moon above their horizon, and are everywhere of the same magnitude with the same beginning and end; and this universality of lunar eclipses is the reason why it is popularly thought, contrary to the fact, that they are of more frequent occurrence than solar eclipses. The eastern side of the moon, or left-hand side as we look towards her from the north, is that which first immerses and emerges again. The reason of this is, that the proper motion of the moon is swifter than that of the earth's shadow, so that she overtakes it with her east side foremost, passes through it, and leaves it behind to the west. It will be readily understood, from the explanations above given, that total eclipses and those of the longest duration happen in the very nodes of the ecliptic. But from the circumstance of the circle of the shadow being much greater than the moon's disc, total eclipses may happen within a small distance of the nodes, in which case, however, their duration is the less. The further the moon is from her node at the time, the more partial the eclipse is, till, in the limiting case, she just touches the shadow, and passes on unobscured.

3. *Eclipses of the Sun*, so called, are caused, as we have stated, by the interposition of the moon between the earth and sun, through which a greater or less portion of the sun is necessarily hid from view. In one sense, a solar eclipse might more properly be called an eclipse of the earth, caused by the moon's shadow falling upon it.

By a process similar to that used in ascertaining the length of the earth's shadow, it can be shewn that the greatest value of the length of the moon's shadow is  $59 \cdot 73$  semi-diameters of the earth; at the same time, we know that the least distance of the moon from the earth is about  $55 \cdot 95$  semi-diameters. It follows that when a conjunction of the sun and moon happens at a time when the length of the shadow and the distance of the moon from the earth are, or are nearly, equal to the values above stated, the moon's shadow extends to the earth and beyond it. Should the shadow in these circumstances fall upon the earth, there will be a total eclipse of the sun at all places within it or over which it moves (fig. 3). If  $l$  be the moon,  $T$  the earth, and  $aBl$  the moon's shadow cast by the sun, there

will be a total eclipse of the sun at every point that is completely within the portion *ab* of the earth's surface. Again, the smallest value of the length of

Fig. 3.

the moon's shadow may be shewn to be 57.76 semi-diameters of the earth, and the greatest distance of the moon from the earth is 63.82 semi-diameters. Suppose the moon interposed between the earth and sun when these values concur, it is clear that the moon's shadow will fall short of the earth. In this case, the sun cannot be altogether hid from any point of the earth's surface; but this case, or one approximate to it, is that in which there will occur an annular eclipse. In the figure, suppose *O* to be the apex of the shadow which falls short of the earth, and conceive the cone of the shadow produced earthwards beyond *O* into a second cone *Ocd*;

Fig. 4.

then from every point within the section *cd* of the earth's surface, the moon will be seen projected as a black disc on the middle of the disc of the sun, the portion unobscured forming a ring or annulus of light. While in the two cases just described the eclipse is total or annular at places within *ab* or *cd*, it will be partial at other places; the moon will appear projected against a portion of the sun's disc, making a circular indentation. To ascertain the places at which the eclipse will be partial, we have merely to form the cone of the penumbra of the moon's shadow in the manner explained in treating of lunar eclipses: at all places on the earth's surface within that cone there will be a partial eclipse. A simple calculation shews what is the observed fact, that the cone of the penumbra is not nearly large enough to embrace the whole of the face of the earth directed to the sun; in other words, solar eclipses are not universal, like those of the moon, i. e., they are not seen from all places that have the sun above their horizon at the time of the eclipse, which is the reason that though they are of more frequent occurrence than lunar eclipses, the latter are commonly supposed to occur more frequently.

If one could take up a position in space from which he could command a view of the whole face of the earth turned to the sun during a lunar eclipse, the phenomena which he would observe would be somewhat as follows. Marking the point of the earth first touched by the penumbra of the moon's shadow, he would observe the obscuration spreading therefrom over a wide and wider area as the penumbra advanced, till at last, supposing him to be viewing the case of a total eclipse, there appeared the umbral cone marking the earth with a dark spot. By and by, the whole penumbral shadow would be on the earth. The black spot would then appear to travel onwards with the motion of the shadow, and in its centre, in a course determined by the composition of the proper motion of the shadow or moon, and the motion of rotation of the earth. Part of the globe would be free from the affection, and, in the course of time, the umbral spot would

progress over different portions of the earth in succession, till at last it passed off the earth's surface, drawing after it the penumbral shadow. Could the spectator mark on the globe the various places affected by the shadow, with their degrees of shading, he would have a perfect chart of the course of the eclipse. The small belt of the globe traversed by the umbra would mark all places at which the eclipse would be total, while the degrees of shading over places adjoining that belt on both sides would indicate the magnitude of the partial eclipse as seen from them. The breadth of the belt traversed by the umbra, when the sun's distance is greatest and the moon's least, is estimated at about 180 miles; and in the same case the penumbra is estimated to cover a circular space of 4900 miles in diameter, the eclipse happening exactly at the node. If the eclipse does not happen at the node, it is clear that the axis of the shadow must be inclined to the plane of the ecliptic, that the shadow will be cut obliquely, and therefore that the part of the earth in shade will be oval. It may here be stated that astronomers usually calculate beforehand the motion of the shadow over the earth's surface, and prepare charts to exhibit its motion. Such a chart an observer from a position outside the earth would have it in his power to make from observation.

Of the commoner phenomena attending an eclipse of the sun, as regards the appearance of that luminary, nothing need be said; they are perfectly analogous to those of lunar eclipses, except in the case of the eclipse being annular. There are other appearances, however, attending an eclipse of the sun, especially when it is total, that are very remarkable. The almost instantaneous darkening of the orb of day, more particularly when it is unlooked for, is calculated to impress a spectator with vague terror; even when expected, it fills the mind with awe, as a demonstration of the forces and motions of the mechanism of the universe. The sudden darkness, too, is impressive from its *strangeness* as much as from occurring by day; it resembles neither the darkness of night nor the gloom of twilight. The cone of the moon's shadow, though it completely envelopes the spectator, does not, as we have explained, enclose the whole atmosphere above his horizon. The mass of unenclosed air accordingly catches the sunlight, and reflects it into the region of the total eclipse, making there a peculiar twilight. Stars and planets appear, and all animals are dismayed by the dismal aspect of nature.—See Mahoud-Bey's Report of the Total Eclipse of July 1860. Mr Warren De la Rue, who was one of an expedition of scientific men who went to Spain to witness the same eclipse, gives the following account of the aspects of nature near the time of totality: 'When the sun was reduced to a small crescent, the shadows of all objects were depicted with great sharpness and blackness, reminding one of the effects of illumination with the electric light. The sky at this period assumed an indigo tint, and the landscape was tinged with a bronze hue.'—*Athenæum*, 1860, vol. ii. page 259. At totality, there was still light enough to enable the observer to draw without the aid of his lamp, while the sky near the sun presented a deep indigo, and thence passed through a sepia tint to red and brilliant orange near the horizon. It must be said, however, that the strange appearance here recorded is exceptional, and probably not such as could ever occur in our latitude. There is one set of phenomena attending total eclipses of the sun, which are at once strange and invariable, and the causes of which cannot be said to be properly understood. As long as the total eclipse lasts, there appears round the sun and moon a luminous corona,

as in fig. 5, while beyond the corona appear very brilliant prominences, frequently of a rose tint. These prominences were first observed during the total eclipse of 8th July 1842; but there seems to

Fig. 5.—Appearance round the Sun during Total Eclipse.

be no reason for doubting that they are constant attendants on eclipses. They were lately observed during the eclipse of 18th July 1860, when their appearance was such as to exclude the notion that they are due to irregularities in the moon's surface. Several authorities are disposed to refer them to the brighter portions or *faculae* in the sun's surface (see SUN); and Mr De la Rue observes, that the sun's rotation in the course of the two days succeeding the eclipse brought to view *faculae*, that at the time of eclipse would have just occupied the positions at which the prominences appeared.

In the eclipse of 1860, the light of the corona was a silvery white, and it extended beyond the moon's limb about eight-tenths of her diameter. The corona consisted first of a bright ring of about 2' wide, and then an exterior and fainter ring of about 3', beyond which, for a mean distance of about 2', extended a glory of small rays—the whole corona extending to 7' beyond the moon's limb. From the corona, at intervals, projected individual rays of remarkable size, and five in number: one of 9' length; another of 14', and shaped like the point of a star; a third, sabre-shaped, and extending 28'; a fourth, 28'; and a fifth, 10'. It may be mentioned that the notes taken by the members of the expedition to Spain have been all submitted to the astronomer-royal, with a view to his reporting on the eclipse. The report, which is looked forward to with interest, has not yet appeared.

4. *Prediction of Solar Eclipses.*—The period of 18 Julian years 11 days, referred to in treating of the prediction of lunar eclipses, applies equally to solar eclipses with lunar; but the ancients, who understood that fact, could find no law of recurrence of solar eclipses within that period, so as to predict them. The reason of the failure is obvious; for though solar eclipses recur in a fixed order within the cycle, they are not visible at the same places on their recurrence as when first observed. By modern methods, however, eclipses of the sun may be predicted, with all their circumstances of time and places of observation, with the most perfect certainty. We shall not, however, attempt to explain what these methods are; suffice it that they resemble those already generally described as

applied in the case of lunar eclipses. At the time of a solar eclipse, the sun and moon are in conjunction; they are also in or near the same node; and no eclipse can happen if they are further than 17' from the node, or if the latitude of the moon, viewed from the earth, exceeds the sum of the apparent semi-diameters of the sun and moon. When within these limits, it is a problem of numbers and of spherical trigonometry to ascertain the nature of the eclipse, if any, which will happen.

The number of eclipses of the sun and moon together in a year cannot be less than two, or more than seven; the most usual number is four, and it is rare to have more than six. The explanation of the limitation of the number of eclipses is connected with the fact, that the sun passes by both nodes but once in a year, except in the case of his passing one early in the year, in which case, owing to the recession of the moon's nodes, he will again pass it a little before the end of the year. From the smallness of the cone of the moon's shadow, total solar eclipses are extremely unfrequent in any one place, compared with the frequency of their actual occurrence. At Paris, there was only one total eclipse of the sun in the 18th c., that of 1724, and there will not be another till near the close of the 19th century. In London, not one total eclipse was witnessed during the 575 years, 1140 to 1715.

ECLIPSES OF THE SATELLITES. See SATELLITES.

ECLIPTIC is the name given to the great circle of the heavens round which the sun *seems* to travel, from west to east, in the course of a year. It took its name from the early observed fact, that eclipses happen only when both bodies are in or near this path. A little attention about sunset or sunrise shews that the sun is constantly altering his position among the stars visible near him, leaving them every day a little further to the west; and that this motion is not exactly east and west, or parallel to the equator, becomes also evident by observing that the sun's height at mid-day is constantly altering. It is further observed that, twice a year, about March 21 and September 23, the sun is exactly on the equator. The two points of the equator on which the sun then stands are the equinoctial points, and are the intersections of the equator and ecliptic. Again, there are two days in the year on which the sun reaches his greatest and his least mid-day elevation: the first is the 21st of June, the second the 21st of December. On these days, the sun has reached his greatest distance from the equator either way, and the points in his course where he thus seems to pause or halt in his retreat from the equator are called the solstices (*solis stationes*). These four points are distant from one another by a quadrant of the circle, or 90°. Each quadrant is divided into three arcs of 30°, and thus the whole ecliptic is divided into 12 arcs of that length, called Signs of the Zodiac (q. v.). These arcs or signs have been named after constellations through which the ecliptic passes. As the equinoctial points are not fixed, but recede yearly westwards about 50 seconds, and in a century about 1° 23', the same constellations and signs that coincided when the division of the ecliptic took place, no longer coincide. The constellation of the Ram, for instance, which originally stood in the first arc or sign, now stands in the second, every constellation having advanced forward 30°, or a whole sign. Modern astronomers therefore pay little attention

to these constellations and signs, but count longitudes from the existing spring equinoctial point from 0° to 360°.

Not only do the points change where the ecliptic and equator cross each other, but the angle of their inclination, called the obliquity of the ecliptic, is also variable. It is at present nearly 23½°, and is diminishing at the rate of about 50 seconds in a century. Were it to go on diminishing always, the ecliptic and the equator would at last coincide, and the earth would then have an everlasting spring. The decrease, however, has a limit; the obliquity oscillates between two definite bounds, which it can never pass. It has been calculated that it was at its greatest 2000 n.c., and was then nearly 23° 53'. Since then, it has been decreasing, and will continue to do so till about the year 6600 A. D., when it will be at its least, and about 22° 54'. These slight alterations cannot sensibly affect the seasons.

The physical cause of this change of the obliquity is the action of the other planets, especially Jupiter, Mars, and Venus, on the mass of the earth. The fact of the change was known to astronomers in very ancient times; Herodotus mentions an old tradition of the Egyptians, that the ecliptic had formerly been perpendicular to the equator—a notion into which they were most probably led by observing, for a long series of years, that its obliquity was constantly diminishing. There can be little doubt that the Chaldeans arrived at the epoch of 403,000 years before the entry of Alexander into Babylon, to which they proudly referred for their first astronomical observations, by computing the time when the ecliptic was perpendicular to the equator, on the supposition of its obliquity diminishing 1' in 100 years. Though it was not till after the discovery of the law of gravitation that the change on the obliquity could be explained, yet that it was changing was believed in by many astronomers, although some doubted whether the differences in the values at different times were not due to errors of observation. The earliest known measure of the obliquity of the ecliptic was made by Teheou Kong, the regent of China. Among the western nations, the earliest measurements were made by Pytheas and by Eratosthenes.

ÉCOLE POLYTECHNIQUE is one of the most celebrated military academies in France. In 1793, all the public establishments in Paris were in a convulsed state, owing to the Revolution. In 1794, M. Lamblardie, director of the *Ponts et Chaussées*, proposed the establishment of an *École Centrale des Travaux Publics*, to educate young men for military, naval, and civil engineering. Monge and Carnot favouring his plan, it was carried out, and a school established at the Palais Bourbon. The first list of professors comprised names which afterwards acquired European celebrity—including those of Lagrange, Prony, Monge, Hachette, Hassenfratz, Foureroy, Vauquelin, Berthollet, Chaptal, Pelletier, Guyton-Morveau, and Merimée. In 1795, the name was changed to E. P.; many alterations were made in the organisation; artillery studies were included in the course; and the pupils were ordered to wear a uniform. When Napoleon went to Egypt, 40 pupils from the E. P. accompanied him, many of whom greatly distinguished themselves. Napoleon made the organisation of the school more strictly military in 1804, to identify it more fully with the army. The school was dissolved in 1816, again in 1830, and again in 1832, on account of the impetuous way in which the pupils mixed themselves up with the political disturbances of those years; but as the school suited the military genius of the French nation, it was re-established on each occasion, after the restoration of tranquillity. Candidates

can be admitted only by competitive examinations, which take place yearly. A proclamation from the War Office, made public before the 1st of April, informs intending competitors of the subjects on which they are to be examined, and the time when the examinations begin. To be eligible as a candidate, the youth must be French, and must be more than sixteen, and less than twenty years of age before the 1st of January following; but soldiers are admissible up to the age of twenty-five, provided they can give proof of two years of service in the regular army. The cost of board alone is 1000 francs (nearly £42) a year. A complete course of instruction lasts for two years; when the pupils who have satisfactorily passed the final examinations have the privilege of choosing, from among the various public services supplied from this school, the particular branch they wish to enter, such as artillery, engineers, the staff, the department of telegraphs, or some of the other government monopolies. The school was re-organised by a decree of the 1st November 1852. Its present title is *École Impériale Polytechnique*.

ÉCO'NOMY, a Socialist village of Pennsylvania, in the United States, stands on the right bank of the Ohio, about 17 miles below Pittsburg. The settlement was planted in 1825 by immigrants from Germany. The inhabitants own everything in common—3500 acres of land, upwards of 100 houses, with a church, a school, a museum, and manufactories of wool, cotton, and silk.

ECONOMY, POLITICAL. See POLITICAL ECONOMY.

ÉCORCHÉ, a figure in which the muscles are represented, stripped of the skin, for purposes of artistic study, is called by the French an *écorché*, and from them we have borrowed the term. From a portion of the figure, the upper muscles are also removed, so as to exhibit those which lie nearer to the bone. It is not uncommon to represent the *écorché* in action, in the form of the Fighting Gladiator. The first person who did so was Salvage, a French artist and anatomist. In order to render the studies of pupils more complete, Salvage has had this figure engraved in all the points of view, and more or less denuded of flesh, till at last it is little more than a skeleton, the only muscles represented being those which immediately cover the bones. Figures of this kind can now be procured both in plaster and papier-mâché.

ÉCOUTES (Fr. *écouter*, to listen), in military operations connected with siege-works, are listening-places. They are small galleries, excavated at regular distances, and going out beneath and beyond the glacis, towards the lines and batteries of the besiegers. Their purpose is, to enable the garrison to hear and estimate the works being carried on by the sappers and miners of the enemy.

ECSTASY (Gr. *ekstasis*, a transposition, a change of situation or condition; applied to the mind in the sense of a state in which it is altered or fundamentally changed in character by some absorbing emotion), a word applied to those states of mind, which, without amounting to Insanity (q. v.), in respect of the temporary character of the affection, are marked by mental alienation, and altered or diminished consciousness. A person in ecstasy may be violently moved, or completely passive; convulsed, or rigid, or flaccid in all the limbs; silent, or uttering unmeaning or excited language, or assuming the character of a prophet or inspired person; having, or not having intelligence of what is going on around him. The varieties are infinite, because this morbid state of the mind is nothing more in reality than the fixing of it in a particular attitude, as it were, in connection with an

overmastering idea, emotion, or sensation, which causes all other external phenomena to be disregarded. Perhaps the most common form, or, at all events, that which is best known, is religious ecstasy, closely allied to monomania and religious delusion of every kind; often simulated, but also occurring as a real disease, as in the case of those 'struck' in revival meetings, and in the older histories of the conversions of Cambuslang, the *convulsionnaires* of St Médard, and the epidemics of religious excitement mentioned under Dancing Mania (q. v.) It is also common to speak of the ecstasy of terror, and the expression is correct in exaggerated cases, where fear completely paralyses both the consciousness and the power of motion and expression; so also there is an ecstasy of joy, of love, of hate, of meditation; and in some physical states as Catalepsy (q. v.), Hysteria (q. v.), Mesmerism (q. v.), a true ecstasy is one of the phenomena, inasmuch as the proper consciousness of the individual is temporarily abolished, or so much changed in character as to lead almost to the loss of the sense of personal identity. Some of the cases of presumed Double Consciousness (q. v.) are no doubt of this kind; and generally the same may be said of the state of the mind in many dreams and visions, and also in Somnambulism (q. v.). A striking picture of this form of ecstasy is the well-known sleep-walking scene in *Macbeth*, where the lady's mind is so completely preoccupied with the supposed bloodstain on her hands, that though her eyes are open, we are told that 'their sense is shut,' and the mind is also excluded from all the ordinary avenues of communication.

**ECTOZO'A** (Gr. *ektos*, without, and *zoos*, living), a term which has been introduced, as in contradistinction to *Entozoa*, to designate those parasitic animals which live upon the external parts of other animals, as lice, ticks, &c. Such also are many of the entomostracous crustaceans, parasitic upon fishes. It is a question of much importance, not yet satisfactorily answered, if any of these creatures are the causes of diseased states, in connection with which they are sometimes found in particular abundance, or if their presence in unusual numbers is to be ascribed to disease previously existing.

**ECTROPION** (Gr. *ek*, and *trepo*, I turn out), an everted condition of an eyelid, in consequence of which it does not cover the globe of the eye. It is capable of being remedied by a slight surgical operation.

**ECTROTIC** (from Gr. *ectroma*, abortion), a term applied to methods of treatment which aim at preventing the development of a disease.

**ECTYPOGRAPHY**, a method of etching, in which the lines are raised on the plate, in place of being sunk into it. See **ETCHING**.

**ECTYPUM**, a cast in relief of an ornamental design, produced from a mould.

**ECUADOR**, the Spanish term for *Equator*, is the name of that fragment of Colombia (q. v.) which lies on both sides of the equinoctial line. In lat. it extends from 1° 40' N. to 5° 50' S., while in W. long. it stretches from 69° to 81° 20'. It measures, therefore, from north to south fully 500 miles, and from east to west nearly 850, presenting an area of about 300,000 square miles. It is bounded by New Granada, Brazil, Peru, and the Pacific. Toward the east it is drained by the Amazon, which receives all the rivers that fall down the eastern slopes of the Andes, while the country west of the Andes is drained chiefly by the Mira, the Esmerelda, and the Guayaquil—the last-named stream being more available for navigation than any

other on the same coast of South America. The country is traversed, nearly in the line of a meridian, by the two ranges of the Andes, which, alternating between union and separation, sometimes run into what are called knots, and sometimes enclose, at great elevations, plateaus or table-lands. Among these last, ranging from south to north, the most important are those of Cuenca, Hambato, and Quito—their respective heights above the sea being, in feet, 8640, 8860, and 9543. Lofly as these plateaus or table-lands are, they are beset, nay almost shut out from the world, by pinnacles of occasionally more than equal altitude above their own level. Of these the most remarkable are Chimborazo and Cotopaxi (q. v.). In connection with these physical features, the country is subject to volcanoes and earthquakes—the latter frequently occurring, and the former numbering altogether no fewer than sixteen. The climate comprises every possible variety. Hyperborean cold marks the snow-capped mountains; a temperature at once moderate and uniform renders the upland plains so many paradises; while, on both sides of the dividing ridge, intense heat oppresses the lower valleys. The rainfall is different in different localities. In the basin of the Guayaquil, there is regularly a wet season; between it and Cape San Lorenzo, almost perpetual drought prevails; and, in the other direction, the upper tributaries of the Amazon are said to be fed by almost perpetual rains.

The population is about two-thirds of a million, pretty equally divided, it is believed, between Spaniards, Aborigines, and Mestizoes, with a very inconsiderable admixture of Africans. The chief cities are Quito, the capital, and Guayaquil, the emporium of foreign trade; and the towns of the second class are Riobamba, Puno, Cuenca, and Loxa. The government appears to have been constituted on the model of the United States of North America, having a president and vice-president, with a senate and a house of representatives. The external commerce is slowly but steadily advancing. Between 1852 and 1858, the imports had increased from £303,180 to £506,456; and the exports from £304,385 to £474,324. During the same interval, the British vessels—both entrances and clearances taken together—had multiplied from 22 to 82; being, at the close, fully one-half more numerous than the vessels of all other nations beyond the limits of Spanish America. In 1858, the principal articles of import, in order of value, were cottons—more than a fourth of the whole—woollens, wines, spirits, groceries, soap and candles, hardware, flour, linens, &c. In that year, the chief heads of export, also in order of value, were cocoa—about 55 per cent. of the entire amount—the precious metals, timber, bark, hides, orchilla, tobacco, &c.

**ECUMENICAL** (Gr. *oikoumenikos*), i. e., universal, a term applied to ecclesiastical councils, regarded as representing the whole Christian Church, or the church of the whole world (*oikoumenē*), and to the orthodox or Catholic Church, regarded as opposed to heretical and merely local sects. The Roman Catholics claim the designation as appropriate to their own church. It is a title of patriarchs, archbishops, and ecclesiastical superintendents of provinces.

**ECZEMA** (from a Greek verb, 'to boil out'), an eruption of small vesicles on various parts of the skin, usually crowded together, with little or no inflammation around their bases, and unattended by fever.

**EDDA**. There are two works which bear this title—the *Edda Semundar hins Froda*, or *Edda of Semund the Wise*, and *Snorri Sturluson's Edda*. The former and older of these is a collection of the most ancient mythological and heroic Scandinavian

songs, the date of whose composition may probably be referred to different periods between the 6th and 8th centuries. These songs, which are supposed to have been collected and arranged by Sæmund Sigfusson, surnamed Frodi, an Icelandic priest, who was born between 1054 and 1057, and died in 1133, were discovered and first brought before the notice of European scholars in 1643, by Brynjolf Svendson, Bishop of Skalholt, who applied to them the name of Edda, or 'grandmother.' This collection was published entire at Stockholm, 1818, in 8vo, by A. A. Afzelius, after the text of Professor Rask; and at Copenhagen, in 3 vols. 4to, 1787—1828, with a Latin translation, glossaries, &c. The third volume of this edition, which was completed by Professor Finn Magnussen, consists chiefly of a very learned and copious Lexicon Mythologicum by the editor. A complete edition of the text of this Edda was also published by Professor Munch at Christiania, 1847, and by Möbius in 1859; while a German version of both Eddas was made by Snorroek in 1851. Ettmüller has made a German translation of all the poems connected with the Nibelungen cycle; while the brothers Grimm have translated a part of Sæmund's Edda under the title of *Dreizehn Lieder in der Ursprache mit einer doppelten Uebersetzung*, &c. The Snorra Edda is a prose composition, and treats of Scandinavian mythology and of the language and modes of composition of the ancient skalds. As the name implies, it is referred to Snorri Sturleson (q. v.), the learned author of the *Hæmskringla*, who was born in Iceland in 1178, and died by assassination in 1241, on his return from Norway, where he had lived in the capacity of skald or court-poet. This Edda, which was first arranged in 1628 by the Icelandic bishop, Arngrim Johnson, was published by Resen in 1665, under the title *Edda Islandorum An. Chr. MCCXV. Conscripta per Snorronem Sturla, Islandice, Danice, Latine, ex Antiq. Codicibus*, &c. A complete edition of the prose E., and the most copious of all, was published at Stockholm by Professor Rask, in 8vo, 1818. The first volume of the edition from the Arne Magnussen text appeared in 1848, with a Latin translation and notes, and a German edition of both Eddas, with glossary, &c., was published in 1859 by Lünig.

E'DDOES. See Cocco.

E'DDYSTONE, a group of gneiss rocks, daily

Elevation of Eddystone Light-house.

submerged by the tide, in the English Channel, 9 miles off the Cornish coast, and 14 miles south-

west of Plymouth Breakwater. The rocks lie in lat. 50° 10' 51" N., and long. 4° 15' 53" E., and have 12 to 150 fathoms water around. The frequent shipwrecks on these rocks led to the erection of a light-house on them by Mr Winstanley, 1696—1709. It was a wooden polygon, 100 feet high, with a stone base; but a storm in 1703 completely washed it away, with the architect. Another light-house was built, 1706—1709, also of wood, with a stone base, and 92 feet high, by Mr Rudyerd, a silkmerecer. This erection was burned in 1755. The present building, known as the Eddystone Light-house,

Section of Eddystone Light-house.

and noted for its strength and the engineering skill it displays, was constructed by Mr Smeaton in 1757—1759, on the model, it is said, of the trunk of the oak-tree. It stands on the sloping side of one of the rocks, and is built of blocks, generally one to two tons weight, of Portland oolite, encased in granite. The granite is dove-tailed into the solid rock. The whole forms a circular tower 85 feet high, and rising from the base with a gentle curve. The base is 26½ feet diameter, and has 13 feet of solid masonry on it, and the tower contracts to 15 feet diameter at the top. The light is a fixed one, at the height of 72 feet above the water, and is seen at the distance of 13 miles. See LIGHT-HOUSES.

EDELINCK, GERARD, a celebrated engraver, born at Antwerp 1627, died in Paris in 1707. He was invited to Paris by Colbert in 1665, and patronised by Louis XIV. He engraved numerous portraits, and many of Le Brun's works. All his works are executed with the graver with admirable clearness and precision.

E'DEN, according to the Hebrew Scriptures, the first residence of man. The description given of it in the book of Genesis is brief, obscure, and, in appearance legendary. The allegorical theory will be noticed under FALL (q. v.). In general, however, scholars have preferred to understand the story literally, and to believe that the writer or writers of it meant it to be so understood; but they have not, therefore, been unanimous as to the historical reality, or even the geographical position of Eden. The difference in their modes of apprehending the contents of the Hebrew Scriptures has manifested itself in this as in other *veritate questiones* of biblical criticism. Josephus and several of the Fathers conceived that Eden was a term denoting the entire region between the Ganges and Nile; Calvin, Huet, Bochart, Wells, &c., have, with slight differences of detail, concluded in favour of

Kornah in Babylonia, not far from the Persian Gulf; Reland, Calmet, Hales, Faber, J. Pye Smith, in favour of Armenia, near the sources of the Tigris and Euphrates; Le Clerc, in favour of the region near Damascus; while the modern German school of biblical critics, convinced that the Hebrew account is traditional, and, in its present form, of very late composition, and impressed, besides, with the vast antiquity of the far East, have, almost without exception, turned their eyes in that direction, and sought the cradle of the human race in Bactria or Cashmere, or the region lying to the north of it, a part of which is to this day called *Audyana*, the 'Garden.' It may also be mentioned that the Mohammedans believe Eden to have been in one of the seven heavens—some say the moon—and that the expulsion from paradise consisted in Adam being cast down upon the earth after the Fall. It is useless seeking to identify the river-system of Eden with anything known at present. There is no river on the face of the globe of which the Euphrates and Tigris (Hiddekel) are separate 'heads' (whether this means 'sources' or 'channels'), as they are said to be in the 2d chapter of Genesis, for, as Major Rennell has shewn, although the Euphrates and Tigris *now* unite for a short space on their way to the Persian Gulf, yet, until the time of Alexander the Great, they kept entirely distinct courses; and therefore it has been assumed that the 'Deluge' completely altered the physical character of the region denoted by the term Eden. This was Luther's notion, to which, however, it has been objected, that the narrative in Genesis is so worded as to convey the idea that the countries and rivers spoken of were still existing in the time of the historian. Besides, the science of geology has thrown so much doubt on the universality of a Deluge so late as the period assigned to Noah, that it is hazardous to argue on the hypothesis of any extensive physical changes having taken place since the first appearance of man on the planet; at least, if that be dated only some six thousand years back. It will thus be seen that the question of the locality of Eden, or of the exact sense in which the Mosaic narrative is to be understood, is involved in inexplicable mystery; and it has become a general opinion, that the spiritual significance of this primeval story is what principally concerns Christians—an opinion which derives force from the total silence of the New Testament in reference to the subject.

EDEN, a river rising in the east of Westmoreland, in the Pennine Chain. It runs north-north-west through the east of Westmoreland and Cumberland, past Appleby and Carlisle, and ends in a fine estuary at the upper part of the Solway Firth, after a course of 65 miles.

EDENTA'TA (Lat. toothless), an order of *Mammalia* established by Cuvier, and generally received by naturalists. Cuvier remarks, that 'although brought together by a purely negative character, the E. have, nevertheless, 'some positive mutual relations, particularly in the great claws which encompass the ends of their toes, and which more or less approximate to the nature of hoofs; also in a certain slowness or want of agility, obviously arising from the peculiar organisation of their limbs.' He included among them, however, the *Monotremata*, which, although so few in number, are now generally separated, on account of the very important differences of organisation which characterise them. The remaining E. are divided into two tribes—1. *Tardigrada* (slow-paced), containing only the Sloths; and, 2. *Efodentia* (diggers), containing Armadillos, Pangolins, Ant-eaters, &c. The ant-eaters and pangolins are the only E.

that are absolutely destitute of teeth; but none of the order have any teeth in the forepart of their jaws, and their teeth are comparatively imperfect in structure, being destitute of enamel and distinct roots. The sloths alone subsist on vegetable food, the rest chiefly on insects or on animal substances in a decaying state. The whole number of existing species of E. is not great; but they appear to have been more numerous and of much greater size in a former geological period, as the remains of the *Mylodon*, *Megatherium*, and *Megalonyx* testify.

ED'ESSA (modern name, *Urfah*, or *Oryfa*), a very ancient city, on the river Daisan, in the north of Mesopotamia, 78 miles south-west of Diarbekir, although the Christian or Mohammedan legend, ascribing its foundation to Nimrod, or Khabiba, a female contemporary of Abraham, is unworthy of any credence. With the conquest of Persia by the Greeks, the history of E. first becomes clearer. Seleucus, in particular, is said to have done much for the aggrandisement of the city. Christianity was introduced into E. at an early period. In the reign of Trajan, the place was made tributary to Rome, and in 216 A.D. became a Roman military colony, under the name of *Colonia Marcia Edesseuorum*. During this period, its importance in the history of the Christian Church continued to increase. More than 300 monasteries are said to have been included within its walls; it was the seat of Ephraim Syrus and his school, and played an important part in the Arian and other controversies. With the extension of the religion of Islam, E. fell into the hands of the Arabian califs. Christianity declined, and wars at home and abroad during the califate, destroyed likewise its temporal splendour and prosperity, till, in 1040, it fell into the possession of the Seljuk Turks. The Byzantine emperors succeeded in recovering E., but the viceroy contrived to make himself independent. He was, however, hard pressed by the Turks, and this rendered it easy for the crusader Baldwin, the brother of Godfrey of Bouillon, to gain possession of the city (1097 A.D.), and make it the capital of a Latin principality, and the bulwark of the kingdom of Jerusalem. Under the Frankish princes, E. held out valiantly against the Mussulmans, till at length Zengi, ruler of Mosul, succeeded in taking the town and citadel in the year 1144, when all the Christian churches were converted into mosques. An attempt made by the inhabitants to throw off the Turkish yoke, completed the ruin of E.: the Edessenes were defeated by Nur-ed-din; and all who were not massacred, were sold as slaves. After many vicissitudes, in the course of which E. fell successively into the hands of the sultans of Egypt, the Byzantines, the Mongols, Turkomans, and Persians, the city was finally conquered by the Turks, and has ever since formed a portion of the Turkish dominions. It now contains 40,000 inhabitants, of whom 2000 are Armenian Christians; the rest are Turks, Arabians, Kurds, and Jews. At present, E. has numerous mosques and bazaars; manufactures of cotton goods, goldsmiths' wares, and morocco leather, commerce in British manufactures obtained by way of Aleppo, and a large trade in corn, &c., with Syria. E. is regarded by the Easterns as a sacred city, because they believe it to have been the residence of Abraham.

EDFOU (Coptic, *Atbô*; Egypt. *Hut*; anc. *Apolinopolis Magna*), a town of Upper Egypt, is situated on the left bank of the Nile, in lat. 25° N., and long. 32° 45' E. It contains the remains of two temples, which are considered the finest remains of antiquity in Egypt. The larger of these temples

was commenced by Ptolemaeus Philometor 181 B.C., but does not appear to have been completed till the reign of Claudius. There appears, however, to have been a temple there in the reign of Thothmes II. Its length is about 400 feet, its breadth 150. Its entrance is by a gateway 50 feet high, between two immense truncated pylones, 37 feet wide at the base, and 114 feet high. These are adorned with masterly sculptures. Passing through this entrance, the court is reached; it is 161 feet long, and 110 feet wide, enclosed by a splendid colonnade of 32 pillars, each differing in design, and surrounded by walls, between which and the pillars there is a stone roof, forming a covered portico. The interior of this court is to a great extent filled up with rubbish, and occupied by wretched dwellings, many of which also are built upon the roof of the temple. Within the temple, there are several chambers, one of which, about 33 feet by 17, contained the image of the deity; in it was also a zodiac. The effect of the whole is grand and imposing, impressing the mind with the harmony and perfect beauty of the design. An inscription on the outer wall recorded the endowment of the temple by Ptolemy Alexander I., and Darius, Nectanebo, and Nectanebes II. The smaller temple, erected by Physcon and Lathyrus, consists only of two chambers. Its walls are covered with hieroglyphics representing the life of *Horus*, the son of *Kneph* and *Athor*, who were worshipped in the great temple. These temples have been lately entirely cleared by Mariette. E. has at present a population of about 2000. Its manufactures are blue cotton cloths, and earthen-ware similar to the ancient Egyptian pottery.—Wilkinson, *Modern Egypt*, p. 274; Brugsch, *Reiseberichte*, p. 225; Lepsius, *Egypt and Ethiopia*, p. 117.

**EDGECUMBE.**—1. A bay in the east coast of Australia, lies within the province of Queensland, near lat. 20° S., and long. 148° E. It is sheltered on every side but the north, its east barrier terminating in Cape Gloucester.—2. A mountain in what was formerly Russian America, marks the N.W. point at the mouth of Norfolk Sound, which connects the settlement of New Archangel on the island of Sitka with the open ocean. It rises from the water's edge as an almost perfect cone, which, during nearly the whole year, is capped with snow. It has been an active volcano within the recollection of some of the Russian colonists; and, even at the present day, the neighbourhood presents indications of subterranean energy, such as tremblings of the earth, hot springs, and eruptions of smoke and ashes. See AMERICA.

**EDGEHILL, BATTLE OF.** The first great battle of the Civil War was fought on Sunday, 23d October 1642, between the royalist forces under Charles and the parliamentarians under the Earl of Essex. It was the intention of Charles, who had been lying at Shrewsbury, to march upon London by Wolverhampton, Birmingham, and Kenilworth; and Essex, who had thrown himself into Worcester, on being informed of the king's plans, marched forward to intercept him, and entered the village of Keinton, in Warwickshire, on the evening of the 22d. On the following morning, the royalist army was discovered a little in advance, and drawn up in order of battle on the elevation of Edgehill. The king's forces had the advantage in numbers and in cavalry, as well as in position; Essex, however, had the more formidable train of artillery. Charles had commanded that hostilities should be delayed until the enemy should open fire; accordingly no movement took place till about two o'clock, when Essex commenced the fight by firing upon the royalists, who imme-

diately replied with their cannon. The royalists then began to descend the hill, and Prince Rupert, who led the right wing, charged with his cavalry the left wing of the parliamentarians, broke it, and pursued it madly to Keinton, where his men, regardless of the main army, busied themselves in plunder. This was the fatal movement of the day. The right wing of the parliamentarians had charged and recharged with the greatest success, until, after some stubborn fighting around the royal standard, the royalists broke, and retreated toward the hill. That night 4000 men lay slain at the foot of Edgehill, and of these the greater number were royalists.

**EDGEWORTH, MARIA**, the daughter of Richard Lovell Edgeworth of Edgeworthstown, county of Longford, Ireland, was born at Hare Hatch near Reading, Berkshire, in the year 1767. In 1782, her father returned to Ireland, accompanied by his family, to whose education he earnestly devoted himself. Maria's talents quickly developed themselves. Her first literary effort was written in conjunction with her father, and was entitled *Essays on Practical Education* (1798). In 1801 appeared the *Essay on Irish Bulls*, which was also in part the work of Mr Edgeworth. But it was in the sphere of fiction that Miss E. won her greatest triumphs. In 1801 she published *Castle Rackrent*, the first of a pretty extensive series of novels characterised in general by a quiet agreeable humour, excellent sense, and lively delineation of character and manners. It has been objected by critics, however, that some of them are too manifestly didactic to please as fiction should please. In 1803 appeared *Belinda*; in 1804, *Popular Tales*; in 1806, *Leonora*; in 1809, *Tales of Fashionable Life*; and in 1812, a second series of the same. The last of the series was 'Helen,' which was published in 1834. Among the most successful of her *Tales of Fashionable Life* were 'Ennui' and 'The Absentee.' Miss E.'s stories for children—the last of which, *Orlando*, appeared in *Chambers's Library for Young People*—are deserving of high praise. This gifted and universally respected authoress died at Edgeworthstown, 21st May 1849.

**EDGINGS** are indispensable to neatness in gardening, except where parterres are cut out of a lawn, but more especially to separate gravel-walks from cultivated ground. They are sometimes made of stone, or of deal; sometimes of ornamental wicker-work, and now not unfrequently of wirework; but for many purposes, the best edgings are formed of low-growing evergreen plants, and none are so common in Britain as those of dwarf box, which, when carefully trimmed, are very pleasing to the eye, and do not require renewal for a number of years. Thrift or sea-pink is another not uncommon edging, is beautiful at all times, and particularly so when in flower, but requires frequent renewal. The double daisy, often planted as an edging, also requires frequent renewal. Turf-edgings are sometimes employed for wide flower-borders.

**'EDIBLE BIRDS' NESTS,** or **EDIBLE SWALLOWS' NESTS.** See NESTS, EDIBLE.

**EDICT** (Lat. *edictum*). The power of making edicts (*jus edicendi*) belonged generally to the higher magistrates at Rome; but it was by the curule ædiles, and more extensively still by two prætors—the *prætor urbanus*, and the *prætor peregrinus*—that it was prominently exercised. In a province, the jurisdiction of the prætor passed to the *præses*. As this power was co-extensive with the possession of what were called the honours (*honores*), it was frequently spoken of as the *jus honorarium*; and from its being exercised chiefly by the prætors, it was also known as the *jus prætorium*. The edicts of

the prætors are mentioned by Gaius among the sources of the Roman law; but, strictly speaking, they are to be considered as *rules promulgated* by the magistrates on entering on office, rather than as expressions of the will of the Roman people, either direct or indirect. The edict of one prætor was not binding on his successor, but very often edicts were adopted and confirmed, and this came gradually to constitute a very important body of law. They were frequently known by the names of their first promulgators, though they were often named with reference to the formula and the *actio* which they established. The power of promulgating edicts is supposed to have flowed down from the kings to the consuls, and through them to the prætors, and thus to have formed part of what we should call the royal prerogative. Even in Cicero's time, the study of the edict had become a regular branch of the study of the law. In 67 B.C., the Lex Cornelia provided against the abuse of passing edicts for the decision of particular cases by requiring the prætors to decide in conformity with the edicts which they promulgated with reference to their whole tenure of office, which were known as perpetual edicts. Servius Sulpicius, the friend of Cicero, addressed to Brutus a work on the subject; and Ofilus made what was probably a compilation of the various edicta, resembling the subsequent one by Julian. The object of the edict, according to the Roman jurists, was to aid, supplement, and correct the civil law, and to render it more conducive to the public service, and they speak of it as 'the living voice of the civil law.' It was, in short, an indirect form of legislation, which public opinion had sanctioned for the public convenience; and there can be no doubt that it contributed what was ultimately the most valuable part of the Roman law. There were many commentators on the edicts under the emperors, amongst whom Labeo is mentioned and cited by Ulpian (*Dig.* 4, tit. 3, s. 9). Julian is supposed to have collected and arranged the edicts, and given to them a systematic form. Gaius, Ulpian, and Paulus composed treatises on the edicts of the *curule ædiles*; and it is chiefly from the writings of these and the other jurists excerpted in the *Digest*, that we know anything of the character of the edict, the portions of it which have been preserved being mere fragments. They have been collected by Wieling in his *Fragmenta Edicti Perpetui* (Frank. 1733).

EDICT OF NANTES. See NANTES.

EDICTAL CITATION, or INTIMATION. By the former practice of Scotland, where the party to be cited before a civil court was out of Scotland, the citation required to be given by a messenger-at-arms making proclamation at the market-cross of Edinburgh, and at the pier and shore of Leith. The idea, of course, was, that the fact was thus more likely to reach the absent party than if it had been intimated or published in any other manner.—*Erskine*, b. i. tit. 2, s. 18. But the practice in this matter was altered by the so-called Judicature Act (6 Geo. IV. c. 120), and the subsequent statute, 13 and 14 Vict. c. 36, s. 22, which enacted that services against persons forth of Scotland should be done by delivery of copies at the record office of the keeper of the records of the Court of Session. Abstracts of the copies delivered to the keeper are ordered to be recorded by him, and to be printed periodically at the end of each successive fourteen days, and the record is to be at all times open for inspection. In criminal cases, the old forms still remain unaltered.

EDINBURGH, the capital of Scotland, and chief town in the county of Mid-Lothian, occupies a picturesque situation on a cluster of eminences, at

a distance of about a mile and a half from the Firth of Forth (q. v.), which is here about six miles in breadth. The outskirts extend almost to the shore, and a connection has thus been formed on the north with Leith, the ancient port; Newhaven, a fishing village; and Granton, a modern and rising port. The admirable position of E. has induced the comparison with Athens, from which, as well as its literary fame, it takes the title 'Modern Athens.' The Gaelic name of the city is 'Dunedin.'

The castle, which crowns the highest point in the city, was undoubtedly built first, a town gradually forming on the top and sides of the ridge, which slopes downwards to the east. For some centuries the city was confined entirely to this ridge or hill, and was flanked on the north by a lake or marsh called the *Nor' Loch*. The remaining means of defence was a wall built by the citizens about the middle of the 15th century, a few relics of which, of different eras, still exist. E. was therefore a fortified town, protected by the castle at its western extremity. When David I. was induced by his piety and munificence to found the Abbey of Holyrood in the low ground eastward of the city, he at the same time empowered the canons of this religious house to found a burgh in a westerly direction towards the city of E., and thus was built the Canongate, afterwards united to the city. The beautiful abbey itself has been a ruin since the fall of its roof in 1768. In connection with the abbey sprung up the palace, which became a favourite abode of the Scottish sovereigns. Not, however, till about the era of the murder of James I. at Perth in 1437, did E. become the recognised capital of the kingdom. Neither Perth nor Scone, Stirling nor Dunfermline, being able to offer to royalty security against the designs of the nobles, E. with its castle was thenceforth selected as the only place of safety for the royal household, the parliament, the mint, and the various important government offices. By this means rising in importance, E. became densely peopled, and the houses were built to an unusual height, that the inhabitants might keep within the walls for the sake of protection. The town then consisted of the original main way called the High Street, reaching to the Canongate, and a parallel way, narrow and confined, on the south, called the Cowgate, connected with each other by upwards of a hundred narrow cross alleys or closes, between dense clusters of houses. Most of these houses consisted of a succession of floors or flats, each being a separate dwelling, and of such floors there were seldom fewer than six, and sometimes ten or twelve towering to an immense height, and rendered still more imposing from being built on an eminence.

The citizens remained content with these confined limits till about the middle of the 18th century. Between 1763 and 1769, the North Bridge was erected, connecting the old city with the fields on the north, on which the *New Town* was beginning to be built. Shortly afterwards, in 1788, the line of this bridge was extended southwards by twenty-two arches (the South Bridge), only one of which is seen where the structure spans the Cowgate, and thus a level way was opened to the southern suburbs, which have since rivalled the new town in rapid growth. George the Fourth's Bridge was erected over the same valley a short distance to the westward, a considerable time afterwards. The *Nor' Loch* was drained and partially bridged over by the Mound formed from the earth dug from the foundations of the new town, and its situation is occupied by fine public and private gardens which now lie in the centre of modern E., and separate Princes Street, the southmost and most picturesque street of the

new town, from the old town. Two other bridges give access to E.—the Regent's Bridge, Waterloo Place, which arches the valley between Princes Street and the Calton Hill to the east; and at the west end, the fine Dean Bridge over the Water of Leith, which is 106 feet high. Quite recently, a very handsome and commodious bridge has been completed by the railway company, near to and parallel with the North Bridge. The new town being built with much regularity in straight streets, and in squares and crescents with numerous gardens, contrasts with the crowded, though picturesque masses of the old town. The dilapidated and dangerous state of part of the old town, and the necessities of sanitary ameliorations in the overcrowded buildings, have occasioned great changes of recent years, and several new streets have been opened up through the most crowded and ruinous localities.

