ed by Lord Lindſay, that they dared to do more, and would not ſuffer religion to be overthrown. On this the King perceiving a number of people crowding into the room, withdrew into another without making any reply, ordering the door to be ſhut. By this the petitioners were ſo much enraged, that on their return to the church the moſt furious reſolutions were taken; and had it not been for the activity of Sir Alexander Home the provoſt, and Mr Watt the deacon-convener who aſſembled the crafts in his Majeſty's behalf, it is more than probable that the door would have been forced, and an end put to his life. This affront was ſo much reſented by the King, that he thought proper to declare Edinburgh an unfit place of reſidence for the court or the adminiſtration of juſtice. In conſequence of this declaration, he commanded the college of juſtice, the inferior judges, and the nobility and barons, to retire from Edinburgh, and not to return without expreſs licence. This unexpected declaration threw the whole town into conſternation, and brought back the magiſtrates and principal inhabitants to a ſenſe of their duty. With the clergy it was far otherwiſe. They railed againſt the King in the moſt furious manner; and endeavouring to perſuade the people to take up arms, the magiſtrates were ordered to impriſon them: but they eſcaped by a timely flight. A deputation of the moſt reſpectable burgeſſes was then ſent to the King at Linlithgow, with a view to mitigate his reſentment. But he refuſed to be pacified; and on the laſt day of December 1596 entered the town between two rows of his ſoldiers who lined the ſtreets, while the citizens were commanded to keep within their houſes. A convention of the eſtates was held in the Tolbooth, before whom the magiſtrates made the moſt abject ſubmiſſions, but all in vain. The convention declared one of the late tumults, in which an attack had been made upon the King's perſon, to be high treaſon; and ordained, that if the magiſtrates did not find out the authors, the city itſelf ſhould be ſubjected to all the penalties due to that crime. It was even propoſed to raze the town to the foundation, and erect a pillar on the ſpot where it had ſtood, as a monument of its crimes. The inhabitants were now reduced to the utmoſt deſpair; but Queen Elizabeth interpoſing in behalf of the city, the King thought proper to abate ſomewhat of his rigour. A criminal proſecution, however, was commenced, and the town-council were commanded to appear at Perth by the firſt of February. On their petition, the time for their appearance was prolonged to the firſt of March; and the attendance of 13 of the common-council was declared ſufficient, provided they had a proper commiſſion from the reſt. The trial commenced on the fifth day of the month; and one of the number having failed in his attendance, the cauſe was immediately decided againſt the council: they were declared rebels, and their revenues forfeited.

12
gain re-
ted into
our.

For 15 days the city continued in the utmoſt confuſion; but at laſt, on their earneſt ſupplication, and offering to ſubmit entirely to the King's mercy, the community were reſtored on the following conditions, which they had formerly proffered: That they ſhould continue to make a moſt diligent ſearch for the authors of the tumult, in order to bring them to condign puniſhment; that none of the ſeditious miniſters ſhould be allowed to return to their charges, and no others admitted without his Majeſty's conſent; and that in the election of their magiſtrates they ſhould preſent a liſt of the candidates to the King and his lords of council and ſeſſion, whom his Majeſty and their lordſhips might approve or reject at pleaſure. To theſe conditions the King now added ſome others; *viz.* that the houſes which had been poſſeſſed by the miniſters ſhould be delivered up to the King; and that the clergymen ſhould afterwards live diſperſed through the town, every one in his own pariſh: That the town-council houſe ſhould be appointed for accommodating the court of exchequer; and that the town ſhould become bound for the ſafety of the lords of ſeſſion from any attempts of the burgeſſes, under a penalty of 40,000 merks; and, laſtly, that the town ſhould immediately pay 20,000 merks to his Majeſty.

Edinburgh.

Upon theſe terms a reconciliation took place; which appears to have been very complete, as the King not only allowed the degraded miniſters to be replaced, but in 1610 conferred a mark of his favour on the town, by allowing the provoſt to have a ſword of ſtate carried before him, and the magiſtrates to wear gowns on public occaſions. In 1618 he paid his laſt viſit to this city, when he was received with the moſt extravagant pomp and magnificence. See Scotland.

13
Proceedings of the magiſtrates, &c.

The events which during this period, regard the internal police of the city, were principally the following. After the unfortunate battle at Pinkey, the magiſtrates, probably apprehending that now their power was enlarged by reaſon of the common calamity, proceeded in ſome reſpects in a very arbitrary manner; forcing the inhabitants to furniſh materials for the public works; enjoining merchants to bring home ſilver to be coined at the mint; and ordering lanterns to be hung out at proper places to burn till nine at night, &c. Another invaſion from England being apprehended in 1558, the city raiſed 1450 men for its defence, among whom there are ſaid to have been 200 tailors, ſo that their profeſſion ſeems to have been in a very flouriſhing ſtate at that time. During the diſturbances which happened at the reformation, and of which a particular account is given under the article Scotland, it was enacted, that the figure of St Giles ſhould be cut out of the town ſtandard, and that of a thiſtle inſerted in its place. It was likewiſe enacted, that none but thoſe who profeſſed the reformed religion ſhould ſerve in any office whatever; and the better to preſerve that extraordinary appearance of ſanctity which was affected, a pillar was erected in the North Loch, for the purpoſe of ducking fornicators.

In 1595, the boys of the High School roſe againſt their maſters; and ſuch was the barbariſm of thoſe days, that one of theſe ſtriplings ſhot a magiſtrate with a piſtol, who had come along with the reſt to reduce them to obedience. The reaſon of the uproar was, that they were in that year refuſed two vacations, which had been cuſtomary in former times: however, they were at laſt obliged to ſubmit, and ever ſince have been allowed only one for about ſix weeks in the autumn. The ſame year the houſe of one of the bailies was aſſaulted by the tradeſmens ſons, aſſiſted by journeymen who had not received the freedom of the town: he eſcaped with his life, but the offenders were baniſhed the city for ever.

14
Diſturbances in the time of Charles I.

In the beginning of the reign of Charles I. a perfect harmony ſeems to have ſubſiſted between the court and the city of Edinburgh; for in 1627 king Charles I. preſented the city with a new ſword and gown to be worn by the provoſt at the times appointed by his father James VI. Next year he paid a viſit to this capital, and was received by the magiſtrates in a moſt pompous manner; but ſoon after this the diſturbances aroſe which were not terminated but by the death of that unfortunate monarch. Theſe commenced on an attempt of Charles to introduce Epiſcopacy into the kingdom; and the firſt ſtep towards this was the erection of the three Lothians and part of Berwick into a dioceſe, Edinburgh being the epiſcopal ſeat, and the church of St Giles the cathedral. An account of the diſturbance occaſioned by the firſt attempt to read the prayer-book there, is given under the article Britain; but though the attempt was given over, the minds of the people were not to be quieted. Next winter they reſorted to town in ſuch multitudes, that the privy-council thought proper to publiſh two acts; by one of which the people were commanded, under ſevere penalties, to leave the town in 24 hours; and by the other, the court of ſeſſion was removed to Linlithgow. The populace and their leaders were ſo much enraged by the latter, that lord Traquair and ſome of the biſhops narrowly eſcaped with their lives; and next year (1638) matters became ſtill more ſerious. For now, the king having provoked his ſubjects throughout all Scotland with the innovations he attempted in religion, Edinburgh was made the general place of rendezvous, and the moſt formidable aſſociations took place; an account of which has already been given under the article Britain. Each of the towns in Scotland had a copy; and that which belonged to Edinburgh, crowded with 5000 names, is ſtill preſerved among the records of the city. Notwithſtanding this diſagreement, however, the king once more viſited Edinburgh in 1641, and was entertained by the magiſtrates at an expence of 12,000l. Scots. It does not appear that after this the city was in any way particularly concerned with the diſturbances which followed either throughout the remainder of the reign of Charles I. the commonwealth, or the reign of Charles II. In 1680 the duke of York with his ducheſs, the princeſs Anne, and the whole court of Scotland, were entertained by the city in the Parliament Houſe, at the expence of 15,000l. Scots. At this time it is ſaid that the ſcheme of building the bridge over the North Loch was firſt projected by the duke.

15
Regulations made by the magiſtrates.

From the time that king James VI. paid his laſt viſit to Edinburgh in 1618, till the time of the union in 1707, a conſiderable number of private regulations were made by the magiſtrates; ſome of them evidently calculated for the good of the city, others ſtrongly characteriſtic of that violent ſpirit of fanaticiſm which prevailed ſo much in the laſt century. Among the former was an act paſſed in 1621, that the houſes, inſtead of being covered with ſtraw or boards, ſhould have their roofs conſtructed of ſlate, tiles, or lead. This act was renewed in 1667; and in 1698 an act was paſſed regulating their height alſo. By this they were reſtrained to five ſtories, and the thickneſs of the wall determined to be three feet at bottom. In 1684 a lantern with a candle was ordered to be hung out in the firſt floor of every houſe in order to light the ſtreets at night; and there were two coaches with four horſes each ordered to be bought for the uſe of the magiſtrates; but it does not appear how long they continued to be uſed. In 1681 the court of ſeſſion diſcontinued its ſittings in ſummer: but as this was found to be attended with inconvenience, an act was paſſed for their reſtoration, which has continued ever ſince. During the time of the civil war in 1649, the city was viſited by the plague, which is the laſt time that dreadful diſtemper hath made its appearance in this country. The infection was ſo violent, that the city was almoſt depopulated, the priſoners were diſcharged from the tolbooth, and an act was made for giving one Dr Joannes Politius a ſalary of 80l. Scots per month, for viſiting thoſe who were infected with the diſeaſe. In 1677 the firſt coffee-houſes were allowed to be opened, but none without a licence: and the ſame year the town-council regulated the price of penny-weddings; ordaining the men to pay no more than two ſhillings, and the women 18 pence; very extravagant prices having been exacted before.

In contradiſtinction to theſe ſalutary acts, we may ſtate thoſe which ſhow an extravagant deſire of preſerving the appearance of virtue in the female ſex, as if it had been poſſible for others to inſpire them with virtuous notions if they had not imbibed them of themſelves. In 1633 an act of council was paſſed, by which women were forbidden to wear plaids over their faces, under penalty of five pounds and the forfeiture of the plaid for the firſt fault. Baniſhment was the puniſhment of the third. The reaſon aſſigned for this act was, that matrons were not known from ſtrumpets and looſe women, while the plaid continued to be worn over the face. This act was renewed in 1637 and 1638. Succeeding town-councils continued to ſhow the ſame regard to theſe matters; for in 1695 they enacted, that no inn-keeper, vintner, or ale-ſeller, ſhould for the future employ women as waiters or ſervants, under the penalty of five ſhillings ſterling for each.