Altogether built of durable sandstone from quarries in the neighbourhood, the general aspect of the houses is that of great solidity. Among the most interesting features of the town are the Castle, in which are shewn the ancient regalia of Scotland; the Parliament House, used by the Scottish parliament before the Union; St Giles's Cathedral, now being restored, with a magnificent crown over the transept; the Abbey and Palace of Holyrood (q. v.); the Bank of Scotland, recently rebuilt; the Scott Monument, designed by a native self-taught artist; Heriot's (q. v.) and Donaldson's (q. v.) Hospitals; the General Register House, where all heritable titles and state documents are recorded and preserved; the Post-office; the Royal Institution, where the Royal Society, and the Society of Antiquaries of Scotland, meet; National Gallery; the University and Museum of Science and Art; the episcopal churches (St John's and St Paul's); and the banks, clubs, insurance offices, and hotels of Princes Street and George Street. The unfinished National Monument on the Calton Hill is striking from its position. A new cathedral, and a spacious new infirmary, are being built. The country round E. is finely varied. From Arthur's Seat and Salisbury Crags, on the south-east, the eye wanders to the Braid Hills on the south, and the richly wooded Corstorphine Hill on the west, all within a mile or two of the town; while further off begin the Pentland Hills, four miles to the south-east; and to the north the Firth of Forth, and the Fife coast and hills, form a magnificent background. The climate is bracing and healthy, although the situation is exposed, not so much rain falling as on the west coast, and high winds are very prevalent.

E. is not an important manufacturing town, though it derives considerable commercial importance from its various banks and insurance offices, round which revolve no mean portion of the monetary capital of Scotland. The principal industries are brewing (two-thirds of all the ale or beer brewed in Scotland being made in or near E.), printing and publishing with the kindred arts (see BOOK-TRADE), distilling, ironfounding, tanning, and coachbuilding, manufacture of articles in india-rubber, of house furniture, and of jewellery, and the rearing of young trees in nurseries in and around the town, for which the climate is favourable.

E. is the place of residence of considerable numbers of the Scottish landed gentry, and its society is regarded as unusually polished from the predominance of the professional and literary elements in its composition. This arises partly from its being a university town, and partly from the presence of the Supreme Law Courts of Scotland (see COLLEGE OF JUSTICE), all the important legal business being attracted thither on that account;

the Edinburgh lawyers have charge of most of the landed estates throughout the northern part of the kingdom, so that there is an unusual number of advocates (barristers), writers to the signet, and solicitors (attorneys and conveyancers) and accountants. Its medical practitioners—surgeons and physicians—have a high reputation. E. is much resorted to for the sake of education, for its University (q. v.) and medical schools, its High School (of which Sir Walter Scott, Lords Brougham and Jeffrey, &c., were pupils), and its numerous private schools. There is also a Free Church Divinity College. The opening in 1869 of the Merchant Company's schools, which (by utilising certain surplus hospital funds) provide high-class instruction at moderate charges for about 5000 male and female pupils, has added to the influx of residents desirous of availing themselves of this boon. For the poorer classes, part of the enormous funds of George Heriot's charity have been diverted for cheaper schools throughout the town. Fettes College is a foundation school on the model of Rugby and Eton, and is a handsome edifice.

E. is largely resorted to by visitors to the Highlands of Scotland, and has an unusual number of hotels. There is a good theatre, and abundance of amusement, including a large open-air gymnasium. In the southern environs are fine open links or downs, where the game of Golf (q. v.) has been played from time immemorial. Excellent street cabs are to be found, and tramways are laid to the suburbs.

E. is the seat of various Scottish Boards (Poor-law Supervision, Lunacy, Fisheries, School, Northern Lighthouses, &c.); in it the Established and Free churches hold their annual assemblies and courts, as do the United Presbyterians.

E. is a royal burgh, governed by a town-council composed of 41 members. The town-council elects from its own body a Lord Provost and six bailies, who constitute the civic magistracy. E. is represented by two members in parliament.

In 1821, the pop. was 112,235; in 1861, it was 167,851; and in 1871, 196,979. Number of inhabited houses, 10,529; parliamentary and municipal constituency, 24,071.

EDINBURGH, THE UNIVERSITY OF, took its rise from a bequest in 1558 by Robert Reid, Bishop of Orkney, of 8000 merks; but the sum was retained for a considerable time by the Abbot of Kinloss. The magistrates of the city, on the faith of receiving the bequest, purchased in 1563 a portion of the ground on which the present university stands. Queen Mary was anxious that the proposed institution should succeed, and bestowed upon it grants of confiscated church property. The university was formally founded by King James VI. in 1582 by royal charter, in virtue of which the corporation, up till 1858, remained its patrons or governors. In 1583 the work of instruction began under Robert Rollock, the first regent. Originally, the university consisted of but one class and one regent or teacher. The regent had charge of the students from their enrolment to their laureaion at the close of the fourth session of study. As the university prospered, additions were made to the staff of regents, and separate chairs for the several branches were founded. In the beginning of the 17th c., the Senatus Academicus consisted of a principal and four regents. The first theological chair was instituted in 1642, and the first professor of medicine was appointed in 1685. After 1688, the university of E., along with its sister universities, was subjected to a parliamentary visitation. The commission was issued in 1690, and till the close of the century the university was under its control. Under this supervision, a separate chair of Greek was established; and after 1708, the present arrangement of

the Faculty of Arts came into existence. About this period, the Faculty of Law was created. During the 18th c., the professoriate rapidly increased; and in 1760, the *Senatus Academicus* contained 18 professors besides the principal. Seventeen chairs have since been added. In 1838, an act of parliament was passed, by which the constitution of the university was materially changed. The government was taken out of the hands of the lord provost, magistrates, and town-council of the city, and placed in the *Senatus Academicus* and a university court; and the patronage of the chairs—from 1582 in possession of the corporation—was transferred to seven curators, three of whom are nominated by the university court, and four by the town-council. A general council was also established, consisting of graduates of the university, and all persons who, up till August 1861, could satisfy the university commissioners that they had given attendance on four complete sessions of the university, two of these sessions being in the course of study in the Faculty of Arts. The members of this body, together with the professors and university court, have the right of voting in the election of a representative in parliament for the universities of Edinburgh and St Andrews.

*Matriculation, Faculties, Degrees.*—Students entering any class in the university, are required to inscribe their names in the General Matriculation Album of the university, which is the legal record of attendance; and the production of the matriculation ticket admits to the Library, and, on certain days, to the Natural History Museum. The university consists of the Faculties of Arts, Medicine, Theology, and Law. The Faculty of Arts comprises the chairs of Humanity, Latin, Greek, Mathematics, Logic and Metaphysics, Moral Philosophy, Natural Philosophy, Rhetoric and Belles Lettres, Universal History, Practical Astronomy, Agriculture, Music, Sanscrit, Engineering, Geology, and Political Economy. Attendance on the first seven of these is incumbent on every one proceeding to the degree of M.A. The Medical Faculty comprises the chairs of Institutes of Medicine, *Materia Medica*, Medical Jurisprudence, Chemistry, Surgery, Practice of Physic, Anatomy, Pathology, Midwifery, Clinical Medicine, Clinical Surgery, Botany, Natural History. The Faculty of Theology comprises the chairs of Divinity, Ecclesiastical History, Biblical Criticism and Antiquities, Hebrew. The Faculty of Law comprises the chairs of Civil Law, Law of Scotland, Conveyancing. The degrees granted by the university are Master of Arts, Bachelor of Medicine, Master of Surgery, Doctor of Medicine, Bachelor of Divinity, Doctor of Divinity, Bachelor of Laws, Doctor of Laws.

*Libraries, Museum, Societies.*—The University Library originated in a bequest, in 1580, by Mr Clement Little. The bequest amounted to about 300 volumes. It enjoyed the right of receiving every book entered in Stationers' Hall, but a composition of £575 per annum in lieu of the privilege was subsequently accepted. The University Library contains about 135,000 printed volumes, and 500 volumes of MSS. The university also contains subsidiary libraries, such as the Theological Library, the Humanity Class Library, &c. The Natural History Museum was established in 1812, and received a government grant of £200 per annum. It was in 1854 transferred to the new Museum of Science and Art, where it forms a Natural History Department, of which the Professor of Natural History is the *Regius* keeper. The Anatomical Museum was founded by the town-council and the *Senatus Academicus* in 1826. The Botanical Museum is stationed in the Botanic Garden, which

is in connection with the university, and several valuable museums exist as appendages to classes. There are several societies in connection with the university, which meet in its buildings during the winter session.

*Bursaries.*—There are from 106 to 108 bursaries and prizes connected with the university of E., and the total yearly amount of these may be estimated at from £1800 to £1900. These bursaries are appropriated to the different Faculties, and are in the patronage of the *Senatus*, the town-council, and of private individuals. Their yearly values range from £5 to £90, and they are generally held for a period of four years.

*Scholarships and Fellowships.*—There have been recently instituted about 23 scholarships, of the value of from £30 to £100, and seven fellowships, from £100 to £160 per annum.

*Students.*—The number of students has of late been steadily increasing, and in 1872—1873 reached the large number of 1875. The present buildings are now found insufficient for so great an attendance, and it is contemplated removing the Medical Department to new buildings, which are to be erected in the immediate neighbourhood of the New Royal Infirmary.

EDINBURGH REVIEW, the first of the great critical periodicals which form a distinguishing feature of the literature of the 19th century. It was started in October 1802 by a knot of young men living in the northern metropolis, the principal of whom were Francis Jeffrey (q. v.), Sidney Smith (q. v.), F. Horner, and Henry Brougham (q. v.). So much was secrecy felt or believed to be necessary to the success of the undertaking, that, according to the account which Lord Jeffrey gave to Mr Robert Chambers in 1846, 'the dark divans' of the reviewers were held for some time 'in a dingy room of Willison's printing-office in Craig's Close,' to which each repaired alone, and 'by back approaches or different lanes.' Of the first number, 750 copies were printed; the demand exceeded this limited supply; 750 more were thrown off, and successive editions followed. In 1808, the circulation had risen to about 9000, and it is believed to have reached its maximum—from which it has declined—in 1813, when 12,000 or 13,000 copies were printed. The pay of contributors was at first ten guineas a sheet, but shortly after 'the *minimum*,' says Jeffrey, 'was raised to sixteen guineas, at which it remained during my reign. Two-thirds of the articles were, however, paid much higher, averaging, I should think, from twenty to twenty-five guineas a sheet on the whole number.' The original publisher was the well-known Constable. The political views advocated in the early pages of the *Edinburgh Review* were *Whig*, and to these it has consistently adhered to the present day. Its influence in developing and strengthening the political convictions of the Whig party cannot be over-estimated; but its power was even more visible, certainly more immediately palpable, in literature. Amid the feeble and effete periodicals of the day, it burst like a bombshell. The keenness of criticism, the sharpness of wit, the brilliancy of style, the vigour of mind and comprehensiveness of knowledge exhibited by the writers, excited amazement and fear in the world of letters; and although, in the case of Wordsworth, Southey, and other writers of a certain school, unfairness of a flagrant kind was undoubtedly exhibited and persevered in, yet impartial justice was, on the whole, administered, and the rising generation of authors strained their utmost to escape the lash. Since the period of Jeffrey, the most brilliant contributor to the *Edinburgh Review* was the late Lord Macaulay.

**EDINBURGHSHIRE**, or **MID-LOTHIAN**, the metropolitan county of Scotland, lying on the south side of the Firth of Forth. Its greatest length from east to west is 36 miles, and its breadth 18 miles, with an area of 397 square miles. From the south border, the Pentland Hills (mean height 1000 feet, and highest point 1839 feet) and the Moorfoot Hills (mean height 800 feet, and highest point 2136 feet) run north-east through the county. In the north are fertile plains, varied by gentle slopes, ridges, and hills of trap. The coast, 13 miles long, is partly sandy, and is studded with towns, villages, and piers. The chief rivers are not above 20 miles long, and are the Esk, Leith Water, Almond Water, and Gala Water. Four great roads and five great railways traverse the county. E. chiefly consists of carboniferous strata, with protrusions of trap. Some lower Silurian rocks occur in the south-east. Coal and iron are chiefly worked in the broad valley of the Esk. Here the bed of coal extends 15 by 8 miles, and contains 33 seams  $\frac{3}{4}$  of a foot to 6 feet thick. The fine sandstone quarries of Craighleith contain large fossil trees, and the limestone of Bardicoune is famed for fossil fishes. Cold and dry east winds prevail in spring. Clay-soil predominates. The county is chiefly agricultural, with large farms. The harvest is a week earlier on the coast than at the height of 200 feet, and a fortnight earlier than at the height of 600 feet. Near the metropolis are extensive nurseries, vegetable and fruit gardens, and dairy pastures. In 1857, two-fifths of the county was in crop, the chief crops being oats, turnips, barley, wheat, beans, pease, and potatoes. Pop. (1861) 273,869. In 1851, E. had 259,435 inhabitants; 230 places of worship (66 Established, 49 Free, 40 United Presbyterian); 399 day-schools, with 37,274 scholars. E. returns one member to parliament for the county. It contains 44 parishes. The chief towns are Edinburgh, the metropolis of Scotland; Leith, its seaport; Dalkeith, Musselburgh, and Portobello. In E. have been found cairns, stone circles, Roman coins and utensils, and traces of Roman camps and burying-places. E. was included in the Roman province Valentia, and Cramond is supposed to have been a chief Roman port. It afterwards formed part of the kingdom of Northumbria, 446—1020, the Anglo-Saxons from the north of England coming to settle here. The county contains many feudal and ecclesiastical remains, as Borthwick Castle, Craigmillar Castle, and Roslin Chapel. (1871—pop. 328,335.)

**EDISTO**, a river of South Carolina, flows through the south-west part of the state, being formed near Branchville of the North Edisto and the South Edisto, and entering the Atlantic by two arms respectively named from the two confluents. Edisto also designates the island which separates those two arms. The stream is navigable for 100 miles upwards, and its mouth is about 20 miles to the south-west of Charleston.

**EDMONSTONE ISLAND**, an outpost, as it were, of the Delta of the Ganges towards the Bay of Bengal, is situated at the mouth of the Hoogly, the most westerly arm of the great river above mentioned. It is the arena of a continuous conflict between the fluvial currents and the oceanic tides. From being merely a sand-bank, it came, not many years ago, to be covered with shrubs, and even to yield a supply of fresh water. After having been adopted, under this new phase, as a marine station, it has since then been abandoned, in consequence of the encroachments of the sea. E. I. is in lat. 21° 32' N., and long. 88° 20' E.

**EDMONTON**, a large village in the north-east of Middlesex, near the Kerr, 7 miles north-north-

east of London. Pop. of parish (1861) 10,919. It contains many villas of London merchants, &c. Charles Lamb is buried in the churchyard here. E. is connected with Cowper's humorous poem of *John Gilpin*.

**EDMUND IRONSIDE**, king of the Anglo-Saxons, son of Ethelred II., and half-brother of Edward the Confessor, was born in 989. He calls for notice chiefly as the great opponent of Canute and the Danish party. On the death of Ethelred, the Danes proclaimed Canute king of England; but the citizens of London declared for E., who drew together his forces, and engaged Canute, first at Pen, in Dorsetshire (or, as other accounts say, at Gillingham, in Somersetshire), then at Sceaestan, and again at Ottenford, or Otford, in Kent, in all of which battles he was victorious; but a severe defeat which he sustained at Assandun, in Essex, compelled him to a compromise with his adversaries. An arrangement was entered into by which England was divided between the two kings, Canute obtaining possession of Mercia and Northumbria, the rest falling to the share of Edmund. It was also agreed that on the death of either, the survivor was to succeed him. E. having died a few weeks after this agreement had been drawn up, Canute became king of all England. E. received the surname of *Ironsides*, either from his great strength or from the colour of his armour.

**EDMUND'S (St) HALL**, Oxford, derives its name from St Edmund, Archbishop of Canterbury in the reign of Henry III. As early as 1269, it appears to have been purchased by the canons of Osney, and devoted to purposes of education. On the dissolution of religious houses under Henry VIII., it fell into the hands of two citizens of Oxford, who sold it to William Denyse, provost of Queen's College. The provost devised it to his college, and that society accordingly now nominates the principal of St Edmund's Hall. There are ten exhibitions attached to the hall, value £30 per annum, appropriated to students designed for holy orders, and in the gift of the principal. In 1860, there were about seventy names on the books.

**EDOM** (New Testament, *IDUMEA*), a word signifying 'red.' It was, according to Gen. xxv. 29—34, the name given to Esau on account of the red pottage supplied to him by his brother Jacob. Hence, the country which Esau afterwards obtained was called the land of Edom, but previously Mount Seir. The ruddy hue of the mountain-range, however, may have had something to do with the naming of the region. E. comprised a strip of country 100 miles long by 20 broad, lying between the south of Palestine and the Gulf of Akabah (an arm of the Red Sea). It is a wild, mountainous region, with the desert on the east and west of it; but rugged though it looks, it contains rich glens and terraces, where flowers, and shrubs, and trees spring up luxuriantly. Its capital was Bozrah (now Buseirah), in the extreme north; its seaports were Elath and Eziongaber, in the extreme south, at the head of the Gulf of Akabah. During the reigns of David and Solomon, E. appears to have been under subjection to the Israelites; but when the kingdom of Israel began to decline, the Edomites repeatedly ravaged the southern borders of Palestine, which circumstance is perhaps the reason why they are so terribly denounced by some of the prophets. At a later period, the term Edom (now giving way to the Greek form *Idumæa*) designated the region between the Gulf of Akabah and the Mediterranean, including a part of the south of Palestine. The revival of Jewish power under the Maccabean princes once more brought

Idumæa under Jewish sway. The people were compelled to conform to the laws and customs of their conquerors, and the country was for the future ruled by Jewish prefects, one of whom, called Antipater, who was born in the country, acquired the friendship of the Roman emperor, and was appointed procurator of all Judæa. His son was the famous Herod the Great, 'king of the Jews.' In the 7th c. A. D., E. was overrun by the Arabs, and has ever since shared the fortunes of Arabia.

**EDRIOPHTHALMA** (Gr. sessile-eyed), a section of the class of Crustaceans, consisting of those *malacostracous* crustaceans which have the eyes sessile—not mounted upon stalks. They also differ from the other malacostraca in having the organs of respiration connected with the organs of locomotion; some of them, which constitute the two orders *Amphipoda* and *Levmodipoda*, having the respiratory organs connected only with the true or thoracic legs, whilst in the remaining order, *Isopoda*, they are connected only with the abdominal or false legs. The E. are generally marine; many of the

Edriophthalma:

1, *Caprella phasma*; 2, *Cyamus Balanarius*.

*Amphipoda*, however, are inhabitants of fresh water; some of the *Isopoda*—as the armadillo and woodlouse—are terrestrial, but are inhabitants of damp places. Many both of the marine and fresh-water species spend their lives rather among the weeds and decaying matters of the shore than in the water, to consume these being apparently their office in the system of nature; some have organs adapted for leaping and for burrowing in the sand, as the common Sandhopper (*Talitrus locusta*), one of the *Amphipoda*, of which countless myriads are to be seen on all our sandy shores, attracting the admiration even of the most careless; some burrow in more solid substances, as the *Limnoria terebrans*, one of the marine *Isopoda*, which too frequently effects the destruction of piers, dock-gates, &c., perforating them in every direction. Many of the E. are parasitic, some of them on whales, some even on prawns and other crustaceans. Some of the parasitic E. are destitute both of eyes and antennæ.

**EDRISI**, **ABU ABDALLAH MOHAMMAD BNU ABDALLAH BNU EDRIS**, **AL-HAMUDI**, **SHERIF**, also called **AL-EDRISI**, **AL-SIKILI** (**SICILIAN**), or **AL-RODJARI** (**ROGEE'S**), one of the most eminent Arabic geographers, and a descendant of the royal family of the Edrisites—who traced their origin to Mohammed himself—was born at Ceuta or Sibta (Civitas) in the year 1099. He studied at Cordova, and early distinguished himself by the extraordinary range and versatility of his talents. He excelled in nearly all the then known branches of science and art; but it was geography which at a very early age seems more than any other science to have attracted him.

Having completed his studies, he travelled and visited Constantinople, Asia Minor, Egypt, Morocco, Andalusia, and the coasts of France and England. Roger II., king of Sicily, invited him, on his return, to his court, and lavished upon him all the honours which it was in his power to bestow. A favourite wish of this monarch—one of the most refined and liberal-minded men of his age—had long been to have a representation of the earth, founded on the most recent observations. He accordingly invited travellers from all parts of the world to assist him by sending their itineraries, their measurements of longitudes and latitudes, their observations and adventures—in short, all they had seen or heard on their journeys. The collection of this material occupied fifteen years, at the end of which it was handed over to Edrisi. Thus guided, he drew up a map, on a globe of pure silver, weighing 450 Roman pounds (50,400 drachmas), in which the whole of the then known world was represented. He, like Ptolemy, divided it into seven climates, beginning at the equinoctial line, and continuing northwards to the limits of extreme cold, and intersected each of these with eleven 'regions,' represented by perpendicular lines, without any regard to the political or physical features of the respective countries. In explanation of this map, he wrote a book (1153), *Nuzhat al-Moshtak*, &c., in which a full account is given of the towns, mountains, rivers, &c., proceeding from west to east, according to the order of the climates. Careful as he was in observing and collecting, he could not, in the then state of society and communication, but fall occasionally into serious blunders; but on the whole his statements are peculiarly trustworthy; and being the clearest and most reliable exposition of the state of geographical knowledge in those days, the book remained the great and sole authority down to the time of the Portuguese discoveries. An extract of it was first edited at Rome in 1592, in Arabic, entitled *Nubian Geography*, and reprinted in the monastery of Khesruan, in the Lebanon, with Syriac characters, in 1597—both editions incorrect in the highest degree. The very title was a mistake, the editors having, by a misinterpretation of a passage, been led to believe that E. was a Nubian. Bernardino Baldi translated this extract into Italian in 1600, but his translation was never published. The first published translation was a Latin one, made in Paris (1619) by Gabriel Sionita and Johannes Esromita, a work teeming with the most absurd blunders; and Domenico Maeri translated this Latin translation into Italian. Rosario Gregorio's Latin version of the portion referring to Sicily was published with the text in a collection of Tardia in 1790. Hartmann wrote an excellent Latin commentary on the portion treating on Africa (Göttingen, 1791 and 1796), and another on the first three chapters of Spain (Marburg, 1802—1803). The entire description of Spain was published with a translation by J. Antonie Condé (Madrid, 1799).

The translation of E.'s whole work, in French, was made from two MSS. in the Imperial Library, by Jaubert, and published (Paris, 1830 and 1840), but it is unfortunately not sufficiently faithful. The full text has never been edited.

We shall only add that the incidents of E.'s life have given rise to interminable discussions. The year and place of his death, as also his creed, whether Mohammedan or Christian, still remain vexed questions. Chief authorities regarding E. are Hadji Kalifah, Schnurrer, De Sacy, Slane, Quatremère, Reinaud, Amari, &c.

**EDUCATION** is an art, the art, namely, of drawing out (*Lat. educere*) or developing the faculties—of training human beings for the functions for

which they are destined. Now, in order to the perfection of an art, it must be founded on a corresponding science; and of nothing is this more true than of education. Before we can hope to mould a human being in a desired way, the nature of that being must be well known. The knowledge of man's nature is usually comprehended under three divisions: the constitution of his body (physiology); the constitution of his mind (psychology); his moral and religious nature (ethics and religion). If we suppose these branches of knowledge thoroughly investigated, they would furnish the solution of the two main points on which all questions of education turn: first—What are the dispositions and acquirements which it is most desirable to implant and foster? in other words, What is the end or aim that the educator ought to pursue? and second—What are the best means to attain that end? But the sciences above named are themselves in too imperfect and unsettled a state to be the basis of any theoretical plan that would be generally accepted; for our knowledge of living beings, and still more of moral beings, must, as is now well understood, be the last to acquire the shape and certainty of science. See SCIENCE. It is needless, therefore, to look as yet for any complete theory or *philosophy of education*. Education has existed as an art from the very infancy of society, but it is as yet mostly an empirical art, the rules and methods of which have been arrived at by the blind groping of experience—by the process of trial and error. The art of education is still in the condition in which the art of agriculture was until the present century, when, by the aid of chemistry and vegetable physiology, then arriving at something like perfection, a scientific foundation was laid for it by Liebig and others. Even were the sciences of physiology, psychology, and ethics, on a more satisfactory footing, they would not be immediately serviceable as a foundation for a theory of education, without a preliminary step. This would consist in deducing from them an intermediate science, embodying the *laws of the formation of character*. According to J. S. Mill, it is a body of doctrine of this nature, to which he proposes to give the name of Ethology (Gr. *ethos*, habit, custom), that would properly be 'the science of which education is the art.' But so far is such a science from being yet constructed, that it is only lately that the necessity for it has been pointed out. Notwithstanding this lack of scientific foundation, the practical art of education has, in recent times, undergone great improvement in almost all its details. It is chiefly in discussions on the subject that the want of fixed scientific principles makes itself felt. A debate on any topic connected with education usually presents little but a hopeless chaos of conflicting opinions, the most inconsistent arguments being often urged in favour of the same view. What renders the confusion greater, education is a subject on which every one thinks himself or herself capable of pronouncing an opinion. But this is only another indication of the want of fixed scientific principles. No one presumes to meddle with a question of astronomy or of chemistry unless he has made it the study of a life. In like manner, it is to be hoped that, in proportion as we advance to a philosophy of education, there will be fewer who will take upon themselves to settle off-hand the most difficult questions regarding it.

In the present article, we can do little more than notice the chief divisions into which the subject of education naturally falls, together with the leading questions that give rise to differences of opinion.

*Definition.*—It is necessary at the outset to limit the application of the term education. In the widest

sense of the word, a man is educated, either for good or evil, by everything that he experiences from his cradle to his grave. But in the more limited and usual sense, the term education is confined to the efforts made, of set purpose, to train men in a particular way—the efforts of the grown up part of a community to inform the intellect and mould the character of the young; and more especially to the labours of professional educators, or schoolmasters. It is evident, however, that school education cannot be understood or practised rightly except by those who have mastered the idea of education in its widest sense. It is only the educator who can appreciate the influences which have gone before his own, which are running parallel with them, and will come after them, that is in a position to judge of the course to be pursued.

*Moral Training.*—The means employed in education fall naturally under two heads: discipline, or moral training; and instruction, or the imparting of information; although the two often run into each other. Under the head of discipline, come the forming of habits of order, self-control, obedience, civility, love of truth, and reverence for what is good and great. All but the mere outward forms of these is beyond the power of direct teaching; they are imbibed through the silent influence of example. The child instinctively respects and reverences what it sees others respect and reverence; above all, the unselfish affections are called forth only by the breath of affection from without. In this part of the process, it is evident that the school and the professional educator only play a part along with other influences. Nor do they even play the chief part; the home and neighbourhood are here the predominant educators.—We cannot here enter into the vexed question of the teaching of religion in schools; it falls under the head of NATIONAL EDUCATION; as does also the question between voluntary and state schools.

As the process of moral development, through the general surrounding influences, is for the most part unconscious on the part both of those who act and those who are acted upon, it has not yet secured the attention it deserves; in fact, the other branch of the subject, viz., instruction, or intellectual education, being more particularly the business of the schoolmaster, has come in common language to usurp the whole field, so that, by education, we seldom mean more than the imparting of information—instruction.

*Instruction.*—The business of instruction involves two main considerations—1. What to teach? and 2. How to teach it?

1. Of the vast mass of truths composing the sum of human knowledge, which are to be selected as the *encyclopaedia* or curriculum of study for youth? In determining this question, it is to be borne in mind that every truth learned serves two uses—as knowledge to be acted upon, and as mental discipline. In selecting, then, what to teach, we have to consider, not only what is in itself most useful, but also what has the greatest degree of improving effect. On this point, we agree with a recent writer, that 'we may be quite sure that the acquirement of those classes of facts which are most useful for regulating the conduct, involves a mental exercise best fitted for strengthening the faculties.' If this is true, the prominence given to the teaching of the dead languages of Greece and Rome, in modern education generally, is more than questionable. It is not disputed that a course of the classics, well taught and well learned, is a good intellectual discipline; but so is any kind of knowledge, well taught and well learned, a good intellectual discipline—better than more valuable

knowledge imperfectly taught and learned. The question is, whether an equally good culture of the faculties would not be got from a systematic course of equal duration of English and other modern languages, together with logic and moral and physical science. In this case, the subject-matter of the teaching would be an acquisition of great value in after-life to every one, which cannot be said of the other. In the learned professions, no doubt, and for those following literary pursuits, a knowledge of Greek and Latin is of direct use, and will doubtless continue an indispensable element of education; but perhaps three-fourths of those who receive what is called a 'liberal' education, and therefore devote the strength of six or seven years to Greek and Latin, never open a book in these languages from the time they leave school. We are not prepared to maintain that the same effects in the way of discipline have as yet been actually produced, on any great scale at least, by the teaching of science and of modern languages, as result from the drill of the classical schools; but we believe that this arises from the fact, that no such course of instruction has hitherto been pursued with the same system and perseverance which characterize classical schools.

In respect of direct utility, the things most necessary to know, are those that bear most directly—

1. On the preservation of life and health, and the proper performance of the more common industrial labours. This involves a knowledge of our own bodies and of the bodies of which the universe is made up; in other words, more or less of the knowledge which, when put into systematic forms, is known as the sciences of physiology, natural philosophy, and the other physical sciences.

2. A knowledge of our moral relations. Besides a knowledge of the ordinary moral duties, and the high religious sanctions with which they are enforced, this implies some acquaintance with the laws of economy.

3. As a preliminary step, and as the medium through which all other knowledge is conveyed, there is required a knowledge of the mother-tongue, and the faculty of reading and writing it. Allied to language is a knowledge of counting and measuring, and the naming and classifying of the objects of which the world is composed (natural history), together with a knowledge of the countries and places on the earth's surface (geography).

4. The cultivation of the taste and the imagination, or the faculties which derive pleasure from music, painting, sculpture, architecture, poetry, and works of fiction.

Under the head SCIENCE will be given a complete tabular view of the various branches of human knowledge or sciences, together with the corresponding arts or applications. It will there be shewn that there is a natural order of dependency among the fundamental sciences, which determines the order in which the different kinds of facts should be taken up in learning. (An admirable mapping out of the whole field of knowledge in relation to Education, is given by Dr Neil Arnott in his *Survey of Human Progress*. Lond. 1861.)

The different offices and employments characteristic of an advanced state of society, require a corresponding difference in the amount of knowledge and skill possessed by those who are to fill them—a difference which is vaguely and inadequately expressed in the usual division of schools into primary schools, middle or higher schools, and universities.

A course of primary instruction embraces only what is considered absolutely indispensable. Not that there is a limit to the degree of intelligence

that is desirable in any class of the community; but for those who must, from early years, spend most of their time in manual labour, i. e., for the vast majority of the race, there is a very short limit to the degree possible. The grand question here would be to determine the order of desirableness of the different subjects to be taught, so that, beginning with the most indispensable, more and more might be added as circumstances would permit. Until recently, reading, writing, and arithmetic were considered the beginning and end of a course of primary instruction. These, however, are not so much knowledge themselves as instruments for acquiring knowledge; and therefore the primary teacher in the present day considers it his duty to give, in addition, as much information of a directly useful kind as possible. But in avoiding one error, he not unfrequently falls into the opposite; for, after all, the three branches above named are the first and most indispensable steps in instruction. Those who can read and write may acquire information after leaving school. Reading and writing, unless learned at school, are, as a rule, never learned; and thus the grand access to knowledge remains for ever shut. Nor is it enough to have made a beginning in the arts of reading, writing, and counting; unless such a degree of facility is acquired before leaving school as to render the exercise a pleasure, it is not kept up in after-life, and the little that was learned is soon forgotten. We believe that in all schools, but especially where the children are liable to be early withdrawn, everything else ought to be held secondary until the painful stage in learning to read, write, and count is fairly got over. With regard to the positive knowledge hitherto got in primary schools, there is a general feeling that few teachers succeed in giving it a direct bearing on the actual concerns of life. Hence the aversion expressed in many quarters to the introduction of the 'ologies' into common schools, and the rather vague demand for the teaching of 'common things.'

Middle or secondary schools either serve for those who have leisure for a higher degree of culture than the elementary course above described, or they serve as nurseries for the highest kind of educational institutions, viz., the universities. Under the head of secondary schools may be ranged the institutions that go by the names of high schools, academies, grammar-schools (the *gymnasiums* of Germany, and the *colleges* of France). In these, the course of instruction usually embraces other languages besides the mother-tongue, and more or less of the elements of the various sciences. The titles of a series of text-books, such as those composing Chambers's *Educational Course*, give a notion of the great variety of subjects that are considered requisite in middle-class education. Much yet remains to be done to chalk out a judicious course of middle-class instruction—sufficiently wide to be a foundation for after-acquisitions, and yet not so multifarious and detailed as to be impossible to overtake except as ill-digested eram.—Where preparation for the university is the object, Greek and Latin are the chief subjects of attention.

The highest degree of culture is represented by the Universities (q. v.).

*Special or Technical Education.*—Up to a certain point, the education of all young persons is, or ought to be, substantially the same; for the end in all cases is to train them up to be intelligent, virtuous, and active men and women, capable of turning their talents to account in whatever situation they may be placed. But in all civilised societies, the duties and employments are so diverse, that the members must begin betimes to receive special training, according to their future destination. This special

training is either of an intellectual or a mechanical kind, or it may partake of both. This branching off of education into special tracks is conspicuous in the higher education given in universities, where from the very first there have been—besides the Faculty, as it is called, of Philosophy, including a number of branches of a general nature—special departments or faculties of Law, Medicine, and Theology. But besides these ‘professions,’ as they are styled, a number of branches of industry have in recent times, by the application of scientific processes, and from other causes, risen into a condition which requires, at least for those who are to direct them, a special range of instruction and information; such are engineering, mining, chemistry applied to the arts (technology), for which special schools are now established in most centres of industry. There are two ‘specialties’ which, from the immense numbers engaged in them, assume unwonted importance—namely, Agriculture (see AGRICULTURAL SCHOOLS), and Commerce. So prominent a place does commerce hold in this country, that any school which is above an elementary school, and at the same time not a classical school, usually gets the name of commercial. The chief points in a special education for the mercantile life are usually held to be, facility in writing and calculating, and a knowledge of book-keeping. What would seem to be the most essential part of a mercantile education, is usually neglected—the principles, namely, of political economy—the science of wealth.

*Industrial Education.*—The acquiring of mechanical skill for a particular handicraft or occupation—in other words, apprenticeship—is, properly speaking, a part of education; but as it is not usually begun until the school education is considered finished, it hardly falls within our province. Yet the abrupt separation of these two stages is attended with evils that are beginning to make themselves felt. For, first, the poorer classes, either from necessity or cupidity, are induced to withdraw their children from school as soon as their labour can be turned to any account; so that, in the language of one of Her Majesty’s Inspectors of Schools, ‘in that branch of the population to which public measures apply, all education ceases before the age of twelve, and more commonly at nine years of age.’ When to this is added the irregular attendance even during the few years that they are nominally at school—from three to four days a week is the average—the result is, that this class remain virtually uneducated; comparatively few have got over the initial mechanical difficulties of reading and writing, so as to keep up the habit in after-life, and thus they soon lose the little acquirements they had made.

On the other hand, to continue the intellectual and moral education of youth up to the age of fourteen or sixteen, as is the common practice among the middle classes, and among the well-to-do of the artisan class, and then abruptly to break this off, and begin at once an industrial occupation on the full time of an adult who has been used to the work, is, on the face of it, an irrational way of proceeding. The power of applying steadily, day after day, to one occupation, is the hardest lesson for man to learn; it is that which, more perhaps than anything else, distinguishes civilised man from savage and semi-barbarous man; and as the boy is ‘the barbarian of the civilised community,’ this aversion to steady industry is yet strong in him. It is surely wise, then, to break him into it gradually; to begin, while yet his school education is going on, by short exercises of his industrial faculties at first, and gradually increase the daily hours of work as his physical strength and powers of will become hardened. We believe that many a youth who, on the

usual system, breaks down at the very commencement of his industrial career, runs away from his apprenticeship, and becomes instead, idle, perhaps a scamp, for life, might, by a gradual initiation, have become an industrious man and good member of society. So far, again, would this plan be from infringing upon the usual education given at school, that it is only in some such way that, in a country like ours, the school education of those who have to earn their own bread can be prolonged to the age necessary for learning much that every member of the community should know.

Theoretically, we believe it to be indisputable, that school education and industrial training ought, for some time at least, to be conjoined. How to make them dovetail into one another in practice, is one of the chief educational problems of the day. One step towards it has been made in the *half-time system* enforced by act of parliament with regard to children employed in factories. Children may be employed as early as the age of eight years, but the mill-hours of all between the ages of eight and thirteen are limited to six hours and a half daily; nor can they be employed even for that length of time but on condition of receiving three hours’ schooling daily. Experience has established the fact, that in proportion to the hours spent in school, these ‘half-timers’ learn much quicker, and make more rapid progress, than the whole-day scholars; at the same time, whether they are destined to be factory-workers for life or not, they are acquiring habits of industry and manual dexterity which are of essential use in any future employment.

Industrial training is now conjoined, to a greater or less extent, with school-teaching in almost all institutions for the education of pauper children—parochial union schools, ragged schools, as well as in professedly industrial schools. See INDUSTRIAL SCHOOLS, RAGGED SCHOOLS, REFORMATORIES. The chief difficulty in this movement is to find fitting work. And here it may be observed, that the object is not to teach particular trades with a view to the boys following these in after-life; this, though it were desirable, would obviously be impracticable as a general system. The object is, to promote the health, to develop the strength of the muscles, and give them pliancy and general docility, and to induce habits of steady and patient endurance of work.

The industrial training of girls is of yet more urgent necessity than that of boys. The ordinary domestic operations involved in household management ought naturally to be learned at home under the guidance and example of the mother; and the object at school, in a right and normal state of things, would be to initiate the girls in things, in the way of improvements, that their several homes might not exhibit—to insure progress, in short. But unhappily, in the homes of the great mass of the operative population of these islands, the mother is at present quite unfit for this primary duty. The extension of the factory system of work, instead of the domestic, has revolutionised the domestic life of a great part of the operative population, and with our *laissez-faire* policy in education, we have allowed a generation to spring up, in which a great part of the married women have lost whatever traditional housewifery their mothers might have had, and can neither cook, wash, nor sew. The consequence is, that the food of the household is unsavoury, indigestible, unwholesome, and at the same time unthrifty; while the whole *ménage* has that character of untidiness and discomfort that often drives the husband to the pot-house. For girls of this class, there is needed a training in some public institution in the very elements of

housewifery; while, for all classes, there is great need for instruction in a better style of cookery than that generally prevalent. Among the 'common things' taught to all girls ought to be, how to spend a given weekly income on a given household to the greatest advantage. See DOMESTIC MANAGEMENT.

2. 'How to teach it.'—It is a great error to suppose, that because a man knows a thing, he can therefore teach it. Teaching is one of the most difficult arts, and requires natural aptitude and acquired skill. The necessity of special study and practical training or apprenticeship to make a schoolmaster, is a discovery of recent date, and has given rise to teachers' seminaries or Normal Schools (q. v.), where they receive special instruction in the most approved methods of teaching, and practice in their application. It is to the greater acquaintance with right methods, on the part of schoolmasters, that we are to look for the solution of one of the greatest difficulties—how, namely, to overtake all the work that is necessary to be done in the school-period of life, without keeping the learners too many hours a day at their tasks. As things are usually managed, very little of the time devoted to lessons is spent in actually learning anything whatever; as any one may satisfy himself by calling to mind how his own time was spent while seated on the school-benches. There is here a rich mine waiting to be worked—the gold-fields of future generations. It is not to be disputed, that three hours of hearty, spirited exertion will do more, in the way of learning, than is accomplished in six hours in most schools. The three hours thus set free would be clear gain; for time spent in trifling or in heartless fagging is utterly lost. The child is all the while plagued without being profited, and would be better employed in being happy in his own way. This matter of the happiness of the young has not yet received the attention it deserves in schemes of education. As Sidney Smith has well expressed it, 'if you make them happy now, you make them happy twenty years hence, by the memory of it;' so that while looking after the formation of other valuable habits, the educator must not overlook the habit of happiness.

Increased economy of time in teaching, besides setting free sufficient time for play, would admit the more general introduction into school education of military drill (including gymnastics). This, in addition to its immediate purpose (see VOLUNTEERS), would be a most valuable aid in moral education, by promoting habits of prompt obedience, order, and politeness. On this subject, see *Communications from Edwin Chadwick, Esq., respecting Half-time and Military and Naval Drill*, made to the Education Commission, and printed among parliamentary papers. 1861.

For further information on the subject of this article, see, in addition to the references already given, the heads INFANT SCHOOLS, EVENING SCHOOLS, LANCASTERIAN and MADRAS SYSTEMS, PESTALOZZI, HAMILTONIAN SYSTEM, &c.

EDUCATION, MILITARY, is now superintended, so far as concerns regimental schools, by a particular department of the War Office. In this sense, it does not really mean military education, but schooling of a humble kind supplied to soldiers and their children. In its proper sense, the term relates to the professional training of those destined to be officers in the army. This is not to so great a degree under government control in England as in continental countries. See ARTILLERY, SCHOOLS OF; CADETS' COLLEGE; CROYDON (Addiscombe); DUKE OF YORK'S SCHOOL; MILITARY SCHOOLS; REGIMENTAL SCHOOLS; SANDHURST; STAFF COLLEGE.

EDUR, a Rajpnt state of Guzerat, is tributary to the Guicowar, being, in common with his immediate dominions, subject to the political superintendence of the presidency of Bombay. With a revenue of nearly £25,000, it maintains a force of about 1000 men. Its capital, of the same name, containing about 10,000 inhabitants, is in lat. 23° 50' N., and long. 73° 3' E.

EDWARD THE CONFESSOR, king of the Anglo-Saxons, was born at Islip, in Oxfordshire, about the year 1004. On the death of his father, Ethelred, in 1016, Canute the Dane obtained possession of the throne, and in the following year married Emma, the mother of Edward, by whom he had two sons, Harold and Hardicanute. Until the death of Canute in 1035, E. lived in Normandy; he then made an ineffectual attempt to establish his authority in England; but his mother Emma had now transferred her affections to her younger children; and she exerted all her influence and energy in favour of Hardicanute, who, on the death of his brother Harold in 1040, became sole ruler of the Anglo-Saxon kingdom. Hardicanute, however, was generous enough to invite his half-brother to England, whither accordingly E. went, and was honourably received. On the death of Hardicanute in 1042, E. was declared king. The person chiefly instrumental in bringing about this result was Earl Godwin, whose only daughter, Editha, was married to the king in 1044. The lady only became his queen, not the partner of his bed. For this revolting asceticism, the honour (if it be such) of canonisation, and the title of Confessor, was conferred on him, about one hundred years after his death, by Pope Alexander III. Scrupulous as E. was in regard to one of the passions, he had no repugnance to gratify another of a far less justifiable kind. His first act after his accession, was to deprive his mother of all her treasures—lifting even the cattle and corn from her fields, and, according to some accounts, endeavouring to compass her death. The whole of E.'s reign is simply the record of the growth and struggles of the Norman or court party with the national or Anglo-Saxon party; for an account of which see articles GODWIN and HAROLD. E.'s wars with the Welsh in 1057 and 1063, and with the Northumbrians in 1065, were short and successful. He died 5th January 1066, and was succeeded by Harold, son of Earl Godwin. The prosperity which England enjoyed during the reign of E. was owing to its not being exposed to the wasteful calamities of foreign invasion, while its free intercourse with France, or at least with Normandy, greatly civilised and refined the somewhat Boeotian habits and manners of its inhabitants.

EDWARD I., king of England, was the eldest son of Henry III. by his wife Eleanor, daughter of Raymond, Count of Provence, and was born at Westminster, June 16, 1239. That union of valour and intelligence which characterised him was exhibited at an early period. At the commencement of the struggle between Henry and his barons, Prince E., who was then governor of the duchy of Guienne, came over to England, and boldly declared his dissatisfaction with his father's conduct. Subsequently, he took the king's side in the war, and by his vigorous generalship put an end to the insurrection in a few years, but there is no evidence to shew that he had changed his opinion of Henry's policy; and it is remarkable that he himself, during the whole of his reign, carefully avoided coming into collision with his nobles. When the last of the Crusades was organised, at the instigation of Pope Gregory X., Prince E.

arranged with Louis, king of France, to take part in it. Louis died before reaching Palestine, but the former landed at Acre in 1271. Nothing, however, of any consequence was achieved; and in the following year he set out on his return to England. At Messina, he heard of his father's death, whereupon he proceeded to France, and did homage to Philippe III. for his French possessions, arriving in England 25th July 1274. He and his queen, Eleanor, were crowned at Westminster on the 19th of August following. His first military expedition, after his accession to the throne, was directed against the Welsh. After a contest of nearly ten years—in the course of which the famous Prince Llewellyn was slain at Llanfair, 11th December 1282—Wales was finally subdued and incorporated with England. His next ambition was to possess himself of Scotland. The death, in 1290, of Margaret, granddaughter of Alexander III., and known as the Maiden of Norway, who was to have been married to E.'s son, seemed to have frustrated his design; but the selfishness of the ten competitors for the Scottish crown who now appeared, induced them to acknowledge E. as *Lord Paramount* of Scotland, each hoping that he would thereby secure the English monarch's support. The competitors were also foolish enough to make him umpire among them, or perhaps it would be more correct to say, they were not powerful enough to refuse his arbitration. Be that as it may, E. decided in favour of John Baliol at Berwick, 17th November 1292; and Baliol immediately took the oath of fealty to him; and on the 26th of December did homage to the English king for his crown at Newcastle. The patriotism and pride of the Scottish nation took fire at such humiliation, and in a short time Baliol was hurried by his subjects into a war with England. In 1296, E. entered Scotland, devastating it with fire and sword. He penetrated as far north as Elgin, compelled Baliol to resign the kingdom, and governed the country by means of his own officers. It was during this expedition that he carried off from the cathedral of Scone the celebrated stone on which the kings of Scotland used to be crowned, and which is now in Westminster Abbey. A second rising took place in Scotland in the following summer. The leader on this occasion was William Wallace (q. v.), whom tradition represents as the most heroic and unselfish of patriots. He was completely successful for a time, chiefly it is to be supposed on account of the absence of Edward. In the spring of 1298, however, that sovereign again made his appearance in Scotland, and gave battle to Wallace at Falkirk, on the 22d of July. Partly through treachery, and partly, no doubt, through the superior generalship of E., who is considered to have been the first military commander of his time in Europe, the Scottish forces were entirely defeated. The next five years were spent by the English king in reducing the country to obedience—with very imperfect success, however. In the summer of 1303, he led a third large army into Scotland, and once more spread havoc and ruin to the shores of the Moray Firth. The last castle that held out against him was Stirling, which did not yield till the 20th of July 1304. E. wintered at Dumfermline. Some time after this, Wallace either fell into his hands, or was betrayed, and on the 23d August 1305, was hanged, drawn, and quartered as a traitor, at Smithfield, in London. E. now probably thought that he had no further danger to dread from Scotland, but if so, he was quickly undeceived. Robert Bruce, Earl of Carrick, grandson of the chief rival of Baliol, suddenly left the English court, where he had been residing, in the beginning of 1306, unfurled once more the

banner of Scottish independence, and on the 27th March of that year was crowned at Scone. An English army, under the Earl of Pembroke, was immediately despatched to Scotland; and at the close of the year, the king himself set out to chastise Bruce. But worn with the 'strife and strife' of many years, the cares of his own kingdom, and the anxieties of conquest, E. only lived to reach Burgh-on-Sands, a village beyond Carlisle, where he expired, 6th July 1307, 'in sight of that country,' says Lord Hailes, 'which he had devoted to destruction.'