The following anecdote may perhaps make the virtues of theſe legiſlators themſelves wear a ſuſpicious aſpect. In 1649 the city having borrowed L. 40,000 Scots, in order to raiſe their quota of men for his majeſty, the payment of it was abſolutely refuſed by the town-council when a demand was made for that purpoſe. That they might not, however, depend entirely upon their own opinion in a matter of ſuch importance, they took that of the General Aſſembly upon the ſubject; and it was determined by theſe reverend divines, that they were not in conſcience bound to pay for an unlawful engagement which their predeceſſors had entered into. But in 1652, Cromwell's parliament, who pretended to no leſs ſanctity than they, declared themſelves of a very different opinion; and on the application of one of the creditors, forced them to repay the ſum.

The treatment which the brave marquis of Montroſe met with, likewiſe fixes an indelible ſtigma both upon the magiſtrates and clergy at that time. Having been put under ſentence of excommunication, no perſon was allowed to ſpeak to him or do him the leaſt office of friendſhip. Being met without the city by the magiſtrates and town-guard, he was by them conducted in a kind of gloomy proceſſion through the ſtreets bare-

bareheaded, and in an elevated cart made for the purpoſe; the other priſoners walking two and two before him. At the time of his execution he was attended by one of the miniſters, who, according to his own account, did not chooſe to return till *he had ſeen him caſten over the ladder*.

The union in 1707 had almoſt produced a war between the two kingdoms which it was deſigned to unite; and on that occaſion Edinburgh became a ſcene of the moſt violent diſturbances, of which a particular account is given under the article Britain. During the time the act was paſſing, it was found abſolutely neceſſary for the guards and four regiments of foot to do duty in the city. The diſturbances were augmented by the diſagreement of the two members of parliament; and notwithſtanding the victory gained at that time by the court party, Sir Patrick Johnſton the provoſt, who voted for the union, was obliged afterwards to leave the country. In 1715 the city remained faithful to the royal cauſe, and proper meaſures were taken for its defence. A committee of ſafety was appointed, the city-guard increaſed, and 400 men raiſed at the expence of the town. The trained bands likewiſe were ordered out, 100 of whom mounted guard every night: by which precautions the rebels were prevented from attempting the city: they however made themſelves maſters of the citadel of Leith; but fearing an attack from the duke of Argyle, they abandoned it in the night-time. A ſcheme was even laid for becoming maſters of the caſtle of Edinburgh; for which purpoſe they bribed a ſerjeant to place their ſcaling ladders. Thus ſome of the rebels got up to the top of the walls before any alarm was given; but in the mean time the plot being diſcovered by the ſerjeant's wife, her huſband was hanged over the place where he had attempted to introduce the rebels. The expence of the armament which the city had been at on this occaſion amounted to about 1700l. which was repaid by government in the year 1721.

The loyalty of this city was ſtill farther remarkable in the year 1725, when diſturbances were excited in all parts of the kingdom, particularly in the city of Glaſgow, concerning the exciſe-bill; for all remained quiet in Edinburgh, notwithſtanding the violent outcries that were made elſewhere: and ſo remarkable was the tranquillity in the metropolis, that government afterwards returned thanks to the magiſtrates for it. In 1736, however, the city had again the misfortune to fall under the royal diſpleaſure, on the following account. Two ſmugglers having been detected in ſtealing their own goods out of a cuſtom-houſe, were condemned to be hanged. The crime was looked upon as trivial; and therefore a general murmur prevailed among the populace, which was no doubt heightened by the following accident. At that time it had been cuſtomary for perſons condemned to die to be carried each Sunday to the church, called from that circumſtance the *Tolbooth-church*. The two priſoners juſt mentioned were conducted in the uſual way, guarded by three ſoldiers, to prevent their making their eſcape: but having once gone thither a little before the congregation met, one of the priſoners ſeized one of the guards in each hand, and the other in his teeth, calling out to his companion to run; which he immediately did with ſuch ſpeed, that he ſoon got out of ſight, and was never heard of afterwards. The perſon who had thus procured the life of his companion without regard to his own, would no doubt become a general object of compaſſion; and of courſe, when led to the place of execution, the guard were ſeverely pelted by the mob, and ſome of them, according to the teſtimony of the witneſſes who were ſworn on the occaſion, pretty much wounded. By this Captain Porteous, who commanded the guard, was ſo much provoked, that he gave orders to fire, by which ſix people were killed and eleven wounded. The evidence, however, even of the fact that the orders to fire were given, appears not to have been altogether unexceptionable; nevertheleſs, on this he was tried and condemned to be executed. At that time the king was abſent at Hanover, having left the regency in the hands of the queen; and the caſe of the unfortunate Porteous having been repreſented to her, ſhe was pleaſed to grant him a reprieve: but ſuch was the inveteracy of the people againſt him, that they determined not to allow him to avail himſelf of the royal clemency. On the day that had been appointed for his execution, therefore, a number of people aſſembled, ſhut the gates of the city, and burnt the door of the priſon, the ſame which the mob would formerly have broke open in order to murder king James. They then took out Porteous, whom it was found impoſſible to reſcue out of their hands, though every method that the magiſtrates could take for that purpoſe in ſuch a confuſion was made uſe of. It was even proved, that the member of parliament went to the commander in chief, and requeſted that he would ſend a party of ſoldiers to quell the diſturbance, but was abſolutely denied this requeſt, becauſe he could not produce a written order from the provoſt to this purport; which, in the confuſion then exiſting in the city, could neither have been expected to be given by the provoſt, nor would it have been ſafe for any perſon to have carried it about him. Thus the unhappy victim was left in the hands of his executioners; and being dragged by them to the place deſtined for receiving his fate, was hanged on a dyer's ſign-poſt. As they had not brought a rope along with them, they broke open a ſhop where they knew they were to be had; and having taken out what they wanted, left the money upon the table, and retired without committing any other diſorder.

19
Government highly incenſed on that account.

Such an atrocious inſult on government could not but be highly reſented. A royal proclamation was iſſued, offering a pardon to any accomplice, and a reward of L. 200 to any perſon who would diſcover one of thoſe concerned. The proclamation was ordered to be read from every pulpit in Scotland the firſt Sunday of every month for a twelvemonth: but ſo divided were the people in their opinions about this matter, that many of the clergy heſitated exceedingly about complying with the royal order, by which they were brought in danger of being turned out of their livings; while thoſe who complied were rendered ſo unpopular, that their ſituation was rendered ſtill worſe than the others. All the efforts of government, however, were inſufficient to produce any diſcovery; by which, no doubt, the court were ſtill more exaſperated: and it was now determined to execute vengeance on the magiſtrates and city at large. Alexander Wilſon, the provoſt at that time, was impriſoned three weeks before he could be admitted to bail; after which, he and the four bailies, with the lords of juſticiary, were ordered to attend the houſe of peers at London. On their arrival there, a debate enſued, whether the lords ſhould attend in their robes or not? but at laſt it was agreed, that they ſhould attend in their robes at the bar. This, however, was refuſed by their lordſhips, who inſiſted that they ſhould be examined within the bar; upon which the affair of their examination was dropped altogether. A bill was at laſt paſſed both houſes, by which it was enacted, that the city of Edinburgh ſhould be fined in 2000 l. for the benefit of Porteous's widow (though ſhe was prevailed upon to accept of L. 1500 for the whole); and the provoſt was declared incapable of ever ſerving government again in any capacity whatever. To prevent ſuch cataſtrophes in time coming, the town-council enacted, that, on the firſt appearance of an inſurrection, the chief officers in the different ſocieties and corporations ſhould repair to the council, to receive the orders of the magiſtrates for the quelling of the tumult, under the penalty of 8l. 6 s. 8 d. for each omiſſion.

20
The city taken by the rebels in 1745.

In 1745, the city was inveſted by the Pretender's army; and on the 17th of September, the Netherbow-gate being opened to let a coach paſs, a party of Highlanders, who had reached the gate undiſcovered, ruſhed in, and took poſſeſſion of the city. The inhabitants were commanded to deliver up their arms at the palace of Holyroodhouſe: a certain quantity of military ſtores was required from the city, under pain of military execution; and an aſſeſſment of 2 s. 6 d. upon the pound was impoſed upon the *real* rents within the city and liberties, for defraying that expence.

The Pretender's army guarded all the avenues to the caſtle; but no ſigns of hoſtility enſued till the 25th of the month, when the garriſon being alarmed from ſome unknown cauſe, a number of cannon were diſcharged at the guard placed at the Weſt-port, but with very little effect. This gave occaſion to an order to the guard at the weigh-houſe, to prevent all intercourſe between the city and caſtle; and then the governor acquainted the provoſt by letter, that unleſs the communication was preſerved, he would be obliged to diſlodge the guard by means of artillery. A deputation was next ſent to the Pretender; acquainting him with the danger the city was in, and intreating him to withdraw the guard. With this he refuſed to comply; and the Highland centinels firing at ſome people who were carrying proviſions into the caſtle, a pretty ſmart cannonading enſued, which ſet on fire ſeveral houſes, killed ſome people, and did other damage. The Pretender then conſented to diſmiſs the guard, and the cannonading ceaſed. After the battle of Culloden, the provoſt of Edinburgh was obliged to ſtand a very long and ſevere trial, firſt at London and then at Edinburgh, for not defending the city againſt the rebels; which, from the ſituation and extent of the walls, every one muſt have ſeen to be impoſſible.

During this trial a very uncommon circumſtance happened; the jury having ſat two days, inſiſted that they could ſit no longer, and prayed for a ſhort reſpite. As the urgency of the caſe was apparent, and both parties agreed, the court, after long reaſoning, adjourned till the day following, taking the jury bound under a penalty of L. 500 each; when the court continued ſitting two days longer, and the jury were one day incloſed. The event was, that the provoſt was exculpated.

2
Gover ment city r red.

After the battle of Culloden the duke of Cumberland cauſed fourteen of the rebel ſtandards to be burned at the croſs: that of the pretender was carried by the common executioner, the others by chimney-ſweepers; the heralds proclaiming the name of the commanders to whom they belonged as they were thrown into the fire. At this time the city of Edinburgh felt a temporary inconvenience from the election of their magiſtrates not having taken place at the uſual time; ſo that it became neceſſary to apply to his majeſty for the reſtoration of the government of the city. This was readily granted, the burgeſſes being allowed a poll-tax; after which an entire new ſet of magiſtrates was returned, all of them friends to the houſe of Hanover; and ſoon after the freedom of the city in a gold box was preſented to the duke of Cumberland.

With theſe tranſactions all interferences betwixt government and the metropolis of Scotland were ended; the reſt of its hiſtory therefore only conſiſts of internal occurrences, the regulations made by its own magiſtrates for the benefit of the city, their applications to government for leave to improve it, or the execution of theſe improvements; of which we ſhall now give a brief detail.