E. possessed most of the qualities that go to form a great ruler: valour, prudence, inexhaustible energy, and pertinacity are visible in his whole career. He was ambitious, it is true, but in his age, ambition was looked upon as a virtue rather than as a crime; it was the natural accompaniment of kingly courage. His relations to Scotland were also unfortunate. Few people of any understanding, however, now doubt that the best thing possible for that country would have been a peaceful union with England, for at that time there was no hatred or jealousy between the two nations. The death of the Maiden of Norway destroyed every chance of such a union, and the great mistake committed by E. was his endeavouring to bring about by force what could prove beneficial only when it was the result of voluntary agreement. The effect of his mad endeavour was to plant in the breasts of the two nations the *germs* of a hitherto unknown hostility, which, in subsequent generations, worked incalculable mischief, and the traces of which have not wholly disappeared even at the present day. As a civil ruler, E. is entitled to the highest praise. Immense progress was made during his reign in the establishment and improvement of law and order throughout the land, the reformation of civil abuses, and the restriction of ecclesiastical jurisdiction and encroachments. He has been called the English Justinian; and both Hale and Blackstone affirm, that 'the very scheme and model of the administration of common justice between man and man was entirely settled by this king.' Ireland and Wales participated in the benefits of English law. It was during E.'s reign, too, that the representation of the Commons of England first became regular; but probably the greatest advantage obtained by the nation, was the declaration that the right or privilege of levying taxes resided in the parliament. In general, it may be said that E. ruled in harmony with the ideas and desires of the best heads among his nobles and burgesses; and though touchy on the question of his prerogative, like every Plantagenet, and very cruel in his treatment of the Jews, he must be regarded, on the whole, as one of the most enlightened, liberal, and sagacious monarchs of his age.

EDWARD II., son of the preceding, was born at Caernarvon, in Wales, 25th April 1284, and in 1301 was created Prince of Wales, being the first heir-apparent of the English throne who bore that title. He accompanied his father on his various expeditions into Scotland, and on the death of the latter at Burgh-on-Sands, he led the English army as far north as Cunnock, in Ayrshire, after which he returned to his own country. At home, E.'s conduct was contemptible. While still a youth, he had conceived an extraordinary admiration and fondness for a witty, clever, but dissolute creature called Piers Gaveston, the son of a Gascon knight. After he became king, there was no limit to the honours heaped on the favourite. When he went to France, in the beginning of 1305, to conclude a marriage with Isabella, daughter of Philippe V., king of France, Gaveston was left guardian of the kingdom.

The nobles were indignant, and demanded his banishment. Twice was Gaveston forced to leave England, but as often was he recalled by the weak monarch, whose love for him was sheer infatuation. At last the nobles rose in arms, besieged Gaveston in Scarborough Castle, and having forced him to surrender, hanged him at Warwick, 19th June 1312. Two years after this, E. invaded Scotland at the head of the greatest army ever collected in England—amounting, according to some historians, to 100,000 men. At Bannockburn, on the 24th June 1314, he was encountered by Robert Bruce (q. v.), and defeated with immense slaughter. This victory put Scotland and England on equal terms for all time coming, and made the notion of a military subjugation of the former country by the latter be given up. Finally, in 1319, after numerous petty successes on the part of the Scotch, E. concluded a truce with them for two years. He now exhibited again his imbecile passion for favourites. The person selected on this occasion was Hugh le Despencer. Once more the nobles rebelled, and both Hugh le Despencer and his father were banished in July 1321, but some months after, were recalled by E., and many of the nobles, among others, the Earl of Lancaster, were beheaded in the following year. Immediately after, E. invaded Scotland for the last time, and penetrated as far as Culross, in Fife; but having achieved no particular success, he concluded a truce with that nation for thirteen years, and returned to England. A dispute now arose between him and Charles IV. of France, brother of his wife Isabella, in regard to the territories which he held in that country. Charles seized them, whereupon E. sent over Isabella to remonstrate, and, if possible, to effect an amicable arrangement between them. Isabella, it would appear, despised her husband, and disliked the Despenchers. Meeting at the French court many English nobles who, entertaining similar feelings, had left their country to avoid the enmity of the favourites, she was easily induced to make common cause with them against her husband and the Despenchers. At the same time, she formed a connection of a criminal kind with Roger de Mortimer, one of the most powerful of the exiles. This of course more thoroughly involved her in the plot against Edward; and having obtained possession of the young Prince of Wales, afterwards Edward III., she embarked from Dort, in Holland, with a large body of malcontents, and landed at Orwell in Suffolk, 22d September 1326. The queen and the banished nobles were soon joined by all the influential persons in England. E. fled, but was taken prisoner at Neath Abbey, in Glamorganshire; the Despenchers, father and son, were executed; and the monarch himself, after being formally deposed, 25th January 1327, was murdered in Berkeley Castle, 20th September of the same year. He left two sons and two daughters.

EDWARD III., son of the preceding, was born at Windsor, 13th November 1312, and ascended the throne, 25th January 1327. During his minority, the country was governed nominally by a council of twelve nobles and bishops, but really by Mortimer and his paramour Isabella. On the 24th January 1328, the young king married Philippa, daughter of the Earl of Hainault; and two years after, resolving to take the power into his own hands, he seized Mortimer, and put him to death, 29th November 1330, and banished his mother, Isabella, to her house at Risings (where she lived for twenty-seven years). He next invaded Scotland, to assist Edward Baliol, son of John Baliol, who, in the confusion that ensued on the death of the great Bruce, had made a descent on the country, and got himself crowned at Scone. A bloody battle was fought at

Halidon Hill, near Berwick, 19th July 1333, in which the Scots were completely defeated. Baliol now assumed the authority of a king, and did homage to E. for his possessions, the result of which act was, that he had to flee the kingdom in a few months, for the thing most intolerable to the Scottish spirit was that any monarch should dare, or fancy he had a right, to surrender the independence of his country. In the course of three years, E. thrice invaded Scotland; but though he frightfully wasted the country, and brought armies with him such as could not be successfully opposed, he could not break the invincible spirit of the people, who, after each invasion had rolled over them like a flood, rose and rallied with a still more stubborn and impassioned resolution to be free. But the scene of E.'s great exploits was France. Charles IV. having died without a son, Philippe of Valois, the nearest heir by the male line, ascended the throne, under the title of Philippe VI. E. claimed the crown in right of his mother Isabella, sister of Charles; but as the law of France expressly excluded females from enjoying sovereign rights, it is manifest that E.'s claim was utterly groundless. The English king admitted that his mother, being a female, could not inherit the crown of France, but affirmed that he, as her *son*, might. But it is clear that he could not receive from his mother rights to which she herself had no claim. Yet never was a bad cause ennobled with more splendid triumphs. E. declared war against Philippe in 1337. His first campaign was not very remarkable; but in 1346, accompanied by his eldest son, known as the Black Prince, he again invaded France, conquered a great part of Normandy, marched to the very gates of Paris, and on the 26th August 1346, inflicted a tremendous defeat on the French at Crécy (q. v.). Here the Black Prince, though only sixteen, exhibited the courage and the prowess of a veteran, slaying with his own hand the king of Bohemia, who fought on the side of France. After some further successes, such as the reduction of Calais, a truce was concluded between the two nations for several years. Meanwhile, the Scots had sustained a severe defeat at Neville's Cross, near Durham, their king (David) being taken prisoner. In 1356, the war with France was renewed, and on the 19th September of that year, the Black Prince obtained a brilliant victory at Poitiers, King John of France (Philippe having been dead for some years) falling into his hands. The Scotch monarch was released for a ransom of £100,000 in 1357, and King John in 1360, when a peace was concluded between the French and the English, by which the latter were to retain their conquests. King John, however, finding it not consistent with the honour or desire of his country that such a peace should be carried out, magnanimously returned to captivity, and died in London, 8th April 1364. Shortly before this date, David, king of Scotland, whose residence in England had extinguished the little patriotism he ever had, entered into a secret agreement with E., in virtue of which his kingdom—if he died without male issue—was to be handed over to the English sovereign. Meanwhile, the Black Prince, who had married Joanna, daughter of the Earl of Kent, had received from his father Aquitaine and Gascony, and ruled there for some time very prosperously; but ultimately involving himself and his father in a war with France, which was disastrous in its issues, he was obliged, in 1374, to conclude a truce for three years. E. waged war no more. In spite of his brilliant victories, in spite of the dazzling valour of his son, he was at the last unsuccessful. Neither in Scotland nor in France did he realise his desires. Affairs at home were no

less unsatisfactory in the last years of his life. He quarrelled with his parliaments, and the Black Prince led the opposition. The latter, however, died 8th June 1376, in the 46th year of his age. E. himself expired on the 21st June 1377, after a reign of 51 years. By his wife, Philippa, he had seven sons and five daughters, several of whom died young. He was succeeded by his grandson Richard, son of the Black Prince, who ascended the throne as Richard II.—The reign of E. was marked by the great progress made in law—a greater number of important new laws being passed than in all the preceding reigns since the Conquest. Among these laws were several indicating the increasing repugnance of Englishmen to ecclesiastical, and especially to papal jurisdiction. Trial by jury also now began to supersede other modes of trial. Justices of peace likewise make their earliest appearance in this reign, and legal proceedings were ordered to be carried on henceforth in English, and not in French. Sir James Mackintosh is of opinion, that though E.'s victories left few lasting acquisitions, yet they surrounded the name of his country with a lustre which produced strength and safety—an opinion which appears, on the whole, to be well founded. It remains to be said that E.'s reign witnessed the culmination of chivalry, and in the Black Prince, possessed a splendid example of its virtues and its vices. The fine arts, especially architecture and poetry, also attained a grand development. Chaucer, Gower, and several eminent chroniclers, flourished at this time, and in the sphere of religious reform stands out the noble and thoroughly English figure of Wickliffe.

EDWARD IV., son of Richard Duke of York, and great-grandson of Edmund Duke of York, who was the 5th son of Edward III., was born at Rouen, 29th April 1441 (or, according to another account, in September 1442). His original title was that of Earl of March. It would be quite impossible, in the short space at our disposal, to clear our way through the jungle of family relations by which Richard Duke of York, the father of Edward IV., traced his right to the throne. Suffice it to say, that in 1460 the bloody struggle between the *Yorkists* (the party headed by Richard Duke of York, who at first professed only a desire to remove from the king, Henry VI., his pernicious councillors) and the *Lancastrians* (the party of the sovereign) ceased for a moment. The Yorkists, on the whole, had been victorious on the battle-field, and their leader contrived to induce parliament to appoint him Henry's successor. Shortly after, however, Henry's wife—the brave Queen Margaret—raised an army in the north, and on the 31st December 1460, encountered and overthrew York on Wakefield Green, the duke himself being slain. But this reverse was compensated for by the success of his son Edward, who, after routing the royal or Lancastrian forces, under the Earls of Pembroke and Ormond, at Mortimer's Cross, near Hereford, marched towards London, which he entered on the 28th February 1461. He immediately presented his claim to the crown to parliament, which admitted its validity, and on the 4th of March ascended the throne as Edward IV., amid the acclamations of the citizens of London, with whom he was a great favourite. For three years he had to struggle hard to keep his position. His first victory over the Lancastrians was obtained at Towton, in Yorkshire, 29th March 1461, hardly one month after his accession. Finally, in May 1464, a few days after the victory at Hexham, Henry himself fell into E.'s hands. This closed the war for a time. About this time, E. married Elizabeth Woodville, widow of Sir Thomas Gray. This marriage gave great offence to the Earl of Warwick,

by far the most powerful of E.'s adherents, who was at that time engaged in prosecuting an alliance between E. and the sister-in-law of Louis XI., king of France. In 1469, Warwick openly declared against him, joined Queen Margaret, and compelled E. to flee the country. King Henry was released from the Tower, where he had been a prisoner for six years, and once more invested with royal authority. But in the spring of 1471, E. landed at the Humber, proceeded swiftly to London, seized the person of Henry, and was again hailed king by the inhabitants. Warwick now gathered an army, and hurried to encounter him. The two met at Barnet, where Warwick was defeated and slain, April 1471. In the course of the next month, E. routed the Lancastrians at Tewkesbury, capturing both Queen Margaret and her son, Prince Edward. The latter was murdered the day after the battle; the queen, herself, after an imprisonment of four years, was ransomed by the French monarch. E. died 9th April 1483, the later years of his reign presenting few political incidents of any moment. E. was an able commander, as his numerous victories shew, but he was dissolute in the extreme. It was during his reign that printing was introduced into England, as also silk manufactures. In law, few notable changes occurred, but the practice of indirect pleading dates from this period, which is also illustrated with the names of distinguished legists, such as Littleton and Fortescue.

EDWARD V., son of the preceding, was born 4th November 1470. The story of his life is brief and tragic. At the death of his father, he was living at Ludlow, in Shropshire, a boy of thirteen. When the news reached Ludlow, Earl Rivers, his uncle by the mother's side, set out with him for London. Richard Duke of Gloucester, however, contrived to obtain possession of his person at Northampton, and brought him to the capital himself, in the beginning of May 1483. Towards the end of the same month, Richard was appointed Protector of the kingdom. About the middle of June, the young Duke of York, brother of Edward V., also fell into his hands. The two hapless boys were then removed to the Tower, and were never more heard of. The general, and in all probability the correct opinion is, that they were murdered by command of Gloucester himself. All attempts to whitewash 'the bloody and devouring chief' have signally failed.

EDWARD VI., son of Henry VIII. by his wife Jane Seymour, was born at Hampton Court, 12th October 1537. The events which happened during his brief reign were of great importance, but they were of course brought about by others, E. being too young (he was not sixteen when he died) to exercise any personal influence on the statesmen or the tendencies of his age. On the death of Henry in 1547, Edward Seymour, Earl of Hertford, became Protector of the kingdom. He was attached to the principles of the Reformation, and during his rule, great strides were made towards the establishment of Protestantism in England. The images were removed from the churches; refractory Roman Catholic bishops were imprisoned; the laity were allowed the cup at the ceremony of the Lord's Supper; all ecclesiastical processes were ordered to run in the king's name; Henry's famous six articles (known as the Bloody Statute) were repealed; a new service-book, compiled by Cranmer and Ridley, assisted by eleven other divines, was drawn up, and ordered to be used, and is known as the *First Prayer-book of Edward VI.* (see COMMON PRAYER BOOK); and the celibacy of the clergy ceased to be obligatory. In war, Seymour shewed himself to be a brave general. During the first year of his protectorate, he invaded Scotland, on

account of the refusal of the Scottish government to fulfil the contract into which it had entered with Henry VIII., by which it was agreed that Mary Queen of Scots should marry Edward. The battle of Pinkie followed, on the 10th September 1547, in which the Scots were completely beaten; and Seymour, now Duke of Somerset, might have inflicted most serious damage on the whole country if his presence had not been required at home. He returned to find that his brother, Lord Seymour, had been caballing against him. Somerset had him arrested, tried, and condemned for treason, and on the 20th of March 1549, he was beheaded on Tower Hill. In the summer of the same year the Protector quelled an insurrection of the populace headed by one Kett, a tanner; but in the course of a few months, a more dangerous adversary appeared in the person of John Dudley, Earl of Warwick, whose party, by dint of insinuations against Somerset, excited the nation against him, and at last compelled the king to sign his deposition. On the 14th of October, Somerset was placed in the Tower; and on the 1st of December 1551, he was tried before the House of Lords for treason, condemned, and executed, 22d of January 1552. The people regretted, with good reason, his death, for Dudley was both a worse and a weaker man than himself. Before Somerset's execution, Dudley had been created Duke of Northumberland. He was himself (judging from his dying declaration) a Catholic, but he certainly took no means to re-establish the old religion. His great aim was to secure the succession to the throne of England for his family. With this view, he married his son, Lord Guildford Dudley, to Lady Jane Grey, daughter of the Duchess of Suffolk, to whom, by the will of Henry VIII., fell the crown, in default of issue by Edward, Mary, or Elizabeth. Northumberland now worked upon the weak and dying Edward to exclude Mary and Elizabeth, and nominate Lady Jane Grey as his successor. E. at last consented, and a document settling the succession on this lady was drawn up in June 1552. The king lived only a few weeks after, dying on the 6th of July. Subsequent events entirely frustrated Northumberland's design. King E., during his short reign, founded a great number of grammar-schools, which still exist, and are known as *King Edward's Schools*.

EDWARDS, HENRI MILNE. See MILNE-EDWARDS, HENRI.

EDWARDS, JONATHAN, a celebrated American divine and metaphysician, was born at Windsor, in the state of Connecticut, 5th October 1703, entered Yale College in 1716, took his degree of B.A. in the following year, and in 1722 was licensed to preach the gospel. Towards the close of 1723, he was appointed tutor of Yale College, an office which he filled with distinguished success. In 1726, he accepted an invitation to become colleague to his maternal grandfather, Mr Stoddard, in a church at Northampton, and was ordained in February 1727. Here he laboured with intense zeal for more than twenty-three years, at the end of which period he was dismissed by his congregation. The immediate cause of the rupture between him and his hearers, was his insisting that no 'unconverted' persons should be allowed to approach the Lord's Table; but some years before, he had alienated the regards of a large number of the influential members of the church by denouncing the reading and circulation of certain books which were immoral and injurious, and by attempting to make a public example of the offenders. E. was a powerful and impressive preacher, sombre and even gloomy in his religious opinions and sentiments, but earnest,

unaffected, and nobly conscientious. During the famous 'Revival' of 1740—1741, he was much sought after as a preacher, and is in fact often regarded as the originator of that movement. Certain it is that as early as 1734, a local manifestation of religious enthusiasm had taken place in his own parish, of which he published an account, entitled *A Faithful Narrative of the Surprising Work of God, in the Conversion of many Hundred Souls in Northampton*. The quarrel between E. and his congregation shews, however, that the 'revival' had not exercised any very strong influence on the community in general, since only a few years elapsed between the ecstasies of devotion and the circulation of obscenity. After his dismissal in 1750, E. became a missionary among the Indians of Massachusetts. While residing at Stockbridge in that state, he composed his famous treatises on the *Freedom of the Will* and *Original Sin*. In 1757, he was chosen president of Princeton College, New Jersey, whither he proceeded in January 1758, but was cut off by small-pox on the 22d of March in the same year.—E. will always be considered a master in dogmatic theology. Calvinism had probably never so powerful a defender. According to the late Robert Hall, 'he ranks with the brightest luminaries of the Christian Church, not excluding any country or any age since the apostolic.' His great characteristics are depth and comprehensiveness of argument; and were it not that the age for such discussions as E. loved is gone by, few writings would be more worthy of patient study than those of this illustrious divine. Besides the works already mentioned, E. wrote a *Treatise concerning Religious Affections*, the *History of Redemption*, a *Dissertation concerning the End for which God created the World*, and a *Dissertation concerning the True Nature of Christian Virtue*. The last three were posthumously published. A complete edition of E.'s works was published by Dr Timothy Dwight in ten vols. (1809), and another at London in 1817. A third was published in 1840, containing an essay by Henry Rogers, and a memoir by Sereno E. Dwight.—JONATHAN EDWARDS, D.D. (born 1745, died 1801), the son of the preceding, was a person of similar character to his father, and, curiously enough, experienced similar vicissitudes of fortune. Both were tutors in the seminaries in which they were educated; were dismissed on account of their religious opinions; were settled again in retired situations; were elected to the presidentship of a college; and in a short time after they were inaugurated, died at nearly the same age. The younger Edwards was also a writer of sermons and theological treatises.

EDWIN, an English Saxon prince, was the son of Ella, king of Northumbria, who died about 589. He succeeded to the throne at the age of three years, but a neighbouring potentate, Ethelfrith, invaded and conquered his territories, whereupon the infant E. was carried into North Wales, and was there educated. When he grew up to man's estate, Ethelfrith, fearing that his power would not be secure so long as E. lived, forced him from his asylum, and for many years he wandered about a disguised fugitive. Reaching East Anglia, he claimed the protection of King Redwald, which was readily granted. While residing there, Ethelfrith sent messengers to Redwald, requiring him to deliver E. into his hands, and threatening war in the event of a refusal. Redwald promised to accede to the request. A friend made known the resolve to the prince, and counselled flight; to this E. would not consent, but sat down without the palace, brooding over his misfortunes. While sitting there, Bede states that an unknown person approached him, and

promised release from all his sufferings, if he would listen to what should be afterwards taught him. The apparition then placed its hand upon his head, and, bidding him remember the interview and the sign, disappeared.

Redwald's queen pleaded the cause of E., and he finally determined to protect him. Raising an army, Redwald surprised Ethelfrith on the Idel, in Nottinghamshire, and defeated and slew him in 617. When E. regained his kingdom, he wooed Edilberga, daughter of Ethelbert of Kent. Her brother, who was a Christian, objected to her alliance with an idolater; but E. promised that he would not interfere with her religious belief. The princess became his wife; and Paulinus, who had been sent by Gregory to assist Augustine in his mission, accompanied her as her bishop.

About this time, E.'s life was attempted by an assassin, sent by the king of Wessex. He escaped with a slight wound, and on the same night the queen was delivered of a daughter. The king thanked his idols for the birth, but Paulinus directed his thankfulness to the Christian Saviour. The king promised to accept the new faith, if Heaven would grant him victory over the king of Wessex. His child and eleven of his household then received the rite of baptism. Raising an army, he defeated his foe, but delayed to fulfil his promise. Paulinus, having heard of the apparition which appeared to him while residing at the court of Redwald, one day entered the apartment in which E. sat, and placing his hand upon his head, asked him if he remembered the sign. The king was visibly affected, and at once assembled his Witenagemote to deliberate on the matter of the new religion. Coifi, the high priest, spoke first, and intimated his willingness to desert the idols, and embrace the Christian faith. A thane next rose and pronounced the beautiful speech which has been versified by so many poets, but which is most effective in the simple serious Saxon of the chroniclers. Coifi then headed the people in destroying the idol temple.

E. and the nobility of his kingdom were baptized in the eleventh year of his reign. Thereafter, he became the most powerful prince in England. He subdued a part of Wales, and his power extended northward to the Lothians. In 634, he fell in battle at Hatfield Chase, in Yorkshire; and in that disastrous fight, one of his children, and the greater portion of his army, perished. The history of this prince has been made the subject of a beautiful poem (*Edwin of Deira*, 1861) by Alexander Smith.

EECLOO', a town of Belgium, in the province of East Flanders, stands on the high road between Ghent and Bruges, and is 12 miles north-west from the former. It is clean and well built; and has manufactures of woollens, cottons, hats, tobacco, chocolate, soap, &c.; also breweries, distilleries, vinegar-works, salt-refineries, dye-works, oil-mills, and a thriving trade in linen, cattle, and timber, as well as in grain, for which it has a large weekly market. Pop. 9300.

EEL, a name popularly given to all serpent-shaped or worm-shaped fishes, and sometimes extended to other animals of similar form, but otherwise extremely different, as the *eels* in paste, in vinegar, &c. The fishes to which this name is most commonly applied are *malacopterous* fishes destitute of ventral fins, and having the body covered by a soft thick slimy skin, the scales very minute, and often almost invisible, or entirely wanting. Most of them were included in the Linnaean genus *Muræna*, and now constitute the family *Murænidae*, divided by some naturalists into the families *Synbranchidae*, *Murænidae*, *Anguillidae*, *Congeridae*, and

*Ophisuridae*. All these have the skeleton destitute of ribs, and the fin-rays not jointed; whilst the *Gymnotidae*, including the Electric Eels (see GYMNOTUS), have ribs encompassing the belly, and the fin-rays jointed or branched. In all the eels, the gill-orifices are very small, and are situated far back, so that there is a long passage from the gill-chamber outwards; and hence, the gills not soon becoming dry, these fishes can remain out of water for a considerable time without injury, and some of them occasionally leave it of their own accord. The smallness of the gill-opening is also regarded as probably indicative of feebleness of respiration; and this, as in reptiles, is connected with extreme tenacity of life.—The *Synbranchidae* have the gill-passages so united under a common integument, as to present externally only a single orifice. They are almost destitute of fins. The species are few, and found only in tropical and subtropical seas.—The *Murænidae* are also generally destitute of fins, or nearly so; they are all destitute of scales. They are all marine.—The *Anguillidae*, on the contrary, are fresh-water fishes, although some of them occasionally visit the sea. They have pretty large pectoral fins, anal and dorsal fins extending to and encompassing the tip of the tail, and numerous longish scales imbedded in groups in the skin, so as to resemble lattice-work. To these the Congers (q. v.), although marine, are very nearly allied. The *Ophisuridae*, or Snake-eels (q. v.), of the Mediterranean and other seas, are more widely different, and are easily distinguished by the tail ending in a conical finless point.

Until recently, all the British fresh-water eels were confounded together as of one species (*Anguilla vulgaris*): Mr Yarrell was the first accurately to distinguish them, and to shew that there are at least three, if not four species, differing considerably in form, and in anatomical characters, as the number and form of the vertebrae, &c. Two of these seem to be very generally diffused, the SHARP-NOSED E. (*A. acutirostris* or *A. vulgaris*) and the BROAD-NOSED E. (*A. latirostris*). The difference in the form of the

Heads of Eels:

1, The Snig (*Anguilla mediostrois*); 2, Broad-nosed Eel (*Anguilla latirostris*); 3, The Grig (*Anguilla Platyce*).

snout, which these names indicate, is very marked and obvious, and the general form of the sharp-nosed E. is also more slender.—The SNIG E. (*A. mediostrois*), found in some of the English rivers, is intermediate in the form of its snout, and is considered superior to the other kinds for the table. Its cervical vertebrae are destitute of the spinous processes which are found in both the other species. It is comparatively small. The sharp-nosed E. seems to attain the greatest size, sometimes almost

thirty pounds-weight. It migrates on the approach of winter to the warmer brackish water of estuaries, often entering water which is perfectly salt; or if migration is impossible, it buries itself in mud.

Eel-spear.

Eels are taken in great numbers during winter by means of *eel-spears*, or forks with several prongs, plunged into the mud. Sometimes they are dugged out of the mud of river-banks, where large numbers are found congregated together. The eels which descend to estuaries or to the sea deposit their spawn there, and countless multitudes of young eels ascend rivers in spring. The passage of the young eels is called on the Thames the *eel-fare*, from a Saxou word

signifying to pass or travel. So strong is the instinct which impels them, that they surmount obstacles apparently far more than sufficient to arrest their progress; they have been seen to ascend the large posts of floodgates, 'those which die, stick to the posts; others, which get a little higher, meet with the same fate, until at last a sufficient layer of them is formed to enable the rest to overcome the difficulty of the passage.' Young eels have also sometimes been met with in large numbers performing migrations on land among moist grass, generally in the evening or during the night; but the purpose of these migrations is not very well understood, nor are they known to take place with regularity.—Those eels which cannot migrate to the sea, breed in inland rivers and lakes.

Eels are very averse to cold, and to this is ascribed their winter descent to brackish water, or hiding of themselves in mud. The number of known species is large, but they all belong to the temperate and warmer regions of the globe. In these also, the marine fishes to which the name *E.* is sometimes extended, chiefly abound.

There is a prejudice in some countries—particularly in Scotland—against eating eels, on account of their serpent-like appearance; but generally, as in England, they are highly esteemed. The London market is very largely supplied with eels from Holland; they are sent over alive in welled vessels.

There are various means besides those already noticed employed for the capture of the eel. Weirs and stages are erected across rivers, and baskets, or *bucks*, as they are termed, fixed in them for the taking of the eels during their migrations. These baskets are of large size, and shaped like a huge Chinese jar, in the mouth of which is fitted a sort of funnel-shaped mouse-trap entrance, composed of flexible withy rods coming inwards to a point, and through which the eels can easily force their way; but when they turn about to find the entrance again, it is closed against them. When the eels are running, as it is termed—that is, during their migrations—many hundredweights are often taken in these basket-traps in a single night. *Eel-pots* are also used for their capture. These are of a similar nature to the bucks, but are smaller and more slender. They are sunk, by means of bricks tied to them, in the most likely runs or narrow spaces between weeds, or close to banks, and through which eels are likely to run. After a thunderstorm, eels always run well, as it disturbs them greatly. Eels are also caught by means of night-lines. These are long lines with heavy weights at each end, and in the middle if necessary, with hooks tied on every yard. These hooks are baited with pieces

of dead fish, minnows, or worms. The line is sunk, and laid across stream—or, if fishing for conger-eels, in the sea—with, if it be thought necessary, a small buoy at one end, to recover the line by. These eel-lines should be hauled as early in the morning as possible, or the best eels will be found to have worked themselves off, leaving a mass of knots and slime behind them, to shew where they have been. *Snigging* is a favourite amusement with

Eel Snigging Apparatus.\*

some anglers. A rod or a long stick is provided, bent round at the slender end like the top of a very well used fishing-rod; on the point is fixed a single ring; through this ring is passed a piece of string; one end of this is held in the fisherman's hand. To the other end, on some fine but strong cord, is fastened a stout darning-needle, tied to the cord by the middle. The needle is then baited, or thrust lengthwise into a large lob-worm, until the fine cord alone comes out of the head of the worm. The worm is then drawn up to the ring of the rod. The fisherman then seeks for some hole in which he thinks an eel may be, and applying the point of the rod, pushes the worm into it. As soon as the fisherman believes an eel has swallowed the bait, he gives a slight pull to the string; and the needle, which has gone down the eel's throat inside the worm perfectly straight, being tied by the middle, turns crosswise in the eel's throat or stomach, and hooks him. *Clod-fishing* is thus practised: a quantity of lob-worms are strung by means of a needle on to some stout worsted until a considerable bunch of them is obtained; this is tied to the end of a cord, which is again tied to a stout pole. When the eels are on the move, the fisherman takes his station with a pail half-full of water within reach; he then drops his clod into the water, and allows it to sink to the bottom. As soon as he feels an eel tugging at it, he steadily and quickly, but without jerk, raises the bait from the water. The eel frequently has its teeth so entangled in the worsted as to be unable to let go, and thus is lifted from the water. The bait is held over the pail, a shake or two dislodges the eel, and the clod is then dropped into the water again, to fish for more. Sometimes two or even three eels come up at once, and a great number are often taken thus.

**EEL-POUT**, a name given in some parts of England to the burbot, and on some parts of the Scottish coast to the viviparous blenny.

**EELS** in paste, vinegar, &c., are animalcules (*Infusoria*) of the family *Fibronide*. When at rest, they appear like very minute hairs, or bits of very fine thread. Some of them wind themselves about in a spiral form when they move. The species are numerous, and they occur in almost all vegetable substances beginning to corrupt and undergo decay, which they hasten. They are found also in decaying animal matter, and have recently been detected in diseased animal tissues; but the species found in such situations have not the elongated form which has given the

\* The above figures are taken from Blaine's *Encyclopædia of Rural Sports*. Longmans, London. In this excellent work there is a very full description of the various methods of fishing for eels.

name cells to those inhabiting paste a few days old, stale vinegar, &c., or occurring in diseased parts of living vegetables. Whether or not the origination of disease is to be ascribed to their presence in animal tissues, is not yet well ascertained; but in living vegetables, this appears to be certainly the case, particularly in the disease of wheat called Ear-cockles (q. v.).

EFAT. See SHOA, ABYSSINIA.

EFFARÉ, or EFFRAYÉ (Fr.), in Heraldry, signifies that the animal to which it refers is to be represented as rearing on its hind-legs, as if it were frightened or enraged.

EFFECT. The general impression produced on the mind by the first sight of a picture or other work of art, or the impression which it produces when seen from so great a distance as to render the details invisible. The term has reference both to design and colouring, both of which, if correctly indicated, may be judged of with perfect confidence before either has been completed in detail. Bold sketches of their works are generally made by careful artists beforehand, for the purpose of adjusting the composition and colouring so as to produce the desired effect.

EFFENDI, a title of honour among the Turks, bestowed upon civil dignitaries and persons of various ranks, in contradistinction to the title of Aga, borne by courtiers and military men. The word is equivalent to the English Sir, or the French Monsieur, and is frequently added to the name of an office. Thus, the sultan's first physician is termed *Hakim-effendi*; the priest in the seraglio, *Imam-effendi*; and the Minister of Foreign Affairs, *Reis-effendi*, &c.

EFFERVESCING DRAUGHTS. See AERATED WATERS.

EFFIGY (Lat. *effigies*), a likeness or representation either of the whole figure or of the head and face, as on a coin. See BRASS, MONUMENTAL. It is scarcely an artistic word.

EFFLORESCENCE is the term applied to the appearance of a white incrustation on the walls of buildings, or when a salt loses its water of crystallisation, and presents a white powdery appearance on the surface. Common washing-soda exposed to the air affords a good illustration of this phenomenon.

EFFRAYÉ. See EFFARÉ.

EFT, a term of Anglo-Saxon origin, applied both to lizards and newts, which—notwithstanding the important differences between them—were until recently confounded even by naturalists. The Scotch word *ask* seems to be the exact equivalent of the English *eft*. In works of natural history, the term *eft* is now used as synonymous with NEWT (q. v.).

E'GBERT, the most celebrated of the Anglo-Saxon kings before Alfred, was the son of Aickmund, who is said to have reigned in Kent, and was a descendant of the House of Cerdic. In 787, on the death of Cynwulf, king of Wessex, E. laid claim to the throne, but had to give way to another claimant, Brihtric, who was the more powerful of the two. E. was compelled to flee, and took refuge at the court of Charlemagne. Here he remained for thirteen years, until, in 800, on the death of Brihtric, he was summoned to England to fill the throne of Wessex. England was at this time divided into three great sovereignties: Northumbria, extending over what were occasionally the separate kingdoms of Deira and Bernicia; Mercia, which had now subjugated the petty powers of Kent, Essex, and East Anglia; and Wessex, which had absorbed Sussex. For the first

nine years of his reign, E. drew no sword. His mild government completed the attachment of his subjects, and the peace which he maintained fostered his strength. In 809, however, he marched against the Britons of the west, and after fighting five years in Cornwall and Devon, he succeeded in subduing the wild tribes to at least a temporary subjection. In 823, the most important event in his career took place. At that time a dispute had arisen between the East Angles and their Mercian conquerors, and the former sent ambassadors to E. imploring aid and protection. E. joined the East Angles with an army which, according to the old chroniclers, had a peculiarly fighting appearance, being 'lean, meagre, pale, and long-breathed.' The encounter between the Mercians and the East Angles with their ally took place at Ellandûn (the modern Wilton, according to some), where a furious battle was fought, in which the Mercians were defeated with great slaughter. By this battle the power of Mercia was broken, and Essex and Kent, formerly Mercian provinces, became incorporated with Wessex. For four years after the great battle of Ellandûn, Mercia remained the seat of discontent and strife, and E., in 827, taking advantage of his opportunity, led thither an invading force, and reduced the country to a state of vassalage. Turning next his arms against Northumbria, he compelled that sovereignty also to acknowledge his supremacy (827—828). He afterwards penetrated into Wales, where, in like manner, success attended his arms.

E., now virtually king of England, though both he and his successors until the time of Alfred were in the habit of designating themselves only kings of Wessex, found it necessary, after a few years' comparatively peaceful rule, to direct his attention to a new and foreign enemy. The Danes, who had been making frequent descents upon the island since 832, and who in that year had defeated the forces of E., reappeared in 835 on the coast of Cornwall, where they were joined by numbers of the Cornish Britons. E., however, at the head of his West Saxons, met them at Hengestes-dûn (Hengstone), and in a great battle completely overthrew them. In the following year, he died, after a reign of 37 years.—In E., ambition and prudence, bravery, talent, and courtesy were blended in such a manner as to form a monarch not unworthy to be the first king of England.

E'GEDE, HANS, was born in Norland, in Norway, January 31, 1681, studied in Copenhagen, and was appointed to the church of Vaagen in Norway in 1707. Having determined to proceed to Greenland to convert the natives, he resigned his *cure* at the end of ten years; and, after devoting himself with assiduity to the study of the language, embarked for Greenland, with his wife and sons, in 1721. He remained fifteen years in Greenland, during which time he laboured zealously among the people, and by his preaching and teaching secured a permanent footing there for the Christian mission, which owed its origin to him. On his return to Copenhagen, he employed himself in instructing missionaries in the dialects of Greenland; and in 1740 he was made a bishop. He died in 1758. He has described the course and success of his labours in *Det gamle Grønlands nye Perustration* (Copenh. 1729 and 1741). He was ably seconded in his labours by his wife and his sons, Povel and Niels.—POVEL EGEDE, who was his father's successor in Greenland, and was also a bishop, translated the gospels and several devotional works into the Greenland language, and compiled a grammar and dictionary for the use of the Greenland mission; the latter appeared in 1750 under the title *Dictionarium Grønlandico-danico-latinitum*.

**EGER**, a town and river of Austria, in the province of Bohemia.—1. The town E. stands on a rock on the right bank of the stream of the same name, is 90 miles west of Prague, and near the Bohemian frontier. Formerly, it was a border fortress of some importance; its walls, however, have been almost entirely pulled down, and its fosses filled up with rubbish. Among the conspicuous edifices of E. are its churches, of which there are seven—one of them, the deanery church, very handsome; the market-place, within which is the large town-hall; two monasteries, a Dominican and a Franciscan; and the barracks. East of the market-place is the house of the burgomaster in which Wallenstein was assassinated in 1634. The ruins of the imperial burg or citadel, formerly the residence of kings and emperors, is situated in an angle of the fortifications above the river. From the midst of these ruins rises a singular square black tower, constructed of masses of volcanic tufa. The Double Chapel, consisting of two stories, the upper supported by graceful marble pillars, is a fine specimen of Gothic architecture. An avenue, nearly three miles long, leads from E. to Franzenbrunn (q. v.). E. has manufactures of broadcloth, kerseymeres, cottons, chintz, leather, soap, &c. Pop. about 10,000.—2. The river E. rises twelve miles north-west of the town of E., flows first south-east to E., then advances in a general north-eastern direction, passing Elbogen, Saaz, Birdin, and Theresienstadt, near which town it joins the Elbe, after a course, including windings, of about 120 miles. Its current is rapid, its banks high, its bed stony, and no part of its course is navigable.

**EGERIA** was the name of the Nymph or Camena from whom, according to the legend, King Numa received the ritual of public worship which he established in Rome. The grove where Numa met the goddess to receive her instructions was dedicated by him to the Camenæ. Roman legends speak of two groves dedicated to E.—one near Aricia, the other before the Porta Capena at Rome, where the grotto of E. is still shewn.

**EGG**, or **EIGG**, an island 12 miles off the west coast of Inverness-shire, and 8 miles south-west of the south point of Skye. It is  $4\frac{1}{2}$  miles long by  $2\frac{1}{2}$  broad. It consists chiefly of trap, which in the north alternates with sandstone and limestone, the latter rocks containing oolitic fossils, carbonised wood, and coal. The Seuir of Egg, in the south-west, rises 1339 feet. The upper 470 feet of this hill is a mass or vein of pitchstone,  $1\frac{1}{2}$  mile long, and 100 feet broad. Some of the pitchstone forms straight, inclined, or curved columns, from a few inches to nearly two feet in diameter. In one place, the pitchstone overlies red sandstone, eouglomerate, trap, and the silicified wood of an oolitic pine. In the south part of the isle is a large cave, entered by a narrow opening, through which only one person can creep at a time. Here it is traditionally related that the Laird of Macleod, to revenge an injury done to some of his clan, smoked to death all the inhabitants (200 Macdonalds) of the isle, who had hid themselves in the cave.

**EGG (ovum)**. In a great majority of the different kinds of animals, reproduction takes place by means of eggs; in other words, the animals are *oviparous*. It is only in the *Mammalia* that we find animals truly *viviparous*; whilst the *marsupial* quadrupeds and the *monotremata* form connecting links, in this part of their natural history, between the *mammalia* which are *viviparous* in the fullest sense of the term, and the warm-blooded animals (birds) which are *oviparous*.

To the articles REPRODUCTION and DEVELOPMENT

OF THE EMBRYO, we must refer for an exhibition of the differences between *oviparous* and *viviparous* reproduction, and of that original and essential agreement in important particulars, which has been strongly asserted in the saying, *Omne animal ex ovo* (Every animal is produced from an egg). To the article DEVELOPMENT OF THE EMBRYO also reference must be made for what may be called the *history* of the egg, and the development and uses of its several parts.

The number of eggs varies extremely in different animals, some birds producing only one at a time, or in a year, others twenty or nearly so, whilst the roe of the herring, salmon, and many other fishes, contains myriads of eggs. The eggs of some animals are enveloped in a gelatinous mass; those of some are joined together, and are laid in a kind of string; those of others are connected together in various ways. For notice of such peculiarities, we must refer to the articles on different classes of animals.

The economical uses of eggs are well known. The eggs chiefly used are those of birds, although the eggs of turtles are also in great repute as an article of food and luxury, and those of fresh-water tortoises are valued for the oil which they yield. The birds' eggs chiefly used for food are those of the species commonly domesticated as poultry, and others allied to them—gallinaceous birds and web-footed birds. Of gallinaceous birds, the common domestic fowl, the turkey, the peahen, and the guinea-fowl, produce the eggs most generally used and brought to market in different parts of the world; of web-footed birds, the common duck is in this respect the most important, although the eggs of other *Anatide* are also used for food, and those of some of the other web-footed marine-birds are much sought after by the inhabitants of the wild and rocky shores which they frequent. Thus, the eggs of gulls and guillemots afford an important article of food to the people of St Kilda, and of some of the Orkney and Shetland Islands, as well as to the inhabitants of Iceland and other far northern regions. It is in quest of eggs, as well as of young birds, that the dangers of the most tremendous precipices are braved by men whom their companions let down by ropes, and who gather the eggs from the rock ledges. The coasts of Labrador are also visited by *eggers*, who collect the eggs of sea-birds, and carry them for sale to some of the American ports. The eggs of some of the sea-birds of the West Indies are of considerable commercial importance. See EGG-BIRD.

**EGG, CHEMISTRY OF**. An ordinary good-sized hen's egg weighs about 1000 grains, of which the white constitutes 600 grains, the yolk 300, and the shell 100. The white or *glaire* of the egg is a strong solution of Albumen (q. v.) in water, and whilst readily miscible with water in its ordinary state, it becomes insoluble when subjected to heat, as in boiling an egg. In 100 parts, the white or *glaire* of egg consists of—water, 80; dry albumen,  $15\frac{1}{2}$ ; salts, &c.,  $4\frac{1}{2}$ . The yolk or *yolk* of the egg is composed of a strong solution of albumen, through which multitudes of minute globules of oil are suspended, which render it essentially an emulsion. In 100 parts, it consists of—water,  $53\frac{1}{2}$ ; dry albumen,  $17\frac{1}{2}$ ; oil (with small proportion of salts),  $28\frac{3}{4}$ .

**EGG, MUNDANE**. See MUNDANE EGG.

**EGG TRADE**. English poultry does not supply eggs in sufficient quantity to meet the home-demand, on account partly of the large consumption in manufactures. The deficiency is made up by importations, chiefly from France. There are no means of ascertaining the number of eggs produced by English poultry in the course of a year; but the importations

EGGA—EGG-PLANT.

are recorded in parliamentary papers. These importations have largely increased within the last few years. In 1844, they amounted to about 67 millions; in 1860, to nearly 160 millions. Eggs were, until recently, estimated for custom-house purposes by the cubic foot; and in 1859, out of 740,000 cubic feet imported, 650,000 were from France, and the rest principally from Belgium. The computed real value of this total was set down at £336,000, being about 9s. per cubic foot of about 200 eggs. The imported eggs are seldom equal in quality to those home-produced; they are often packed in damp straw, the odour from which penetrates the shell, and imparts an unpleasant flavour to the egg. There is a certain warmth in new-laid or good eggs, which tends to ferment the damp straw, or other substance in which they are packed, and this fermentation re-acts upon the eggs in the way stated. Until the recent removal of the duty, imported eggs paid 4*d.* per cubic foot if from British possessions, and 8*d.* if from foreign countries.

EGGA, a large town of Western Africa, Yoruba country, is situated on the right bank of the Niger, in lat. 8° 43' N., long. 6° 20' E. It is said to be two miles long. Its streets are narrow; the houses are principally huts built of clay, the walls smooth, and stained with indigo. Great quantities of narrow cotton cloth, only a few inches in breadth, and generally dyed blue, are manufactured here. The inhabitants are enterprising and commercial, many of them possess canoes, in which they trade up and down the Niger. These canoes are covered by a sort of shed, under which the traders sleep at night. The chief articles of trade are beautifully carved calabashes, cloth net-work, corn, yams, sweet potatoes, dried fish, and a few European articles, as beads and gunpowder. The population, which is said to be immense, is partly Mohammedan and partly pagan.

EGGAR MOTH, the name of certain species of moth, of the genus *Lasiocampa*, allied to the silk-worm moths. One species (*L. trifolii*), of a uniform foxy

Eggar Moth and Caterpillar (*Lasiocampa trifolii*).

ochreous colour, with wings expanding about two inches, produces a caterpillar as thick as a swan's quill, hairy, and ochreous brown, which feeds sometimes on broom, but frequently in clover-fields.

EGG-BIRD (*Hydrochelidon fuliginosum* or *Sterna fuliginosa*), a bird of the gull family, sometimes called the SOOTY TERN. It is fully larger than the common tern of the British shores; has a long, slender, nearly straight, compressed, sharp bill; very long, narrow, and pointed wings, and a long deeply forked

tail; the general colour is glossy black on the upper parts, except the forehead and the edges of the wings, which, with the under parts, are white. It abounds in the West Indian seas, and is to be seen in myriads on and near some of the keys or low

Egg-Bird, or Sooty Tern (*Hydrochelidon fuliginosum*).

barren islets where it breeds. When visitors land on these keys, the disturbed birds rise and fly about in clouds which darken the air, whilst their turmoil overpowers even the roar of the breakers. The nest of the E. is merely a little excavation in the sand, and usually contains three eggs, which are fully two inches long, of a pale-cream colour, sparingly marked with light-brown and purple tints. The eggs are esteemed delicious, and form an object of profitable adventure in the months of March, April, and May, to the crews of numerous small vessels, fitted out from Kingston, Havannah, and other West Indian ports. Curious customs prevail among the egg-gatherers at the most frequented keys, and common consent has established a kind of code of laws among them. The eggs remain fresh and fit for use only for a short time. Along with the eggs of the E., those of the Noddy are also gathered, and those of the Sandwich Tern and other allied species; and the name egg-bird, with some prefix, is sometimes extended in the West Indies to several of the terns.

EGG-PLANT (*Solanum melongena*), an annual

Egg-plant (*Solanum*):

A, purple variety; B, white variety.

usually less than two feet high, with stem partially woody; fruit very much resembling an egg in

appearance, and varying in size from that of a hen's egg to that of a swan's egg, in colour generally white, yellow, or violet. The fruit is much used as food, not only in the East Indies, of which the plant is a native, but in warm countries generally, into which it has been introduced, its cultivation extending to comparatively northern regions which have a warm though not long summer. In Britain, the E. is scarcely to be seen except in hothouses. The fruit is known by various names—as Egg-apple, Auberjine, Brinjal, &c. It is also sometimes called Mad Apple and Jews' Apple, names probably transferred to it from the poisonous Apple of Sodom (*Solanum Sodomæum*).

EGHAM, a village in the north-west of Surrey, on the left bank of the Thames, 18 miles west of London. In the vicinity is Runnymede, a meadow on the Thames, where King John conferred with his barons before signing the Magna Charta in 1215. Near also is Cooper's Hill, rendered famous by Denham and Pope.