2
Salar ſtowe the p

In the year 1716, the city firſt beſtowed a ſettled ſalary on the provoſt, in order to enable him to ſupport the dignity of firſt magiſtrate. This was at firſt L. 300; but has ſince been augmented to L. 500, which his lordſhip ſtill enjoys. In 1718 it was recommended to the magiſtrates to diſtinguiſh themſelves by wearing coats of black velvet, for which they were allowed L. 10; but this act being abrogated in 1754, gold chains were aſſigned as badges of their office, which they ſtill continue to wear. Provoſt Kincaid happened to die in office in the year 1777; which being a very rare accident, perhaps the only one of the kind to be met with in the records of Edinburgh, he was buried with great ſolemnity, and a vaſt concourſe of people attended.

2
Acco tum

Tumults have been frequent in Edinburgh, chiefly on account of the dearneſs of proviſions. In 1740 Bell's mills were firſt attacked by the populace, and afterwards Leith mills: nor could the rioters be diſperſed till the military had fired among them, and wounded three, of whom one died; and it was found neceſſary to order ſome dragoons into the city in order to preſerve tranquillity. In 1742 another violent tumult took place, owing to a cuſtom of ſtealing dead bodies from their graves for anatomical purpoſes, which had then become common. The populace beat to arms, threatened deſtruction to the ſurgeons: and in ſpite of all the efforts of the magiſtrates demoliſhed the houſe of the beadle at St Cuthbert's. In 1756, new diſturbances, which required the aſſiſtance of the military, took place: the cauſe at this time was the impreſſing of men for the war which was then commencing. A diſturbance was likewiſe excited in 1760. This was occaſioned by the footmen, who till then were allowed to follow their maſters into the playhouſe, and now took upon them to diſturb the entertainment of the company; the conſequence of which was, that they were turned out, and have ever ſince been obliged to wait for their maſters. In 1763 and 1765, the tumults on account of the price of proviſions were renewed; many of the meal-mongers had their urgh

their houſes broken open and their ſhops deſtroyed. The magiſtrates, as uſual, were obliged to call in a party of dragoons to quell the diſturbance; but at the ſame time, to put an effectual ſtop, as far as was in their power, to theſe proceedings for the future, they gave ſecurity, that people who brought grain or proviſion into the market ſhould be ſecured in their property. Since that time there have been no tumults directly on the account of proviſions; though in 1784 a terrible riot and attack of a diſtillery at Canonmills took place, on a ſuppoſition that the diſtillers enhanced the price of meal by uſing unmalted grain. The attack was repelled by the ſervants of the diſtillery; but the mob could not be quelled until the ſheriff called the ſoldiers quartered in the caſtle to his aſſiſtance. The ſame night a party of rioters ſet out for Ford, a place ten miles to the ſouthward, where there was likewiſe a large diſtillery; which, as there was none to make any oppoſition, they ſoon deſtroyed. One man was killed in this riot at Edinburgh by the fire of a ſervant of the diſtillery, and ſeveral of the rioters were afterwards ſecured and puniſhed.

In the years 1778 and 1779 two very alarming diſturbances happened, which threatened a great deal of bloodſhed, though happily they were terminated without any. The firſt was a mutiny of the earl of Seaforth's Highland regiment, who were at this time quartered in the caſtle. Theſe having been ordered to embark, for ſome reaſon or other unanimouſly refuſed, and poſted themſelves on the top of Arthur's ſeat, where they continued for two days. Troops were collected to prevent their eſcape, and the inhabitants were ordered to keep within doors at the firſt toll of the great bell, which was to be a ſignal of violence about to take place; but fortunately all the fears, naturally ariſing from the expectation of this event, were diſſipated by an accommodation. The other happened on account of the attempt to repeal the penal laws againſt the Papiſts; and was much more alarming than the other, as being the effect of a premeditated ſcheme and determined reſolution to oppoſe government. On the 2d of February 1779 a mob aſſembled in the evening, burned a Popiſh chapel, and plundered another. Next day they renewed their depredations; deſtroying and carrying off the books, furniture, &c. of ſeveral Popiſh prieſts and others of that perſuaſion. The riot continued all that day, though the aſſiſtance of the military was called in; but happily no lives were loſt, nor was there any firing. The city was afterwards obliged to make good the damage ſuſtained by the Catholics on this occaſion, which was eſtimated at L.1500. This year alſo an unlucky accident happened at Leith. About 50 Highland recruits having refuſed to embark, a party of the South Fencibles was ſent to take them priſoners. Unexpectedly, however, the Highlanders ſtood upon their defence; when, after ſome words, a firing commenced on both ſides, and about one half of the Highlanders were killed and wounded, the remainder being taken priſoners and carried to the caſtle. Captain Mansfield and two or three privates were killed in this affray.

We ſhall cloſe this hiſtory of Edinburgh with a general account of the improvements which have lately taken place in it, and of which a particular deſcription will afterwards be given. Theſe began in the year 1753, when the foundation-ſtone of the Exchange was laid, at which time there was a grand proceſſion, and the greateſt concourſe of people ever known in Edinburgh. A triumphal arch was erected for the purpoſe, through which the proceſſion paſſed, and medals were ſcattered among the populace. In 1756 the high ſtreet was cleared by the removal of the croſs; though many regretted this, on account of its being a very ancient and elegant building. In the middle it had an unicorn placed on the top of a pillar 20 feet high; but this fine ornament was broken to pieces by the giving way of the tackle by which it was attempted to remove it. It is now again erected at Drum, a ſeat belonging to lord Somerville, about four miles from Edinburgh. In 1763 the firſt ſtone of the north bridge was laid by provoſt Drummond; and in 1767 an act of parliament was obtained for extending the royalty of the city over the fields to the northward, where the New Town is now ſituated. About the ſame time a ſpot of ground upon the ſouth ſide of the town was purchaſed by a private perſon for L.1200, which being feued out for building, gave riſe to the increaſe of the town on that quarter; and this proceeded the more rapidly, as the houſes built there were free from the dues impoſed upon others ſubject to the royalty. In 1774 the foundation of the Regiſter-Office was laid. In 1784 the project for rendering the acceſs to the town equally eaſy on both ſides was begun to be put in execution by laying the foundation of the ſouth bridge. At the ſame time a great improvement was made by reducing the height of the ſtreet ſeveral feet all the way from the place where the croſs ſtood to the Netherbow; by which means the aſcent is rendered more eaſy, not only for carriages, but alſo for perſons who walk on foot. At the ſame time, the ſtreet was farther cleared by the removal of the town guard-houſe, which had long been complained of as an encumbrance. It is ſtill farther in contemplation to remove the Luckenbooths: and when this is accompliſhed, with other improvements by which it muſt neceſſarily be accompanied, it is to be queſtioned whether any city in Britain will be able to vie with Edinburgh in elegance and beauty.

Edinburgh.

Having thus given a conciſe hiſtory of the city from its earlieſt foundation, we ſhall now proceed to deſcribe it in its moſt improved ſtate.

25
Deſcription of Edinburgh.

Edinburgh is ſituated upon a ſteep hill, riſing from eaſt to weſt, and terminating in a high and inacceſſible rock, upon which the caſtle ſtands. At the eaſt end or lower extremity of this hill ſtands the abbey of Holyrood-houſe, or king's palace, diſtant from the caſtle upwards of a mile; and betwixt which, along the top of the ridge, and almoſt in a ſtraight line, runs the high-ſtreet. On each ſide, and parallel to this ridge or hill, is another ridge of ground lower than that in the middle, and which does not extend ſo far to the eaſt; that on the ſouth being intercepted by Saliſbury-rocks and Arthur's-ſeat, a hill of about 800 feet of perpendicular height; and that on the north by the Calton-hill, conſiderably lower than Arthur's-ſeat: ſo that the ſituation of this city is moſt ſingular and romantic; the eaſt or lower part of the town lying between two hills; and the weſt or higher part riſing up towards

towards a third hill, little inferior in height to the higheſt of the other two, upon which, as has been obſerved, the caſtle is built, and overlooks the town.

The buildings of the town terminate at the diſtance of about 200 yards from the caſtle-gate; which ſpace affords a moſt delightful as well as convenient and healthful walk to the inhabitants. The proſpect from this ſpot is perhaps the fineſt any where to be met with, for extent, beauty, and variety.

In the valley or hollow betwixt the mid and the ſouth ridges, and nearly parallel to the high-ſtreet, is another ſtreet called the Cowgate; and the town has now extended itſelf over moſt part of that ſouth ridge alſo. Betwixt the mid and the north ridges was a loch, which, till of very late, terminated the town on that ſide. From the high-ſtreet towards the loch on the north, and Cowgate on the ſouth, run narrow croſs ſtreets or lanes, called *wynds* and *cloſes*, which grow ſteeper and ſteeper the farther weſt or nearer the caſtle; ſo that, were it not for the cloſeneſs and great height of the buildings, this city, from its ſituation and plan, might naturally be expected to be the beſt aired, as well as the cleaneſt, in Europe. The former, notwithſtanding theſe diſadvantages, it enjoys in an eminent degree; but we cannot compliment it upon the latter, notwithſtanding every poſſible means has been uſed by the magiſtrates for that purpoſe.

The ſteepneſs of the aſcent makes the acceſs to the high-ſtreet from the north and ſouth very difficult; which no doubt greatly retarded the enlargement of the city. To remedy this inconvenience on the north, and with a view to extend the town on that quarter, a moſt elegant bridge has been thrown over the north loch, which joins the north ridge to the middle of the high-ſtreet, by ſo eaſy an aſcent as one in ſixteen; and in purſuance of the deſign, a plan of a new town to the north was fixed upon, and is now nearly finiſhed, with an elegance and taſte that does honour to this country. In like manner, to facilitate the acceſs from the ſouth ſide, a bridge has been thrown over the valley through which the Cowgate runs; which, if not equally elegant with the north bridge, is certainly as convenient.

26
Account of the gradual increaſe of Edinburgh

The gradual increaſe of the city of Edinburgh may in ſome degree be underſtood from the traces of its ancient walls that ſtill remain. James II. in 1450, firſt beſtowed on the community the privilege of fortifying the city with a wall, and empowered them to levy a tax upon the inhabitants for defraying the expence. When the city was firſt fortified, the wall reached no further than the preſent water-houſe, or reſervoir, on the caſtle-hill: from thence to the foot of Halkerſton's wynd, juſt below the new-bridge, the city was defended by the north-loch; an inconſiderable moraſs, which, being formerly overflowed, formed a ſmall lake that hath ſince been drained. From this place to the foot of Leith-wynd, it does not appear how the city was fortified: but from the foot of Leith-wynd to the Nether-bow-port it was defended only by a range of houſes; and when theſe had become ruinous, a wall was built in their place. The original wall of Edinburgh, therefore, began at the foot of the north-eaſt rock of the caſtle. Here it was ſtrengthened by a ſmall fortreſs, the ruins of which are ſtill to be ſeen, and are called the *well-houſe tower*, from their having a ſpring in their neighbourhood. When the wall came oppoſite to the reſervoir, it was carried quite acroſs the hill, having a gate on the top for making a communication between the town and caſtle. In going down the hill, it went ſlanting in an oblique direction to the firſt angle in going down the Weſt-bow, where was a gate named the *Upper-bow port*, one of the hooks of which ſtill remains. Thence it proceeded eaſtward in ſuch a manner, as would have cut off not only all the Cowgate, but ſome part of the parliament-houſe; and being continued as far as the mint-cloſe, it turned to the north-eaſt, and connected itſelf with the buildings on the north ſide of the high-ſtreet, where was the original *Nether-bow Port*, about 50 yards weſt from that which afterwards went by the ſame name.