E'GINHARD, or EINHARD, the biographer of Charlemagne, was born towards the end of the reign of Pippin, or the beginning of that of Charlemagne. At an early age, he repaired to the court of the latter monarch, and became a pupil of Alcuin. His talents and acquirements gained him the favour of the emperor, who appointed him his private secretary, and superintendent of public buildings. E. accompanied the emperor in all his marches and journeys, never separating from him except on one occasion, when he was despatched by Charlemagne on a mission to Pope Leo. On the death of the emperor, he was appointed preceptor to Lothaire, son of Louis le Débonnaire, and for a number of years afterwards appears to have been lay abbot of various monasteries; but ultimately becoming tired of secular life, he retired to the secluded town of Mühlheim. Here he erected a monastery, and changed the name of the place from Mühlheim to Seligenstadt (City of the Blessed). He now agreed with his wife to consider her only as a sister, and became a monk. E. died 25th July 844, and was buried beside his wife, who died in 839. The two coffins are now shewn in the chapel of the castle at Erbach. The counts of Erbach trace their descent from Eginhard. His *Vita Caroli Magni*, completed about the year 820, with respect to plan and execution, as well as language and style, is incontestably the most important historical work of a biographical character that has come down to us from the middle ages. It was frequently used as a school-book, and was therefore copied *ad infinitum*. The best German edition is that of Pertz, in the *Monumenta Germaniæ Historica*. His *Epistola*, 62 in number, are also of considerable value in a historical point of view. The French consider the edition of E.'s works by M. Teulet, with a translation, and life of E. (1848), to be the best and most complete. E.'s second work, the *Annales Regum Francorum, Pippini, Caroli Magni, Ludowici Imperatoris*, embraces the period from 741 to 829. According to a pretty legend, E.'s wife, Emma, was a daughter of Charlemagne. A mutual affection had arisen between them, and on one occasion when the lovers were enjoying a nightly interview, a sudden fall of snow covered the spacious court, thus rendering retreat impossible without leading to a discovery. As the traces of female footsteps could not excite suspicion, Emma carried her lover across the court on her shoulders. This scene, it is said, was observed from a window by Charlemagne, who united the affectionate pair in marriage. On this legend Fouqué has founded his romance of *Eginhard and Emma*.

E'GLANTINE, a name sometimes given to the Sweet Brier (*Rosa rubiginosa*), but also sometimes to other of the smaller-flowered species of rose.

EGLINTON, EARL OF. See MONTGOMERIE.

E'GMONT, besides indicating several other places of inferior interest, designates the principal harbour of the Falkland Islands, and also an active volcano in New Zealand.—1. Port E. is formed on the north coast of the more westerly of the principal two islands of the group, its seaward barriers being the islets of Keppel and Saunders. It is in lat. 51° 21' S., and long. 60° W. The anchorage is good; and the shores afford fresh water, but are almost destitute of wood.—2. Mount E. is on the northerly island of its own group, rising 8840 feet above the sea. It is 18 miles to the south of New Plymouth, in lat. 39° 15' S., and long. 174° 13' E.

EGMONT, LAMORAL, COUNT, PRINCE OF GAVRE, was born in the castle of La Hamaide, in Hainault, in 1522; and inherited his property and titles from his elder brother Charles. He accompanied Charles V. on his expedition against Algiers in 1541, and followed that monarch afterwards in all his campaigns, but without distinguishing himself greatly. After the accession of Philip to the throne, E. commanded, with great success, the cavalry, in the battle of St Quentin, 1557, and next year in that of Gravelines; and when Philip finally returned to Spain, he left E. governor of Flanders and Artois. In this position, E. entered into alliance with the party in the Netherlands that were dissatisfied with the Catholic policy of Philip, and from a courtier became all at once a man of the people. His proud, imperious character, however, and his subsequent conduct, have induced many to suppose that, like his bosom-friend the Prince of Orange, he was less actuated in this by high motives than by self-interest, or at least by disappointed ambition. The more common opinion, however, is, that he was a humane and virtuous patriot, who, although indifferent to Protestantism as a religion, was anxious to do justice to all the members of that oppressed faith. When Margaret, Duchess of Parma, against the will of the Protestant party, was made regent-general of the Netherlands, E. and the Prince of Orange entered the council of state, and held the command of the few Spanish troops. At first he sided with the party who were discontented with the infringement of the liberties of the provinces, and the introduction of the inquisition; but when insurrections broke out, he at last broke with the Prince of Orange and the 'Beggars' League,' as it was called. He seemed to have restored order, and to be maintaining it, when, in April 1567, the Duke of Alba was sent as lieutenant-general to the Netherlands. The Prince of Orange and other chiefs of the insurrection left the country; E., wishing to save his private property, remained, thinking his return to the court had secured his safety. When Alba entered Brussels, 22d August, E. went to meet him, and sought to secure his favour by presents. He appeared to have gained his confidence, when suddenly, after a sitting of the council, he and Count Hoorn were treacherously seized, and carried to the citadel of Ghent. The states of Brabant sought to withdraw E. from the bloody tribunal, as it was called, instituted by Alba, and E., as a knight of the Golden Fleece, denied its competency. But all in vain. He was called upon to justify himself against ninety counts of accusation; and as he persisted in protesting against the incompetency of the court, and thus left many of the points unanswered, he

was held guilty of contumacy, and along with Count Hoorn condemned to death. On the following day, June 4, 1568, they were both beheaded in the market-place of Brussels. Although E. hoped for pardon to the last, and intercession was made for him from the highest quarters, he died with the greatest composure. It is related that as he received the fatal stroke, Johanna Lavi, who had been his mistress, fell down dead, and the people, in a paroxysm of sympathy, dipped handkerchiefs in the blood that seemed shed in martyrdom to freedom. E. left eleven legitimate children, of whom three were sons. The whole of his property, movable and immovable, was confiscated with the greatest rigour. See *Correspondance de Marguerite d'Autriche, Duchesse de Parme* (Bruss. 1842), and *Correspondance de Philippe II. sur les Affaires des Pays-Bas* (Bruss. 1848—1851, 2 vols.). Goethe has made the death of E. the subject of a tragedy.

EGRET, a name often given to various species of Heron (q. v.), particularly those which, at least during the breeding season, have the feathers on the lower part of the back lengthened and their barbs loose, so that this part of the plumage is very soft and flowing. Most of the egrets have beautiful white plumage. The distinction between egrets and other herons is not, however, very strongly marked, and the names are often used indiscriminately, although the name E. is never given to the common heron. E. plumes are used for ornamental purposes, particularly the occipital crest and scapulars of the *LITTLE E.* (*Ardea garzetta*); and the name E. (Fr. *aigrette*) has become a common term for a tuft of

Little Egret (*Ardea garzetta*).

feathers, although it is said to be derived from the French *aigre*, harsh, on account of the harshness of the voice of the bird. In old English bills of fare, egrets are mentioned as if they were abundant; and not fewer than 1000 'egrittes' are included in the bill of fare of a single great feast, given at the enthronisation of George Neville, Archbishop of York, in the reign of Edward IV.; but as there is no other evidence that any species of E. was ever otherwise than of very rare occurrence in Britain, great probability seems to attach to the opinion originally advanced by Dr Fleming, that perhaps the lapwing might be meant, 'the most common bird with a crest.'

EGYPT, a country in North-east Africa, extending from the Mediterranean to the first cataract of the Nile, that of Syene, from lat. 24° 6' to 31° 36' N. The name is derived from the Greek *Aigyptos*,

a word of uncertain derivation, and as old as the age of Homer. In the Hieroglyphs and Coptic, it was called *Kemi* or the Black Land, from the colour of the soil; and by the Hebrews *Masr* or *Mitsraim*, modified by the Assyrians into *Musr*, and by the Persians into *Mudroya*. The country may be described as the bed of the Nile, the cultivated territory only extending to the limits of the inundation. This river runs from the cataracts of Assouan, in a

Egypt.

northerly direction, to Denderah, where there is one great bend to the west; and a few miles north of Cairo (lat. 30° 15' N.), the river divides into two main streams, forming the Rosetta and Damietta branches. The other five mouths, which existed in antiquity, have silted up; the alluvial district enclosed by these mouths, and supposed by the ancients to have been gained from the sea, formed the ancient Delta. The basin of the Nile is formed by the ranges of the Arabian hills on the east, and the Libyan on the west side. The rate of deposit of mud is supposed to be about 6 inches in a century. The eastern chain of mountains rises to about 1000 feet above the level of the sea. The great physical peculiarity of Egypt is the absence of rain, the land being only irrigated by the annual overflow of the Nile. The climate is remarkably mild and sound, especially south of the Delta; and in the desert, from Cairo to Alexandria, the air contains more moisture than to the south. From the middle of August to December, west winds prevail; east winds from that time till March; after that, unhealthy south winds or Khamsin till June; and from June till August the north or Etesian winds. Earthquakes are occasionally felt;

and the temperature varies from 84° F. to 32°. The most remarkable phenomenon is, however, the regular increase of the Nile, fed by the fall of the tropical rains, which commence in 11° N. lat., in the spring; and falling first into the White, and then Blue Nile, reach Egypt in the middle, and the Delta in the end of June. In the middle of July, the red water appears, and the rise may be dated from that time; it attains its maximum at the end of September, and begins to decline visibly in the middle of October, and subsides to its minimum in April. At the end of November, the irrigated land has dried, and is sown, and is covered with green crops, which last till the end of February. In March is the harvest. The state of the Nile, in fact, marks the season more accurately than the variation of temperature. E. is by no means remarkably healthy, as, in addition to the visitations of plague and cholera, ophthalmia, diarrhoea, dysentery, and boils often prevail, and European, and even Nigritic races cannot be acclimatised.

*Geology.*—E. is separated from Nubia by a low hilly region about fifty miles broad from north to south, composed of granitic rocks. The same crystalline rocks extend up the shore of the Red Sea to near the opening of the Gulf of Suez, stretching inland for fully thirty miles. The scenery in this district is wild and rude, and the course of the Nile is frequently interrupted by cliffs and broken masses of granite, forming magnificent cataracts. The granitic region terminates at Assouan, the ancient Syene. From the rocks here were obtained the materials for the colossal and monolithic monuments of Egypt. The valley of Upper Egypt is bounded by two ranges of hills running northward—the Arabian range on the right, the Libyan on the left of the river, both alike composed of cretaceous strata, the predominant rock being sandstone. This is a durable and easily worked stone, and was consequently extensively used in the erection of ancient temples. The city of Thebes was built of it. The cretaceous sandstone extends from the granitic rocks forming the first cataract at Assouan for about 85 miles to Esné, where it is covered by a limestone belonging to the upper chalk series. This continues on both sides of the valley for about 130 miles, when it is covered by a tertiary nummulite limestone, which forms the further prolongation northward of both ranges of hills. Because of the easy disintegration of these beds, the scenery in the limestone districts is tame and monotonous; frequent table-lands occur, on one of which are built the three pyramids of Gizeh, the material employed being the predominant limestone.

Over a large extent of E., these rocks are covered with moving desert sands, and in the flat lands bordering the Nile, with the alluvium brought down by its waters, and which has formed the Delta at its mouth. This alluvium consists of an argillaceous earth or loam, more or less mixed with sand and a quartzose sand, probably derived from the adjacent deserts by violent winds. It is remarkable that this sedimentary deposit has no traces of stratification, and also that within short distances, great varieties are observed in what are apparently synchronous deposits. Mr Horner's recent examination of the Nile deposits, and the striking conclusions he deduces from his observations, have caused considerable attention to be paid to these deposits lately. See MEMPHIS.

*Natural History and Productions.*—The fertile valley of the Nile and the desert regions which enclose it, are very different, not only in their botany, but in their zoology. One of the most notable of Egyptian quadrupeds is the hippopotamus, which formerly reached the Delta, but is now

to be seen only in the more southern parts of the Nile. The giraffe is occasionally found within the southern borders of Egypt. The jackal and hyæna are common; also the ichneumon (q. v.), so much celebrated among the ancients; and the jerboa. The one-humped camel was originally introduced by the Ptolemies for the transit of the Indian trade. The other usual domestic quadrupeds have existed from the most ancient times. Of domestic birds, water-fowl were anciently the most numerous; the gallinaceous poultry now common not being probably of older date than the Persian invasion. Pigeons have always been abundant. The Egyptian vulture (q. v.) is a common and notable bird, as is also the ibis (q. v.), held sacred by the ancient Egyptians, and of which many fables have been related. The ostrich sometimes occurs in the desert. Of reptiles, the most famous is the crocodile of the Nile; monitors (q. v.) are also abundant, saurian reptiles of considerable size. Smaller lizards abound. The trionyx, or soft tortoise, is plentiful in the Nile. Serpents are numerous: amongst the most venomous and dreaded of which are the asp (q. v.) or haje, and the cerastes (q. v.). E. abounds in fish, the most remarkable being the Binny (see BARBEL), the *Latus* (one of the perch family), the Bayad or *Silurus*, the *Chromis Nilotica*, and the *Mormyrus oxyrhynchus*. The sacred beetle (*Scarabæus sacer*) is one of the most remarkable insects. Locusts are a dreaded pest. E. is still notable also for the abundance of the other creatures mentioned by Moses as its plagues.—Many of the European trees and plants are found in E.; the date-palm, the doom-palm, the sycamore, acacias, tamarisks, &c., are among its more peculiar botanical productions; also the papyrus (*p-apsu*), which anciently supplied material for paper, and the lotus (*shain*) or water-lily of the Nile. The extensive culture of papyrus has been, in modern times, replaced by that of the sugarcane, cotton, indigo, and tobacco; and the plant has almost disappeared. Gourds and melons have always abounded. To the wheat and barley of antiquity have been added maize and durra. E. is very deficient in timber trees; the Pharaohs obtained cedar from Lebanon and ebony from Ethiopia. The rocks of E. afforded the stones used in its edifices and sculptures; granite, syenite, basalt (at Assouan), breccia (in the Cosseir Road), porphyry (from the quarries of Gebel Doshan, opened in the reign of the Emperor Claudius), sandstone, and limestone. Alabaster (found at Tel-el-amarna) has been used from the earliest periods to the present day. Emeralds are produced by the mines of Gebel Zabara; salt, natron, and—since 1850—sulphur, are among the other mineral productions of Egypt.

*Divisions.*—The country was anciently divided into 44 nomes—22 in Upper, and as many in Lower Egypt. Each nome or department had a separate local municipal government of a nomarch or lieutenant-governor, *ha*, besides governors of the cities, of the temples, scribes, judges, and other functionaries. Their limits were measured and defined by landmarks. This division, as old as the 4th dynasty, varied in number at different times. Under Sethos I. or Sesostris, there were 36 nomes—10 in the Thebaid, 10 in the Delta, and 16 in Middle Egypt. At the time of the geographer Ptolemy, there were 47—the Antinoites having been added. The country beyond the cataracts to Hierosycaminos was named at the Roman period Dodekaskoinos. In 400 A. D., Egypt was divided into Augusta Prima and Secunda on the east, and *Aegyptiaca* on the west, the Heptanomis as far as Oxyrhynchus was named Arabia, then Thebais Proxima as far as Panopolis, and Thebais Supra to Philæ. Under the Arabs, E. has

been divided into Masr-el-Bahri or the Delta; the Faioum, El Bostani, or Middle Egypt; and Es Said or Upper Egypt.

The most remarkable antiquities of the country will be found described under the names of the places where they occur: see ABOUSAMBUL, ALEXANDRIA, EDFOU, MEMPHIS, THEBES, &c.; while the more remarkable objects of antiquity will be given under their names, as NILOMETER, OBELISK, PYRAMID, &c.

The population of the country must have been large at the earliest period, as 100,000 men were employed in the construction of the Great Pyramid alone during the 4th dynasty. It has been placed at 7,000,000 under the Pharaohs, distributed in 1800 towns, which had increased to 2000 under Amasis, 525 B.C., and upwards of 3000 under the Ptolemies. In the reign of Nero, it amounted to 7,500,000, without the natives of Alexandria, which at the time of Diodorus contained 300,000 inhabitants. By the census of 1859, the population was 5,125,000, although by that of 1844 it was as low as 2,500,000. The great bulk of the inhabitants consists of native Mohammedans; the Copts (q. v.) are estimated at 150,000, and the rest is composed of Bedouin Arabs, Negroes, Abyssinians, Turks, Syrians, Greeks, Armenians, Jews, and Western Europeans. The original population appears, both from the language and the physical conformation of the mummies, to have been of Asiatic origin, afterwards blended with Ethiopian by subsequent irruptions and conquests; but there appears to have been an aboriginal race at an early period, of copper colour, fair proportioned, although with rather thin legs, large feet, rather high cheek-bones, and large lips. According to Herodotus, Diodorus, and Plato, the system of castes prevailed in Egypt. The first of these authors says there were seven castes—of priests, warriors, cowherds, swineherds, innkeepers, interpreters, and pilots. Diodorus makes only five—priests, soldiers, cultivators, shepherds, and artisans; and Plato the same. The evidence of the monuments, however, shews that these were rather conditions of society than castes, as the different orders not only intermarried, but even, as in the case of priests and soldiers, held both employments. As in all bureaucracies, the sons often obtained the same employments as their fathers.

**Religion.**—The Egyptian religion was a philosophical pantheism, the various attributes of the Deity being divided amongst the different gods of the Pantheon. Unlike the Greek, where a god was honoured in a separate temple, each Egyptian divinity was accompanied by a *put* or 'company' of companion-gods. The principal nomes and cities had each a family group of gods, consisting of a parent deity, a wife and sister, and a son. Thus Ptah or Vulcan, the eponymous and principal god of Memphis, formed a circle with the goddesses Pasht and Bast; and his son Nefer Tum, Amen Ra at Thebes, was allied with Mu, Nit, and Khonsu. These tetrads, or rather triads, for the female principle was dualised, were often accompanied by inferior deities; and personifications of the elements, passions, and senses, and feelings were introduced. The worship of some triads, however, became universal—that of Osiris, Isis, and Horus being found all over Egypt at the earliest

period. The gods, indeed, are stated by the Greeks to have been divided into three or more orders. The first contained eight gods; the second, twelve; the third, an unknown number. The eight gods of the first order were Ptah, Ra, Shu, Seb, Osiris, Set or Typhon, and Horus, according to the Memphite; and Amen, Mentu, Atum, Shu, Seb, Osiris, Set, Horus, and Sebak, according to the Theban version. Great uncertainty prevails about the gods of the second and third order, and still greater difficulty about the genesis and nature of the gods, different doctrines prevailing at different times and places; and the tendency to fuse different gods into one, particularly at a later period: Amen Ra, for example, being identified with Horus; and Horus, Ra, Chnum, Mentu, and Tum being merely considered the sun at different periods of his diurnal course. Very little light is thrown on the esoteric nature of the deities by the monuments, and the classical sources are untrustworthy; but the antagonism of good and evil is shown by the opposition of the solar gods and the great dragon Apap, a type of darkness, and the hostility of Osiris and Set or Typhon. Some of the gods were self-existent, others emanated from a father, and some were born of a mother only, and others were the children of greater gods. Their energies and powers differed, and their types, generally with human bodies, have often the heads of the animals which were their living emblems, instead of the human. A few foreign deities became at the close of the 18th dynasty engrafted into the religious system—as *Bar*, Baal; *Ashlarata*, Ashtaroth; *Anta*, Anaitis; *Ken*, Kiun; *Respu*, Reseph; *Set*, Satan. All the gods had human passions and affections, and their mode of action was material; they walked on earth, or sailed through ethereal space on boats. The principal deities are Ptah, the opener, represented as a bow-legged dwarf or fetus; the Phœnician Pataikos, the creator of the world, the sun and moon, out of chaos (*ha*) or matter (*Mu*), to whom belong Pasht, 'the lioness,' and Bast, Bubastis, lion-headed goddesses presiding over fire, and Nefer Tum, his son, a god wearing a lotus on his head. Next in the cosmic order is Khnum—worshipped at Elephantine—the ram-headed god of the liquid element, who also created the matter of which the gods were made; and connected with him are the goddesses Heka the Frog, or primeval formation, Sati, or 'sunbeam,' and Anuka, alluding to the genesis of the cosmos. The Theban triad comprised Amen Ra, 'the hidden' power of the sun, the Jupiter; *Mu*, the 'Mother' goddess or 'Matter,' the Juno; *Nat*, the 'Shuttle,' the Minerva; and Khonsu, 'Force' or Hercules, a lunar type. A subordinate type of Ammon is Khem, 'the enshrined,' who, as *Harnekt*, or Powerful Horus, unites beginning and end, or cause and effect. The solar worship comprises *Ra*, the Sun, who traversing the 'sba,' or empyreal space of Gates, passes each hour a separate region, and as he descends behind the west hills of the horizon, becomes Atum, also a demiurge; while as Mentu, a hawk-headed god, he is Mars, and as Khepra, a scarab-headed god, the male creative or existent principle, and is identified with Amen, Khnum, and other deities. Day and night, Ra and his satellites pursue the Apap or 'Giant' Darkness with alternate success. The souls of the blessed

Pasht.

Amen Ra.

were introduced. The worship of some triads, however, became universal—that of Osiris, Isis, and Horus being found all over Egypt at the earliest

come off from earth, and entering the boat of Ra, there enjoy the perpetual streams of light which emanate from his orb. From Ra or Helios spring Shu and Tef the Gemini, Athor and Ma. Seb or 'Time,' and Nu or the 'Firmament,' gave birth to Osiris, Isis, Nephthys, Set, and the elder Horus, a group of terrestrial and infernal deities. The myth of Osiris destroyed by his brother Set, hewn in pieces, recovered by Isis, and avenged by Horus his son, embalmed by Anubis and the geni of the

Anup, or Anubis.

Thoth.

dead, and defended by Thoth, the Egyptian Logos, at the 'great judgment' before his accusers, Set and the conspirators, was the type of the judgment and future destiny of man, and all deceased were called by his name. See OSIRIS. Numerous inferior deities, such as Hapi, the Nile, appear either as other forms of the superior deities or local varieties of the myths. Each deity had its sacred animal, which received a local worship, and which was considered to be the 'second life' of the deity it represented. The special animal selected was installed in the adytum of the temple, and gave oracular responses. The most remarkable of these animals was the Apis bull of Memphis, whose worship had a national extension. The Egyptians believed in the transmigration of souls, and all not sufficiently pure to be admitted into the courts of the sun, or whose bodies had perished before the expiration of 3000 years, passed from body to body (see EMBALMING), having first descended to the Hades, and passed through the appointed trials and regions, endeavouring to reach the manifestation to light. In this progress, the soul was required to know and tell the names of the doors, regions, and their guardian demons through which it had to pass.

*Chronology and History.*—One of the most important points of Egyptian history is the chronological, involving as it does the date of the earliest historical epoch of man. In the time of Ptolemy Philadelphus, in the 3d c. B. C., Manetho of Sebennytus, high-priest of Heliopolis, drew up, at the request of the king, a history, in which he divided the space of time from Menes to the reconquest of Egypt by Darius II. into 30 dynasties. The work of Manetho has perished, but chronological epitomes remain in the works of Julius Africanus, a writer of 300 A. D., and Eusebius, and George the Syncellus, 800 A. D. Besides the Bible, Herodotus, Diodorus, Josephus, and other writers, especially Eratosthenes, also contained sources of chronological information, and the learned of Europe for the last three centuries had endeavoured to reconcile the conflicting statements of these authors, the discrepancy of their ciphers, and the inaccuracy of their details. Even in Biblical chronology, the Hebrew, Samaritan, and Septuagint versions gave

very different results; but in England the chronology of Usher, which, from the Hebrew, placed 4004 B. C. as the date of creation, and 2348 B. C. for the Deluge, has somehow obtained the sanction of theological writers. To reconcile these conflicting authorities, two schools of chronological critics, called of the Long and Short Chronology, have arisen, and the epoch of Menes has been placed by the advocates of the long chronology, as Böeckh, at 5702 B. C., by Bunsen, at 3643 B. C., by Lepsius, at 3892 B. C., by Henry, at 5305 B. C.; while the same date falls, according to Sharpe, 2000 B. C., to Nolan, 2673 B. C., and Poole, 2717 B. C. Unfortunately, the monumental information is defective at certain periods, while in all, the national custom of dating in kings' reigns only, without the use of the controlling date of any cycle, renders the subject still more obscure; for the Sothic cycle, or Dogstar period of 1461 vague years, was not in official use. The celebrated hieratic papyrus at Turin, of the age of the 19th dynasty, which contained a system of chronology arranged on a principle of cyclic and regnal years, has unfortunately suffered so much mutilation that it is impossible to reconstruct it satisfactorily. It is therefore better to arrange the history according to the dynastic successions of Manetho, giving these as waves of time, leaving the question of their duration to individual judgment. At present, the elaborate systems of chronology are only chronological draughts from recollection of a vast ruin, each more or less happy or defective in some particular respects or general conception. There are not sufficient monumental data for a sure conclusion about the remoter dynasties. Mythically, Egypt was said to have been first governed by a dynasty of gods, who, according to Manetho and other Greek authors, were Vulcan or Ptah, Helios the Sun or Ra, Sôs or Shu, Saturn or Seb, Osiris or Heshar, Typhon or Seti, and Horus or Hor. These gods reigned 13,900 years, and were succeeded by the Manes and demigods, whose reign occupied 4000 more years. But considerable difference exists in the lists—that of Thebes giving Amen, Mentu, Tum, Su and Seb, Osiris, Seti, and Horus; that of Memphis, Ptah, Ra, Shu, Seb, Osiris, Set, and Horus. After the reigns of the gods, the epoch of Menes is the first point in the chronology of the history of ancient Egypt, and has been placed, as above mentioned, by the rival systems of chronology.

No contemporary monuments of Menes exist, but he is said by tradition to have corrupted the simplicity of the patriarchal life of the nation, instituted the first laws, and divine worship, founded the temple of Ptah by turning the course of the Nile, by means of a barrage, to the west at Koshicsh, and to have founded Menefer or Memphis, after some expeditions against the Libyans, and to have been devoured by a crocodile. The statue of Menes is represented borne in ancestral procession in the reigns of Rameses II. and III. at Thebes, but no contemporary monument of this monarch exists. His successor Athothis, wrote a work upon anatomy, and built the palace of Memphis. The other kings of this dynasty were Kenkenes, Venephes, who built the Pyramids at Ko or Kochohe, Micbis, Semempses, and Biencches; but their names have not been identified, nor do any monuments of them remain. This dynasty reigned about 250 years, and was succeeded by the 2d, which lasted about 300 years, but of which no contemporary monuments remain. This dynasty, however, introduced the worship of sacred animals, and abolished the Salic law, which had hitherto prevailed. With the 3d dynasty of Memphites, which endured about 200 years, monumental history properly begins, the monumental king Seneferu of this dynasty having conquered the Sinitic

peninsula, and opened the copper mines of the Wady Magara. The 4th dynasty, also of Memphites, had an existence of 284 years. The celebrated canon of Turin contains fragments of the duration of the reigns and lives of the monarchs of this line, some of which were prolonged to upwards of 90 years. Monumental remains are found of Soris. The two Khufus built the two great Pyramids of Gizeh, and held the Arabian peninsula in subjection. Cheops, or the elder of the two Khufus, constructed the largest of this group of the pyramids by means of a forced conscription, and was regarded as a detestable and impious tyrant. Subsequently, he repented, and wrote a book in honour of the gods, which enjoyed a great reputation. Khafren, his successor, built the second of the great pyramids, and Mencheres, or Mycerinus, the third pyramid. The so-called book of the Ritual, which dates from this period, and the high civilisation which Memphis had then attained, mark an epoch in Egyptian civilisation, and the numerous tombs, in the vicinity of the pyramid, constructed during this and the subsequent dynasty, exhibit a highly progressing state of civilisation; the cultivation of farms, the chase, the arts, enjoyed a great deal of the attention of the Egyptians; but horses and wheel-carriages were alike unknown, although the simpler mechanical instruments and manufactured articles had been invented.

The 4th dynasty began, according to Lepsius, 3427 B.C. The 5th, which monumentally appears a continuation of the 4th, terminates with Annos or Onnos, who was killed by his guards. His sepulchre was the pyramid of the Mastabat-el-Faraoun, near Saqqarah. This 5th dynasty was, however, from Elephantine, and appears to have ruled in Upper as well as Lower Egypt, monuments of it being found in the Thebaid. Considerable difference, however, exists between Lepsius and Bunsen in the assignment of the royal cartouches of this period, Lepsius assigning them to the 5th, and Bunsen to the 3d dynasty. The group of the Abooseer Pyramids is of this age. The next dynasty, the 6th, a Memphite, was more remarkable, and tombs and numerous small objects of the period are found in Upper and Central Egypt, and in the valley of Hamamat, leading from Coptos to the Red Sea. The principal monarchs of this line were Othoes, killed by his guards; Phiops or Apappus, whose reign extended to 100 years; and Nitocris, whom the legends represent as drowning the murderers of her brother, and constructing the third Gizeh Pyramid, in which she was buried, and which she perhaps enlarged from the old original sepulchre of Mycerinus, having added to it the revetment of red syenitic granite. Of the 7th dynasty, two names, An and Assa, are supposed to have been found; but the monumental connection between the close of the 6th and 11th dynasties, has not been even conjecturally restored, from the conflicting tablets of Karnak and Abydos, and the mutilated papyrus of Turin. It is not possible to follow the order of the succession till the 11th dynasty, nor are there monuments either of a public or sepulchral nature to shew the existence of the intermediate period, rendered more unintelligible by the contemptuous silence of the lists of Manetho, one tyrant, Achthees, being alone mentioned in them. Considerable discrepancy exists between the canon of Turin and the lists of Manetho relative to this period; the canon making two dynasties—one of six, the other of 17 kings between the 6th and the 12th dynasty; Manetho, 86 kings, and about 500 years. The impossibility of reconciling these statements has given rise to the idea, that the lists were respectively Memphite and

Theban, each having contemporary kings. The existence, however, of the 11th dynasty, consisting of a line of monarchs called Hantefs and Mentuhetps, has been proved by the discoveries of their coffins in the tombs at Gournah and the El Assasifs, and the tablets of the island of Konosso and others, referring to the construction of the fortress of Coptos and in honour of the local god. The successive reigns and monarchs of the 12th dynasty are fixed by numerous monuments. Amenemha I., the founder of the line, opened the quarries of Tourah, embellished An or Heliopolis, and founded the temple of Amen at Thebes, reigning nine years alone, and seven with Osirtesen I., his successor. A historical papyrus recording his dreams and other facts of this reign remains. The monuments of Osirtesen I. exist in the Faoum at Benihasan and Heliopolis; he subjected some of the Ethiopian tribes. During his reign there occurred a famine; and in the 38th year of his reign, he associated Amenemha II. into the government for four years. Little of historical import is known of his successors, Amenemha II. and Osirtesen II., except their conquest of Kash or Ethiopia, and the arrival of a tribe of 36 Amu or Semitics in the sixth year of Osirtesen II. These resemble, in their costume and physiognomy, the Hebrews, and have been supposed to represent the arrival of Jacob in Egypt. Osirtesen III., his successor, established the southern frontier at Samneh, which he fortified; and was subsequently deified in Nubia, and received, in the reign of Thothmes III., a worship in that region, and fortified Coptos. His successor, Amenemha III., excavated the Birket-el-Keroum or Moeris lake; constructed the Labyrinth, composed of 6000 rooms; the Pyramid of Crocodilopolis, in its vicinity; and the temple of the goddess Athor at the Sabent-el-Khadem. His successors, Amenemha IV. and the queen Sebeknefru, are only known from the remains of the Labyrinth, and some inferior monuments. The same difficulty of tracing the succession which exists between the 6th and 12th, occurs again between the 12th and 15th. The most plausible conjecture, however, is that the 13th (Diospolite) and the 14th Xoite dynasty, in Lower Egypt, were contemporaneous, and that the 15th and 16th Theban and Diospolitan had for their contemporaries the 17th Hykshos or Shepherd dynasty in Lower Egypt. The monarchs of the 14th dynasty appear from the monuments to have been occupied in regulating the course of the Nile at Samneh, while their power reached from the isle of Argo to El Hamamat, and they engaged in traffic with the Phœnicians. About 2000 B.C., the advance of the Assyrians in Asia, or some internal revolution, precipitated the so-called Hykshos or Shepherd Kings, who appear to have been Arabs or Phœnicians, on Lower Egypt. These invaders overthrew the Xoite dynasty of Lower Egypt, took Memphis by assault, and established themselves in the city of Haouar or Avaris, subsequently called Tanis, where their monuments still exist. But the Egyptian rulers of Upper Egypt overthrew their rule, and under Ra-skenen, the last king of the 16th dynasty, Avaris was invested, while his successor, Aahmes I., of the 17th, took it by assault, besieged Sarahan or Sharon, and attacked the mountaineers of Nubia. The Hykshos endeavoured to substitute the worship of Sut or Set for Ra or the Sun, but Aahmes I. restored the ancient temples, and opened the quarries of Tourah. Amenophis I., his son and successor, who reigned under the tutelage of his mother, continued the Ethiopian campaigns, and embellished Thebes. Thothmes I. carried his arms to Tombos, in the heart of Nubia, and into

Naharaina or Mesopotamia, and embellished Thebes. Thothmes II., who reigned under the guardianship of Hatasu, defeated the Shos. His brother and successor, Thothmes III., elevated E. to the highest

Head of  
Thothmes III.

pinnacle of glory; and by the victory of Megiddo, in his 23d year, subjected the whole of Syria and part of Mesopotamia to his arms, receiving immense tributes from Kash and the Ethiopian races of the south, the islands of the sea, and Assyria, Babylon, Phœnicia, and Central Asia, and endowing the Temple of Thebes with the revenues of tributary cities. A calendar preserved at Elephantine recording the heliacal rise of the Dog-star on the 28th Epiphi, shews that the year 1444 B.C. fell in his reign. Thothmes III. recovered the copper mines of Magarah, and decorated all Egypt. Amenophis II. continued the conquests of the Ruten, took Nineveh by assault, and vanquished the Ethiopians. Thothmes IV. is supposed to have erected the Great Sphinx. Amenophis III. maintained the frontiers of the empire. At this period, a heresy became introduced into E., favoured by the queen Taia. Amenophis IV. became a worshipper of the Aten or solar orb, to the exclusion of the other deities of E., especially of Amen Ra. The capital was removed to Tel-el-Amarna or Alabastron; the king changed his name to Akhuenatnen, and a succession of three heretic monarchs ruled E. for about 33 years, till Haremhebi or Horus restored the orthodox faith and the limits of empire.

The link which connects the last monarchs of the 18th to the monarchs of the 19th dynasty has been lost; but Horus was succeeded by Rameses I.—the first of a long line of monarchs—who appears to have formed a treaty with the Khita or Hittites, and to have advanced the conquests of E. to the Wady Halfa. He was succeeded by Seti I. or Sethos, who attacked the Remenu or Armenians, the Rutennu, and the Shasu or Shepherds, who had again advanced to the Pa-khetem or Pithoum, on the confines of Egypt. Naharaina or Mesopotamia, and Sharu or Syria, Pânt or Phœnicia, had also been invaded by his arms. The city of Atsh or Katsh, the supposed Cadytis, was also besieged by Sethos, whose Asiatic victories introduced into E. the worship of Baal and Ashtaroth. Tyre, Avathus, and Bethanath in Canaan, were garrisoned by his forces. E. was also embellished with many noble monuments in his reign. He was buried in a deep excavated rock-tomb in the Biban-el-Molook—the kings of the 18th and 19th dynasties having substituted long excavated tunnels or syringes, in the mountains of the Arabian chain of Western Thebes, for the ostentatious pyramids in use from the 4th to the 12th dynasty, which attracted the cupidity of the invaders of Egypt. Rameses II., the son of Seti I., seems to have succeeded him at the very youthful age of seven. In his fifth year, he defeated the Khita and their Syrian confederates at the battle of Katsh, in which many of the princes and officers of the Khita were drowned in the river Arunata, or Orontes. The battle endured two days, and the panegyric of an Egyptian scribe, Pentaur, has invested Rameses with the power of a god. The war lasted till his ninth year, and the king took Shaluma or Salem, the ancient site of

Jerusalem, and other cities. In his twenty-first year, a treaty of peace and extradition was established between the two countries, and Rameses

Rameses II.

married a princess of this nation. It is the tablet of this monarch which is found at the Nahr-el-Kelb, or Passes of the Lycus, near Beyrout. This monarch subjected Ethiopia, which had revolted, to his arms, reimposed the tribute, and placed the country again under the government of the princes of Ethiopia, or Egyptian viceroys. He also established a fleet on the Mediterranean. His name and reputation formed the basis of the legendary Sesostris; the exploits of the monarchs of the 18th dynasty, and probably of his successors, being united with his fame. The reign of Rameses, although it exhibits a decline of art, yet demonstrates E. to have been in the height of its glory; and his epoch appears to have been about 1322 B. C., a special calendar having been sculptured to record the coincidence of the heliacal rising of the Dog-star and 1st Thoth, or commencement of the fixed and canicular year. His place of burial is uncertain—perhaps in the vaults of the Ramesseum. His thirteenth son, Merienptah or Menephtes, succeeded him upon the throne, transferred the capital to Memphis, successfully contended with the Tamahu or Libyans and the Rabu, and appears to be the Amenophis of Manetho, and the Pharaoh of the Exodus. He introduced the heretical worship of Sut, Seth, or Typhon, and was succeeded by Sethos II., Amenmes, Siphah, Tausri, and Setinekht, whose inglorious reigns close the 19th dynasty. The connection of Rameses III. with the previous dynasty is obscure. This monarch was chiefly at war with the Philistines, and the other maritime tribes of Greece and Asia Minor, and gained naval victories in the Mediterranean, and repeated the conquest of Ethiopia. He was followed by the splendid but inglorious line of the Ramessids, the sixth of whom gained victories in Ethiopia; and the twelfth of whom, having married a princess of the land of Bakhten, sent the ark of the god Khous to Bakhten, at the request of the monarch of that country, for the cure of the queen's sister. The fall of this dynasty appears to have been owing to internal revolution, as their Tanite successors held the office of high priests of Amen Ra at Thebes. They held the government for 130 years, and entertained foreign relations, one of the monarchs having married a princess of the Rutennu. The 22d dynasty, the monumental, is rather confused. They were also high priests of Amen Ra. Shashank I. is the Biblical Shishak. His invasion

of Israel, with 12,000 chariots and 60,000 cavalry, and the capture of Jerusalem, is recorded on the portico of the Bubastites at Karnak. The other monarchs of this line, Osorkon I., Takehot I., and their successors, have left no remarkable records; and the dynasty, which appears of foreign origin, is more chronologically than historically important, the taking of Jerusalem falling between 989 and 959 B.C. The 23d Tanite dynasty, which succeeded it, exhibits a decadence in E., and was succeeded by the 24th dynasty, of a single monarch, the celebrated Bakenrenf or Bocchoris, who reformed the laws; but having been taken prisoner by the Ethiopian Sabaco, of the 25th dynasty, was burned alive. From this period, the history of E. becomes involved with that of Judea and Greece. Triphaka came to the assistance of Hezekiah against Sennacherib, and built the temple of Gebel Barkal. According to this Assyrian cuneiform inscription, the Ethiopians were expelled by the Assyrians, and the country placed under various monarchs. This state of affairs was closed by the rise of Psammitichus I. of the 26th dynasty, who, by the aid of Greek mercenaries, overthrew the other petty princes. His age marks a revival in art, and restoration of the old constitution of the empire. His successor, Nekao or Necho II., planned the canal across the isthmus of Suez, from which he desisted, warned by the advice of an oracle, after having lost 120,000 men in the attempt. Under his reign, the Phœnician navigators first passed the line. After defeating Josiah, king of Judah, and conquering Palestine, he was himself defeated by Nebuchadnezzar at Karkemish. Psammitichus II. carried his arms into Ethiopia. Apries, his successor, having lost all the conquests, was deposed by Amasis, his successor, and strangled. Amasis favoured in different ways the Greek colonies in E., and married a Cyrenaean wife, and conquered Cyprus, but incurred the enmity of Cambyses, who overthrew his son and successor at the battle of Pelusium (526—527 B.C.). Cambyses treated E. with considerable moderation, but after an unsuccessful expedition against the Ethiopians, lost his reason, stabbed the bull Apis, and committed various atrocities. His successor, Darius I., governed E. with more prudence; but Xerxes I. and Artaxerxes I. had successively to reduce it to subjection, which they did in spite of assistance rendered to it by the Athenians. The 27th dynasty of Persians was followed by the Saite line, the 28th, Amyrtaeus and Pausiris, who still held ground against the Persians; the 29th, Mendesian dynasty of Nephelches and Achoreus, maintained a Greek alliance; and the 30th, Sebennytic, consisted of Nectanebes I., who successfully resisted Pharnabazus and the Iphicrates; of Teos, who employed Agesilaus; and Nectanebes II., who fled into Ethiopia before the Persians (340 B.C.).

From this time, E. remained a province of Persia till its conquest by Alexander the Great, who founded Alexandria. Subsequently, E. passed under the Greek rule, and the language of the government, and the administration and philosophy, became essentially Greek. The court of the Ptolemies became the centre of learning and philosophy; and Ptolemy Philadelphus, successful in his external wars, built the Museum, founded the library of Alexandria, purchased the most valuable of manuscripts, engaged the most celebrated professors, and had the Septuagint translation made of the Hebrew Scriptures, and the Egyptian history of Manetho drawn up. His successor, Euergetes, pushed the southern limits of his empire to Axum. Philopator (221—204 B.C.) warred with Antiochus,

persecuted the Jews, and encouraged learning. Epiphanes (204—180 B.C.) encountered repeated rebellions, and was succeeded by Philometor (180—145 B.C.) and Euergetes II. (145—116 B.C.), by Soter II. and Cleopatra till 106 B.C., and by Alexander (87 B.C.), under whom Thebes rebelled; then by Cleopatra Berenice, Alexander II. (80 B.C.), and Neos Dionysus (51 B.C.), and finally by the celebrated Cleopatra; and after the battle of Actium (30 B.C.), E. passed into the condition of a province of Rome, governed always by a Roman governor of the equestrian, not senatorial rank.

The most important events in E. under the Roman rule were—the introduction of the Julian year by Augustus (24 B.C.), the visit of Vespasian to Alexandria (70 A.D.), and that of Hadrian (122 A.D.), the development of the Gnostic heresy, the visit of Caracalla (211 A.D.), the conquest of E. by Zenobia (270 A.D.), the revolt of Firmus (272 A.D.), the persecution of Diocletian (304 A.D.), and the rise of Manicheism, the great Arian controversy in the reign of Constantine, the rise of asceticism, magic, and astrology, and the final destruction of paganism (379 A.D.).

At the division of the empire (395 A.D.), E. fell to the Eastern Empire, and, at its fall, had become one of the Great Patriarchates of the Christian Church; but owing to the religious feuds of the Jacobites and Melchites, it became a province of Persia (616 A.D.) for 12 years. The Coptic governor Makankas, who reigned in the name of Heraclius, endeavoured to make himself independent, and invited the arms of the Arabs, and Omar I. easily conquered Egypt, in the nineteenth year of the Hegira (640 A.D.). Although Alexandria was retaken by Constantine III., the Arabs drove him out, and maintained their conquest, and E. remained an appanage of the califat. It afterwards passed into the dynasty of the Thonoundines (868 A.D.), the second of whom extended his kingdom to the Euphrates; but a new dynasty, the Akshidide, succeeded in 935 A.D., to give way to the Fatimide in 969 A.D., under which Cairo was built, and Egypt regained some of its prosperity, although in 1118 A.D. Baldwin I. burned the maritime town of Faramah. Subsequently, it passed under the Ayoubites, and Saladin, who fortified Cairo, built the citadel, excavated the well, and erected the granaries of Jusuf. In 1218 A.D., the Crusaders took Damietta, but were subsequently driven back in 1221 A.D. One of the later princes, Saleh-Nedjim Eddin, built the castle of Rhodah, and created the order of Mamelukes; but Louis IX. of France (1248 A.D.) took Damietta and gained the battle of Mansourah. In 1254, the Ayoubites entirely fell, and E. became subject to the Baharite and Bordjite Mamelukes, under whose government it flourished, and even pushed its conquests to Cyprus and Asia Minor, till, in 1517, Touman Bey fell into the power of Selim I., and E. became a province of the Turks, and administered by pashas. In 1601, the use of tobacco was introduced. Constant rebellions of the Mamelukes, and the violence of contending factions, distracted the country. The most remarkable event of this period was the French invasion by Bonaparte in 1798, which, by the conquest of Alexandria, and the battle of the Pyramids against the Mamelukes, led to the entire subjection of the country, from which the French were finally expelled by the Turks and British in 1801, and the country restored to the Ottoman Porte. The rise of Mohammed Ali in 1806 imparted a galvanic prosperity to E., by the destruction of the Mamelukes, the formation of a regular army, the increase of security, the improvement of the irrigation, and the introduction of European civilisation. In 1816, Mohammed Ali rendered part

of Arabia tributary by means of his son-in-law, Ibrahim; and although he lost his fleet at Navarino in 1827, he was subsequently sufficiently powerful to wrest Syria from the Porte, and to hold it as tributary by the treaty of Kutahia in 1835. Subsequently in arms against the sultan, the victory of Nisib, in 1839, would have elevated him to the throne of Constantinople; but the quadruple alliance in 1840, the fall of St Jean d'Acre to the British, and the evacuation of Syria, left him no alternative but to accept the terms of the four powers, and limit his power to the pashalik of Egypt, guaranteed to himself and his family by the Porte. In 1849, Mohammed Ali died, and was succeeded by Abbas Pasha, his grandson; but his short reign, which gave repose at least to E., terminated in 1854, when Said Pasha succeeded to the government. At the present moment, E. is chiefly under French influence, considerable part of the civil administration being in the hands of European adventurers. Amongst the numerous schemes proposed by foreign engineers may be cited the barrage of the Nile, and the canal of the Isthmus of Suez—gigantic but seemingly impracticable enterprises.

*Civilisation.*—There now only remains to consider the old civilisation of the Egyptians, which had made such strides at an early period of their history. In the sciences, as early as the 4th dynasty, the notation of time, the decimal system of numbers, weights and measures adjusted to a pound of 1400 grains, the geographical division of the country, and the division of the year (of 365 days) into three periods (of four months of 30 days) and twelve months, were already known, while the form of the buildings implies a knowledge of geometry and its sister sciences. An empirical knowledge of astronomy was probably possessed; nor could the arts have reached such a high development without some acquaintance with chemistry; and tradition assigns a knowledge of medicine and anatomy to a still earlier age. The art of literary composition also existed in the 11th dynasty, for fragments of the religious or so-called Hermetic books of that age have reached us (see Papyrus); and Cheops himself

Egyptian Arch:

Tomb at Saggara, arched with stone, of the time of Psammitichus II., whose name occurs on the roof to the left, and other places.

was an author of renown. The language of the period, although concise and obscure, was nevertheless fixed; and a code of manners and morals, under the 6th dynasty, has been handed down. Architecture had attained great refinement at an early

period; not only were the chambers and temples, and other edifices, squared and directed to face the cardinal points, but the use of a kind of false arch, or stones disposed so as to form an angle overhead to relieve superincumbent pressure, *en décharge*, was practised as early as the 4th, and the vault or arch was in existence in the 11th and 18th dynasties, eight centuries before that of the Cloaca Maxima of Rome. Columns were in use as early as the 4th dynasty; and in the 12th, the so-called proto-Doric ones of Benihasan, with their cornices and triglyphs, shew that the Greeks derived this order of

Façade of Egyptian Temple.

architecture from Egypt. The symmetric arrangement of the temples, consisting of rectangular courtyards and hypæthral halls, with their gateways, slightly converging to the apex, and their bold and severe lines, and the obelisk (see OBELISK), and the pyramid (see PYRAMID), forms admirably adapted to resist the inroad of time, not to mention the remarkably fine masonry, prove the high development this art had acquired at the remotest

Decorated Doorway.

age. Nor was sculpture less advanced, for long before Dædalus, the statues of the 4th dynasty, at least 2000 B.C., had been moulded with great accuracy to a fixed canon; and although their architectural employment had rendered their action rectilinear—such as the arms pendent, the left foot advanced, and the feet not detached but when in stone, with the part between them reserved—and the ears were placed too high in the head, and a kind of pillar was fixed behind in standing figures, yet in portraiture they had attained to great perfection. Sculpture, indeed, in the human form was always restricted to a few conventional attitudes; but some of the lions and sphinxes are executed with a spirit surpassing the power of Greek artists. A peculiar kind of bas-relief prevailed in E., the figures being sunk below the surface like the intaglio figures of a gem, but in slightly convex relief, not concave. This style, called *cavo-rilievo*, or *intaglio*, has been most successful in preserving the hieroglyphs and

anaglyphs of the monuments. Bronze statues cast from moulds, and having a leaden or other core,

Head of Rameses II.