Soon after the building of this wall, a new ſtreet was formed on the outſide of it, named the *Cowgate*, which in the 16th century became the reſidence of the nobility, the ſenators of the college of juſtice, and other perſons of the firſt diſtinction. After the fatal battle of Flowden, however, the inhabitants of the Cowgate became very anxious to have themſelves defended by a wall as well as the reſt. The wall of the city was therefore extended to its preſent limits. This new wall begins on the ſouth-eaſt ſide of the rock on which the caſtle is built, and to which the town-wall comes quite cloſe. From thence it deſcends obliquely to the Weſt-port; then aſcends part of a hill on the other ſide, called the *High Riggs;* after which, it runs eaſtward with but little alteration in its courſe, to the Briſto and Potter-row ports, and from thence to the Pleaſance. Here it takes a northerly direction, which it keeps from thence to the Cowgate-port; after which the incloſure is completed to the Netherbow by the houſes of St Mary's wynd. The original Netherbow port being found not well adapted for defence was pulled down, and a new one built in 1571 by the adherents of queen Mary. In 1606, the late handſome building was erected about 50 yards below the place where the former ſtood. It was two ſtories high, and had an elegant ſpire in the middle; but being thought to encumber the ſtreet, and the whole building being in a crazy ſituation, it was pulled down by order of the magiſtrates in 1764.

In the original wall of Edinburgh there was, as has been already obſerved, a port on the caſtle-hill. On the extenſion of the wall, after building the houſes in the Cowgate, this gate was pulled down. That in the upper or weſt bow ſtood for a much longer time, and was pulled down within the memory of ſome perſons lately or perhaps ſtill living. Beſides theſe, there was a third, about 50 yards above the head of the Canongate; but whether there were any more, is uncertain. The ports or gates of the new walls were, 1. The *Weſt-port*, ſituated at the extremity of the Graſs-market; beyond which lies a ſuburb of the town and a borough of regality, called *Portſburgh*. Next to this is a wicket, ſtruck out of the town-wall in 1744, for the purpoſe of making an eaſier communication between the town and the public walks in the meadows, than by Briſto-port. The next to this was *Briſto-port*, built in 1515; beyond which lies a ſuburb called *Briſto-ſtreet*. At a ſmall diſtance from Briſto was the *Potter-row Port*, which took this name from a manufactory of earthen ware in the neighbourhood. Formerly it was called *Kirk of*

*Field*

*Field Port.* Between this and the Cowgate-port ſtood another, called *St Mary's Wynd Port*, which extended from eaſt to weſt acroſs the foot of the Pleaſance, and which was demoliſhed only ſince the middle of the laſt century.—Cloſe to the middle of this ſtood the *Cowgate-port;* which opened a communication between the Cowgate and St Mary's wynd, and the Pleaſance.—The *Nether-bow Port* has been already ſpoken of.—At the foot of Leith-wynd was another gate, known by the name of *Leith-wynd Port*; and within it was a wicket giving acceſs to the church of Trinity College, and which ſtill remains. At the foot of Halkerſton's wynd was another, which, as well as the former, was built about the year 1560. Both of theſe were pulled down ſome years ago, and all the reſt in 1785.—Another ſtill remains at the foot of the Canongate, known by the name of the *Water-gate*.

For 250 years the city of Edinburgh occupied the ſame ſpace of ground, and it is but very lately that its limits have been ſo conſiderably enlarged. In the middle of the 16th century, it is deſcribed as extending in length about an Italian mile, and about half as much in breadth; which anſwers very nearly to its preſent limits, the late enlargements only excepted.—This ſpace of ground, however, was not at that time occupied in the manner it is at preſent. The houſes were neither ſo high nor ſo crowded upon each other as they are now. This was a conſequence of the number of inhabitants increaſing, which has occaſioned the raiſing of the houſes to ſuch an height as is perhaps not to be paralleled in any other part of the world. Till the time of the Reformation, the burying ground of the city extended over all the ſpace occupied by the Parliament-ſquare, and from thence to the Cowgate. The lands lying to the ſouthward of the Cowgate were chiefly laid out in gardens belonging to the convent of Black-friars, and the church of St Mary in the Field. Theſe extended almoſt from the Pleaſance to the Potterrow-port. From the Briſto to the Weſt-Port, the ground was laid out in gardens belonging to the Gray-friars. The magiſtrates, on their application to queen Mary, obtained a grant of the Gray-friars gardens for a burying-place; for which it was given as a reaſon, that they were ſomewhat diſtant from the town. Here, however, it muſt be underſtood, that theſe gardens were diſtant from the houſes, and not without the walls; for they had been incloſed by them long before.—In the time of James I. the houſes within the walls ſeem to have been in general, if not univerſally, covered with thatch or broom; and not above 20 feet high. Even in the year 1621, theſe roofs were ſo common, that they were prohibited by act of parliament, in order to prevents accident from fire.—In the middle of the laſt century, there were neither courts nor ſquares in Edinburgh. The Parliament cloſe or ſquare is the oldeſt of this kind in the city. Miln's ſquare, James's court, &c. were built long after; and Argyle's and Brown's ſquares within theſe 50 years.