Uah-ha-ti-ra.

were first made in E., and subsequently introduced into Greece by Rhœcus. This art flourished best under the earlier dynasties, and had much degenerated in the 19th and 20th, although subsequently revived by the 26th. Painting appeared at the same age chiefly in tempera or whitewashed surfaces, although fresco was occasionally used, and encaustic appears only under the Greeks and Romans. This art, of course, was freer than sculpture, but yet had a rigid architectural character, and followed the same canon as sculpture, the colours used being generally the pure or primitive, and the background uniformly white. The architectural details of Egyptian temples and the hieroglyphs appear to have been always coloured, and added additional charm to the sculptures. The religious papyri

Sistrum.

or rituals were also often embellished with elaborately coloured vignettes, resembling the illuminations of modern manuscripts. Nor had the Egyptians attained less eminence in the art of music, the harp and flute appearing in use as early as

Egyptian Glass-blowers.

the 4th, and heptachord and pentachord lyres as early as the 12th dynasty; besides which, drums, tambourines, flutes, cymbals, trumpets, and guitars, are seen in the 18th, and the national instrument,

the jingling sistrum, in the 4th. Many of the instruments are of great size, and must have produced considerable effect. Nor was the art of song wanting, and measured recitations or songs occur on monuments of the 12th dynasty, while the lays of Maneros traditionally dated to a still earlier period. Poetry, indeed, was at all times in use, and the antithetic genius of the language suggested the application of the strophe and antistrophe (see HIEROGLYPHS), although it is not possible to define the metre. In the mechanical arts, many inventions had been made: the blow-pipe, used as a bellows, appears in the 5th

Bellows.

dynasty; bellows and siphons in the 18th. The saw, the adze, the chisel, press, balance, and

Siphons, used in the year 1455 B.C.

lever appear in the 5th, the harpoon in the 12th, razors in the 12th, the plough and other agricultural implements in the 5th. Glass of an opaque

1, 2, glass bottles represented in the sculptures of Thebes; 3, Captain Henvey's glass bead, about the real size; 4, the hieroglyphics on the bead containing the name of a monarch who lived 1500 B.C.

kind is seen in the 4th, and dated specimens in the reign of Thothmes III. (1445 B.C.), give the priority to E. (see GLASS); the oldest transparent glass, the Assyrian, not dating older than Sargina (711 B.C.). A glazed pottery or porcelain (see POTTERY), the potter's wheel, and the kiln, appear in the 4th; and the art of metallurgy, with the use of tin, at the same period. In the military art, the Egyptians used at an early age defensive armour of shields, cuirasses of quilted leather, and helmets; while spears, clubs, maces, swords, daggers, bows, and hatchets formed their offensive weapons. For sieges, they employed the testudo, ladders, torches and lanterns, and

A Guard apparently with a Lantern.

mines. The army was composed of infantry till the beginning of the 18th dynasty, when war-chariots were introduced; for, prior to that period, the ass only was known and used for transport; and carriages not having been invented, persons and goods were transported, on the panniers of asses, or on a kind of saddle slung between two of these useful animals. War-boats no doubt existed at an early period, and are mentioned as early as the 12th dynasty; but sea-going vessels not till the 18th, and no fleet till the 19th. The Nile, however, was constantly navigated by row-galleys with sails. An extensive commerce was carried on with neighbouring nations, and their tribute enriched the country with slaves, cattle, gems, valuable metals, and objects of curiosity. Rare animals were collected for ostentation. Under the earlier dynasties, the chief occupation of the nation appears to have been rearing cattle, cultivating grain, indulging in banquets, fishing, fowling, and the chase, and the establishment of each noble contained in itself all the organisation and artificers necessary for its maintenance. How transactions were carried on without the use of money, is not very clear, unless gold circulated moulded in the shape of rings adjusted to a given weight, but coin plate is mentioned by its pounds, *maa*, and its ounces, *kat*. The Persians first introduced money. See NUMISMATICS. The wealth of families was, however, spent on the tombs and furniture of the dead, and the preparations for embalming, which were on so vast a scale that filial piety did not disdain to mortgage not only the sepulchres, but the very mummies of its ancestors. See EMBALMING. Amusements were various, from the single-stick and juggling, the dance of almechs, the bull-fight, to draughts, dice, and morris. In fact, ancient Egypt had a material civilisation, which exerted all the requirements of industry, and forgot none of idleness. Pleasure was the object of existence, not, however, untempered by the voice of reason or the appeals of conscience, the moral code of duties being as pure as that of contemporary nations.

The civil government was administered by the three upper castes. The priests, distinguished by their superior knowledge, cleanliness, and godliness, had the ecclesiastical; the temples being administered by high priests and an inferior hierarchy, with overseers, and governors of revenues, domains, and donatives. Each temple, like a monastic institution, had its carefully subdivided organisation, each denizen having a separate charge or jurisdiction. The political and civil government was administered by royal scribes, or secretaries of state, who attended to the revenue, justice, foreign affairs, and all the interests of the executive. Sacred scribes attended to the ecclesiastical interests, and inferior scribes to the local interests. The public works, the collection of grain, and of the linen dues; the cattle, workmen, wells, irrigation, had each their separate superintendents and scribes. The military force of 410,000 men, at a later period, comprising all arms of the service, was ruled with severe discipline, and under the direction of nomarchs (*ha*), colonels (*hrai*), captains (*mer*), and lieutenants (*atnu*). The criminal and civil law was administered by judges (*salem en ash*), who held travelling assizes, and to whose tribunals the necessary officers were attached. The athlophoros or standard-bearer also transmitted the decrees of the royal chancery. The execution of deeds required so many witnesses that fraud evidently often occurred. The superior position of women in the social scale, notwithstanding the permission to marry within degrees of consanguinity usually forbidden, shews that the Egyptians reached a higher point of delicacy and refinement than either their western or eastern contemporaries. Colossal in its art, profound in its philosophy and religion, and in possession of the knowledge of the arts and sciences, E. exhibits the astonishing phenomenon of an unexpectedly high and ancient civilisation. See BUNSEN, *Aegyptens-Stelle*, 5 vols. 8vo, Hamb. and Goth., 1845—1857; LEPSIUS, *Denkmäler der Aegypten*, 12 vols. folio, 1849—1860; ROSSELLINI, *Monumenti dell' Egitto e della Nubia*, 8vo and folio, Pisa, 1840; SHARPE, *History of Egypt*, 8vo, Lond. 1846; BRUNGSCH, *Histoire d'Egypte*, 4to, Leip. 1849; LEPSIUS, *Königsbuch, der Alten Aegypter*, 4to, Ber. 1858; WILKINSON, *Manners and Customs of the Egyptians*, 6 vols. 8vo, Lond. 1847; LANE, *Modern Egyptians*, 2 vols. 8vo, Lond. 1842.

EGYPTIAN VULTURE (*Neophron percnopterus*), one of the smaller Vulturidae, of a genus

Egyptian Vulture and Young.

differing from the true vultures in the slender bill, which is covered for more than half its length with

a naked cere, and sharply hooked at the point. The head and throat are naked, but feathers extend along the back of the neck to the crown. The E. V. is not much larger than a raven. The plumage of the male is white, except the great quill-feathers, which are black. This bird is plentiful in Egypt, where it renders important service—as also in Turkey, Syria, and other countries—in devouring and so cleansing away carrion from the vicinity of human abodes. It is constantly to be seen in the streets of towns, and seems to be aware that it is regarded with favour, and enjoys the protection of mankind. Europeans in Egypt often call it Pharaoh's Hen, or Pharaoh's Chicken. It follows caravans in the desert, to devour whatever dies. Numbers are often seen congregated together, but the E. V. is not truly gregarious, and lives generally in pairs. Its geographic range extends over the whole of Africa, and great part of Asia; it is common in many parts of the south of Europe, is an inhabitant of the Alps and the Pyrenees, sometimes visits more northern regions, and has been killed in England.

EHNINGEN, a town of Württemberg, situated 21 miles south-south-east of Stuttgart, is the rendezvous of a great number of pedlars who traverse the neighbouring districts for the purpose of disposing of their wares. Pop. about 5000.

EHRENBERG, CHRISTIAN GOTTFRIED, one of the most distinguished naturalists of Germany, was born, 19th April 1795, at Delitsch, in Prussian Saxony. Although he had been originally intended for the clerical profession, he early relinquished the study of theology in favour of medicine; and after having attended the classes at the medical faculty at Leipsic for two years, he removed in 1817 to Berlin, where he graduated in medicine in 1818. His favourite study at this period was botany, and his earliest publications are devoted to botanical subjects, and more especially to such as demand the use of the microscope—an instrument with which the name and reputation of E. must ever remain inseparably associated; for to him belongs the merit of having rescued it from the discredit into which it had fallen, and of having been one of the first fully to appreciate its capabilities. In 1820, E. accompanied his friend Hemprich on his travels to the East; and after having visited Egypt, Syria, and Arabia, returned, in 1826, to Berlin, where he was appointed to one of the medical chairs of the university, which he still occupies. The three years which intervened before he again set forth on a scientific expedition, were devoted to the arrangement and classification of some of the abundant materials which he had accumulated in his eastern travels; and to this period belong the composition of his *Akalephen des Rothen Meeres*—which has largely contributed towards our knowledge of the Meduse—and his *Symbolæ Physica*. In 1829, E. accompanied G. Rose and A. von Humboldt on an expedition to the Ural and Altai Mountains, in the course of which he collected materials for his numerous memoirs on the Infusoria, and for his great work, *Infusionsthierehen*, published at Leipsic in 1838, which have identified his name with the history and study of this department of animal life. E. divided the Infusoria into Rotatoria (now found to belong to higher orders of animal life) and Polygastrica, which correspond more nearly with the Infusoria as now admitted, although many of his polygastric organisms have been found to be vegetable structures, and some to be the larval forms of worms, &c. E.'s researches have not been confined to living organisms, but include fossil Infusoria;

and his great work, *Mikrologie*, on the application of the microscope to geology, contains the results of his investigations in this department of inquiry. E. is a member of most of the scientific bodies of Europe, and has, for upwards of forty years, been an active contributor to the scientific literature of his country.

EHRENBREITSTEIN (Honour's Broad Stone), a town and fortress of Rhenish Prussia, is picturesquely situated on the right bank of the Rhine, directly opposite Coblenz, with which it is connected by a bridge of boats. The town of E. has several mills, a tobacco-manufactory, a flourishing trade in wine, corn, and iron, two cattle-markets, and four annual fairs. Pop. 4501. The fortress of E. occupies the summit of a precipitous rock 490 feet high, and has been called the Gibraltar of the Rhine, on account of its great natural strength, and its superior works. On three sides, the fortress is so precipitous as to be perfectly inaccessible; on the fourth and only approachable side, the north-west, it is fortified by three successive lines of defences, one within another. It is defended by 400 pieces of cannon; has cisterns capacious enough to hold a supply of water for three years, and a well sunk 400 feet deep in the rock, and having communication with the Rhine. E. was besieged in vain by the French in 1688, but fell into their hands in 1799, after a siege of fourteen months. Two years after, the French, on leaving E., at the peace of Luneville, blew up the works. It was assigned, however, to Prussia by the Congress of Vienna in 1814, and under that country was restored and thoroughly fortified. It is now one of the strongest forts in Europe. It is capable of accommodating a garrison of 14,000 men, and provisions for 8000 men for ten years can be stowed in its vast magazines. The view from the fortress, which comprehends a considerable portion of the course of the Rhine, including its confluence with the Moselle, is picturesque in the highest degree.

EICHHORN, JOHANN GOTTFRIED, one of the most distinguished scholars produced by Germany, was born at Dörnzimmern, in the principality of Hohenlohe-Oehringen, in 1752, and studied at Göttingen. He first became rector of the school of Ohrdruff, in the duchy of Gotha, afterwards, in 1775, Professor of Oriental Languages in the university of Jena, and in 1788 removed to Göttingen in the like capacity. Of this university he continued a distinguished ornament till his death in 1827.

His scholarship was almost universal, and he has left numerous treatises on a multitude of subjects, both ancient and modern, classical and Oriental, but he is chiefly known in this country as a biblical critic, and a chief of what is called the rational school. E. examined the Scriptures from an anti-supernatural point of view, but applied to their elucidation and criticism an unrivalled knowledge of Oriental and biblical antiquities. Miraculous appearances recorded in the Bible are held by him to be explainable as natural events, and everything is to be brought to the test of reason. Rationalism in this form can hardly be said to exist now, even in Germany; but some of E.'s views as to the historical origin of the canonical gospels have been extensively adopted. His chief works on this subject are a Universal Library of Biblical Literature (*Allgemeine Bibliothek der Biblischen Literatur*, 10 vols. Leip. 1787—1801); an Introduction to the Old Testament (*Einleitung in das Alte Testament*, 4th ed. 5 vols. Gött. 1824); an Introduction to the New Testament (*Einleitung in das Neue Testament*, 5 vols. Gött. 1824—1827); and an

Introduction to the Apocryphal Writings of the Old Testament (*Einführung in die Apokryphischen Schriften des Alten Testaments*, Gött. 1798). In a work entitled Primitive History (*Urgeschichte*, 2 vols. Nürnb. 1790—1793), he subjects the Pentateuch to bold criticism. His last work was a History of the House of Guelf, which he traces back to the 5th c., *Urgeschichte des Hauses Welfen* (Han. 1817).

EICHSTADT (earlier AICHSTÄDT, Lat. *Aureatum*, *Arborfelix*, or *Dryopolis*, the last signifying the same as Aichstädt—viz., oak-town), a town of Bavaria, is situated in a deep valley on the left bank of the Altmühl, about 40 miles west-south-west of Regensburg, in lat. 48°53' N., long. 11°11' E. It consists of the town proper, with four suburbs, is well built, and has several fine squares, one of which is adorned with a fountain, and a statue of St Wilibald, the first Bishop of Eichstadt. Among the notable buildings are the palace of the Duke of Leuchtenberg, containing a museum of antiquities, and some good portraits; the cathedral, founded in 1259, an imposing Gothic structure, with monuments in bronze and marble, good paintings, and fine painted glass; the town-house (1444), with a square tower; and the Wilibaldsburg, or castle of St Wilibald, built on an eminence 1200 feet high, and now used as a barracks. The manufactures are woollen and cotton fabrics, ironmongery, and stoneware; there are also breweries, and several mills. Pop. 7610. E. is of Roman origin, and in 908 was surrounded by walls. The bishopric of E. was founded as early as 745. It came into the possession of Bavaria in 1805. In 1817 it was attached to the landgravate of Leuchtenberg, and in 1817 it was bestowed on Eugene Beauharnois, Duke of Leuchtenberg, in the possession of whose family it still remains.

EICHWALD, EDUARD, a Russian naturalist, was born at Mitau, in Russia, 4th July 1795, and studied the physical sciences and medicine at Berlin, 1814—1817. After spending some years in travel, he returned to Russia, and in 1823 was appointed Professor of Zoology and Midwifery at Kasan. In 1827, he accepted a call to Wilna as Professor of Zoology and Comparative Anatomy; and in 1833 he went to St Petersburg as Professor of Mineralogy and Zoology. E. has been a great traveller for scientific purposes. He has investigated the shores of the Caspian Sea, the Caucasus, Persia, Germany, Switzerland, and France, travelled over the greater part of Russia, including the Scandinavian provinces, and in 1840 made a geological journey through Italy, Sicily, and Algeria. He has unquestionably been of more service to Russia by his geognostic, botanical, and zoological researches than any man since Pallas. His principal writings are—*Zoologia Specialis* (Wilna, 1829—1831), *Plantarum Novarum quæ in Itinere Caspio-Caucas observavit, Fasciculi* (Wilna and Leip. 1831—1833), *Travels to the Caspian Sea and the Caucasus* (Stuttg. 1834—1837), *Memoir on the Mineral Riches of the Western Provinces of Russia* (Wilna, 1835), *Palæozoic Russia* (1840), and in 1851, *The Palæontology of Russia* (St Petersburg, 1851). E. is a member of all the Russian, and of many foreign academies and learned societies.

EIDER, a river of Denmark, forming the boundary-line between Schleswig on the north, and Holstein on the south. It rises 12 miles south-west of Kiel, flows first north-west, then in a general westward direction, though with many windings, and enters the North Sea at Tønning, after a course of about 90 miles. It is navigable as far as Rendsburg, from which town the Schleswig-Holstein Canal stretches east to Kiel

Fiord, on the shore of the Baltic, thus establishing water-communication between the North and Baltic Seas.

EIDER, or EYDER-DUCK (*Somateria*), a genus of oceanic ducks, having the hind toe furnished with a deep lobe, and the bill swollen and elevated at the base, and extending up the forehead, where it is divided down the middle by an elongated projection of feathers. The tertials are elongated, and fall down over the wing. This genus is further characterised by the very abundant development of a fine elastic gray down, particularly on the breast, the valuable *Eyder-down* of commerce.—The COMMON E. (*S. mollissima*) is intermediate in size between a common duck and a goose; not much exceeding the common duck in entire length, because of the comparative shortness of the neck, characteristic of the oceanic ducks, but being about twice its weight. The male is larger than the female; and, in the breeding season, has the under parts black, the upper parts and the neck white, the crown of the head velvety black, the cheeks greenish white. After the breeding season, the white colour almost disappears from the upper parts, and gives place to black, without change of feathers. The female is of

Common Eider-Duck (*Somateria mollissima*).

a pale-brown colour, tinged with red, and varied with transverse marks of dark brown. Young males at first resemble the females, and do not acquire the full adult plumage till their third winter. The young are termed Brattocks in many parts of Scotland. The E. is an inhabitant of the northern parts of the world, abounding on arctic and subarctic shores, and becoming rarer in more southern and temperate regions. It is merely an occasional winter visitant in the middle latitudes of Europe, and the Fern Islands are its most southern breeding-place on the British coasts. In North America, it seldom breeds further south than the Bay of Fundy. Great numbers breed on the coasts of Labrador and more northern parts of America, where hitherto the gathering of the down has been generally neglected; but in Iceland and Norway the breeding-grounds of eiders are carefully protected, and are transmitted as valuable inheritances from father to son. Cattle are sometimes removed from islets, in order to induce the eiders to settle upon them, and a strict watch is kept against dogs and foxes. Promontories are sometimes even formed into artificial islets, on the same account, as the E., like many other sea-birds, prefers islands for its breeding-places, probably on account of their greater quiet and security. The nest is formed of fine sea-weeds,

mosses, and dry twigs, if they are to be had, matted and interlaced. The eggs are usually five, sometimes six or seven in number, about three inches long, and fully two inches broad, of a uniform pale green: they are at first deposited without any down, but as incubation proceeds, the mother strips the down from her breast, and places it about them. By it they are kept warm when she at any time has occasion to leave them, but it seems to be indispensable to their being hatched; for if the eggs and down are removed, and if this is done a second time, so that the female cannot afford a further supply, the male comes and contributes for the third set of eggs the down of his breast, which is of a paler colour. The common practice in Norway and Iceland is to take away the eggs and down twice, leaving the third set of eggs to increase the number of the species. The eiders of the Icelandic and Norwegian breeding-grounds shew so little alarm at the approach of visitors, that the females will permit themselves to be touched as they sit on their nests, the males moving about close beside them, but agitated and disturbed. The nests are often placed so close together that great care is necessary in walking among them to avoid trampling upon them. In the islet of Vidúe, a valuable breeding-ground near Reikiavik, the capital of Iceland, almost every little hollow place between the rocks is occupied by the nests of these fowls; they readily take possession of holes cut for them in rows in the sloping side of a hill; nay, garden-walls and the interiors of buildings are in like manner occupied. In other situations, the birds do not shew quite the same amount of confidence in man.

The E. is sometimes called *St Cuthbert's Duck*, from a rock called *St Cuthbert's Isle*, one of the *Fern Islands*. It seems probable that, with due care, the number of the eiders at the *Fern Islands*, and some of the *Scottish islands*, might be greatly increased, and their down yield a considerable revenue, but at present their eggs are indiscriminately taken with those of other sea-birds, and no protection is extended to them. The eggs are remarkably fine. The flesh of the birds, also, is not unpleasant, and is said to become of superior excellence when they are partially domesticated, and when farinaceous food is mixed in considerable quantity with their natural diet of marine molluscs, crustaceans, &c. The complete domestication of the E. has been successfully attempted, where access could be obtained to the sea.

About half a pound of eider-down is said to be annually obtained from each nest, but this is reduced by cleaning to a quarter of a pound. The elasticity of the down is such that three-quarters of an ounce of it will fill a large hat, although two or three pounds of it may be pressed into a ball and held in the hand. Its extensive use, particularly in Germany and other parts of the continent of Europe, for stuffing the bed-coverings, which there usually supply the place of blankets, &c., is well known. The down taken from birds which have been killed is inferior in quality to that obtained from the nests. The latter is known in commerce as *live down*, the former as *dead down*.

The *KING EIDER*, or *KING DUCK* (*S. spectabilis*), also yields no inconsiderable part of the eider-down of commerce, especially of that which is brought from the Danish settlements in Greenland. This bird belongs to still higher northern latitudes than the common eider. On some parts of the coasts of Greenland, on those of Spitzbergen, Nova Zembla, the North Georgian islands, &c., it occurs in great numbers. A few breed in Iceland and the *Farøe Islands*. In Britain, the bird is a rare visitant. It is of about the same size as the common eider. The female is very similar to the female of that species;

but the male has a remarkable large protuberance over the base of the upper mandible, and the white colour of the neck extends only over the upper part

King Eider (*Somateria spectabilis*).

of the back. Skins of king ducks are made into winter garments by the inhabitants of Siberia and Kamtchatka.

**EIGHT, PIECE OF**, a name once popularly given to the Spanish dollar, as being divided into eight reals.

**EIGHT-FOIL**, used in Heraldry to signify a grass having eight leaves, as the trefoil has three. According to Sylvanus Morgan, it may be used as the difference of the ninth branch of a family.

**EIK**, in the legal phraseology of Scotland, is an addition made to a document for the purpose of meeting circumstances which have subsequently arisen. Thus, a reversion being a deed granted by a borrower, who reserves to himself the right of redeeming the land which he has conveyed in security to the lender (see *WADSET*), an eik to a reversion is a subsequent deed by the reverser acknowledging the receipt of a further sum, and declaring that the property shall not be redeemable until repayment of the additional loan. In like manner, an eik to a confirmation or testament is an addition to the inventory made up by an executor at his confirmation, in consequence of additional effects belonging to the deceased having been discovered. Where the executor appears to have fraudulently omitted or undervalued any effects belonging to the deceased, any creditor or person interested may apply to the commissary to be confirmed executor with reference to these additional effects, *ad omnia vel male appretiatia*.

**EIKON BASILIKÉ**, a work presumed to have been written by Charles I. during his confinement, but now more correctly imputed to another writer. The following are the explanations of M. Guizot on the subject, in his *History of Oliver Cromwell and the English Commonwealth*. 'It is to the *Eikon Basiliké* that Charles I. is principally indebted for the name of the Royal Martyr. The work is not by him; external testimony and internal evidence both combine to remove all doubt on the matter. Dr Gauden, Bishop, first of Exeter and afterwards of Worcester, under the reign of Charles II., was its real author; but the manuscript had probably been perused and approved, perhaps even corrected, by Charles himself during his residence in the Isle of Wight. In any case, it was the real expression and true portraiture of his position, character, and mind, as they had been formed by misfortune; it is remarkable for an elevation of thought which is at once natural and strained; a constant mingling of

blind royal pride and sincere Christian humility; heart-impulses struggling against habits of obstinate self-conscience; true piety in the midst of misguided conduct; invincible, though somewhat inert devotion to his faith, his honour, and his rank; and as all these sentiments are expressed in monotonous language, which, though often emphatic, is always grave, tranquil, and even unctuous, with serenity and sadness, it is not surprising that such a work should have profoundly affected all royalist hearts, and easily persuaded them that it was the king himself who addressed them.'—Vol. i. p. 31.

EILENBURG, a town of Prussian Saxony, is situated on an island of the river Mulde, 26 miles east-north-east of Merseburg. It is reached by two bridges, is surrounded by walls and ditches, and consists of the town proper with four suburbs. The manufactures of E. consist of calico, woollen yarn, tobacco, starch, vinegar, and brandy. Pop. about 9900.

EILETHY'IA, a city of Egypt, anciently Nuben, and known at present by the name of El Kab. The town was anciently walled. The present ruins consist of the remains of small temples dedicated by Rameses II. to Ra; a Ptolemaic temple dedicated to the Eponymous goddess by Physcon or Euergetes II., with additions by Ptolemy Alexander L., and Cleopatra; and another temple dedicated by Amenophis III. to the local deities. The names of other monarchs are also found in the ruins; but the most interesting and important remains are the rock-tombs excavated in the vicinity. That of Aahmes-Pensuben, a functionary, records his military services in the wars of the early monarchs of the 18th dynasty against the Shos or Shepherds, and other Asiatic and Nigritic races. Another, of Pahari, is decorated with paintings representing the pursuits of agriculture. Swine were sacred to the local goddess. The town itself, during the 18th dynasty, appears to have been governed by princes, and some of the tombs appear as late as the 19th and 20th dynasties.—Wilkinson, *Modern Egypt*, vol. ii. p. 270; Champollion, *Notice Descriptive*, p. 265; Brugsch, *Reiseberichte aus Aegypten*, p. 214.

EIMBECK, or EYNBECK, an old town of Hanover, is situated on the Ilme, forty miles south-south-east from Hanover, in lat. 51° 49' N., long. 9° 50' E. It was a place of considerable importance in the 15th c., but has decayed greatly in recent times. It is surrounded by old ruinous walls, which are entered by five gates; its houses are antiquated; its streets narrow, tortuous, and badly paved. One portion of the town, however, which was burned down in 1826, has been rebuilt in a greatly improved manner. E. has manufactures of woollens, cottons, and linens, and chemical products; and has distilleries, breweries, tanneries, and tobacco-factories. E. owes its origin to the pilgrimages made to the Chapel of the Holy Blood, founded here in 1094 by Count Alexander von Darnl. Pop. 5000.

EIMEO, one of the Society Islands, in the Pacific Ocean, lies in lat. 17° 30' S., and long. 150° 10' W., about 30 miles to the west-north-west of Tahiti, the principal member of the group. It measures nine miles by five, and numbers about 1200 inhabitants. It consists of deep valleys and abrupt hills—the former well cultivated, and the latter heavily timbered. It is worthy of notice chiefly as the cradle of Polynesian Christianity. Here, in or about 1814, occurred the first popular manifestation in favour of the new religion; and here was established, as an instrument of

evangelisation, the South Sea College of the London Missionary Society.

EINSIEDELN, a small town of Switzerland, in the canton of Schwytz, and 9 miles north-north-east of the town of that name. It is worthy of mention on account of its Benedictine Abbey, containing a black image of the Virgin, to which about 150,000 pilgrims annually repair. The town has 55 inns and 20 alehouses, supported chiefly by the pilgrims. The dedication festival of the abbey, 14th September, is the great pilgrimage season. The present abbey, one of the finest in Switzerland, was built at the beginning of the 18th c., and is the fifth since the foundation of the abbey, in the 10th century. Its treasury was rifled by the French in 1798. Pop. about 3000.

EIRE, EYRE, JUSTICES IN (corruption of Lat. *in itinere*). By this term, both in England and Scotland, were the judges of Assize (q. v.) formerly designated. Justices in eire were first established in England by the statute of Northampton (1176 A.D.), in the reign of Henry II. At first, they made the circuit of the kingdom once in seven years; but by Magna Charta, c. 12, the chief-justices are directed to send justices through every county once in the year. In Scotland, the chief-justiciar, says Erskine, i. 3. s. 25, was originally bound to hold yearly two justice courts or aires at Edinburgh and Peebles. This court gradually became fixed at Edinburgh. Besides this court, special 'justice-aires' were frequently held in the more remote parts of the country by the king in person, or by judges named by him, twice in the year, in spring and autumn (st. Robert III. c. 30, 1440 c. 5, 1491 c. 29). These courts were discontinued, but revived by 1587, c. 81. The term is still in use in Scotland, where, at the commencement of every circuit, proclamation is made to the lieges to attend the 'circuit eire.'

EISENACH, a town of Germany, Saxe-Weimar, is beautifully situated amid finely wooded hills on the Hørsel, 45 miles west from Weimar. It is a prosperous and industrious town, is surrounded with walls, which are pierced by five gates, and is well built, with wide, clean, and well-paved streets. E. has a ducal palace, a large and handsome building, now used as a court-house; a spacious market-place, including a handsome civic school; numerous churches; and a school of design. Its manufactures are woollen, cotton, and linen goods, soap, white-lead, meerschaum pipe-bowls, leather, and carpets; there are also breweries and tanneries, and oil, powder, and spinning-mills. Pop. 10,000.

On a lofty eminence in the immediate vicinity, surrounded by forests, stands the castle of Wartburg, now used as a prison, but formerly a residence of the landgraves of Thuringia, and worthy of notice as the spot where the Mimesingers (q. v.) assembled to hold a trial of skill in 1207, but chiefly as being the asylum to which Luther, at a time of great danger, was carried by his friend the Elector of Saxony, who, waylaying the great reformer, seized him, with an appearance of violence, and hurried him to this fastness, where he remained in safety from May 1521 to March 1522. The chapel in which Luther preached, as well as the chamber which he inhabited, and in which he discomfited the Evil One by throwing the inkstand at his head, is still pointed out. Another portion of the castle contains a fine armoury, with suits of the 16th and 17th, and even, it is said, of the 13th and 14th centuries.

EISENBERG (Ger. Iron Mountain), a small town of Germany, in the duchy of Saxe-Altenburg, is situated on an eminence near the Saale, 26 miles east of Weimar. It is well built, its chief edifices

being the castle, the observatory, the lyceum, and the town-house. E. has manufactures of woollens, porcelain, and earthenware, and has five annual fairs. Pop. 5000.

EISENERZ, a small town of Austria, in the north of the province of Styria, 20 miles west-north-west of Bruck. Its appearance is dirty and unprepossessing, and it is worthy of mention only for its connection with the Erzberge (ore mountain), at the southern base of which the town lies. This mountain, which is about 2840 feet high, and about five miles in circumference at the base, is literally a solid mass of iron ore, of a quality so rich, that, instead of cutting mines into it and following the metal in veins—which process was formerly adopted here—the top and sides of the rock are quarried from the outside, and the ore is then broken small, and conveyed to the smelting-house without further preparation. Mines have been worked on this mountain for upwards of 1000 years. Arragonite (*Eisenblüte*, or *Flos ferri*), resembling branching coral in form, and of the most beautiful and purest white, is found in grottos in the interior of the mountain. Nowhere else does it occur in equal perfection. E. has 12 smelting-houses, 3 furnaces belonging to government, and a population of 3300, employed in mining.

EISENSTADT, a free town of East Hungary, stands in lat. 47° 50' N., and long. 16° 30' E., 12 miles north-north-west of Oedenburg. It is a walled town, has two gates, and consists principally of three main streets. It has also a Franciscan monastery, containing the burial-vault of the Esterhazy family, who are the proprietors of the palace, which forms the chief architectural feature of Eisenstadt. This palace was built in 1683, but was altered and enlarged in 1805. It contains 200 chambers for guests, and has a saloon sufficiently large to dine 1000 people. Its library contains a magnificent collection of church-music—masses, Hitanies, oratorios, &c., with some of Handel's MSS. In the suburbs is a conservatory, one of the largest in Europe, containing 70,000 specimens of exotic plants. Pop. 5700.

EI'SLEBEN, a town of Prussian Saxony, is situated about 25 miles north-west from Merseburg, in lat. 51° 33' N., long. 11° 35' E. It consists of the Old Town—which is surrounded by walls and ditches, and has seven gates—the New Town, and the suburbs. E. has manufactures of potash and tobacco; in the vicinity are copper and silver mines, and smelting-works. Pop. 10,285. Here, on the 10th November 1483, Luther was born, and here also he died, 16th February 1546. The house in which he was born was partially consumed by fire in 1689. An interesting remnant of it, however, is still extant, having the portrait of Luther placed over the entrance. In the church of St Andrews are the cap, cloak, and other relics of the great reformer.

EISTEDDFODS, the name given to the gatherings of Welsh bards for competition in national minstrelsy. See BARD, and WELSH LANGUAGE AND LITERATURE.

EJECTMENT, ACTION OF (*Ejectio firme*), in English Law, 'is a possessory action, wherein the title to lands and tenements may be tried, and the possession recovered, in all cases where the party claiming title has a right of entry.'—Selwyn's *Nisi Prius*. 'The action of ejectment,' says Lord Mansfield, 'is the creature of Westminster Hall, introduced within time of memory, and moulded gradually into a course of practice by rules of the courts.'—*Fairclain & Fowler v. Shamittle*. 3 Burr. 1292. According to the strict

rules of common law, a person dispossessed of his property in land, &c., was obliged to enforce his right by means of one of the forms of real Action (q. v.) now abolished. But as the form of action differed according to the nature of the possession of the holder of the land, this process was tedious and inconvenient. In order to remedy this defect, the action of ejectment was by degrees adopted as a means of establishing a title to land. This action was at first applicable to the special case where the plaintiff was lessee for years, and it was limited originally to a demand for damages simply. But it is said that as early as the reign of Richard II. or Edward IV., the court gave judgment that the plaintiff should also recover the term and the possession of the land. The action having thus acquired in some measure the character of a real action, it was found convenient to extend its effect. By means of a legal fiction, introduced in the time of Henry VII., the action was first applied to the purpose of enforcing a title to land. The process adopted was as follows: The judges having declared that a tenant for years succeeding in his action should have possession, the claimant of the land commenced by feigning a lease for years granted by himself to an imaginary lessee, John Doe. It would seem that at first the plaintiff actually granted a formal lease to a friend, who was also formally ousted, in order to raise the question of title. But these men of straw being removed as the cause proceeded, it was soon found that they might be altogether dispensed with, and the fictitious John Doe and Richard Roe substituted in their room. The declaration proceeded to state that upon this lease Doe entered, and that Richard Roe, also an imaginary person, had ousted him. Notice of this action was then given to the actual tenant of the lands, together with a letter from the imaginary Richard Roe stating that he should make no appearance to the action, and warning the tenant to defend his own interest. If no appearance was made, judgment was given in favour of the plaintiff, who thereupon became entitled to turn out the tenant in possession. But if the latter made appearance, the first step in the action was a formal acknowledgment by him of his possession of the lands, of the lease in favour of Doe, of Doe's entry, and of the ouster by the tenant himself. These matters, be it remembered, were, in fact, mere fictions; but having been introduced on the record simply to comply with the technical rules of legal title, they were equally readily removed when the real question at issue presented itself. This reduced the cause to the simple question of the right of the plaintiff to grant the lease to Doe, and thus the title to the land became the real question at issue. But it must be observed that this remedy was confined to the case of one having a Right of Entry (q. v.). Where, therefore, a person had suffered a Deforcement or Discontinuance (q. v.), he was still obliged to resort to a real action to establish his right. This state of things continued till 3 and 4 Will. IV. c. 27, whereby the remedy by ejectment was, with a few exceptions, in fact extended to every one who alleged that he was wrongfully dispossessed; but it was at the same time provided that no action should be brought to recover land but within twenty years after the right accrued. But while the remedy was thus extended, the same elaborate string of fictions was suffered to continue until the passing of the Common Law Procedure Act (15 and 16 Viet. c. 76), whereby the ancient machinery is quite swept away. The action now commences by a simple writ addressed to the tenant in possession, and 'to all persons entitled to defend the possession,' setting forth that the plaintiff has asserted a claim to the

land, and calling upon those interested to appear within a certain time to defend their right. The writ also contains a notice that, in default of appearance, the tenant in possession will be ejected. On appearance being made, issue is joined, and the cause proceeds as in ordinary actions. Judgment in ejection will not carry the mesne profits, to recover which a supplementary action is necessary; for particulars of which, see TRESPASS QUARE CLAUSUM FREGIT.

#### EJOO. See GOMUTO.

**EKATERINBURG**, a fortified town in the west of Asiatic Russia, is situated on the eastern slope of the Ural Mountains, on both banks of the Isset, in lat. 56° 50' N., long. 60° 7' E. It is a well-built town, its streets long and straight, but unpaved. As a substitute, however, planks are laid along the sides of the streets, and used as footpaths. The majority of the houses are of wood, but there are also many very handsome stone buildings. In the southern portion of the town, which is connected with the northern by a fine bridge, are the government magazines, the mills, factories, and the market-place. The opposite side, however, is the handsomer. It contains the dwellings of the mine-proprietors and of the merchants, and is laid out in elegant and spacious streets. E. is the seat of administration for the Ural mines, and is in the centre of the mining districts of these mountains. Among its institutions, it has a museum of mineralogy, an excellent chemical laboratory, a school for educating miners, an imperial mint, numerous works for cleansing and amalgamating metals, and for cutting and polishing precious stones. The greater number of the inhabitants are supported by the productiveness of the neighbouring mines. E. stands on the high road between Russia and Siberia, and is therefore a place of brisk trade. In the vicinity are the gold-mines of Niviansk and Beresoff. Pop. 16,497. E. was founded by Peter the Great in 1723. Its average temperature during the year is 31° F.

**EKATERINODAR**, a town of Russia, and capital of the country of the Cossacks of the Black Sea, is situated on the right bank of the river Kuban, about 100 miles from its mouth, in lat. 45° 5' N., long. 39° E. It is surrounded on all sides by swamp and morass. Its houses are almost all of earth, have thatched roofs, and are of one story in height. The streets are broad, regular, and straight, but exceedingly dirty. E. has a cathedral with six wooden towers, and a wooden fortress. Pop. estimated at 9000.

**EKATERINOGRAD**, a town and fortress in the south of Russia, in the government of Caucasus, is situated on the left bank of the Terek, in lat. 43° 40' N., and long. 44° 3' E. It is an important military post of the Cossacks; its houses are regular, but miserably built. A stone triumphal arch was erected at E. by Catharine II., in memory of Prince Potemkin, who founded the town in 1777. Pheasants abound here, and form a principal article of food. Pop. 5000.

**EKATERINOSLAV**, a government of Russia, in the province of South Russia, bounded on the N. by Little Russia, and on the S., reaching in one part to the shores of the Sea of Azov. The government of E., together with that isolated portion of it which lies on the eastern border of the Sea of Azov, and comprises the district of Taganrog and the country of the Azovian Cossacks, has, in all, an area of 25,319 square miles, and in 1856 had 1,039,597 inhabitants. Only about one-third of the entire area consists of cultivable land, the remainder being desert (see STREPE). The climate

is mild, and a great many highly esteemed fruits, as apricots, peaches, cherries, &c., which do not occur in the more northern parts of Russia, are found here. Agriculture is pursued, but the quantity of grain produced is not equal to the consumption. Cattle-grazing is extensively carried on. The chief town is Ekaterinoslav.

**EKATERINOSLAV**, a fortified town of South Russia, is situated on the right bank of the Dnieper, 250 miles north-east from Odessa, in lat. 48° 27' N., long. 35° 5' E. It was founded in 1787 by the Empress Catharine II. The streets are long and broad, but not so clean or so well filled with houses as they might be. E. has manufactures of silk and woollen goods, and an important annual wool-fair. It is the residence of an archbishop. In the vicinity is a palace, now in a ruinous condition, but formerly the residence of Prince Potemkin. Pop. 13,000.

**ELÆAGNUS**, a genus of exogenous plants, of the natural order *Elaagnaceæ*. This order consists of trees and shrubs, usually covered with scurfy scales, and having alternate or opposite entire leaves, without stipules. There are only about thirty known species of this order, all natives of the northern hemisphere, but found both in its warm and cold regions. The Sallowthorn (q. v.) is the only British species. *Shepherdia argentea*, a North American shrub of this order, yields a pleasant fruit. The genus *Elaagnus* consists of a number of deciduous shrubs or low trees, with male and female flowers on the same plant. *E. angustifolia*, the OLEASTER, sometimes called Wild Olive, is a native of the south of Europe and the Levant, a spiny tree of 15—20 feet in height, with lanceolate leaves, which, as well as the young shoots, are hoary with stellate hairs. It is frequently planted in England, for the sake of its silvery white foliage, beautifully contrasting with the green of other trees, and its very fragrant flowers, which are small and of a dull yellow colour.

**ELÆTIS**. See OIL PALM.

**ELÆOCARPACEÆ**, according to some botanists, a natural order of exogenous plants, but regarded by others as merely a sub-order of

*Elæocarpus Cyaneus*:

a, magnified flower; b, petal; c, stamens; d, ripe fruit; e, same cut away, shewing wrinkled seed.

*Tiliaceæ*; the chief distinctions being deeply cut or fringed petals and anthers opening at the apex. The E. are mostly East Indian trees. The fruits of some are eaten; those of some are dried and

put into curries; those of *Elvocarpus serratus* are pickled in brine and eaten with oil in Ceylon, and much resemble olives. *E. cyaneus*, a native of New Holland, is here figured. The deeply wrinkled seed or stone of the fruit of some, particularly *Elvocarpus ganitrus* and *Monocera tuberculata*, being very hard, and having a fine sculptured appearance, are made into beads for necklaces and bracelets, and are sometimes set in gold. They are often called OLIVE NUTS. These beads are frequently worn by religious devotees in India, and are sometimes sold as ornaments in the shops of Europe.

ELÆOCOCCA, a genus of *Euphorbiacea*, the seeds of some of which yield useful oils. The oil obtained from *E. verrucosa* is used for food in Japan, notwithstanding considerable acridity. The tree is cultivated in the Mauritius, and the oil is there used only for burning. That obtained from *E. vernicia* is used in painting in China.

ELÆODENDRON, a genus of trees of the natural order *Celastraceæ*, having a 5-partite calyx, 5 petals, a 5-angled disc, 5 stamens, the ovary immersed in the disc, and a drupaceous fruit. *E. glaucum*, a native of Ceylon and the south of India, is sometimes called the *Ceylon Tea-tree*, from the resemblance of its leaves to those of the tea-shrub. The timber of *E. croceum*, called SAFFRON-wood at the Cape of Good Hope, is much used there in building and cabinet-making; it is fine-grained, hard, and tough. The fruit of *E. Kabu*, another South African species, is eaten by the colonists. That of *E. Aryan* yields an oil similar to olive oil, much used by the Moors.

ELAGABA'LUS, or HELIOGABA'LUS, emperor of Rome, was born at Emesa in 204 A.D. His real name was Varius Avitus Bassianus, but having, when a mere child, been appointed high-priest of the Syro-Pheñician sun-god Elagabal, he assumed the name of that deity. Soon after the death of his cousin Caracalla, E. was proclaimed emperor by the soldiers, in opposition to the legitimate sovereign, Macrinus, who had become obnoxious to the troops from the severity of his discipline. The rivals met in battle at Antioch in 218 A.D. Macrinus was defeated, and E. quietly assumed the purple. His reign, which lasted rather more than three years and nine months, was infamous for the nearly unparalleled debaucheries of every kind in which he indulged. He was murdered in an insurrection of the prætorians in 222 A.D., and was succeeded by his son, Alexander Severus.

ELAND (*Antilope Oreas*), a species of antelope, abounding in South Africa, wherever there are fertile plains and low hills, except in the longest settled and most cultivated parts of Cape Colony, where it has been too much hunted to be any longer of very frequent occurrence. It is described by Livingstone as 'the most magnificent of all antelopes.' It is one of those which are sometimes called *bovine* antelopes, because they seem to approximate a little in some of their characters to the ox-tribe, having a broader muzzle, less slender limbs, and greater bulkiness of form than the antelopes in general. The E., however, is a very graceful and beautiful animal; it is as large as a horse, fully five feet in height at the shoulder, and weighs from seven to nine cwt. The horns—which in the male are about a foot and a half long, and in the female longer and more slender—are almost straight, inclining backwards and outwards; they are pointed, and their great strength is increased by a spiral wreath. The E. has a large protuberance on the larynx, in this resembling the elk, from which, probably on this account, it has

derived its name. It is also known as the *Impoof* or *Impoofoo*. Its tail very much resembles that of an ox, and terminates in a tuft of long black hair. It is a gregarious animal, and the herds are often large. It is generally very fat, and not difficult of

Eland (*Antilope Oreas*).

pursuit, its gentleness also increasing the facilities of the hunter. Its flesh is very much esteemed, particularly the muscles of the thighs, which are dried like tongues. It is surprising that no attempt has been made to domesticate, for useful purposes, an animal very easy of domestication, and possessing so many valuable qualities.

Livingstone discovered a variety of the E. in regions to the north of the Cape Colony, having the body marked with narrow white transverse bands. According to the figure given in his travels, it seems even more bovine in form than the common variety.

ELANET (*Elanus*), a genus of *Falconideæ*, allied to the Kites, which they resemble in many of their characters; but from which they differ in having the short tarsi half covered with feathers, and the claws, except that of the middle toe, rounded

Elanet (*Elanus dispar*).

beneath. The tail is very little forked. One species (*E. melanopterus*) is common in Africa, from Egypt to the Cape of Good Hope, and is found also in India. Another species is the Black-shouldered Hawk (*E. dispar*) of America, the northern limit of which appears to be South Carolina. Both of these feed chiefly on insects, which they catch on the wing, but they also prey on small birds and reptiles.

**ELAPS**, a genus of venomous serpents, inhabiting the warm parts of the world, and chiefly the Indian islands, New Holland, and tropical America. They are of slender and cylindrical form, with an elongated head, and often of bright and beautiful colours. They are not very agile, are said to prey chiefly on other reptiles, and live among the luxuriant vegetation of meadows or of forests.

**ELASTIC TISSUE**, known also as Yellow Fibrous Tissue, is one of the forms of Fibrous Tissue (q. v.). It derives its name from the remarkable physical property which it possesses of permitting its fibres to be drawn out to double their length, and again returning to their original length. It occurs in various ligamentous and other structures of the animal body in which elasticity is required, as, for example, in the vocal chords, the membranes connecting the cartilaginous rings of the trachea, the middle coat of the arteries, the skin, &c.

**ELASTICITY**, or **SPRING**. When an external force acts upon a solid body, it produces at first slight alterations in the relative positions of the particles; and if before these alterations exceed a certain limit, the force ceases to act, the particles return to their former position, and the disfigurement disappears. This power or property of recovering their previous form after alteration, is called elasticity, and we are justified in ascribing it to all bodies, though in very different degrees. It was once believed that there were definite limits within which changes of form produced by pressure or other forces disappeared completely. It was thought, for instance, that when a weight of no great magnitude is suspended from a metallic wire, the slight increase of length which the wire is observed to undergo, is completely lost when the weight is removed; and the limit to which the wire might thus be stretched, and still suffer no permanent increase of length, was called the limit of its elasticity. But recent more accurate experiments have shewn that no such limits exist, at least in the case of metals; or, which is the same thing, that permanent lengthening results, however slightly the wire be loaded—it never contracts again quite so far as it was stretched. It is necessary, therefore, to fix the limit arbitrarily; and this is done by agreeing that it shall be held to begin when the metal in question suffers a permanent elongation of 0.00005 of its length. To get the elastic extensibility of a wire, then, we must compare its length with a weight suspended, with its length when the weight is removed. In this way it is found that the extensions produced are proportional to the extending forces or weights. From this law, then, we can calculate what weight it would require to stretch a wire or rod of a square inch in section to double its own length; supposing it possible to proceed so far without breaking it, and that the law of elasticity continued up to this point unaltered. This weight, which is different for every metal or kind of wood, is called the *coefficient* or *modulus of elasticity* of the particular substance; and is used in mechanics in calculating how far a given weight will extend a wire or rod of given diameter. This coefficient is not constant for the same metal; for all circumstances that increase the density of the metal, increase the modulus of elasticity. Bodies manifest elasticity not only when extended in length, but also when compressed, when bent, or when twisted. If an ivory ball be dropped from a height upon a marble slab smeared with fat and lampblack, when caught after the rebound, it is seen to have touched the marble, not in a point, but in a circle of several lines in diameter; and must therefore have lost for a time its spherical shape over that extent. In the

same way the mark of a well hit golf-ball is pretty broadly shewn upon the face of a club after the stroke. The elasticity shewn by wires and threads of glass when twisted, has been turned to account in the Torsion-balance (q. v.), for measuring other weak forces. Steel, ivory, caoutchouc, &c., are well known for their elastic properties, to which they owe much of their utility.

The propagation of waves of sound through solid bodies depends upon their elasticity; and from observations of this kind made with different substances, the modulus of elasticity for each may be deduced; the results, however, differ slightly from those arrived at by attaching weights, owing to the heat produced by the vibratory movement.

All solid bodies are only imperfectly elastic—that is, they do not quite recover their form and volume when the disturbing force ceases. Liquids and gases, on the contrary, are perfectly elastic, or return exactly to their original bulk or volume when the pressure is removed. The elasticity of liquids and gases, however, acts only in expanding after compression, while that of solids acts also in contracting after extension. The expansive elasticity of liquids and gases is equal to the force used to compress them. Water and other liquids are easily seen to be compressible, by the fact of their conveying sound—a sound-wave being merely a *state* of compression, propagated from each layer of the liquid to the next. The coefficient of elasticity of water determined by Colladon and Sturm, from the velocity of sound in the Lake of Geneva, agrees very well with that determined by direct measurements in Oerstedt's apparatus. The discovery of the compressibility of water is an English one, due to Canton, in 1762. Previous attempts, by Italian and Dutch philosophers, to compress water by hammering a silver shell filled with that fluid, had failed to give any certain result, as the water was forced through the pores of the metal. At a temperature of 50°, one atmosphere compresses water to about 0.999995 of its volume. From the existence of a maximum density temperature for water, some curious consequences arise with regard to the effects of pressure on the fluid. The volumes or bulks which a given quantity of any gas assumes under different pressures, are nearly in inverse proportion to the pressures. See **MARIOTTE'S LAW**. The elasticity of gases is usually measured by the height of the column of mercury that they sustain. The elasticity of gases is a force much and variously employed in the arts of life. See **AIR-GUN**, **AIR-PUMP**, **GUN-POWDER**, &c.

**ELATER**, a Linnæan genus of coleopterous insects, now divided into many genera, and forming the tribe or family *Elateride*. They have a narrow elongated body; the head is in almost all cases inserted deeply into the thorax; a strong spine on the under part of the thorax at its base, fits into a groove; the legs are short, and rather slender. They are generally found upon the flowers and leaves of plants, which are their food. When disturbed, they fold their legs and antennæ close to the body, and let themselves drop to the ground. If they fall on their back, or are placed on it, the shortness of their legs incapacitates them for obtaining another position by the means common to other insects; but they are enabled to do so by a violent muscular exertion, arching the body a little, and suddenly straightening it again, so that they fling themselves into the air with a jerk and a *click*. Hence the names **CLICK-BEETLE** (q. v.) and **SKIP-JACK**. The spine and groove of the thorax are supposed to be of use in this. The larvæ are long, rather slender, with six feet near the head, and a tough skin. Many feed on rotten

wood; others. WIRE-WORMS (q. v.), on the roots of plants. Many are British. Some of the *Elateridae* of tropical regions diffuse from spots on the thorax a strong and beautiful light, and are called Fire-flies (q. v.).

**ELATERIUM**, a drug obtained from the fruit of the SQUIRTING CUCUMBER, or SPIRTING CUCUMBER (*Ecbalium agreste*, formerly known as *Momordica Elaterium*), also called the Wild Cucumber, an annual plant of the natural order Cucurbitacea, a

Wild Cucumber (*Ecbalium agreste*).

native of the south of Europe, common on rubbish in the villages of Greece and the Archipelago. The whole plant is rough, with stiff hairs; it has a trailing branching stem, without tendrils; the leaves are heart-shaped, somewhat lobed and toothed, on long stalks; the flowers axillary, yellow, the male flowers in small racemes; the fruit oblong, about an inch and a half long, grayish green, covered with soft prickles, and finally parting from its stalk, and expelling its seeds along with a thin mucus through the aperture where the stalk was inserted. This remarkable phenomenon is ascribed to osmotic action within the fruit; a thin membrane separating a mucus which immediately surrounds the seeds from a less dense juice which abounds in the succulent part of the fruit, and the quantity of the former being gradually increased at the expense of the latter, till, on the perfect ripening of the fruit, the much distended central cell is opened, to permit its ejection. It is this mucus surrounding the seeds—a thick green mucus of a very peculiar character—which contains the elaterium. To obtain the drug, the juice of the nearly ripened fruit is allowed to stand for a short time, when it becomes turbid, and deposits a sediment. The sediment, carefully collected and dried, is elaterium. It is of a pale grayish-green colour, light and friable, with an acrid taste, and a peculiar not unpleasant odour. It is an exceedingly powerful or drastic purgative, used chiefly in dropsies, and in very small often-repeated doses. It should not be used except under medical advice. It acts as an irritant not only on the eyes, if it comes in contact with them, but even on the fingers of those who handle it. Its properties seem to depend chiefly on a crystalline principle called *Elaterin*. The use of E. was known to the ancients. A few acres of the Squirting Cucumber are grown at Mitcham, in Surrey.

**ELATINA.** See JELATON.

**E/LBA** (Lat. *Iva*, Gr. *Ethalia*), an island belonging to the kingdom of Italy, in the Mediterranean

Sea, between Corsica and the coast of Tuscany, from the latter of which it is separated by the channel of Piombino, a strait 5 miles in breadth. Its greatest length is about 18 miles, and its breadth varies from 3 to 10 miles, this irregularity being caused by indentations both on its northern and southern shores. Its area is about 97 square miles. The coast is bold and precipitous. The surface is traversed from west to east by a chain of mountains, which divides into two spurs at the eastern extremity of the island; the highest summit, Monte della Capana, attaining an elevation of 3600 feet above sea-level. These mountains are for the most part bare; but on their lower ridges, and in the valleys, the vine, olive, mulberry, and other trees flourish. The climate, except in the low-lying districts on the shore, is temperate and healthy. There are few streams in E., but it has numerous wells. The principal products are wines, white, red, and sweet, and of good quality; wheat, Indian corn, vegetables, and water-melons. 50,000 cwts. of salt are produced annually from the salt-pans on the shore. Sheep, goats, pigs, and asses abound, but horned cattle and horses are scarce; the coasts supply fish plentifully. Iron of excellent quality is obtained from a mountain in E., 2 miles in circumference, and 500 feet in height. This hill, which stands on the east coast, is almost entirely a mass of ore, and so rich that it yields from 50 to 75 per cent. E. also yields leadstone, alum, vitriol, and marble. Porto Ferrajo, the capital and residence of the governor, has a population of about 3000. E. has been rendered famous in history from having been Napoleon's place of exile from May 1814 till February 1815. Pop. 21,604.

**ELBE** (called by the Romans *Albis*—i. e. white—and by the Bohemians *Labe*), an important river of Northern Europe. It originates in the confluence of numerous streams which rise at the south-western base of the Schneekoppe (Snowcap), one of the highest summits of the Riesen-Gebirge, a mountain-range on the northern border of Bohemia. The course of the E. begins near lat. 50° 45' N., long. 15° 36' E.; at an elevation of about 4400 feet above sea-level. Its total length, including windings, is estimated at from 600 to 700 miles, and its basin at 58,800 square miles. The average depth of the E. is 10 feet, and its mean breadth 900 feet, although occasionally it has a width of upwards of 1000 feet, and at its mouth of several miles. In the course of its progress to the sea, it is joined by 17 rivers and upwards of 70 streams. From the base of the Schneekoppe, it flows south to Pardubitz, whence it proceeds west to Brandeis, and afterwards in a general north-west direction past Melnik, Leitmeritz, Aussig, and Tetschen, where it quits the Bohemian territory, and enters Saxony. At this point, it is 355 feet wide. Its principal affluent in Bohemia is the Moldau. On its course north-west through Saxony, the E. passes Pirna, Dresden, and Meissen, and entering Prussian Saxony, about seven miles above Mühlberg, it advances to Torgau and Wittenberg, from which point it flows first west, then north-west to Magdeburg, receiving in its progress the Mulde and the Saale, both from the left. From Magdeburg flowing north-east, the E. arrives at the border of Brandenburg, receiving the Havel from the right; then turning north-west, it forms the boundary between Prussian Saxony and Brandenburg, and enters Hanover, through which it flows for upwards of 30 miles. Then still flowing north-west, it forms the boundary of Lanenburg, the Hamburg territory, and Holstein on the north, and Hanover on the south, until it empties itself into the North Sea at Cuxhaven, where it attains a breadth of upwards of 10 miles. At this point,

the tide rises 12 or 13 feet. The E. is divided into several branches between Hamburg on the north, and Harburg on the south, by the numerous islands that there interrupt its course. Vessels of 14 feet draught can at all times ascend to Hamburg. The scenery of the valley of the E., although generally pleasing, is not remarkable in any portion of its course, except that which extends between Aussig and Dresden. Between these two towns, the course of the E. is generally between bold cliffs, and high natural battlements of rock; the banks covered with foliage, wherever a tree can support itself; and occasionally varied by a strip of green glady. It has been said that here the E. has all the variety of the English Wye, on a scale nearly as majestic as that of the Rhine. Its waters are stocked with abundance of highly esteemed fish; beavers likewise build in the stream. Steam-boats ply from Dresden up the river, and down as far as Meissen, as well as from Magdeburg to the sea. The navigation of the E. was formerly impeded by all manner of imposts and monopolies; and, what was quite as bad, sand was allowed to accumulate, so that vessels were often obliged to wait three or four weeks for want of sufficient water. Both of these kinds of impediments have, however, of late years been gradually removed, though much still remains to be done.

ELBERFELD, the most important manufacturing town in Prussia, and one of the most flourishing in all Germany, is situated on both sides of the Wupper, an affluent of the Rhine, 16 miles east-north-east of Düsseldorf. Its site, in the narrow and hill-girt valley of the Wupper, is picturesque and healthy, but the town itself is poorly built, straggling, and irregular, with streets for the most part narrow and dirty. The more recently erected portion of the town, however, is well built, with here and there spacious and imposing buildings, in a high architectural style. E. is chiefly famous for its dyeing, bleaching, and printing establishments, also for its extensive and important manufactures of cotton, silks, tapes, ribbons, merinos, fancy woollen goods, velvets, &c. Bleach-fields occupy a great part of the environs of E., and of the banks of the Wupper, the waters of which are said to possess very valuable bleaching properties. At E., the well known dye, Turkey red, is imparted to yarns, at a cheaper rate, and with more clearness and firmness of colour, than at any other town in Europe. The patterns for the printed goods are designed at E., principally by French artists. E. supports an important establishment, in which young manufacturers and overseers are taught the management of the Jacquard-loom, pattern-drawing, &c. Pop. 54,000, among whom are 14,000 Catholics and 400 Jews. Adjoining E., and united to it by a bridge, is the large town of Barmen (q. v.), also the seat of extensive manufactures.

ELBEUF, or ELBŒUF, a manufacturing town of France, in the department of Seine-Inférieure, is delightfully situated in a picturesque valley on the left bank of the Seine, about 75 miles north-west from Paris. It was originally badly built, but it has recently been greatly improved. Large factories also have arisen rapidly; and a spacious market-place (*champ de foire*), adorned with rows of chestnut-trees, has been erected. The two principal public buildings of E. are the churches of St Etienne and St Jean-Baptiste, both containing fine specimens of richly painted glass. The factories of E. and the vicinity exceed 200 in number; these are for the most part worked by steam-power, and give regular employment to more than the half of the population. The manufactures are principally double-

milled and waterproof cloth, flannel fabrics, billiard table-covers, and light woollens of every colour and description. E. has daily communication with Paris, Rouen, and Le Havre, by steamer. Pop. 17,959. E., which has been called the Leeds of France, had 80 cloth manufactories as early as the 16th century. In consequence of the revocation of the Edict of Nantes, the greater number of the cloth manufacturers emigrated; and it was not till after the Revolution of 1789, and more particularly since the separation of Belgium and France, that industry again began to flourish.

ELBING, a considerable trading and manufacturing town in West Prussia, is situated in the midst of a fertile valley, on the navigable river of the same name, 34 miles east-south-east of Danzig, and 5 miles south of the south-western extremity of the Frische Haff, into which the Elbing flows. It is connected by a canal with the Nogat, the eastern arm of the Vistula. The town was formerly surrounded with walls and mounds, of which, however, there are now but few remains. Of the numerous churches, the most remarkable is the Marienkirche, erected in the 14th century. The gymnasium, founded in the year 1536, contains the town library, consisting of 18,000 volumes. There are likewise several well conducted educational and charitable institutions. The manufactures are chiefly linen and cotton cloths, leather, tobacco, soap, and vinegar. There are also oil manufactories, iron foundries, breweries, dye and print works. E. was founded about the beginning of the 13th c., by colonists from Lübeck and Bremen, who settled round the fortress erected by the German knights. After various vicissitudes, it was annexed to Prussia in 1772, and after a period of decline, has again risen to a thriving condition. The larger vessels unload at Pillau, which serves as the harbour of Elbing. Pop. 25,000.

ELBOW. See ARM.

ELBOW-PIECES, in armour, or *coudières*, were the metal-plates used to cover the junction of the *recor-brace* and *vant-brace*, by which the upper and lower half of the arm were covered. They increased to an enormous size, as in the effigy of Sir Thomas Peyton, in Isleham Church, but again decreased to their normal size. An *Elbow Gauntlet* was a gauntlet of plate reaching to the elbow, adopted from the Asiatics in the 16th century.—Fairholt's *Costume in England*, p. 494.

ELBURZ, a lofty mountain-range that runs longitudinally along the entire southern border of the Caspian Sea. It frequently divides itself into subordinate parallel ridges, enclosing extensive and fertile valleys, many of which are well inhabited and carefully cultivated. Demavend (q. v.), said to be 20,000 feet in height, is one of the highest summits.—Elburz, or Elbruz, is also the name of one of the grandest summits of the Caucasus.

ELCHÉ (anciently, *Ilicé*, or *Ilicie*), a town of Spain, in the province of Alicante, and 16 miles south-west of the town of that name, is picturesquely built on both sides of a steep ravine, near the Elda, a tributary of the Segura, and about two leagues from the sea. It has an Oriental appearance. The climate is eastern, winter is unknown, and around the town rises a huge encircling plantation of palms; the Arab alone is wanting to complete the likeness to an eastern city. E. is a flourishing town, is well built, its streets in general are wide and clean, and it has numerous squares and public walks. The church of Santa Maria is an imposing edifice, with a large dome, five gates, a famous organ, and a tabernacle made of precious marbles. The dates gathered from the palm-plantation around E. are exported from

Alicante; they are not so good as the Barbary dates, though sold as such. Its manufactures are lincens, woollens, and cottons, brandy, wine, cigars, oil, soap, &c.; in these articles there is a considerable trade, as also in cattle, rice, and wool. Pop. about 18,000.

ELCHINGEN, a village of Bavaria, on the left bank of the Danube, about eight miles north-east of Ulm. It is noteworthy as the scene of a battle fought on the 13th October 1805, between the French under Ney and the Austrians under Loudon, in which the latter were defeated. Ney's victory obtained for him the title of Duke of Elchingen.

ELDER, an office-bearer in Presbyterian churches. The name is an exact translation of the Greek *presbyteros*, which occurs frequently in the New Testament, and from which the English word *priest* is derived. That the *presbyteroi* of the churches of the apostolic age were not *priests* in the special sense of that word, in which it denotes a person appointed to offer sacrifice on behalf of others, and to appear for them before God, is admitted by Protestants in general; but there remains much division of opinion as to the precise meaning of the term, and the bearing of the passages in which it occurs on the subject of church government. See BISHOP, INDEPENDENTS, and PRESBYTERIANISM. All are agreed, indeed, that *bishops* and all pastors of congregations are included among *elders* in the scriptural use of the term; but the ordinary use of it is now limited to Presbyterian churches, and in them it has become the usual designation of the office-bearers associated with the minister of each congregation in the care and oversight of the flock. The argument for this class of office-bearers will be found briefly stated in the article PRESBYTERIANISM. They exist in the greater number of the churches of the Reformation; and even in the Church of England, Bishop Burnet states that their introduction was only prevented by Queen Elizabeth's dislike to a proposal, in which, with Burleigh and others of her advisers, she saw danger of an abatement of her prerogative, 'since, if the concerns of religion came into popular hands, there would be a power set up distinct from hers, over which she could have no authority.' In some Protestant churches, elders are appointed only for a certain term of office; but more generally it is until death, resignation, removal from the bounds of the congregation, or deposition. The appointment of elders takes place variously: in the Established Church of Scotland, they have generally been nominated by the kirk-session (consisting of the minister and elders); in the other Presbyterian churches of Britain and America, they are elected by the congregation. In most of the churches of the continent of Europe, which have any kind of connection with the state, there is some regulation of the civil law or some interference of the civil authorities in this matter. The ordination of elders takes place in the congregation, but usually without imposition of hands; a difference between the mode of ordination of elders and ministers for which it is not easy to account, and which has certainly tended to produce a general impression that a greater difference of office subsists than the advocates of Presbyterianism admit. In the Established Church of Scotland, the elders have very generally discharged the functions of Deacons (q. v.), at least as much as those which, according to the theory of Presbyterianism, belong to their own office; an example which, until recently, was almost universally followed in other Presbyterian churches. According to the *Second Book of Discipline* of the Church of Scotland, it is the duty of elders to watch

over the spiritual welfare of the people, to admonish, to visit the sick, to assist in the examination of persons seeking admission to the Lord's Table, &c. Elders, along with ministers, compose all the courts or assemblies of the Presbyterian churches, and have equal votes in all questions.

ELDER (*Sambucus*), a genus of plants of the natural order *Caprifoliaceæ*, consisting chiefly of shrubs and trees, with pinnate leaves, small flowers of which the corolla is wheel-shaped and 5-cleft, and 3-seeded berries. The wood of the young shoots contains a very large pith. The species are very widely distributed.—The Common E. (*S. nigra*), the *Bowtree* of the Scotch, is a native of Europe, the north of Asia, and the north of Africa. It is found

Flower-stock, Leaves, and cluster of Berries of Common Elder (*Sambucus nigra*).

in all parts of Britain. It is a very large shrub, sometimes a small tree, with rather large leaves, and large terminal cymes of cream-coloured flowers, which are followed by small black—or rarely whitish—berries. Its leaves and young shoots diffuse a narcotic odour, and it is said to be dangerous to sleep under its shade. The inner bark has a bitter acid taste. The leaves possess the same properties in a rather milder degree. The flowers have a peculiar sweetish and rather sickening smell, but are much used for making a distilled water—*Elder Flower Water*—which has a very agreeable odour, and is employed both in perfumery and confectionary. Distilled with water alone, they yield a volatile oil, which, on cooling, assumes a buttery consistence. A popular cooling ointment is made by boiling them in lard. They are also used for imparting a flavour to currant-wine and jelly, being added at the time of a slight fermentation which takes place in the spring of the year, after the currant-wine is made; and a wine is made from them which in scent and flavour resembles Frontignac. The clustered flower-buds are pickled, and used like capers. A grateful wine, well known in England, especially about Christmas, is made from the berries; and in some parts of Kent there are large plantations of E. to supply the London market for its manufacture. It is generally drunk hot or *mulled*. The berries are subacid and sweetish, with a rather unpleasant flavour. A rob made from them is a gentle aperient, diuretic, and sudorific, easily administered to children. In some parts of Germany, the poorer people use them as an ingredient in soups. They are said to be used to no small extent in England in the adulteration of port wine, and the manufacture of spurious port wine.—

The wood of the E. is yellow; that of old trees is very hard and tough, takes a fine polish, is used by turners, and as a substitute for box-wood in making mathematical instruments and other articles. Tops of fishing-rods are sometimes made of it. The pith of the young shoots being very light, is generally used to make pith-balls for electrical experiments. Toys for children are also made of it; and few boys are unacquainted with the use of E. branches, from which it has been expelled, for making pop-guns. The E. is very useful as a screen-fence near the sea and in other exposed situations, as it grows with remarkable vigour, and makes great shoots, the destruction of the more tender and less matured parts of which in winter only tends to make it more bushy and useful for shelter. It is readily propagated by portions of its shoots stuck into the ground.—The SCARLET-FRUITED E. (*S. racemosa*), a native of the south of Europe and of Siberia, much resembles the common E., but has softer and more herbaceous shoots, remarkably large buds, which are conspicuous in winter, and racemes of greenish-white flowers, which are followed by scarlet berries, the racemes of ripe fruit having much the appearance of beautiful pieces of coral. It is a frequent ornament of shrubberies in Britain, and when in full fruit, is almost unrivalled in beauty, but more frequently produces its fruit in cold districts than in those where the milder winter induces it to flower before the spring-frosts are over. The juice of its berries is a powerful sudorific.—The DWARF E., or DANEWORT (*S. Ebulus*), is a rather rare British plant, a coarse herbaceous plant, with fetid smell. The inner bark has been employed in dropsical complaints as a hydragogue cathartic, and is given in the form of a decoction prepared by boiling down 1 oz. of the bark in 2 pints of water till the whole is concentrated to 1 pint. The dose is about 4 fluid ounces. In smaller quantities, it is useful as an aperient in certain chronic disorders. The flowers are white when freshly plucked, but become yellow in drying, and consist of a volatile oil, certain gummy, resinous, albuminous, and saline matters, and are stimulant and sudorific. They are employed in the preparation of elder flower water by adding 2 gallons of water and 3 ounces of rectified spirit to 10 pounds of the flowers, and distilling off about 1 gallon. It is a good perfume. White elder ointment is procured by boiling equal weights of lard and elder flowers, and pressing through a cloth. It has an agreeable odour, and is employed as a cooling application to surfaces which are irritable. When the berries are expressed, they yield a purple juice named *elder rob*, which, when diluted with water, is useful in inflammatory and febrile complaints as a cooling drink. It contains malic and citric acids, sugar, gum, &c.

ELDON, BARON, Lord High Chancellor of England. John Scott, better known as Lord Eldon, was born 4th June 1751, in Love Lane, Newcastle, of obscure but respectable parents. William Scott, his father, began life as an apprentice to a 'fitter,' a sort of water-carrier and broker in coal; later in life, he became a 'fitter' himself, and kept a public-house near the quay, to supply drink to his keelmen on the truck-principle; he engaged also in speculations in shipping and marine insurance. By his various occupations he became wealthy, and died worth about £20,000. John Scott's mother was a daughter of a Mr Atkinson of Newcastle, and to her, Lord Campbell, in his *Life of Lord Eldon*, traces the talent inherited by her sons William and John. William became Baron Stowell, and was the head for many years of the High Court of Admiralty. See STOWELL, BARON.

John Scott was educated under the Rev. Hugh Moises, at the grammar-school, Newcastle, and as a boy gave no promise of his subsequent splendid career. On finishing his education under Mr Moises, he, on the 15th May 1766, entered University College, with a view to the church; the following year he obtained a fellowship, and in the summer of 1771 won the prize for the English essay, but did not otherwise distinguish himself. A clandestine marriage, into which he entered with a Miss Surtees in 1772, nearly ruined him; however, by the advice of his brother, he returned with his wife to the university. Here, during the year of grace, he lived on his fellowship and gains as a private tutor; and the year expiring without a church living falling vacant, he betook himself to the study of law. In 1776, he was called to the bar. By this time, his wife's friends had become reconciled to her, and made her some provision; and by the death of his father, in the year of his passing at the bar, E. found himself in possession of £3000. On his own and wife's money, he found he could just manage to live, and so settled on the northern circuit. His success on his first circuit was not great; but in his second year his prospects, through the aid of his brother and friends, began to brighten. It was not, however, till 1780 that prosperity could be said to have dawned upon him. A happy chance then occurred of shewing both his talents and powers of work. The result was speedy affluence. Business poured in upon him; and by 1787 his practice at the equity bar had so increased, that he was forced to give up the eastern half of his circuit.

With success in his profession, E.'s ambition expanded, and he became political. A silk-gown, and then, through the favour of Lord Thurlow, a seat in parliament, were but steps towards knighthood and the post of Solicitor-general conferred on him by Pitt. From this point, his progress was secure, and effected much in the way in which political lawyers usually succeed. In 1793, he became Attorney-general. In 1799, the office of Chief-justice of the Court of Common Pleas falling vacant, his claim to it was not overlooked; and after 17 years' service in the House of Commons, he entered the House of Peers as Baron Eldon. In 1801, on the formation of the Addington ministry, E. ascended the woolsack—a post given to him nominally because of his great anti-Catholic zeal, but really because of his part in the intrigue which ousted his old patron Pitt from office. From this time till 1827, with little intermission, E. continued to occupy the woolsack under successive governments. He was in succession Chancellor under Addington, Pitt, and Lord Liverpool; and when, after the two brief administrations of Canning and Goderich, the Duke of Wellington constructed a cabinet, E. again expected the woolsack, and resented his non-appointment to it. His love of office indeed continued to the last, and in 1835, we find him actually in hopes of office under Peel. In 1834, he ceased to speak in parliament. In 1821, E. was made an earl by George IV.; and in the same year, his brother William was raised to the peerage under the title of Lord Stowell. In 1831, he lost by death his wife, his 'beloved Bessy.' His brother William died in 1836. He himself, after outliving almost all his immediate relations, died in his 87th year, January 3, 1838, leaving behind him a fortune of over half a million sterling.

E. is said to have been a man of very winning and courtly manners, and of a handsome, prepossessing appearance. In the circle of his friends he is said to have been irresistible, and probably to the charms of his manner his success in life was somewhat owing. His career amply proves that he was

a man of the greatest talent, sagacity, and power of managing men. He was undoubtedly a great lawyer, and his judgments, which have been much praised for their accuracy, fill a small library; at the same time, he took so long to arrive at them, that he has been charged with having caused more injustice by delay than worse judges by the iniquity of their decisions. For literature, as for art, he had no feeling, and the style of his decisions is generally detestable. He was a great drinker, though drink seems never to have unlitited him for work; and is said, when he went into retirement, to have spent his time over the newspapers and the gossip of old cronies, preferring their company to that of men of refinement and taste. Undoubtedly, the best of him is seen in his private relations. His love of and devotion to 'Bessy' his wife was truly beautiful. As a public man, he is far from estimable. He was a great canter, whose life was a succession of intrigues and duplicities. He was no statesman; his one aim in politics was power, and his name is unassociated with even a single law intended purely for the public good. For forty years, he was a leading enemy of reform and religious liberty. The champion of the church, he never attended on public worship. Without political principles, his whole stock in trade, as a politician, was zeal against the Roman Catholics, which, however, proved enough, in the then state of society. He is said to have added parsimony to his other defects; but while various circumstances, besides the amount of the fortune which he accumulated, favour this charge, it is probable that his apparent parsimony rose out of habits formed in his family while he was yet struggling; and it is certain he was capable of generous actions. See Twiss's admirable book, *Public and Private Life of the Lord Chancellor Eldon*; *Life of Lord Eldon*, by Lord Campbell; *Sketch of the Lives of Lords Stowell and Eldon*, by Dr W. E. Surtees.

EL DORADO (the Golden, or rather the Gilded Land) existed originally in the imaginations of the Spanish conquerors of America, whose insatiable avarice loved to dream of richer rewards than those of Mexico and Peru. The Castilians found an imitator in Sir Walter Raleigh, who twice visited Guiana in quest of this fabulous region. The name has at last made for itself an abiding-place beyond the furthest limits of Spanish possession. It indicates a county in the north-east of California, of which the capital, Callona, stands near the spot where the first discovery of gold was made in that state. The district in question is drained by some of the northern feeders of the Sacramento, which empties itself into the Bay of San Francisco.

ELÆATIC SCHOOL. The group of ancient Greek philosophers so called begins with Xenophanes of Colophon, who settled in Elea, a Greek city of Lower Italy (whence the name), and includes Parmenides and Zeno, who both belonged to Elea, and also Melissus of Samos. The most flourishing period of this philosophy falls from 540 to 460 B. C. In opposition to the physical philosophy of the Ionic school, and to the doctrine of Heraclitus (q. v.), who denied all being or existence, the Eleatic philosophers made this conception of pure being, unmixed with all marks or properties derived through the senses, the foundation of all their speculations. As being, one and unchangeable, seemed to them to exclude all plurality and alteration of appearances, they gave up, with remarkable consistency, all attempts to explain scientifically the world as we see it; and the startling abruptness of their simple fundamental principle, taken in conjunction with the opposite doctrine of Heraclitus, was one

of the chief causes that led Plato at a later period to attempt a reconciliation between the notions of *being and becoming*, or of absolute existence and phenomena.

ELECAMPANE (*Inula*), a genus of plants of the natural order *Compositæ*, sub-order *Corymbifloræ*, nearly allied to *Aster*. The only important species is the common E. (*I. Helenium*), a native of damp meadows in the middle and south of Europe, rather rare in Britain. This plant was formerly much cultivated for its root, which was used in medicine, and still retains its place in the pharmacopœias, although comparatively neglected. The root has a

Elecampane (*Inula Helenium*).

faint aromatic odour; and a bitter, acrid, and somewhat camphor-like taste. It acts as a gentle stimulant to the organs of secretion, promotes expectoration, and is diuretic and sudorific. It contains a peculiar principle called *Inulin*, which resembles starch, but is deposited unchanged from its solution in boiling water on its cooling, and gives a yellowish instead of a blue colour with iodine; also another peculiar principle called *Helenin*, or *Elecampane Camphor*, which resembles camphor in some of its properties.

ELECTION denotes, in theological language, the divine act by which certain individuals are chosen to salvation in Christ, and the doctrine of election is the doctrine of 'God's everlasting purpose, whereby he hath constantly decreed by his secret counsel to deliver from curse and damnation those whom he has chosen in Christ out of mankind, and to bring them by Christ to everlasting salvation as vessels made to honour.' These words, taken substantially from the articles of religion of the Church of England, may be said to represent, in a moderate form of expression, the orthodox doctrine on the subject of election. Besides this form of the doctrine, there is a lower and a higher form of it, which, apart from technical and polemical language, may be said to spring—the one from the supposed subordination of the divine act or purpose to the divine foreknowledge of human conduct—the other from the exaltation of the divine act or purpose into an absolute and arbitrary supremacy, having no relation whatever to human will or conduct. The former of these extremes corresponds to the Pelagian or Arminian doctrine of election, the latter to the hyper-Augustinian or Calvinistic. The Arminian aims to condition or limit the absolute character of the divine

act in redemption in some way or another; the Calvinist aims to give to this act the most arbitrary and irresponsible character. The one, while not altogether repudiating a doctrine of election, yet gives such prominence to the human conditions of the elective purpose, as (in the view of Calvinists) to destroy it altogether; the other maintains not only a doctrine of election or predestination, but also the correlative doctrine of reprobation. In the view of the Arminian, salvation is within the choice of the human will; in the view of the Calvinist, the human will is of little or no account—the decree of God is everything—and this decree (which Calvin admitted to be a '*decretum horribile*') absolutely determines some to everlasting life and some to everlasting death.—The separation has its source in the will of God, and not in the moral conditions of mankind.

It is obvious, in the mere statement of such views, how audaciously theology has sought to settle questions beyond all human scrutiny and settlement. In the nature of things, the relations between the divine and human will appear indeterminate; and, notwithstanding all the labour of inquiry devoted to such subjects in the past history of opinion, it cannot be said that any advance of thought has been made regarding them. If the mere logic of the question be kept in view, the Calvinistic opinion has the advantage over the Arminian—setting out, as it does, from the recognition of the divine will as absolutely supreme, and the source, consequently, of all subordinate action—a thought which is in the highest degree logically consistent. But then the moral perplexities which arise out of the practical application of this view, and the ease with which it may be perverted into a fanatical and dangerous error, will always repel many minds from its adoption.

Although the expressions election, elect, &c., are frequent in Scripture, it cannot be said that what is known as the theological doctrine of election was acknowledged by the Christian Church till the time of Augustine. The Greek Fathers confined their attention almost entirely to questions purely theological—that is to say, relating to the character and constitution of the Godhead. Gnosticism and Arianism, the two main forms of heretical opinion before Augustine, indicate the channels into which theological discussion had previously run. It was not till the Latin mind had taken up this discussion, that the more practical question of the relation of the divine and human will in redemption came to receive special attention. The controversy between Pelagius and Augustine in the beginning of the 5th c., brought out almost all the aspects of the question which have since, at successive epochs in the history of the church, risen into renewed prominence. The contests between the Scotists and Thomists in the 14th c. between the Arminians and Calvinists, and, within the Roman Church, between the Jansenists and Molinists in the 17th c., are recurring expressions of the same radical conflict or divergency of opinion. The spirit of modern theology is adverse to the logical disputations engendered by such discussions, and finds its more appropriate and useful field of labour in the province of critical and historical inquiry.

**ELECTION COMMITTEE.** See PARLIAMENTARY ELECTION.

**ELECTION LAWS.** See PARLIAMENTARY ELECTION.

**ELECTION OF SCOTTISH PEERS.** See PARLIAMENTARY ELECTION, PEERS, ELECTIVE.

**ELECTORS,** in the German empire, were those great princes who had the right of electing the

emperor or king. In the earliest times, under the Carolingians, the crown was hereditary; afterwards, Germany became formally an elective monarchy, but the election was practically almost limited to the reigning family. Under the Emperor Charles IV., the right of election became limited to the holders of the highest ecclesiastical and civil offices, some of which gradually became hereditary, and connected with territorial principalities, as in the case of the Hohenstaufens and of the Dukes of Bavaria, Saxony, Swabia, &c. Thus there arose seven electors, those of Mayence, Treves, and Cologne (as being the chief primates and chancellors of the empire), the electors of the Palatinate and of Bavaria long exercising the right by turns, and the electors of Brandenburg, Saxony, and Bohemia. From 1400 to 1703, the right was never exercised on the part of Bohemia, but otherwise no change took place from the middle of the 14th c. to the peace of Westphalia. By the peace of Westphalia, an eighth electorate was established, Bavaria and the Palatinate being each allowed the full right; and in 1692, a ninth was added, that of Brunswick-Lüneburg, but not without resistance by the electors and states of the empire, so that the new electorate was not fully recognised till 1710. In 1777, the number was again reduced to eight, the Elector Palatine inheriting Bavaria. The electors held a high and very peculiar position in the German empire. The Golden Bull describes them as 'the seven pillars and lamps of the holy empire.' They had certain important rights and privileges. They were leagued from the year 1338 for the maintenance of their freedom of election against the pope. They had royal dignities, only not the title of Majesty. The territories belonging to their electorates were indivisible.

The peace of Luneville, in 1801, made a great change in the German empire, and subsequent changes took place during the times of French ascendancy, which issued in the dissolution of the ancient German empire. The title of Elector, still used by the Elector of Hesse-Cassel, an electorate which was added along with other new electorates in 1802, is the sole relic of the old dignities, and is now merely nominal.

**ELECTORAL CROWN,** or, more properly, CAP, was a scarlet cap, turned up with ermine, which was worn by the electors of the Empire.

It was closed with a demi-circle of gold, covered with pearls, and on the top was a globe with a cross on it, also of gold.

**ELECTRIC CLOCK.** The regularity of the clock depends, as is well known, on the action of the pendulum, which is isochronous—that is, has the property, within certain limits, of describing long and short arcs in the same time. See PENDULUM. The pendulum, however, left to itself, would, in consequence of the resistance of the air, and of the spring on which it hangs, soon come to rest. An impulse must therefore be given it occasionally, to keep it going. This impulse need not necessarily be exactly the same, for though it might cause the pendulum to make a longer swing at one time than at another, the time of oscillation would not differ. In ordinary clocks, these impulses are given by a heavy weight, and are transmitted to the pendulum through the wheel-work of the clock. No moving power can be more steady than gravity, or less likely to tax the isochronism of the pendulum, but its action on the clock is limited by the distance through which the

Electoral Crown.

## ELECTRIC CLOCK.

weight descends, so that the weight must be periodically wound up, to keep gravity in play. The trouble of winding, though small, still leaves room for the wish that a clock might be constructed going for long periods without external help. Such an instrument the electric clock professes to be, and such really it has proved itself. Several clocks of this kind have been made, which continue to move months, if not years, without attention; but their performance, though good, has not rivalled the steadiness and certainty of the finer gravity clocks. Electric clocks may be divided into two classes—those in which the impulse is given to the pendulum directly by electric power, and those in which it is given by a weight or spring alternately liberated and restrained by electricity. Of the first kind, that invented by Bain is best known. In the ordinary clock, it is the clock that moves the pendulum; in Bain's clock, it is the pendulum that moves the clock. As the construction of the pendulum is the only part of it connected with electricity, we shall confine our notice to a general description of the pendulum action. The lower part of the pendulum arrangement is shewn in the figure. The bob B

Electric Pendulum.

consists of a bobbin of insulated copper wire, and is hollow in the centre, the wires *w, w* from both ends ascending the pendulum rod *R* (the lower part of which alone is seen), and are in metallic connection respectively with the two springs from which the pendulum hangs. Two magnets or bundles of magnetic rods, *NS, N'S'*, are fixed at either side of the bob, and are of such dimensions that the hollow bob in its oscillation can pass a certain way over each without touching. The magnets have their like poles turned towards each other. The two springs of the pendulum rod are in connection with the two poles of a galvanic battery. The wire connecting one of them is made to pass round by a break (not shewn in the fig.), worked by the pendulum rod. When the pendulum is made to move, say towards the right, it shifts a slider, so as to complete the connection between the poles of the battery. The current thereupon descends one of the wires of the pendulum, passes through the coil of wire forming the bob, and ascends by the other. In so doing, it converts the bob into a temporary magnet, the south pole towards the right, and the north pole towards the left. In this way, the south pole of the bob is repelled by the south pole *S* of the right-hand magnet; and its north pole is attracted by the south pole *S'* of the left-hand magnet, so that from this double repulsion and attraction both acting in the same direction, the bob receives an impulse towards the left. Partly, therefore, from this impulse, and partly from its own weight, the pendulum describes its left oscillation; and when it reaches the end of it, it moves the slider so as to cut off the battery current, and then returns towards the right, under the action simply of its own weight. On reaching the extreme right, as before, it receives a fresh impulse; and thus, under the electric force exerted during its left oscillation, the motion of the pendulum is maintained. So long as the electricity is supplied, will the pendulum continue to move. The current required is exceedingly weak, and Bain considered that it could be sufficiently excited by a plate of copper and a plate of zinc sunk into the

ground, and acted upon by the moisture usually found there. This earth-battery, as he called it, was expected to act steadily for years; but the result proved far otherwise, for the soil not unfrequently dried up, leaving no trace of electrical action. The imperfection of the battery has led to a strong prejudice against these clocks stronger, certainly, than they merit. It has been found, however, by those who have employed them for astronomical purposes, that little dependence could be placed on them, and that the proper conditions of pendulum motion were, from the unsteady supply of electricity, interfered with; hence the opinion has been generally accepted, that a pendulum moved immediately by electricity, does not keep very accurate time; and the efforts that have of late been made in electric clock-making have aimed at rendering the pendulum independent of the irregularities of the motive agent.

Before noticing these, it may be well to refer to a very important application that has been made by Mr Jones of Chester of Bain's pendulum. Shortly after the invention of Bain's clock, Professor Wheatstone suggested that any number of such clocks could be made to move simultaneously by the same current of electricity. Mr Jones has turned this idea to account in the following way. A standard clock of the usual construction is made, by regulating the flow of a galvanic current, to control the action of any number of secondary clocks, likewise of ordinary construction. The pendulum of the standard clock, on passing towards the right, touches a spring, placed at the side, thereby completing the battery connection, and a current is transmitted to the secondary clocks in a certain direction. On passing to the left side, the same takes place, but the current is made to go this time in the opposite direction. The pendulums of the secondary clocks are made on Bain's principle, but have, of course, no break to move, as the primary pendulum performs that function. Let us suppose, at first, that all the pendulums are at rest; in this case, no current is transmitted. Let the standard pendulum now be moved to the right, the right spring is touched, and a current at the same instant circulates through the bobs of the secondary pendulums, and they thereby receive a simultaneous impulse towards the left. All the pendulums move then to the left; and on reaching the extremity of this oscillation, the standard pendulum touches the left spring, and the secondary pendulums are now impelled to the right. The motion of the secondary pendulums soon increases, until it reaches its proper extent. The pendulums once set agoing, are, however, not intrusted solely to the stimulus of the electricity, but are moved by their own weights, as in ordinary clocks, so that if the electricity ceased to be sent to them, they would go on without it. It might be supposed that a confusion of the two forces, electricity and gravity, would ensue; such, however, is not the case. While the motion of the clock is intrusted to its own weight, the pendulum submits docilely to the controlling action of the electricity; and thus a secondary clock of little value may be invested with all the perfection of the most costly observatory clock. The success of Jones's pendulum has been severely tested in the arrangement employed by Professor Smyth for firing the one o'clock time-gun at Edinburgh. A clock in the Castle of Edinburgh is made to liberate the trigger of the gun exactly at one o'clock. This clock is regulated on Jones's principle, by a clock at the Observatory on the Calton Hill, nearly a mile distant. The Observatory clock, by means of electricity, sets off a time-ball on a neighbouring monument at the same instant. The fall of the ball, and the flash

of the gun, though occasioned each by its own clock, are perfectly simultaneous.

In the second class of electric clocks, the electricity is not charged immediately with the maintaining of the pendulum motion, but draws up the weight, or liberates the spring which discharges that function. This is the same principle as holds in what is known in horology as the 'remontoir' escapement. Mr Shepherd of London was the first to introduce this principle into electric clock-making, and one of his clocks on a large scale was exhibited at the Great Exhibition of 1851.

**ELECTRIC FISHES.** See **ELECTRICITY, ANIMAL.**

**ELECTRIC LIGHT.** When the ends of two wires which form the poles of a powerful galvanic battery are made to touch, and then are separated for a short distance, the current which passes when the contact is made does not cease with the separation, but forces its way through the intervening air, accompanied with an intense evolution of light and heat. So great is the heat evolved that the most refractory metals are melted by it, and therefore some substance rivalling the metals in conducting power, but much more infusible, must be found to act as the poles, to allow of the continuation of the current in such circumstances. The various forms of carbon are well suited to this purpose; the more compact forms of charcoal answer very well; baked carbon (see **CARBON FOR ELECTRICAL PURPOSES**) answers better; but the coke that is sublimed inside the retorts in the distillation of gas, both for durability and conducting power, makes by far the best poles. Sir Humphry Davy first discovered and described the electric light. Fig. 1 represents a

Fig. 1.

simple arrangement for producing it. The carbon-points P, N are fixed into hollow brass rods, which are connected with the battery by wires entering at the binding screws s, s. The rods slide in the heads of the glass pillars A, A, fixed to a stand, so as to admit of the points being placed at different distances. The wires from the battery poles being properly connected, the points are made to touch, and are then withdrawn a line or two, when the most dazzling light ensues, somewhat approaching the light of the sun in purity and splendour. Its intensity is such as to prevent the eye from examining the particulars of its production. These, however, may be ascertained by projecting with a lens of short focus the images of the points on a screen, when they are seen as shewn in the figure. The light is found to arise chiefly from the intense whiteness of the tips of the carbon rods, and partially from an arch of flame extending from the one to the other. The positive pole is the brightest and the hottest—a fact which may be proved by intercepting the current, when the positive pole continues to appear red for some time after the negative pole has become dark. During the maintenance of the light, a visible change takes place in the condition of the poles. The positive pole experiences a loss of matter—particles of carbon pass from it to the

negative pole, which they partly reach, and partly are burned by the oxygen of the air on the way. The same takes place, though to a much less extent, with the negative pole; so that while the positive pole becomes hollowed out or blunt by its losses, the negative pole remains pointed by its apparent gains. The wasting away, particularly of the positive pole, in a short time renders the distance between the poles too considerable to allow of the passage of the current, and the light is thus suddenly extinguished, until again renewed by contact and removal. The transference of matter between the poles is considered to account for the existence of the arch of flame, and the passage through the air of the current, as thereby a conducting medium extends between the poles. The heat of this arch of flame, or *voltaic arc*, as it is called, is the most intense that can be produced. Platinum melts in it like wax in the flame of a candle. Quartz, the sapphire, magnesia, lime, and other substances equally refractory, are forced by it into a state of fusion. The diamond when placed in it becomes white hot, swells up, fuses, and is reduced to a black mass resembling coke. In this condition, it is still hard enough to scratch glass, but possesses almost no consistency, giving way to the pressure of the fingers. From an analysis of the spectrum given by the electric light, it is found to be caused not by the combustion of the carbon, but by its being brought into a state of incandescence. It is found to abound in violet rays, and is hence well adapted for photographic purposes. The electric light can be produced in a vacuum, and below the surface of water, oils, and other non-conducting liquids. It is thus quite independent of the action of the air, a circumstance which may yet be turned to useful account. With a battery of some fifty Bunsen's elements, a light is produced of very great brilliancy; but when very great power is to be obtained, as well as brilliancy, twice or thrice that number must be employed. Fifty cells give an electricity of the needful tension to produce the light; and if more be employed, they must add to its strength, and not its tension. Thus, if 150 cells be used, they would be best arranged in three batteries, the positive poles of all three being joined to form one positive pole, and similarly with the negative poles. With a battery of forty or fifty cells, no pointing of the rods is necessary, as this is done by the action of the electricity itself.

Various arrangements have been invented for maintaining the steadiness of the electric light. The aim in all such is to keep the carbon points, by some mechanical contrivance, within such a distance of each other that the current can pass between them. Foucault, aided by Duboscq, was the first who constructed an electrical lamp of this description. In it, by aid partly of an electro-magnet, and partly of clock-work, the two points are made to travel towards each other at rates corresponding to those of their consumption, the positive pole in this way travelling faster than the negative. The relative distance of the points, and their position in space, thus remain the same. In the simpler form of electric lamps now constructed, it is only sought to keep the points at the same distance, the wasting away of the negative pole being so slow as not much to alter the absolute position of the light. Among these lamps, that of Mr Hart of Edinburgh deserves notice for its simplicity and efficiency. It is shewn in fig. 2. The current enters by the binding screw L, ascends the hollow pillar K by an insulated wire, passes under the gallery C, and circulates through the coils of the electro-magnet BB. The wire which forms these coils is soldered at its other extremity to the framework supporting the

electro-magnet, so that the whole headpiece of the apparatus may be considered as the positive pole of the arrangement. The rod AA, to the lower part of which the stick of carbon P is fixed, moves up

Fig. 2.

and down in the axis of the headpiece. It passes at E through a hollow cylinder, which rests on the platform H, and has its upper part cut into two halves, moving on hinges, which, when the whole rests on H, lie outwards, and give the rod AA full play to move up or down, when so urged. When, however, the armature F of the electro-magnet is drawn up by the passage of the current, the ring D, which is fixed to it, and which encircles the upper part of the split cylinder E, brings the two halves together, so as firmly to embrace the rod AA, which consequently rises with the armature. The rod AA is roughened by circular file-marks, to render this action the more certain. The current passes from the frame of the electro-magnet into the rod AA, by several surfaces of contact, then by the carbon point P to the opposite point N, and thence by the binding screw L' to the battery. Thus, before the current circulates, the rod AA, and the point P, rest by their weight on the point N. The instant, however, this takes place, the point P is withdrawn to a short distance from N, by the action of the electro-magnet, and all the brilliant effects of the electric light are produced. When the carbon rods, by their wasting away, stand at length so far apart that the current cannot force its way from the one to the other, the current being stopped deprives the electro-magnet of its power, and the armature, in consequence, falls, and allows the point P to drop on N. The contact is thus again renewed, and P is drawn up to its former distance from N. The interval that elapses between the breaking and the renewing of the current is so short, that the steadiness of the light is not interfered with, a sudden, scarcely perceptible blinking being all that indicates such an occurrence. The light continues without interruption till the positive carbon rod is exhausted, which generally takes about an hour, when a renewal at least of the positive rod becomes necessary. A lamp like this gives a splendid illumination to the magic lantern or the solar microscope, the lenses of each being made to slide vertically for a small distance, to allow the centre of the points to be kept always in the optical axis.

The attempts which have been made to substitute the electric light for coal-gas in lighting up streets and public places, have hitherto proved unsuccessful. One element of imperfect success is to be found in the unsteadiness and short duration of the light. By contrivances similar to those described above, the light may be continued for a few hours, but

even then it requires the constant watching of an attendant. Another arises from the striking and unpleasant contrast of light and shadow that accompanies it, rendering, as it were, the surrounding gloom as manifest as its brightness. It has, however, been used with excellent effect where a limited space had to be lit up for a few nights, such as in the construction of bridges across rivers and the like. Were the difficulty of constructing a constant electric lamp completely overcome, there would still remain that of producing a steady current of electricity to keep it in action, if we had no other source than the voltaic battery. The maintaining of some 50 or 100 Bunsen cells in full action for weeks and months together, is a task attended with no ordinary annoyance, and one which of itself would be sufficient to condemn the practicability of the electric light for public illumination. This difficulty, however, is now removed by the employment of electricity generated by magnets (see MAGNETO-ELECTRICITY), which requires nothing but an easily applied mechanical motion for its continued maintenance. An electric light produced from this source has been tried, with promising success, in the South Foreland Light-house.

ELECTRIC TELEGRAPH. See TELEGRAPH.

ELECTRICITY, the name used in connection with an extensive and important class of phenomena, and usually denoting either the unknown cause of the phenomena or the science that treats of them. Most of the phenomena in question fall under the three chief heads of Frictional Electricity, Galvanism, and Magneto-electricity. The present article is confined to the first.

*Historical Sketch.*—Thales, about 600 B. C., refers in his writings to the fact that amber, when rubbed, attracts light and dry bodies. This was the only electric fact known to the ancients. The science of electricity dates properly from the year 1600 A. D., when Gilbert of Colechester published a book, entitled *De Arte Magnetica*, in which he gives a list of substances which he found to possess the same property as amber, and speculates on magnetic and electric forces. He is the inventor of the word electricity, which he derived from the Greek word *electron*, amber. Otto von Guericke, burgo-master of Magdeburg, in his work *Experimenta Nova Magdeburgica* (1672), describes, among his other inventions, the first electric machine ever made, which consisted of a globe of sulphur turned by a handle, and rubbed by a cloth pressed against it by the hand. Hawksbee (1709) constructed a machine in which a glass cylinder, rubbed by the dry hand, replaced Guericke's sulphur globe. Grey and Wehler (1729) were the first to transmit electricity from one point to another, and to distinguish bodies into conductors and non-conductors. Dufay (1733—1745) shewed the identity of electrics and non-conductors, and of non-electrics and conductors, and was the first to discover the two kinds of electricity, and the fundamental principle which regulates their action. Between the years 1733 and 1744, much attention was given in Germany to the construction of electric machines. Up to this time, notwithstanding the inventions of Guericke and Hawksbee, the glass tube rubbed by a piece of cloth which Gilbert first introduced, was used in all experiments. Boze, a professor at Wittenberg, taking the hint from Hawksbee's machine, employed a globe of glass for his machine, and furnished it with a prime conductor. Winkler, a professor at Leipsic, was the first to use a fixed cushion in the machine. The Leyden jar was (1746) discovered accidentally at Leyden by Muschenbroek; but the honour of the discovery has been contested also in favour of Cuneus, a rich burgess of that town, and

Kleist, canon of the cathedral of Camin, in Pomerania. Franklin (1747) shewed the electric conditions of the Leyden jar, and (1752) proved the identity of lightning and electricity by his famous kite experiment. This last was performed with the same object about the same time, and quite independently, by Romas of the town of Nerae, in France. In 1760, Franklin made the first lightning-conductor. Canton, Wilke, and Æpinus (1753—1759) examined the nature of induction. Ramsden (1768) was the first to construct a plate-machine, and Nairn (1780) a two fluid cylinder-machine. The electrophorus was invented by Volta in 1775, and the condenser by the same electrician in 1782. In 1786, Galvani made the discovery which led to the addition of the new branch to the science which bears his name, and which now far exceeds the older branch in extent and practical value. See GALVANISM. In 1787, Coulomb, by means of his torsion-balance, investigated the laws of electric attraction and repulsion. In 1837, Faraday published the first of his researches on induction. Armstrong, in 1840, designed his hydro-electric machine.

*Fundamental Facts.*—Under the head CONDUCTORS (q. v.) it is stated that bodies which do not conduct electricity, or non-conductors, are capable of electrical excitation from friction, and are, in consequence, termed electrics, and that conductors not so affected are called non-electrics. The *fundamental principles* of electricity are illustrated by the *electric pendulum* (fig. 1). A glass tube bent

Fig. 1.

at right angles, so as to project horizontally, is placed on a convenient stand. On the hook in which its upper end terminates, a cocoon thread is hung, to the end of which a pith-ball is attached. The ball is thus doubly insulated by the glass and the silk thread. If a tube of glass be rubbed by a dry silk handkerchief, and brought near the ball, the ball is at first briskly attracted, and then as briskly repelled; and if the tube be then moved towards it, it moves off, keeping at the same distance from it. The ball being so affected, or charged, as it is called, a rod of shell-lac or of sealing-wax, after being rubbed with flannel, attracts it, if possible, more briskly than before, and again sends it off exactly as the glass had done. If the glass tube be now again taken up and rubbed a second time, if necessary, the ball will act towards it as it did towards the sealing-wax. The same series of attractions and repulsions would have taken place if we had begun with the sealing-wax instead of the glass tube. We interpret this experiment in the following way. When glass is rubbed with silk, it becomes invested with a peculiar property, which gives evidence of its existence by attracting a pith-ball or any other light substance; and after contact has communicated this property to the ball or other matter, repulsion takes place between them. In consequence of the ball being suspended by an insulating thread, it retains the property of rubbed glass thus given it; and although then repelled by a body having the same property, it is powerfully attracted by rubbed sealing-wax. After contact again takes place, and the property of rubbed sealing-wax has replaced that of rubbed glass in the ball, the two similarly affected bodies

again repel, and the same series of attractions and repulsions will continue if we present the glass and the wax alternately to the ball. These properties or affections, developed by friction, are called *electricities*—that of glass is called *vitreous electricity*; that of sealing-wax, *resinous electricity*, glass and resin being the type-substances in which they are produced. The electricities here evolved by friction can be produced in a great variety of ways, both mechanical and chemical, but however developed, their characteristics are the same. For vitreous, *positive*, and for resins, *negative*, are now almost universally substituted; and although these terms are meaningless as applied to two similar affections of matter, they have the advantage of being definite, and of having no reference to the source whence the electricities originate. They admit, moreover, of a very convenient contraction, viz., the algebraic + for *positive*, and - for *negative*; and when written in this way, their relative opposition, so to speak, is graphically shewn. We are taught by the above experiment, that *bodies electrified either positively or negatively, attract neutral bodies and bodies affected with electricity of an opposite name to their own, but repel those affected with electricity of the same name*; and that *electricity can be communicated from one body to another by contact*. Contact is not the only way in which electricity is communicated. We find, when we deal with larger bodies than the pith-ball of the experiment, and sometimes even with it, that the passage of a *spark* between two bodies without contact communicates the electricity of the one to the other. The part played by the rubbers in the above experiment must not be overlooked. The silk handkerchief employed to rub the glass assumes the resinous or - electrical state, and the flannel rubber of the sealing-wax the vitreous or +. This cannot, however, be clearly shewn, as the experiment is performed, for the rubbers are in each case tightly embraced by the hand, which carries off their peculiar electricity, so that they give feeble, if any, evidence of electrical excitement. As the rods are held only by their extremities, the electricities of the untouched portions suffer almost no diminution. If, however, the rubbers, as well as the rubbed surfaces, be insulated, as they may be in the electrical machine, they shew opposite electricities. The same thing may be illustrated thus: two similar discs—one of glass, the other brass covered with silk—held by insulating handles, are rubbed together. So long as they are kept touching, no electricity is shewn, for the opposite electricities neutralise each other; but when they are separated, the former shews +, the latter - electricity. Hence we conclude, that *when one electricity is produced, as much of the opposite electricity is produced*.

The relative nature of the rubbing and rubbed surfaces determines the kind of electricity which each assumes. Thus, if glass be rubbed by a cat's fur instead of silk, its electricity is - instead of +. In the following list, each body, when rubbed by any one preceding it, is negatively electrified; by any one succeeding it, positively: cats' fur, smooth glass, linen, feathers, wood, paper, silk, shell-lac, ground glass. When two pieces of the same material are rubbed together, the colder or smoother becomes positively excited. Metal filings rubbing against a plate of the same metal determine - electricity in themselves, and + electricity in the plate. When a white silk ribbon is rubbed by a black one of the same texture, the white one becomes +. A plate of glass becomes + when a stream of air is directed against it from a pair of bellows. The friction caused by steam of high tension issuing from a narrow pipe develops electricities

in the steam and pipe which depend on the material of the latter. This fact has been turned to advantage by Armstrong in the construction of a boiler electrical machine of immense power.

*Induction.*—Free electricity has the power of inducing the bodies in its neighbourhood to assume

Fig. 2.

a peculiar electrical condition; this is exhibited in the following simple way: A brass cylinder, rounded at both ends (fig. 2), is insulated on a glass pillar. Two pith-balls, hung by cotton threads, are attached at either extremity.

When a glass tube is briskly rubbed, and placed within a few inches of the end of the cylinder, the balls at each end diverge, shewing that each pair is charged with similar electricities.

When the glass tube is withdrawn, the balls hang down as before, so that the electrical excitement of the cylinder is merely temporary, and dependent on the proximity of the excited tube.

If, while the balls are apart, a *proof plane*, consisting of a small disc of gilt paper insulated at the end of a glass rod (fig. 3), be made to touch the end next the tube, and then transferred to an electrometer, the electricity is found to be - ; if the same be done at the other end, it is + .

The nearer end of the cylinder is thus induced by the + electricity of the glass to assume the negative electric state; and as no - electricity can be excited without as much + electricity, we find the other end positively electrified to the same extent. It appears, besides, from the positions taken up by them, that both electricities obscure the same attractions and repulsions as the bodies affected by them.

This action of the electricity inducing in the cylinder this peculiar electrical condition, is called induction; and the cylinder in this state is said to be *polarised*

—that is, to have its poles or ends like a magnet, each having its similar, but relatively opposite force. If the hand touch the cylinder, the balls next the tube diverge further than before, and the other two cease to be affected. In this case, electrically speaking, the cylinder is a portion of the ground, for the hand and body are conductors; its surface therefore being increased, more - electricity is developed than before, and the + electricity is thrown back into the ground, and is lost. The - electricity is kept fixed in the part of the cylinder opposite the tube by the + electricity of the latter; and when the hand is first removed, and then the tube, it causes the balls at both ends to diverge permanently. We thus see that electricity can be produced and insulated in conductors by the action of free electricity on them. The + electricity of the further half of the cylinder (fig. 2) is as free and insulated as if no - electricity existed within it. This is shewn by placing a cylinder near the first, forming a continuation of it, as it were, without touching, when the second cylinder, under the induction of the + electricity of the first, is thrown into the same state as the first. This second can induce the same state in a third (fig. 4), and so on. As the excited tube is withdrawn, the whole series

return to their natural condition without being in any way permanently affected. The moment, however, it is again brought near, there is manifested at the further termination of the last a + electricity, which exerts the same influence there as if a portion of the electricity of the tube had been actually communicated or transferred to it.

The air intervening between the tube and the cylinder is termed the *dielectric*, for it is through it that the electric action is propagated. In proof of this, we have only to place a cake of shell-lac between the tube and cylinder (fig. 2), when the polarity of the cylinder will rise higher than before, as would be shewn by the further divergence of the balls; and if this or a similar experiment be conducted with sufficient care, we find that the inductive action varies in amount for each non-conductor.

Induction, therefore, we have reason to conclude, is not the direct action of one body on another, but an action transmitted through the contiguous particles of a non-conducting medium. In further proof of this, Faraday, who was the first to examine the function of the dielectric in induction, has shewn that the action takes place through air in curved as well as in straight lines, which implies the action of an intervening medium. The relative powers of different substances in facilitating induction, are termed by this philosopher *their specific inductive capacities*. The following table by Sir W. S. Harris gives the specific inductive capacities of the more important non-conducting substances, taking that of air as unity: Air, 1.00; resin, 1.77; pitch, 1.80; bees-wax, 1.86; glass, 1.90; sulphur, 1.93; shell-lac, 1.95. All gases, whether simple or compound, have the same inductive capacity, and this is not affected by temperature or density. If a large plate of metal be placed between the glass tube and the cylinder, the polarisation of the cylinder instantly vanishes, for the induction is diverted by it into the ground.

*Theory of Induction.*—Faraday, taking for granted that the dielectric is the essential medium of induction, suggests that the molecules of air and other dielectrics are conducting, but that they are insulated from each other. We have already seen (fig. 4) that by induction, part of the electricity of an insulated body can be in effect transferred to a

surface at some distance from it, without any loss experienced by the exciting body. If, now, we could imagine a series of insulated cylinders diverging in all directions from the glass tube in fig. 4, we have reason to expect that the whole of the electricity of the tube would be in effect transferred to their outer extremities without loss of electricity to the tube. To prove that such would be the case, Faraday took a pewter ice-pail, 10½ inches high, and 7 inches in diameter, and insulated it, placing the outside of it in conducting connection with the knob of a gold-leaf electroscope. An insulated ball, charged with + electricity, was then introduced into it without touching. The pail was thus subjected to polarisation, the - electricity being

diverted by it into the ground.

*Theory of Induction.*—Faraday, taking for granted that the dielectric is the essential medium of induction, suggests that the molecules of air and other dielectrics are conducting, but that they are insulated from each other. We have already seen (fig. 4) that by induction, part of the electricity of an insulated body can be in effect transferred to a

surface at some distance from it, without any loss experienced by the exciting body. If, now, we could imagine a series of insulated cylinders diverging in all directions from the glass tube in fig. 4, we have reason to expect that the whole of the electricity of the tube would be in effect transferred to their outer extremities without loss of electricity to the tube. To prove that such would be the case, Faraday took a pewter ice-pail, 10½ inches high, and 7 inches in diameter, and insulated it, placing the outside of it in conducting connection with the knob of a gold-leaf electroscope. An insulated ball, charged with + electricity, was then introduced into it without touching. The pail was thus subjected to polarisation, the - electricity being

diverted by it into the ground.

*Theory of Induction.*—Faraday, taking for granted that the dielectric is the essential medium of induction, suggests that the molecules of air and other dielectrics are conducting, but that they are insulated from each other. We have already seen (fig. 4) that by induction, part of the electricity of an insulated body can be in effect transferred to a

surface at some distance from it, without any loss experienced by the exciting body. If, now, we could imagine a series of insulated cylinders diverging in all directions from the glass tube in fig. 4, we have reason to expect that the whole of the electricity of the tube would be in effect transferred to their outer extremities without loss of electricity to the tube. To prove that such would be the case, Faraday took a pewter ice-pail, 10½ inches high, and 7 inches in diameter, and insulated it, placing the outside of it in conducting connection with the knob of a gold-leaf electroscope. An insulated ball, charged with + electricity, was then introduced into it without touching. The pail was thus subjected to polarisation, the - electricity being

diverted by it into the ground.

*Theory of Induction.*—Faraday, taking for granted that the dielectric is the essential medium of induction, suggests that the molecules of air and other dielectrics are conducting, but that they are insulated from each other. We have already seen (fig. 4) that by induction, part of the electricity of an insulated body can be in effect transferred to a

surface at some distance from it, without any loss experienced by the exciting body. If, now, we could imagine a series of insulated cylinders diverging in all directions from the glass tube in fig. 4, we have reason to expect that the whole of the electricity of the tube would be in effect transferred to their outer extremities without loss of electricity to the tube. To prove that such would be the case, Faraday took a pewter ice-pail, 10½ inches high, and 7 inches in diameter, and insulated it, placing the outside of it in conducting connection with the knob of a gold-leaf electroscope. An insulated ball, charged with + electricity, was then introduced into it without touching. The pail was thus subjected to polarisation, the - electricity being

diverted by it into the ground.

*Theory of Induction.*—Faraday, taking for granted that the dielectric is the essential medium of induction, suggests that the molecules of air and other dielectrics are conducting, but that they are insulated from each other. We have already seen (fig. 4) that by induction, part of the electricity of an insulated body can be in effect transferred to a

surface at some distance from it, without any loss experienced by the exciting body. If, now, we could imagine a series of insulated cylinders diverging in all directions from the glass tube in fig. 4, we have reason to expect that the whole of the electricity of the tube would be in effect transferred to their outer extremities without loss of electricity to the tube. To prove that such would be the case, Faraday took a pewter ice-pail, 10½ inches high, and 7 inches in diameter, and insulated it, placing the outside of it in conducting connection with the knob of a gold-leaf electroscope. An insulated ball, charged with + electricity, was then introduced into it without touching. The pail was thus subjected to polarisation, the - electricity being

diverted by it into the ground.

Fig. 3.

—that is, to have its poles or ends like a magnet, each having its similar, but relatively opposite force. If the hand touch the cylinder, the balls next the tube diverge further than before, and the other two cease to be affected. In this case, electrically speaking, the cylinder is a portion of the ground, for the hand and body are conductors; its surface therefore being increased, more - electricity is developed than before, and the + electricity is thrown back into the ground, and is lost. The - electricity is kept fixed in the part of the cylinder opposite the tube by the + electricity of the latter; and when the hand is first removed, and then the tube, it causes the balls at both ends to diverge permanently. We thus see that electricity can be produced and insulated in conductors by the action of free electricity on them. The + electricity of the further half of the cylinder (fig. 2) is as free and insulated as if no - electricity existed within it. This is shewn by placing a cylinder near the first, forming a continuation of it, as it were, without touching, when the second cylinder, under the induction of the + electricity of the first, is thrown into the same state as the first. This second can induce the same state in a third (fig. 4), and so on. As the excited tube is withdrawn, the whole series

return to their natural condition without being in any way permanently affected. The moment, however, it is again brought near, there is manifested at the further termination of the last a + electricity, which exerts the same influence there as if a portion of the electricity of the tube had been actually communicated or transferred to it.

The air intervening between the tube and the cylinder is termed the *dielectric*, for it is through it that the electric action is propagated. In proof of this, we have only to place a cake of shell-lac between the tube and cylinder (fig. 2), when the polarity of the cylinder will rise higher than before, as would be shewn by the further divergence of the balls; and if this or a similar experiment be conducted with sufficient care, we find that the inductive action varies in amount for each non-conductor.

Induction, therefore, we have reason to conclude, is not the direct action of one body on another, but an action transmitted through the contiguous particles of a non-conducting medium. In further proof of this, Faraday, who was the first to examine the function of the dielectric in induction, has shewn that the action takes place through air in curved as well as in straight lines, which implies the action of an intervening medium. The relative powers of different substances in facilitating induction, are termed by this philosopher *their specific inductive capacities*. The following table by Sir W. S. Harris gives the specific inductive capacities of the more important non-conducting substances, taking that of air as unity: Air, 1.00; resin, 1.77; pitch, 1.80; bees-wax, 1.86; glass, 1.90; sulphur, 1.93; shell-lac, 1.95. All gases, whether simple or compound, have the same inductive capacity, and this is not affected by temperature or density. If a large plate of metal be placed between the glass tube and the cylinder, the polarisation of the cylinder instantly vanishes, for the induction is diverted by it into the ground.

*Theory of Induction.*—Faraday, taking for granted that the dielectric is the essential medium of induction, suggests that the molecules of air and other dielectrics are conducting, but that they are insulated from each other. We have already seen (fig. 4) that by induction, part of the electricity of an insulated body can be in effect transferred to a

surface at some distance from it, without any loss experienced by the exciting body. If, now, we could imagine a series of insulated cylinders diverging in all directions from the glass tube in fig. 4, we have reason to expect that the whole of the electricity of the tube would be in effect transferred to their outer extremities without loss of electricity to the tube. To prove that such would be the case, Faraday took a pewter ice-pail, 10½ inches high, and 7 inches in diameter, and insulated it, placing the outside of it in conducting connection with the knob of a gold-leaf electroscope. An insulated ball, charged with + electricity, was then introduced into it without touching. The pail was thus subjected to polarisation, the - electricity being

diverted by it into the ground.

*Theory of Induction.*—Faraday, taking for granted that the dielectric is the essential medium of induction, suggests that the molecules of air and other dielectrics are conducting, but that they are insulated from each other. We have already seen (fig. 4) that by induction, part of the electricity of an insulated body can be in effect transferred to a

surface at some distance from it, without any loss experienced by the exciting body. If, now, we could imagine a series of insulated cylinders diverging in all directions from the glass tube in fig. 4, we have reason to expect that the whole of the electricity of the tube would be in effect transferred to their outer extremities without loss of electricity to the tube. To prove that such would be the case, Faraday took a pewter ice-pail, 10½ inches high, and 7 inches in diameter, and insulated it, placing the outside of it in conducting connection with the knob of a gold-leaf electroscope. An insulated ball, charged with + electricity, was then introduced into it without touching. The pail was thus subjected to polarisation, the - electricity being

diverted by it into the ground.

surface at some distance from it, without any loss experienced by the exciting body. If, now, we could imagine a series of insulated cylinders diverging in all directions from the glass tube in fig. 4, we have reason to expect that the whole of the electricity of the tube would be in effect transferred to their outer extremities without loss of electricity to the tube. To prove that such would be the case, Faraday took a pewter ice-pail, 10½ inches high, and 7 inches in diameter, and insulated it, placing the outside of it in conducting connection with the knob of a gold-leaf electroscope. An insulated ball, charged with + electricity, was then introduced into it without touching. The pail was thus subjected to polarisation, the - electricity being

diverted by it into the ground.

*Theory of Induction.*—Faraday, taking for granted that the dielectric is the essential medium of induction, suggests that the molecules of air and other dielectrics are conducting, but that they are insulated from each other. We have already seen (fig. 4) that by induction, part of the electricity of an insulated body can be in effect transferred to a

surface at some distance from it, without any loss experienced by the exciting body. If, now, we could imagine a series of insulated cylinders diverging in all directions from the glass tube in fig. 4, we have reason to expect that the whole of the electricity of the tube would be in effect transferred to their outer extremities without loss of electricity to the tube. To prove that such would be the case, Faraday took a pewter ice-pail, 10½ inches high, and 7 inches in diameter, and insulated it, placing the outside of it in conducting connection with the knob of a gold-leaf electroscope. An insulated ball, charged with + electricity, was then introduced into it without touching. The pail was thus subjected to polarisation, the - electricity being

diverted by it into the ground.

on the inner, and the + electricity on the outer surface. The divergence of the leaves increased as the ball was lowered, until it sunk three inches below the opening, when they remained steadily at the same points. The ball was lowered till it touched the bottom, and communicated its charge to the pail, when the leaves remained in the same state as before, shewing that the + electricity developed by induction on the outer surface was exactly the same in amount as that of the ball itself. He then altered the experiment so as to have four insulated pails inside each other, and the effect on the outmost pail was in no way altered. Here the action of the air between the pails was in effect the same as that of the pails themselves, and if the molecules of air were insulated conductors like these, they would have acted in no way different from what they did. The action of the molecules of air, in certain circumstances, appears to favour the idea, that they are individually conducting. The discharge of electricity by spark through the air, shews that they can be forced to act as conductors; and the currents which proceed from points highly charged with electricity, appear to indicate that they can be attracted and repelled like the pith-balls of our first experiment. It may be urged against the theory, that it is only shifting the difficulty; for by what medium are the molecules of air insulated from one another and from other bodies, and by what means do they act inductively on each other? But this objection relates to the molecular condition of matter, concerning which we are as yet ignorant. The way in which one molecule acts upon another need not be the same as that between mass and mass, for it is to be expected that the molecular relations of matter being final, should have something peculiar. Molecular action, to which we must refer the phenomena of induction, appears to consist in a polarity of each molecule similar to what we find in masses; but how that polarity is propagated, and how each molecule is insulated from discharge, must at present be referred to the final nature or properties of matter. According to this theory, then, an excited body is the centre of polarisation, from which a chain of polarised insulated particles, whether of air or other material, proceed to surrounding uninsulated conductors in straight and curved lines. On the nearer surfaces of these it attracts the opposite electricity to its own, and repels into the ground an electricity of the same name and amount as its own. The leading idea in Faraday's theory is, not the repulsion of one electricity towards itself, but its cor-relation and attraction to the opposite electricity. Electricity is regarded as a polar or double force, which never exhibits one only of its forces, both being necessary to each other's separation and existence.

Faraday considers that the molecules of a dielectric during induction are thrown into a certain polarised condition, which is one of constraint, as it is only sustained by the action of the exciting body. The term *tension* may be applied to this condition; and when we speak of an electricity of high tension, we mean an electricity of high constraining or polarising power, which is exhibited in its force of attraction or repulsion, and in the readiness with which it discharges itself by spark. This is quite in keeping with the strict meaning of 'tension' in general works on electricity, where it refers to the concentration of electricity on one spot; thus, if we give a charged ball as much electricity as it already has, its electric tension is said to be doubled. The constraint of the polarised particles of a dielectric appears to be mechanical as well as electrical, for when the polarisation rises to

too high a pitch, their cohesion is destroyed in a disruptive discharge.

Conductors, according to this theory, are bodies whose molecules have the power of communicating their electricities to each other at low tensions, whilst non-conductors are those whose molecules only acquire this power at high tensions. Wheatstone has shewn, as we shall afterwards see, that facility of discharge is not perfect even in the best conductors, as time is needed for its propagation, and it has been found that the terminal laminae of non-conductors between two charged plates, become penetrated with opposite electricities, which indicates the slow progress of conduction. The molecules of conductors and non-conductors, therefore, have the same power of mutual discharge, but in very different degrees, so that a good non-conductor may be regarded as an excessively slow conductor. When disruptive discharge takes place through a non-conductor, the molecules in the line of discharge seem to be thrown into a state of very exalted tension, and to effect the discharge as if they formed a conducting wire.

*Distribution of Electricity.*—We might take it almost as a self-evident truth, that the greater the surface over which electricity is diffused, the less is its power or tension at any particular point, and so we are taught by experiment. When two equal balls are insulated, and a charge is given to one of them, and then communicated to the other by contact with the first, it is found that both equally divide the charge, but that the tension of the electricity of each is one half of that of the originally charged ball. When a watch guard-chain is charged and laid on the plate of an electroscope by means of a glass rod, the gold leaves diverge most when the chain lies in a heap on the plate; and as it is lifted up, the leaves approach each other, shewing that as the exposed surface of the chain increases, the electric tension of each part diminishes. We are thus taught that a large surface feebly electrified, is equivalent to a small surface highly charged with electricity. This can be accounted for by the theory of induction in the following way. It is assumed that electricity places itself where it can best propagate polarisation through the particles of the dielectric. In the case of the two balls, as each offered the same facility for induction, there was no distinction electrically between them, and an equal distribution necessarily took place. The polarising force, however unaltered in amount, having twice the number of dielectric molecules to act upon, can only effect half the amount of polarity in each. The same method of explanation may be adopted in all such cases.

Experiment teaches us, that electricity is exhibited only on the surfaces of conductors; this is shewn

Fig. 5.

by the apparatus represented in fig. 5. A brass ball is suspended by a silk thread, and covered with two hemispheres, which can be held by insulating handles, and which exactly fit it. A charge

is then communicated to the ball so compounded. When the hemispheres are withdrawn, they are found to take away all the electricity with them, not the slightest charge being left in the ball. The same fact is exhibited by a hollow ball placed on a glass pillar, with a hole in the top large enough to admit a proof plane to the inside. When charged, not the faintest evidence of electricity is found on the inner surface, however thin the material of the ball may be. The thinnest metal plate, when under induction, shews opposite electricities on its two faces. We learn from these and numerous other experiments, that *electricity is only found on the outer surfaces of conductors in an envelope of inappreciable thickness.* This fact is quite in keeping with the theory of induction, for polarisation cannot be propagated towards the interior of a charged body which cannot possibly offer the corresponding opposite electricity, to complete the chain, and the outward polarisation can be manifestly best exerted on the very exterior, if we may use the phrase. This likewise accounts for no electricity being found on the inner surfaces of two gold leaves diverging under the same charge.

We are also taught, by experiment, that the distribution of electricity on the surface of insulated conductors is influenced materially by their form. An electrified ball, for example, exhibits the same tension on every part; and this we should expect, for there is no point *par excellence* where induction is facilitated. This, however, is not always the case, for when a conductor is brought near enough to the ball, the distribution is disturbed, being greatest towards the disturbing body, and least on the side away from it. If induction were propagated from the ball in the same way that light emanates from a candle, we should expect that the opposite electricity developed on adjoining surfaces ought to be of higher tension than on those more remote, in the same way that a body held near a candle is more strongly illuminated than more distant objects. The candle, however, does not show itself brighter on the side next the near object—the distribution of its brightness is the same as before. But in the electrified ball we have a crowding of electricity towards the near object; so that we here learn a striking peculiarity in inductive action, viz., that it is most active where the dielectric channel is shortest. This holds true only for short distances; the disturbing body, for instance, in the case under consideration, has to be brought very near before any inequality in the distribution of electricity on the ball becomes manifest. It is to this concentration of electricity on the side of the approaching conductor that we owe the electric spark; and it is as we near the striking or sparking distance that this disturbance is revealed. The concentration or fixing of electricity on the side of the thinnest and best dielectric, is particularly illustrated in the Condenser (q. v.) and Leyden jar, whose action depends upon it; but in these the dielectric must be very thin to secure decided effect. When a conductor somewhat in the form of a prolate spheroid (fig. 6) is charged, and the electric tension of the several parts tested by the proof plane, it is found to be least at

Fig. 6.

towards either end; and the difference is found to be all the greater as each end becomes more and more pointed. It is found likewise that the electric tension on a point is so great with a considerable charge as to destroy the dielectric condition of the air, the

particles of which become electrified, and carry by convection the charge of the point to surrounding conductors. We therefore learn that *electricity concentrates on points and projections.* This is quite in accordance with the theory of induction. Suppose, for the instant, in the case of the spheroid, that the distribution was equable, and that the opposite electricity was induced on surrounding conductors, how would this react on the electricity of the spheroid? Let us compare the case of one of the small terminal surfaces with a corresponding one in the middle. The proportion of induced surface acting on the terminal surface is much greater than on the central one. This will be much better understood by supposing a microscopic spectator to stand in both positions. On the end surface, he would see nearly all the objects round about except the small portion hidden by the spheroid; whereas, on the middle surface, half of them is hidden by it. What he sees in each position, is the amount of induced surface acting on it. Hence the electricity is drawn more towards the ends, to correspond with the great inductive action there taking place. The same consideration accounts for the intense action of a point.

*Electrometers and Electroscopes.*—These words are generally taken as synonymous; electroscopes, however, should be applied to the instruments which give evidence of electrical excitement without giving the exact measure of it; and electrometers to such as shew both. Fig. 7 represents the *quadrant electrometer.* It consists of a conducting-rod, generally of box-wood or brass, with a graduated semicircle attached above, in the centre of which is a pivot for the rotation of a straw carrying a pith-ball at its outer end. It is used for electricity of high tension, such as that of the electric machine. When placed on the prime conductor of the machine, the whole becomes charged with + electricity, and the ball is repelled first by the electricity of the rod, and then by that of the prime conductor, the height to which it rises being seen on the semicircle. This is not an electrometer in the strict sense of the word, for although it tells us, by the straw rising and falling, when one tension is greater or less than another, it does not tell us by how much, the conditions of its repulsion being too complicated for simple mathematical expression. It can shew us, however, by the indicator standing at the same point, when the electric tension of the machine is the same at one time as another.

Fig. 7.

The *gold-leaf electroscope* is the most convenient instrument for testing electricity of feeble tension.

One of the best of its forms is shewn in fig. 8. A glass ball, about four inches in diameter, rests on a brass tripod, and its neck, about an inch in diameter, is enclosed by a brass collar fixed with shell-lac. A brass plate, with a hole of  $\frac{1}{4}$ th of an inch in diameter in the middle of it, can be screwed air-tight into the collar. Before it is so fitted, a brass rod,  $\frac{1}{8}$ th of an inch in diameter, is fixed by shell-lac or sealing-wax into the hole in the middle, so as to be perfectly insulated from it. The upper end of the rod ends in a brass ball, and the lower end is filed on each side, to allow of two strips of gold-leaf, an inch in length, being attached to

Fig. 8.

it. Before the plate and leaves are finally fixed, the interior of the ball is thoroughly dried, by passing hot dry air into it, so that the ball contains no moisture to carry away the charge of the leaves. When the plate is screwed to the collar, there is no communication between the included and external air. The insulation of the leaves is complete; and they keep their charge, in dry weather, for hours together. When the instrument is used, it may be charged directly, by contact being established with the ball and the body whose electricity we would examine, or a charge may be carried to it by the proof plane, when the leaves diverge according to the charge communicated. When we would ascertain simply the kind of electricity with which a body is charged, we proceed in the following way. A glass tube is rubbed, and brought into the neighbourhood of the brass knob; the leaves diverge by induction, and, when so diverged, the knob is touched with the finger, and the leaves fall to their original position, for they are then out of the line of action. In this state, — electricity is fixed by the action of the + electricity of the tube on the side of the knob next it, and the corresponding + electricity is lost in the ground. When the finger is removed, the + electricity is cut off, while the — electricity remains in the knob; and its presence is manifested by the leaves diverging permanently after the removal of the tube. If, now, a positively electrified body be brought near the knob, it draws away the — electricity from the leaves, and they consequently fall in; but if a negatively electrified body be brought near, it sends the — electricity more to the leaves, so that they diverge further. We are thus enabled to distinguish between a + and a — charge. But it may be asked, why not charge the electrometer immediately with the glass? There are two difficulties in the way of this. If the glass is powerfully electrified, it gives too great a charge; and if feebly, contact between the knob and the glass cannot be effected, although its electricity acts powerfully by induction. We therefore bring the glass rod near the electrometer, and when the leaves diverge sufficiently, we touch the knob with the finger, and withdraw first the finger, then the rod, and the leaves diverge as before. For the more delicate use of the gold-leaf electroscope, see CONDENSER.

*Coulomb's Torsion Balance* (fig. 9) has played an important part in examining the laws of electric forces. A glass canister A,

Fig. 9.

is placed on a wooden frame, and is covered above by a plate of glass or wood; in the middle of this plate a round hole is cut, over which is fixed, by wooden fittings, a long glass tube B, having the graduated rim of a circle attached at its upper end. A circular plate, resting on this rim, closes the upper end of the tube; and when it is turned round, a mark upon it tells the number of degrees through which it has been moved. A cocoon thread or very fine wire is tied to a hook in the centre of the lower side of this

plate, and thence descends to the body of the canister. It carries below a collar of paper or other light material, in which a needle of shell-lac is adjusted, having a disc of gilt paper placed vertically, or a gilt pith-ball at its one end, and a counterpoise at its other. When the plate above

is moved through any number of degrees, the needle below, impelled by the torsion of the thread, comes to rest at the same number on the scale below. This last consists of a strip of paper divided into degrees, pasted round the cylinder at the same height as the needle. In the cover of the canister there is another opening, for the admission of a ball insulated at the end of a rod of shell-lac, and which, when supported by the cover, is on a level with the paper disc of the needle. When the instrument is adjusted for observation, the mark on the upper plate and the paper disc stand each at the zero-points of their respective scales, there being of course no torsion in the thread. The ball is removed, to receive a charge from the body under investigation, and is then placed in the cylinder, when the disc is first attracted, then repelled. Suppose that the disc be driven  $40^\circ$ , as shewn by the lower scale, from the ball, and that the upper plate has to be moved in the opposite direction, through  $160^\circ$  of the upper scale, to bring it back to  $10^\circ$ , the total degree of torsion is  $160^\circ + 40^\circ = 200^\circ$ . If the ball and disc be now discharged, and another charge be given to the ball, which requires  $250^\circ$  of torsion to place the disc at  $10^\circ$ , we have the relation 200 to 250, as that of the repulsive forces of the two charges, for the amount of torsion in degrees is proportional to the twisting force. Without entering further into detail, we may state the two laws that Coulomb established by this instrument: *The intensities of the mutual repulsion or attraction of two invariable quantities of electricity of the same or different names, are in the inverse ratio of the squares of the distance at which these act. The intensities of the total repulsive or attractive action of two electrified bodies placed at an invariable distance, are proportional to the products of their electric charges.*

*Electric Machine.*—In the tube of glass and silk rubber of which we have made frequent mention, we have the embryo of the electric machine, viz. a body which, when rubbed, is positively electrified, and its rubber negatively. The first requisite we should expect in a machine of this nature is a large surface, to give a great amount of electricity. But there is another already casually referred to: glass being a non-conductor, the electricity formed on its surface has not a combined action, so that some arrangement is necessary to

Fig. 10.—Electric Machine.

collect it, and render it available—to act, in fact, as its conducting reservoir. This portion of the machine is denominated the *prime conductor*. The

rubbed surface of the electric machines is either a cylinder or plate of glass, hence we distinguish them into cylinder machines and plate machines. The former, from their more compact form, are the more manageable; and the latter, from both sides of the glass plate being rubbed, are the more powerful forms of the instrument. The description of Winter's plate machine (fig. 10) will be quite sufficient to shew the general requirements and construction of electric machines. It was designed by Carl Winter of Vienna, and its merits, as well as those of some of the best forms of electrical apparatus, have been made widely known by two well-known German works, Müller's *Physik* and Fricke's *Physikalische Technik*. The Edinburgh makers have been lately led to adopt it. It is one of the best existing forms of the machine. The glass plate is turned on the axis *ab*, by means of the handle *c*. The longer end of this axis, consisting of a glass rod, moves in the wooden pillar *d*, and the other rests in the wooden head of the glass pillar *e*. The plate is thus completely insulated, and little loss of its electricity can take place through its supports. The two rubbers, one of which is shewn

Fig. 11.

on the outside, in fig. 11, are triangular pieces of wood, covered with a padding of one or two layers of flannel, enclosed in leather, and they present a flat hard surface to the glass, so that friction between it and them takes place in every part. They are placed in a wooden frame on each side of the plate, and the pressure is regulated by metal springs, fixed to the outside, between them and the frame. Before use, they are covered with an amalgam of mercury, zinc, and tin, which is made to adhere with the aid of a little grease, and which increases immensely the production of electricity. The surfaces of the rubbers are therefore conducting, and are made to communicate by strips of tinfoil with the negative conductor *f* (fig. 10). To prevent the electricity of the glass from discharging itself into the air, before reaching the prime conductor, each rubber has a non-conducting wing fastened to it, which is made of several sheets of oiled silk, kept together by shell-lac varnish, beginning at the rubber with several, and ending with one or two sheets. When the machine is in action, electrical attraction makes them adhere to the plate; but when it is out of action, they may be kept up by a split pin *g*. As the plate turns, the rubbers are kept in the frame by their ledges *h*. The whole framework of the rubbers and negative conductor is supported by the short glass pillar *i*, so that it can be insulated when required. The prime conductor *k*, is a brass ball insulated on the long glass pillar *l*, and to prevent the edges of the ball at the junction dissipating the electricity, the pillar enters the ball by a trumpet-shaped opening. The collection of the electricity from the glass is made by a row of points placed in the grooves, inside of two wooden rings *m, m*, which are attached on each side of the plate to a piece of brass projecting horizontally from the ball of the conductor. The grooves are covered with tinfoil, which conveys the collected electricity to the ball, and the points are kept out of the way of injury by not projecting beyond the grooves.

A section of the ball of the prime conductor is shewn in fig. 12. There are four openings in it:

the lower one for the head of the supporting pillar; the one at the right for the attachment of the collecting apparatus; the one at the left for the stalk of a small brass ball; and the upper one for admitting the lower end of a large wooden ring, removable at pleasure. This last forms the peculiar feature of Winter's machine. It consists of an iron wire bent into the shape shewn in the figure, carefully covered all round with polished wood, and communicating by a brass pin at the foot of the stalk on which it stands with the prime

Fig. 12.

Fig. 13.

conductor. To receive the sparks from the machine, an appendage (fig. 13) termed the spark-drawer is provided. This consists of a wooden pillar of the same height as the prime conductor, in the head of which a brass rod slides, with a large flat ball at the one end and a small ball at the other. All the fittings of the machine are of wood, no metal being used but for the prime and negative conductors. The loss caused by metal fittings in ordinary machines is very considerable. The insulating pillars should be, if possible, of green glass, which, from the absence of lead, is less conducting than flint glass. It is desirable, likewise, to cover them with shell-lac varnish, which prevents the formation of a conducting layer of moisture on them from the atmosphere. On using the machine, it is first necessary to connect the negative conductor by a wire or chain with the ground. As the plate is turned, — electricity is developed on the rubbers, and led to the negative conductor; and + electricity is formed on the glass, which is collected by the points, and transferred to the prime conductor. If the negative conductor were insulated, the electricities of both conductors, being of opposite names, and equal in amount, would act inductively on each other, so that the + electricity of the prime conductor would be to a considerable extent bound by the — electricity of the other conductor. When the latter is connected with the ground, its electric tension is no higher than is due to the inductive action caused by the prime conductor, which at the distance is not great, so that the electricity of the prime conductor is free to throw itself on the objects presented to it. To lessen this attraction, and at the same time to insure the insulation of the + electricity, both conductors are placed as far apart as possible, the distance in Winter's machine being nearly the diameter of the plate. If — electricity is wanted, the negative conductor is insulated, and the prime conductor connected with the ground, when sparks of — electricity are given off by the negative conductor.

The various forms of electric discharge through the air, or, as it is termed, *disruptive discharge*,

can be well seen with Winter's machine. The negative conductor being connected with the ground, with a two-foot plate, we may observe them in the following order. On turning the plate once or twice, a faint snapping sound is heard, and, when the room is darkened, a flickering spark is seen to be thrown out from the two-inch ball projecting from the prime conductor, which has the form of a bush, without leaves, with trunk, branches, and twigs, about ten inches in height. This is one form of what is called the *brush discharge*. Its general direction is horizontal, or not much inclined from it, but it turns to the band or other flat conductor brought near it. If it be received on a ball, its various branches concentrate on it. If the brush proceed from the end of a brass rod, instead of from a ball, it becomes very much diminished in size, and resembles a brush of feathers. The brush discharge, though apparently continuous, has been found by Wheatstone to consist of a series of successive brushes. When discharge is effected from a point, a star or *glow* of light marks its termination, while strong currents of air proceed from it, which are strong enough to blow away the flame of a candle. These currents accompany more or less the various forms of the brush discharge. The particles of air thus carry away the charge from a point to surrounding conductors, and hence a point is said to discharge itself by convection. If we connect the brass rod of the spark drawer with the ground, or the negative conductor, and bring the flat ball opposite to the small ball on the prime conductor, straight brilliant sparks pass between them so long as the distance does not much exceed two inches. Beyond that distance, the sparks become somewhat crooked, and at about four inches the discharge begins to take the form of a brush. If, now, the ring be placed in the conductor, the sparks again pass with readiness, and the brush does not again take place till the ball of the spark drawer is eleven or twelve inches off. The long sparks thus obtained with the aid of the ring are decidedly crooked or forked, with strongly marked lateral branches, which become all the more marked as they lengthen. It would thus seem that the spark has a tendency to break up into branches. When the striking distance is small, this is not perceptible; it is then straight and undivided. As the distance increases, it is crooked, with well marked offshoots; and when the distance is too great, it splits up entirely into a bush or brush.

The function of the ring of Winter's machine is therefore to increase enormously the length of the spark. This would seem to arise in the following way: quantity as well as high tension of electricity is requisite for the long spark. Without the ring, the electricity collected on the prime conductor concentrates on the projecting ball, but it cannot gather strength enough to make a full discharge into the neighbouring spark drawer, for before the quantity is sufficient, the tension of the electricity on the small ball has pushed the polarisation of the molecules of air to their utmost, and a partial or overflow discharge in the form of a brush ensues. When the ring is added, from its thinness and prominent position, it diverts the electricity into it; and before the tension of the electricity on the small ball again rises to discharging point, a large charge is accumulated in the compound conductor, which finds full vent in a powerful and concentrated spark. The wooden envelope appears to act to the core as the oiled silk to the plate; it prevents discharge into the air. The influence of the large flat ball of the spark drawer is of importance; it concentrates, from its size, the inductive action of the charge on itself, and from

its flatness it cannot hasten a premature discharge. Long sparks do not necessarily imply a very powerful machine, but they guarantee good production of electricity, and an insulation so perfect that no power is squandered. For the generality of electrical experiments, sparks of one or two inches are amply sufficient. These, Winter's machine gives readily without the ring; and when occasionally long sparks are wanted, the extension of the prime conductor can be added without inconvenience. It might be supposed that while the long sparks pass, the machine works more powerfully than at other times; but such is not the case, for the long spark occurs only occasionally, and the short one almost incessantly. All the forms of disruptive discharge are accompanied with the peculiar electric odour which arises from the production of ozone (q. v.).

We may now make a short reference to the experiments performed by the machine, illustrative of the general properties of electricity. A wooden head with hair on it illustrates, when placed on the prime conductor, electrical repulsion, by the hairs standing on end. A spoon containing ether is held so as to receive a spark from the projecting ball, when the inflammation of the ether illustrates the heat of the spark. A man standing on an *insulating stool* (a stool with glass legs), with one hand on the conductor, can send sparks, with his other hand, to everything and everybody about him. This illustrates communication of electricity by contact. A few pith-balls are enclosed in a glass jar, having its top and bottom of metal—the former in connection with the prime conductor, and the latter with the ground, when the pith-balls, by their rising and falling, shew the attraction of unlike, and the repulsion of like electricities. The most extraordinary experiment that can be performed with Winter's machine, is the lighting of a gas-jet by a person wholly unconnected with the machine, and standing some eight or ten feet from it. If the person so situated holds the blade of a knife or other point over the gas-burner, at a distance only short of touching, at each long spark from the machine, a small spark passes between the blade and the burner, and this ignites the gas. The reason is as follows: The body of the person in question is electrified negatively by the extensive prime conductor of the machine acting inductively. When the spark passes, the electric tension of the ring falls, and the negative electricity of his body must return to the ground, and taking the easiest route, causes the spark in question. This is quite similar to what is known in thunder-storms as the *back-stroke*: A person in a prominent position, under a highly charged cloud, experiences a violent, sometimes fatal shock at the same time as a flash of lightning, although the flash was not at all near him.

*Leyden Jar*.—This is a glass jar (fig. 14), with a coating of tinfoil pasted carefully inside and out, extending to within a few inches of the mouth. This last is generally closed by a wooden stopper, through which passes the stalk of a brass knob or ball, surmounting the whole. The connection between the inside coating and the ball is completed by a chain extending from the stalk to the bottom of the jar. If this jar be put on an insulating stool, so that sparks can pass from the prime conductor of a machine to the knob, when the jar is thus insulated, one or two sparks pass, and then the charge seems complete, for no more sparks will follow, though the action of the machine is continued; or

Fig. 14.

if they do, they are immediately dissipated from the knob in a brush discharge. If then, however, the knuckle of the experimenter be brought near the outer coating, sparks begin again to pass freely; and for every spark of + electricity that passes between the machine and the knob, a corresponding spark of the same name passes between the knuckle and outer coating. This continues for some time, and then the jar appears to be again saturated. It is now said to be fully charged. The outside of the jar can, in this state, be handled freely, and if it be still on the insulating stool, so may also the knob, although, when the hand first approaches, it receives a slight spark. But if, when the experimenter has one hand on the outer coating, he bring the other hand to the knob, before it can reach it, a straight, highly brilliant spark passes between the knob and his hand, and he experiences a shock of great violence. If he try the same thing again, a feeble spark and shock again ensue, and the jar is now thoroughly discharged. As it is highly inconvenient, if not dangerous, to discharge the jar through the body, *discharging tongs* (fig. 15) are used

Fig. 15.

for that purpose, which consist of two brass arms ending in balls, and moved on a hinge by glass handles.

The following account may be given of the action of the jar: When a spark passes between the conductor and the knob, the + electricity thereby communicated to the inner coating induces polarity in surrounding conductors, the - electricity being turned towards itself. From the knob, it can act upon a wide but distant range of conductors, through the air as the dielectric; and through the glass as dielectric, it can act upon the outer coating. Now, as the outer coating is very much nearer than other conductors, and as glass is a better dielectric than air, by far the most important direction of induction, when the jar is uninsulated, is through the glass. We have, therefore, the electricity given to the knob and inner coating divided, as it were, into two inducing charges—one to the further conductors, and the other to the outer coating. The former of these we may call the free charge, as it acts in the usual way through the air; and the latter, the bound charge, for it has a special conductor and dielectric. When the jar is insulated, we find that, after one or two sparks, it refuses to take more. This comes from the outer coating refusing to be further polarised, or, which is the same thing, the insulated electricity can more easily transmit polarisation to surrounding conductors through the knob than by means of the + electricity induced on the outer side of the outer coating. When, however, the outer coating is connected with the ground, either by spark or contact, the polarisation can reach its final termination, the ground, much more easily through the thin sheet of glass than through the air, so that every spark that the jar now receives goes, for the most part, to the bound charge, and a small fraction only to the free charge. What goes to the bound charge must have a corresponding - electricity on the outside coating; and for every amount of - electricity thus fixed on the outer coating, a corresponding amount of + electricity must be sent from the outer coating, either silently, when in contact, or by spark, when nearly so, into the ground; and what goes to the free charge has its - electricity imperceptibly induced in surrounding conductors. The jar thus receives rather more + electricity inside than - electricity outside; the

latter, however, being by far the largest fraction of the total - electricity induced. After a few more turns of the plate, a second limit is reached, and the sparks refuse again either to travel or to be retained. This arises from the air offering an easier channel for induction than the glass, the particles of which now offer more resistance to further polarisation than those of air to a disruptive discharge. The thinner the jar is, the longer must it be before this state of things ensues, for induction prefers the shortest channel. If the glass could be made of indefinite thinness, it would offer perfect facility for induction, and other conductors would not then come into competition with the outer coating. The free charge could not consequently exist, and there would be no limit to the charge which the jar could receive. Practically, however, we must make our jars of some thickness, and that we find must not be too small, for as the glass gets thinner the polarisation of its particles rises higher; and when it is too thin, the polarisation rises higher than the cohesion of its particles can bear, and a disruptive discharge takes place through it. Such a *spontaneous discharge* sometimes occurs with ordinary jars at their thinnest part; and as the fracture which it there causes in its passage makes the jar useless, it is usual not to charge a jar to saturation. The beau-ideal of a Leyden jar would be one whose dielectric was of excessive thinness and insulating power, a condition manifestly unattainable. The two charges are bound by mutual attraction to each side of the glass; but if both coatings could be simultaneously removed, as in the condenser, each would give striking evidence of its high electric tension. The outside coating can be touched without shock, for the - electricity is next the glass, and the + electricity has been lost in the ground, of which the outer surface of the coating, as well as the hand, forms a part. The inner coating, or its representative knob, may not be touched while the jar is uninsulated, for the discharge of the two coatings would be effected through the ground and body. When it is insulated, it may be touched, after, however, receiving a small spark, arising partly from the discharge of the free charge, and partly of a minute portion of the bound charge, arising from the nearness of the hand at contact increasing the amount of the free charge at the expense of the previously bound charge. The electricity is, as in the case of the outer coating, next the glass; and the knob and visible surface of the inner coating forms, as in the former case, a portion of the ground. But the minute loss of bound + electricity from the inner coating leaves a corresponding amount of - electricity free in the outer coating, which, when taken away, is, as before, accompanied by a minute portion of the bound charge; and thus, while the jar is insulated by touching alternately the knob and the outer coating, we gradually discharge it. When we wish to discharge the jar with the tongs, we place one ball on the outer coating, and bring the other round to the knob, when the discharging spark takes place. The length of this spark is many times longer than the thickness of the glass, which shews that a discharge takes place more easily through the air than through a glass plate of much inferior thickness.

On bringing the ball of the tongs, after the first discharge, nearer to the knob, a feeble *secondary discharge* follows, arising from the electricity which, under the intense action, had penetrated the glass, in the endeavour to force a conducting passage through it, being partially left in it. It is to this state of conduction into which the surfaces of the glass are forced, that we may attribute the fact,

that the charge appears to lodge more on the glass than on the coatings, the latter merely serving to aid in giving completion to their semi-conducting state. This is usually illustrated by a jar with movable coatings, which, when charged, can be taken to pieces. The jar being insulated, the inner coating is first removed, then the jar is lifted from the outer coating. Both coatings being completely discharged, the whole is again put up, and a discharge of very considerable power is obtained.

With respect to the striking distance, or that through which the air-discharge takes place, it has been found that it is proportional to the amount of the charge, and inversely proportional to the extent of the coatings. Thus, when a jar is half charged, the striking distance is half what it is with a full charge; and to keep the same striking distance for a jar of twice the size, a double charge is necessary. The amount of the charge is correctly enough known by the number of turns of the plate of the machine. When great accuracy is wanted, the outer coating of the insulated jar is made to spark into the knob of a small jar, whose outer coating is connected with the ground, and which is so made that its two coatings can discharge themselves. Each discharge of the small jar measures so much electricity fixed on the large jar; such a measurer is denominated a *unit jar*.

For great power, large surfaces are necessary. This can be obtained either by constructing a large jar or by uniting several small jars together, so as to act as one. The latter method is preferable, as we can vary the surface according to the number of jars employed. A combination of small jars united together as one is called an *electric battery*. A very convenient form of electric battery is shewn in fig. 16. The knobs of each jar communicate with

Fig. 16.

a large central one by means of arms of brass moving on hinges, and the outer coatings are put in conducting connection, by being placed on an insulated stool covered with tinfoil. The interior coatings are conveniently charged by a long projecting arm from the central knob, and the exterior ones by connecting the stool with the knob of the unit jar, or by a wire with the ground. Any jar can be thrown out of action by throwing back its arm.

By discharging the Leyden jar or electric battery through particular channels, we obtain some beautiful illustrations of the power of electricity. When the discharge is effected through thin wires of gold or platinum, the heat accompanying its passage is so great as to dissipate them in vapour. The expansion of the air caused by the spark is shewn by the *electric*

*mortar*. This is a wooden mortar with two wires entering air-tight at the opposite sides of the breach, with a small wooden ball fitting closely in the muzzle. The spark passing between these wires in discharge causes a sufficient expansion of the air within the mortar to drive the ball to some distance off. When the discharge is made through gunpowder, it tosses the grains violently about, but causes no ignition; when, however, it is retarded by introducing an imperfect conductor, such as a wet string, into the circuit, the gunpowder is fired. When the discharge is made through glass by two points pressing against its opposite surfaces, a small hole is drilled into the glass. To assist in such experiments, the universal discharger (fig. 17) is used. This consists of two

Fig. 17.

arms of brass mounted on glass pillars, so that their position and distance can be easily adjusted, and of a small movable table placed between them, the whole resting on a wooden foot.

*Velocity of Electrical Discharge.*—The rapidity with which electrical discharge takes place is so great, that we might well despair of reaching any definite information about it. Wheatstone, by means of a revolving mirror, determined its rate of propagation in certain circumstances. A small mirror was made to revolve fifty times a second, and the reflection of the electric spark was observed in it. Any one who takes a mirror in his hand and makes it revolve, sees that objects are apparently displaced by it, and it admits of an easy geometrical demonstration, that the reflected image describes an angle the double of that of the mirror. If, while the small mirror rotates at this rate, the image of a spark should shew a displacement of  $90^\circ$ , we know that the mirror has moved through  $45^\circ$ , and the time during which this takes place is  $\frac{45}{360}$  of  $\frac{1}{50}$  =  $\frac{1}{400}$  of a second. If the duration of the spark, then, had been  $\frac{1}{100}$  of a second, we should have seen its image move through  $90^\circ$ . The eye, however, during this time would not have been able to discern any difference between the beginning and the end of the spark, so that the  $90^\circ$  would have appeared as one arc of light. Examined in this way, however, the spark of a machine and of a Leyden jar were seen as if the mirror had been at rest. Thus analysed with an apparatus where a duration of  $\frac{1}{100000}$  part of a second would have shewn an arc of  $1^\circ$ , the electric spark appears instantaneous. The discharge of a Leyden jar through a long wire is not so instantaneous. Wheatstone's method of finding this was as follows: Six balls (fig. 18) were arranged in pairs, each pair being quite near the other. The ball 2 was connected with 3 by a copper wire a quarter of a mile in length, so were also 4 and 5—the dotted lines in the figure marking simply the connection. When discharge took place, the electricity of the inner coating was

Fig. 18.

communicated to 1, and of the outer coating to 6. Supposing charge to travel from the inner to the outer coating, it would proceed from 1 to 2 by spark, then by the long copper wire to 3, by spark to 4, by the other long wire to 5, and by spark to 6. To the eye, the three sparks seemed simultaneous. In the mirror, however, they presented the appearance of three arcs of equal length, the middle one rather behind the others (fig. 19). In this instance, the mirror revolved 800 times a second, and the retardation of the middle line was about  $\frac{1}{2}$ . The time, therefore, taken by the discharge to travel from 2 to 3, or 5 to 4, a quarter of a mile, was  $\frac{1}{360} \times \frac{1}{800} = \frac{1}{1,152,000}$  of a second, which

Fig. 19.

corresponds to 288,000 miles per second; greater than the velocity of light, which is only 194,000 miles per second. In the same manner, it was calculated from the lengths of the arcs, which were 24', that the duration of each spark was  $\frac{1}{24,000}$  of a second. It thus appeared that the discharge was a successive one, not, at least, as instantaneous as through a short conductor. This prodigious velocity is only that of discharge, not that of electric action. The fact of both side-sparks occurring at the same instant, shews that induction must have been fully established along the whole line before discharge took place. One would imagine, from the dual nature of electric force, that the velocity of induction must be indefinitely great.

*Electric Theories.*—There are two theories which have played an important part in the history of the science—the two-fluid theory of Dufay, and the one-fluid theory of Franklin. According to the former, matter is pervaded with two highly elastic imponderable electric fluids—one, the vitreous; the other, the resinous. These are supposed to repel themselves, but attract each other. Neutral bodies give no evidence of their presence, for they are there neutralised the one by the other; but when by friction or other operation the fluids are separated, each body observes the attractions and repulsions of the fluid it happens to have. According to the latter, there is only one electric fluid which repels itself, but attracts matter. Friction determines a gain of the fluid to the positive, and a loss to the negative body. Of the two theories, Dufay's is generally preferred, because the perfect similarity of each electricity, separately considered, is better represented by two similar fluids, than by a fluid on the one hand, and matter on the other. Either theory can give a graphic explanation of electric phenomena; but this does not necessarily imply their truth, for any theory which made allowance for the double nature of electric force could not fail to be in some degree satisfactory. It is extremely questionable whether electricity is a fluid at all. It is true that the distribution of electricity on the surfaces of conductors is that of one of the fluids supposed; but to act as a fluid, and to be a fluid, are two very different things, and something more is needed than mere analogy to prove electric fluidity. If such a fluid existed, we might expect to have some traces of its separate existence; but experiment teaches us that electricity is never manifested or transmitted apart from ponderable matter. It is difficult to conceive of fluids of the nature supposed. They are, in fact, quite as peculiar as the phenomena which they are intended to explain; still, the science of electricity is very much indebted to the supposition of its fluidity. It has served to lessen the abstractions of the science, and to simplify the comprehension of phenomena, much in the same

way that the balls of an abacus, though not numbers, facilitate calculation by being dealt with as such. Electricity appears as a peculiar affection of matter, but we are yet quite at sea as to the essential nature of that affection.

**ELECTRICITY, ANIMAL.** In this article we shall notice (1) the electricity developed by the so-called electrical fishes; (2) the electric properties of muscle and nerve; and (3) the electric phenomena of membranes and glands.

1. Although the peculiar powers of the torpedo and of the gymnotus were well known to the ancients, the first scientific discovery in this department of electricity was the determination of the electrical character of the shock of the torpedo by Walsh in 1772 ('Of the Electric Properties of the Torpedo,' *Phil. Trans.* 1773). From that date to the present time, the electric organs of certain fishes, which will be immediately mentioned, have been made the object of special study by some of our greatest anatomists and physiologists, amongst whom may be named John Hunter, Galvani, Rudolphi, Knox, Valentin, Pacini, Matteucci, Goodsir, and Jobert de Lamballe, who has published a special work, entitled *Des Appareils Electriques des Poissons Electriques* (Paris, 1858), accompanied by a magnificent volume of Plates.

The species of electrical fish which has been the longest known, is the *Raia torpedo*, or electric ray, which has much the appearance of a skate. It is common in the Bay of Biscay and in the Mediterranean, but is seldom met with on the shores of Britain. It grows to a considerable size, and is often above 80 lbs. in weight. It is now usually regarded as not a true ray, but as constituting a distinct genus, to which the terms *torpedo* and *marcine* have been applied by different naturalists—the latter name being derived from the Greek word *marke*, which was given to it by Aristotle. The electric organs or batteries are placed on each side, in the spaces between the pectoral fins, the head, and gills. See TORPEDO. Each battery consists of a number (varying according to the age of the

Electrical Apparatus of Torpedo:

c, the electric organs; e, hair; mc, spinal cord; a, eye and optic nerve; np, pneumogastric or eighth nerve; n, spinal nerves.

animal) of hexagonal prisms, which extend perpendicularly between the dorsal and abdominal surfaces, and present somewhat of a resemblance in shape and arrangement to the cells of a honey-comb. Four nerves, which are branches of the fifth and eighth cerebral pairs, go to each battery; and the

nervous centre of the electrical apparatus is, therefore, the *medulla oblongata*. Several species of *narcine* are known, all of which possess the electric property.

The ordinary rays and skates possess an organ in the tail which closely resembles the electric organ of other fishes, but its function is still doubtful; and in opposition to the view of its electric nature, it may be mentioned that while Dr Starke (to whom the discovery of this organ is due) found it in the tail of every species of true ray, both Professor Goodsir and M. Robin ascertained it to be wanting in the tail of the *torpedo*.

The *Gymnotus electricus*, or electrical eel, is little inferior in celebrity to the *torpedo*. It is common in all the streams which flow into the Orinoco, and is generally procured from Surinam. It is usually three or four feet in length, but may reach a length of six feet. The whole of its viscera lie close to the head, and the anal aperture is only two inches behind the mouth; all the rest of the body inferiorly is occupied by the electrical apparatus, which consists of four batteries—viz., two on either side, and one above the other—the uppermost or dorsal being the larger. These batteries consist of a number of piles placed horizontally in a direction from head to tail; and from this circumstance, as well as from their peculiar structure, they were compared by Redi to galvanic troughs. The number of these piles in the greater battery, is from thirty to sixty; in the lesser, from eight to fourteen. These batteries are supplied by about 224 pair of nerves on each side, derived from the inferior or motor roots of the spinal nerves.

Humboldt, both in his *Personal Narrative* and in his *Views of Nature*, gives a graphic account of the mode in which the Indians catch wild horses through the agency of the *gymnotus*. Faraday made numerous observations on a specimen, forty inches in length, which was exhibited in the Adelaide Gallery some years ago. He calculated that, at each medium discharge, the animal emitted as great a force as the highest charge of a Leyden battery of fifteen jars, exposing 3500 square inches of coated surface. The strongest shocks were obtained by touching the fish simultaneously near the head and near the tail; scarcely any shock being felt if the hands be placed, one on each side of the fish, at the same distance from either extremity; the amount of the shock, as might have been expected, varying with the length of the column which produces it. The shocks have sufficient power to stun, or even to kill fish; and the same discharge produces a more powerful effect upon a large fish than it does upon a small one, since the larger animal exposes a larger conducting surface to the water, through which the electricity is passing, and, consequently, it receives a more violent shock. On one occasion, when a live fish was put into the tub, which was 46 inches in diameter, the animal was seen to coil itself into a semicircle, the fish lying across the diameter; this was the most favourable position for giving the strongest shock; an instant afterwards, the fish floated dead upon its side, and was then devoured by the *Gymnotus* (q. v.).

The shock of both the *torpedo* and the *gymnotus* gives rise to momentary currents of sufficient intensity to deflect the galvanometer, to magnetise a needle, and to decompose iodide of potassium; and from both fish, sparks have been obtained.

We next come to the electrical fishes of the genus *Malapterurus*. The only fish of this genus whose electrical organs have been examined and described, is the *M. electricus* of the Nile, called Raash or Thunder-fish by the Arabs. It has barbules dependent from the region of the mouth, like the common

barbel; and its smooth skin is diversified with irregularly shaped spots. Its length is from eight to fourteen inches. The batteries are two in number, 'separated,' to adopt Professor Goodsir's description, 'but at the same time intimately connected to one another in the mesal plane along the dorsal and ventral margins of the body, so as to form a continuous layer of a gelatinous consistence closely adherent to the skin, and enclosing as in a sac the entire animal, except the head and fins.' The structure of these batteries is very complicated, and we shall not attempt to explain it.

In the year 1854, a new electrical fish became known to us, belonging to the same genus as the one just described. It is found in the muddy brackish water of the river Old Calabar, which empties itself into the Bight of Benin. The fish has, accordingly, been named the *Malapterurus Benimensis* by Mr Andrew Murray, who has described and figured it in the *Edinburgh Philosophical Journal* for July 1855. It is much smaller than the Nilotic species, and the formulae of the number of fin-rays differ in the two species. We believe that this new species has been dissected by Professor Goodsir, but we are not aware that the results have been published. See MALAPTERURUS.

Our limits will not allow of our noticing the successive opinions which have been entertained regarding the action of the electric organs in fishes. Those of our readers who wish to investigate this abstruse subject, may be referred to Professor Goodsir's memoir, 'On the Present State of Organic Electricity,' in the *Edinburgh Philosophical Journal* for October 1855. We cannot conclude our notice of electric fishes without directing the attention of our readers to an extremely interesting memoir by the late Professor George Wilson, 'On the Electric Fishes as the earliest Electric Machines employed by Mankind,' which is contained in the *Edinburgh Philosophical Journal* for October 1857, in which he discusses (1) the antiquity of the practice of using the electrical fishes as remedial agents, and (2) the extent or generality of that practice.

2. The study of the electrical properties of muscle and nerve dates from the period (1786—1794) in which Galvani made his great discoveries. Having first ascertained that contractions were produced by electricity in the muscles of a recently killed frog, he subsequently found that similar contractions occurred when two dissimilar metals in contact with one another were brought in contact with the nerve and muscles respectively of the frog's leg. The experiment may be readily made in the following manner: Expose the crural nerve, N, of a recently killed frog; touch it with a strap of zinc, Z, and at the same time touch the surface of the thigh with one end of a bit of copper wire, C. At the moment

that the other end of the wire is brought in contact with the zinc, the limb is convulsed; but the convulsions cease when the two metals are separated from each other, though they are still in contact with the animal tissues; and they are renewed when the zinc and copper are again made to touch. At first, Galvani believed that the contractions were due to electricity evolved by the

metals, but finally he concluded that it is produced by the animal textures themselves. No important step in this direction was afterwards taken till 1827, when Nobili, with his improved Galvanometer (q. v.), discovered the electric current of the frog. He found that when the circuit of the nerve and muscles of the leg is closed by the instrument, a deviation of the needle, to the extent sometimes of 30°, occurs, due to a current which passes in the limb from the toes upwards, and which could be increased when several frogs were simultaneously included in the experiment. Undoubted proof was thus afforded that electricity is developed in connection with muscle and nerve.

The researches of Matteucci, confirmed by the subsequent investigations of Dubois Reymond, have demonstrated the existence of what is termed the *muscular current* in living animals. They shew that in the living animal an electrical current is perpetually circulating between the internal portion and the external surface of a muscle—a current due probably to the chemical changes which are always occurring in the animal tissues. This muscular current ceases in warm-blooded animals in a very few minutes after their death; but in cold-blooded animals, as in the frog, it continues for a much longer period. The following is perhaps the best experiment for shewing the existence of the muscular current. Five or six frogs are killed by dividing the spinal column just behind the head; the lower limbs are removed, and the integuments stripped off them; the thighs are next separated from the legs at the knee-joint, and are cut across transversely. The lower halves of these prepared thighs are then placed upon a varnished board, and so arranged that the knee-joint of one limb shall be in contact with the transverse section of the next, and thus a muscular pile is formed, consisting of ten or twelve elements; the terminal pieces of this pile are each made to dip into a separate small cavity in the board, in which a little distilled water is placed. If the wires of a sensitive galvanometer be attached to a pair of platinum plates, and these plates be placed simultaneously, one into each cavity in connection with the muscular pile, a deviation of the galvanometer needle will be observed in a direction which indicates the existence of a current passing from the centre or cut transverse surface of the muscle towards its exterior.

Dubois Reymond has subsequently shewn, by the use of extremely sensitive instruments, that even the smallest shreds of muscular tissue exhibit proof of the existence of such a current; and he has established the general law, that any point of the natural or artificial *longitudinal* section of a muscle is positive in relation to any point of the natural or artificial *transverse* section.

3. The electrical relation of membranes and glands have been especially studied by Mr Baxter, whose 'Experimental Inquiry, undertaken with a View of ascertaining whether any or what Signs of Current Electricity are manifested during the Organic Process of Secretion in Living Animals,' is published in the *Philosophical Transactions* for 1848 and 1852.

His chief conclusions regarding the electrical condition of the intestinal mucous membrane are:

1. When the electrodes of a galvanometer are brought into communication—one with the mucous membrane of the alimentary canal, and the other with the blood flowing from the same part—a deviation of the needle takes place, indicating that the mucous secretion and the blood are in opposite electrical states.

2. The effect ceases after death, and may be considered as arising from the decomposition of the

blood—viz., from the changes which occur during the formation of the secreted product and venous blood.

His conclusions regarding the electrical relations of the secretions and blood of the liver, kidney, and mammary gland, are as follow:

1. During biliary secretion, the bile and the venous blood flowing from the hepatic veins are in opposite electrical states.

2. During urinary secretion, the urine and the venous blood flowing from the renal vein are in opposite electrical states.

3. During mammary secretion, the milk and the venous blood flowing from the mammary veins are in opposite electrical states.

For further information on this subject, the reader is referred to Matteucci's *Lectures on the Physical Phenomena of Living Beings*, translated by Dr Pereira; to his series of 'Electro-Physiological Researches,' published in the *Philosophical Transactions*; and to Dubois Reymond's *Untersuchungen über Thier-Electricität*.

**ELECTRICITY, MEDICAL.** Electricity, in its application to medicine and surgery, is employed in the following forms: 1. *Electrisation*, by electricity of high tension, as obtained by friction of glass in the common electrical machine; 2. *Galvanisation*, by current electricity of quantity, as set in motion by the voltaic battery; and 3. *Furadisation*, by induced or interrupted currents, produced by magneto-electric or electro-magnetic induction coil machines.

*Electrisation*.—Frictional electricity is now seldom employed in therapeutics, on account of the inconvenience experienced in the management and insulation of the glass or common electrical machines; yet the powerful stimulant and counter-irritative effect of sparks drawn from the affected parts is still recommended in paralytic affections, in Chorea and other nervous diseases; and the succussion produced by shocks from the Leyden jar is undoubtedly the most effectual remedy in Amenorrhœa.

*Galvanisation*.—The effect of passing a voltaic current from a battery of many elements through the living body, is to cause a shock or contraction of the muscular tissues, succeeded with a distinct interval by a momentary sensation or flow of heat due to the electric and nervous (?) polarisation of the circuit. During the continued passage of the current, slight tingling sensations and elevation of temperature are observed, especially in those parts in contact with the electrodes or poles, which become painful and congested, and finally inflamed and ulcerated. On opening the circuit, the depolarisation of the tissues which ensues is accompanied by a second shock and subsequent glow of heat, which are powerful in proportion to the length of time the circuit has remained closed. The amount of contraction in the muscle has relation to the *intensity* rather than the *quantity* of electricity passed through it—that is, to the rapidity with which the electric state is changed, rather than the amount of that change. The calorific effect of the current is proportionate to its *quantity*. Thus, a single pair of plates of platinum and zinc, an inch square (charged with chromic acid), will, under ordinary circumstances, exercise little or no physiological effect; but if the same pair be divided, so as to form a compound battery of twelve smaller pairs, its application will be attended with the shocks and calorific effects described. A further division into twenty-four or more pairs increases the shock, but the sensation of heat becomes less marked. With certain limitations, therefore, the shock of the battery depends on the number of its elements, without regard to their size, its calorific effect to the area of its plates. The nerves of the organs

## ELECTRO-CHEMICAL ORDER OF THE ELEMENTS—ELECTRO-METALLURGY.

of special sense, when subjected to galvanisation, evidence phenomena peculiar to their proper function. Thus, the passage of the current through the retina is attended by the sensation of a flash of light, which is bluish when the positive pole is applied to the eye, and tinged with the complementary orange when the force is transmitted in the opposite direction. A faint sensation of light is also perceived when the skin of the face or mucous membrane of the mouth is galvanised, caused by reflex action from the sentient filaments of the fifth pair of nerves which are distributed to those parts. Galvanisation of the ear gives rise to bubbling, ringing, or cracking sounds, and occasionally to distinctly musical tones; that of the tongue, to an acid taste under the positive pole, and an alkaline taste under the opposite one; that of the lining membrane of the nose, to sneezing and a peculiar smell, which differs with the direction of the current. The continuous gentle action of small single and compound voltaic arrangements has been more or less successfully employed in paralysis, amaurosis, and neuralgia, either by application to the surface of the body, or carried directly to the affected parts by needles thrust into them (galvano-puncture). More powerful batteries, consisting of six or eight cells of the carbon battery of Bunsen, the nitric acid battery of Grove, or the platinised zinc battery of Strehlill Wright, have been used to coagulate the fibrinous contents of aneurismal sacs—to decompose calculi in the bladder (?)—and to render platinum plates or wires incandescent, for the surgical cauterisation of internal parts not otherwise easily accessible.

*Faradisation.*—The instruments employed for the exhibition of interrupted or induced currents are the magneto-electric and the electro-magnetic coil machines. In the first, the electricity is set in motion in a long thin wire coiled round a bar of iron or keeper maintained in constant whirling motion before the poles of a permanent horseshoe-magnet, the magnet with every half revolution magnetising the keeper alternately in opposite directions, while the constantly recurring magnetism of the keeper in its turn induces impulses of alternating currents in the coil-wire. The disadvantages of the magneto-electric machine, therefore, are, that it is not self-acting, and that its currents pass alternately in opposite directions. In the electro-magnetic machine, the thick coil-wire, wound over a core of iron, is made to conduct the current from a single voltaic pair which magnetises the iron. When the battery-current is interrupted, the iron core becomes instantly demagnetised, and this change in its magnetic condition is attended with a rearrangement of the polarity of the coil-wire, and the passage through it of an impulse of induced electricity. By a simple arrangement, the magnetised iron is made to interrupt and renew the battery-current; and the machine thus rendered self-acting, furnishes a rapid succession of momentary currents passing in the same direction, and of much greater quantity than those of the magneto-electric machine. Currents higher in tension, less in quantity, and more resembling frictional electricity, may be obtained from an additional coil ('secondary coil') of very thin and long wire wound over the former one, but they are not of much importance in medical practice.

The physiological action of the coil-machines is equivalent to that of rapidly repeated discharges from a large Leyden jar weakly charged; and as the time engaged by the passage of each impulse in the succession of discharges is too short to permit the development of any decided polarisation of the tissues, the distinct calorific effects which accompany the commencement and cessation of the *galvanic* discharge do not occur. The continued passage of

the interrupted currents acts chiefly as a mechanical stimulant, first exciting, and after a time depressing the vitality of the part in the circuit; and its effects have been very closely imitated by vibratory impulses, produced altogether irrespective of electrical agency.

Faradisation is applicable to a great variety of chronic diseases in which a deficiency of functional energy exists: in paralytic affections unconnected with active disease of the nervous centres, mercurial and lead palsy, and in that produced by rheumatic affection and exposure to cold; in nervous or hysterical Aphonia, or loss of voice; in Amaurosis (q. v.), when not connected with inflammatory or organic disease; in Nyctalopia, or night-blindness; in Amenorrhœa, when uncomplicated with active disease of the uterus; in suppression of the lacteal secretion; in Constipation (q. v.) from deficiency in the peristaltic action of the intestines; in Paralysis of the bladder (?), and with very doubtful effect in the induction of uterine contraction; in suspended animation from drowning, narcotic poisons, &c. In spasmodic and neuralgic diseases, the benefit of Faradisation is less to be depended on; but a very gentle and long-continued application of it has afforded relief in the distressing starting of the lower limbs which occurs in Paraplegia or Paralysis of the lower half of the body; in 'Writer's Cramp,' and spasmodic forms of Hysteria; in Tic-douloureux, Sciatica, and hysterical Neuralgia. Faradisation by electro-puncture has been successfully employed to induce the union of non-united fractures, the currents being passed between the disjoined ends of the bones; and to excite absorption in Bronchocele and Hydrocele, though with more doubtful effect. The intense sparks from the 'secondary coil' have been used in place of those obtained by frictional electricity; and lastly, it has been proposed to employ the brilliant streams from powerful induction coils confined in fine 'vacuum tubes' of glass, to illuminate internal parts of the body, for the performance of surgical operations, &c.

**ELECTRO-CHEMICAL ORDER OF THE ELEMENTS.** In the action of gases, liquids, and solids upon each other, as in the construction of galvanic batteries, it has been observed that certain elements are readily acted upon, and give rise to electric currents, whilst others are, under the same circumstances, comparatively passive. This has led to the tabulation of the simple substances into a group, where the more readily acted upon, or electro-positive element, is placed at the one end of the series, and the less active, or electro-negative element, at the opposite end. The following table, mainly constructed by Berzelius, will shew the electric order of the majority of the elements.

<i>Electro-positive.</i>	Tin.	Tungsten.
Potassium.	Bismuth.	Molybdenum.
Sodium.	Copper.	Vanadium.
Lithium.	Silver.	Chromium.
Barium.	Mercury.	Arsenic.
Strontium.	Palladium.	Phosphorus.
Calcium.	Platinum.	Iodine.
Magnesium.	Gold.	Bromine.
Aluminium.	Hydrogen.	Chlorine.
Uranium.	Silicon.	Fluorine.
Manganese.	Titanium.	Nitrogen.
Nickel.	Tellurium.	Selenium.
Cobalt.	Antimony.	Sulphur.
Cadmium.	Carbon.	Oxygen.
Lead.	Boron.	<i>Electro-negative.</i>

**ELECTROLYSIS, or ELECTRO-CHEMISTRY.** See GALVANISM.

**ELECTRO-MAGNETISM.** See MAGNETISM and MAGNETO-ELECTRICITY.

**ELECTRO-METALLURGY.** See GALVANISM.

## ELECTRO-MOTIVE MACHINES. See MAGNETO-ELECTRICITY.

**ELECTROPHORUS.** This generally consists of a tin mould filled with shell-lac, and a movable metal cover, with a glass handle, as shewn in the figure. The shell-lac is poured in when melted, and it is mixed with some other substance, to make it less brittle. Five parts of shell-lac, one of wax, and one of Venice turpentine, is given as a good mixture. When used, the surface of the cake of shell-lac is smartly beaten with a cat's fur or foxtail. The cover is then put

Electrophorus.

on, and touched with the finger, which receives a slight spark of - electricity, just before contact takes place; and after the finger is removed, the cover, when lifted by its insulating handle, gives a brisk spark of + electricity to anything presented to it. This can be repeated for several minutes without any apparent exhaustion of the source of electricity; and in dry weather, sparks can be got in this way hours, and frequently days, after the cake has been beaten.

The action of the electrophorus may be thus accounted for. When the surface of the cake of shell-lac is beaten, the friction excites - electricity on it. This acts inductively all round, but the tin mould being the nearest conductor, and shell-lac a good dielectric, the induction becomes concentrated on it, + electricity becoming fixed on the side next the shell-lac, and - electricity being sent to the ground. The - electricity of the upper surface of the shell-lac is thus fixed by the + electricity of the mould. When the cover is put on the cake, the contact between the two is not sufficient to allow the latter to communicate its charge to the former. The cover is thus acted on inductively, not conductively. The - electricity of the cake, then, has the choice of two channels for its induction, either through the cake to the mould, or through a very thin film of air to the cover. The latter, from its offering so short a passage through the dielectric, has the preference, and the inductive action of the charge is diverted from the mould to the cover, and the + electricity on the other side of the cake is thus liberated and lost in the ground. The cover being strongly polarised, + electricity is induced and fixed on its lower surface, and - electricity on its upper, this last being transmitted to the ground by the finger. When the finger is withdrawn, and then the cover, the + electricity of the latter is free to discharge itself by spark, and inductive action again takes the direction of the mould, once more attracting + electricity to it. The induced polarity of the cover is attended with no loss to the charge of the shell-lac, which can thus continue to act with the same efficiency. The loss of electricity that all charged bodies experience in air, and especially when moist, at length discharges the cake, but this takes place all the less readily, that when the electricity is not needed to act on the cover, it is kept bound by the + electricity induced by it in the mould. In order that the + electricity of the mould should have liberty, so to speak, to come and go, the electrophorus must not be insulated; and when it is so, the action on the cover is feeble, if at all perceptible.

## ELECTRO-PLATING, ELECTRO-TYPE. See GALVANISM.

**ELECTRUM** is a term used to designate native gold as it is associated with silver. It is also applied to amber.

**ELECTUARY** (Lat. *eliger, electum*, I make choice), a form of medicinal preparation in which the remedy is enveloped or suspended in honey or syrup, so as to make a mixture of thick semi-fluid consistence.

**ELEGIT, ESTATE BY**, the right in lands which is enjoyed by one who has acquired the land under writ of *Elegit* (q. v.).

**ELEGIT, WRIT OF**, a writ whereby a creditor in England can seize the lands of his debtor in satisfaction of his claim. Before the reign of Edward I., a creditor could not enforce a claim of debt against the lands. But by statute of Westminster the second, 13 Edw. I. c. 18, it was enacted that the goods and chattels of the debtor should first be appraised, and if these were not sufficient, that the half of the freehold lands of the debtor should be delivered to the creditor, to be held by him until the debt was paid out of the rents and profits thereof. By 1 and 2 Vict. c. 110, the whole of the lands, including copyhold and customary lands, are made subject to the debt. A creditor who has seized the lands, is not entitled to take the person of his debtor; so that the creditor must make his choice to take the goods and person, or the goods and land, but he cannot attach land and person.

**ELEGY** (Gr. *elegia*), according to its derivation, signifies, exclusively, a song of lamentation, but the term was employed at an early period by the Greeks to designate any poem written in distiches. The alternation, peculiar to this measure, of the hexameter, or strictly narrative verse, with the more fiery pentameter, gives to this whole species of poetry its individual character, which consists in the connection of subjective feelings and emotions with external incidents or objects. The elegy, therefore, can often be chiefly, but never altogether narrative. The effect of the measure is further shewn in the circumstance, that earnest, long-sustained feelings, rarely violent passions, are expressed in the elegy. Of the numerous elegies of the Greeks, few have come down to us. Those still extant consist partly of encouragements to patriotism, as in Callinus and Tyrtaeus, and partly of lessons of practical wisdom, as in Solon and Theognis. Sometimes also it expressed yearning desire or mild sorrow, or amorous complaints. This was especially the case at Alexandria. Among the Romans, Catullus was the first good elegiac writer; after him came Propertius, Tibullus, and Ovid. Tibullus, in particular, brought the erotic elegy to its highest perfection. All are marked by the absence of political or moral feeling. They lived at a time when it was dangerous to express the one, and unfashionable to express the other—viz., the Augustan age. In modern times, the term *elegy* is applied in England to any serious piece where a tone of melancholy pervades the sentiments, whether grief is actually expressed or not; as, for example, Gray's '*Elegy*, written in a country church-yard.'

**ELEGY, in Music**, is a composition depicting feelings of mourning, sadness, longing or ardent desire, and love.

**ELEMENTAL SPIRITS**, beings who, according to the popular belief of the middle ages, presided over the four 'elements,' living in and ruling them. The elemental spirits of fire were called Salamanders; those of water, Undines; those of the air, Sylphs; and those of the earth, Gnomes. These

imaginary beings play a part in Pope's mock-heroic poem, *The Rape of the Lock*.

**ELEMENTS**, in Astronomy, are those numerical quantities, and those principles deduced from astronomical observations and calculations, which are employed in the construction of tables exhibiting the planetary motions. They include the greatest, least, and mean distances of the planets from the sun, the eccentricities of their orbits, their mean motions, daily and annual, with the motions of their aphelia, and the inclinations of their orbits to the ecliptic; their masses and densities, &c. The elements of the different planets and of their satellites will be found under their names. The reader will find tables of the elements of all bodies in our system in most books on astronomy. See in particular Herschel's *Elements of Astronomy*.

**ELEMENTS, CHEMICAL.** The word elements has a very different signification in modern science from what it once had. The earliest of the Greek philosophers assumed either a single element, or several, the modifications and combinations of which they held to give rise to all the things that we see. The most common assumption was that of four elements—fire, air, water, and earth. This corresponds to the four forms under which modern science considers matter as existing—viz., imponderable, gaseous, liquid, and solid; while by elements are understood the simple component ingredients of bodies under whatever form they exist. Neither air, water, nor earth are elements in this sense, for they can be decomposed into simpler ingredients, and fire is a combination of light and heat. It is not pretended that any of the substances called elements are absolutely simple, that is, contain only one kind of matter; but only that hitherto they have not been decomposed. The number of so-called simple bodies, or elements, recognised by chemists at the present time (1861) is 63, of which some have been known from ancient times, such as the metals gold, silver, lead, copper, tin, and mercury; others are of more recent date; whilst within the last year, two new metallic elements have been added to the list—viz., Cesium and Rubidium, both of which were discovered by Professor Bunsen of Heidelberg, by the aid of the new branch of practical chemistry named *Spectrum analysis*. The elements are divided into two great classes—the *non-metals* and *metals*. The latter are the more numerous class, there being altogether 50, whilst the non-metals number only 13. The following table gives the names of the elements at present known.

TABLE OF THE ELEMENTARY SUBSTANCES.

NON-METALLIC.		
Oxygen.	Silicon.	Chlorine.
Hydrogen.	Sulphur.	Bromine.
Nitrogen.	Selenium.	Iodine.
Carbon.	Phosphorus.	Fluorine.
Boron.		
METALLIC.		
Potassium.	Lanthanum.	Palladium.
Sodium.	Didymium.	Rhodium.
Lithium.	Chromium.	Iridium.
Cesium.	Zinc.	Ruthenium.
Rubidium.	Manganese.	Osmium.
Barium.	Nickel.	Antimony.
Strontium.	Cobalt.	Tin.
Calcium.	Iron.	Tungsten.
Magnesium.	Lead.	Molybdenum.
Aluminium.	Silver.	Vanadium.
Beryllium ( <i>Glucium</i> ).	Mercury.	Tantalum ( <i>Columbium</i> ).
Zirconium.	Copper.	
Thorium.	Bismuth.	Platinum.
Yttrium.	Cadmium.	
Erbium.	Uranium.	
Terbium.	Gold.	
Cerium.	Platinum.	
		Arsenic.

The more rare elements are printed in *italics*. Although the classification adopted above is a convenient one for the study of the elements, yet there is no decided line of demarcation between the metallic and non-metallic (otherwise called metalloïd) series. The metals are generally recognised (1) by their power of reflecting light, as exhibited in the lustre of burnished gold, and even in ordinary mirrors, which owe their power of reflecting light to the amalgam of the metals mercury and tin, present on the glass; (2) by their power of conducting heat; and (3) by their ready transmission of electricity. The non-metals or metalloïds are regarded as not possessing all these three attributes. The non-metals carbon and silicon, however, in certain forms conduct electricity, whilst the metals arsenic and tellurium very closely resemble the metalloïds in many of their properties. In the combinations of the various elements with each other, the non-metals constitute the electro-negative ingredient, and, as a rule, are insulators in the galvanic current; whilst the metals form the electro-positive element of the combination, and are conductors of the electric fluid. Again, in their combination with oxygen, the non-metals form more or less powerful acids, whilst the metals produce more or less powerful bases. At ordinary temperatures, five of the elements are gaseous—viz., oxygen, hydrogen, nitrogen, chlorine, and fluorine; two are liquid—viz., bromine and mercury; whilst the remaining fifty-six are solid.

**ELEMI**, a fragrant resinous substance, obtained from different species of the natural order *Amyridaceæ*. It was formerly brought chiefly from Egypt or Ethiopia, and was referred to a tree called *Amyris elemifera*. Part of the E. of commerce is now brought from America, and is obtained from trees of other genera, but of the same natural order, particularly *Icica Icicariba*, which grows in Brazil and other warm parts of America. In dry weather, incisions are made in the bark, from which the resinous juice flows abundantly, and hardens in the sun. It is collected once a day, and put into casks. It is at first soft and unctuous, but becomes hard and brittle by age. *Elaphrium elemiferum* is believed to yield the greater part of the E. of Mexico. E. is usually in large, pale-yellow, semi-transparent masses, fragile, softening by the heat of the hand, with a smell somewhat resembling that of fennel. It is soluble in alcohol, except a white crystallisable residue, which is very light, inodorous, and tasteless, and which is called *Elemine*. The properties of E., however, chiefly depend on a volatile oil, which may be obtained from it by distillation. E. is used in the preparation of stimulant plasters and ointments.

**ELEPHANT**, a geographical term of obvious origin, indicates various localities in Asia and Africa.—1. Elephant Point, a promontory of Pegu, in Further India, marks the west extremity of the mouth of the Rangoon, the most easterly arm of the Irrawaddy. It is in lat. 16° 28' N., and long. 96° 25' E.—2. Elephant Bay, an inlet of the Atlantic, on the coast of Benguela, South-west Africa, in lat. 13° 14' S., and long. 12° 33' E., has excellent anchorage, but no fresh water.—3. Elephant Island, in Senegambia, is about 100 miles up the Gambia.—4. Elephant River, in the Cape Colony of South Africa, enters the Atlantic after a course of 140 miles, about lat. 31½° S., and long. 18° E.

**ELEPHANT, SEA** (*Macrorhinus proboscideus*), also known as the **ELEPHANT SEAL**, the **PROBOSCIS SEAL**, &c., is the largest of the Seal family (*Phocidæ*), an inhabitant of the seas of the southern hemisphere. It is more than twice as large as an elephant, being

sometimes thirty feet in length, with a circumference of about eighteen feet at the thickest part, which is at the chest, immediately behind the fore-flippers or swimming-paws; the body tapering towards the tail. The colour is grayish, bluish gray, or more rarely blackish brown. The whole

the proboscis of the elephant, but in its ordinary state hangs flaccid on the face, becoming distended like the wattle of a turkey when the animal is

Sea-Elephant (*Macrorhinus proboscideus*).

body is covered with very short hair, distributed in patches, giving it a spotted appearance somewhat like watered silk. The swimming-paws are large and powerful; the fore-paws have five nails, the thumb-nail easily distinguishable from the others; the hind-paws have not even the rudiments of nails, but are beautifully constructed like the webbed foot of a bird, so as to expand, and increase the power of swimming. The true tail is very short, not more than six inches long. The head is larger in proportion than in many seals; the eyes are very large and prominent, with eyebrows of coarse hair; the whiskers are composed of very long and coarse spirally twisted hairs; there are no external ears; the canine teeth are remarkably large and massive, somewhat assuming the character of tusks. The nose of the males is very remarkable, being prolonged into a kind of proboscis of about a foot long, which, however, is not at all an organ of prehension, and, indeed, seems to serve no purpose whatever analogous to those which are served by

1, Skull and Teeth of Sea-Elephant; 2, Swimming-paw, or Flipper.

reused to passion of any kind, and in particular presenting this distended appearance during the rutting season. At that season, also, the males have furious combats, the victor winning for himself a whole herd of females. When the proboscis is dilated, the voice of the sea-elephant, which usually is like the lowing of an ox, is completely changed, and becomes a loud and extraordinary gurgling.

Sea-elephants are found on Kerguelen's Land, Juan Fernandez, South Georgia, the States Islands, South Shetland, the Falkland Islands, &c. They migrate southwards at the beginning of summer, and northwards at the approach of winter, thus avoiding the extremes of heat and cold. A single individual sometimes yields 1400 or 1500 pounds or 70 gallons of excellent oil, on account of which these animals are pursued to an extent that seems to have already much reduced the numbers of the species. They are either shot or killed by means of long lances. Cuttle-fish and other cephalopods seem to be their principal food; but remains of marine plants have also been found in the stomach.

The skin of the sea-elephant is not at all valued on account of its fur, but its thickness and strength make it very useful for harness-making and similar purposes. The flesh is black, oily, and indigestible; the tongue (salted) alone being esteemed a delicacy. The principal product, however, is the oil, which burns slowly, with a clear flame, and without smoke or disagreeable odour.