The *New Town* was projected in the year 1752; but as the magiſtrates could not then procure an extenſion of the royalty, the execution of the deſign was ſuſpended for ſome time. In 1767, an act was obtained, by which the royalty was extended over the fields to the northward of the city; upon which advertiſements were publiſhed by the magiſtrates, deſiring proper plans to be given in. Plans were given in accordingly, and that deſigned by Mr James Craig architect was adopted. Immediately afterwards, people were invited to purchaſe lots from the town-council; and ſuch as purchaſed became bound to conform to the rules of the plan. In the mean time, however, the town-council had ſecretly reſerved to themſelves a privilege of departing from their own plan; which they afterwards made uſe of in ſuch a manner as produced a law-ſuit. According to the plan held forth to the purchaſers, a canal was to be made through that place where the north-loch had been, and the bank on the north ſide of it laid out in terraces: but inſtead of this, by an act of council, liberty was reſerved to the town to build upon this ſpot; and therefore, when many gentlemen had built genteel houſes in the new town on faith of the plan, they were ſurpriſed to find the ſpot appointed for terraces and a canal, beginning to be covered with mean irregular buildings, and work-houſes for tradeſmen. This deviation was immediately complained of; but as the magiſtrates ſhowed no inclination to grant any redreſs, a proſecution was commenced againſt them before the Lords of Seſſion. In that court the cauſe was given againſt the purſuers, who thereupon appealed to the Houſe of Lords. Here the ſentence of the Court of Seſſion was reverſed, and the cauſe remitted to the conſideration of their Lordſhips. At laſt, after an expenſive conteſt, matters were accommodated. The principal term of accommodation was, that ſome part of the ground was to be laid out in terraces and a canal; but the time of diſpoſing it in that manner, was referred to the Lord Preſident of the Court of Seſſion and the Lord Chief Baron of the Exchequer.—The fall of part of the bridge, hereafter mentioned, proved a very conſiderable diſadvantage to the new town; as it neceſſarily induced a ſuſpicion that the paſſage, by means of the bridge, could never be rendered ſafe. An overſight of the magiſtrates proved of more eſſential detriment. A piece of ground lay to the ſouthward of the old town, in a ſituation very proper for building. This the magiſtrates had an opportunity of purchaſing for 1200l; which, however, they neglected, and it was bought by a private perſon, who immediately feued it out in lots for building, as has been already mentioned. The magiſtrates then began to ſee the conſequence, namely, that this ſpot being free from the duties to which the royalty of Edinburgh is ſubject, people would chooſe to reſide there rather than in the New Town. Upon this they offered the purchaſer 2000l. for the ground for which he had paid 1200l.; but as he demanded 20,000l. the bargain did not take place. Notwithſtanding theſe diſcouragements, the New Town is now almoſt finiſhed; and from the advantages of its ſituation, and its being built according to a regular plan, it hath undoubtedly a ſuperiority over any city in Britain. By its ſituation, however, it is remarkably expoſed to ſtorms of wind, which, at Edinburgh, ſometimes rage with uncommon violence.

It has three ſtreets, almoſt a mile in length, running from eaſt to weſt, interſected with croſs ſtreets at proper diſtances. The moſt northerly, called *Queen's Street*, is 100 feet broad, and commands an extenſive proſpect of the Forth, the county of Fife, and the ſhipping in the river. That called *George's Street*, which is in the middle, is no leſs than 1·5 feet wide. It is terminated at each end by two very elegant and extenſive ſquares; that on the eaſt end is called *St Andrew's Square*; the other, tho' not yet finiſhed, nor indeed begun, is to be named *Charlotte's Square*. Prince's ſtreet is the moſt ſoutherly; and extends from the northern extremity of the bridge, quite to the weſt end of the town; though as that is not yet finiſhed, we cannot ſay whether it will be done exactly according to the plan laid down, as there has been a propoſal made by a private perſon of continuing the whole a conſiderable way farther to the weſtward, to end in a circus. The reaſon given for this propoſed innovation is, that the road to Glaſgow and other parts in the weſt will thus be rendered more eaſy, as it will then lie along the new bridge over the Water of Leith at Bell's mills, which is much more convenient than that juſt now in uſe.

The moſt remarkable public buildings in Edinburgh are:

28 Public buildings deſcribed.

1. *The Caſtle.* This ſtands on a high rock, acceſſible only on the eaſt ſide. On all others it is very ſteep, and in ſome places perpendicular. It is about 300 feet high from its baſe: ſo that, before the invention of artillery, it might well have been deemed impregnable; though the event ſhowed that it was not.—The entry to this fortreſs is defended by an outer barrier of palliſadoes; within this is a dry ditch, draw-bridge, and gate, defended by two batteries which flank it; and the whole is commanded by an half-moon mounted with braſs cannon, carrying balls of 12 pounds. Beyond theſe are two gate-ways, the firſt of which is very ſtrong, and has two portculliſes. Immediately beyond the ſecond gate-way, on the right hand, is a battery mounted with braſs cannon, carrying balls of 12 and 18 pounds weight. On the north ſide are a mortar and ſome gun batteries.—The upper part of the caſtle contains a half-moon battery, a chapel, a parade for exerciſe, and a number of houſes in the form of a ſquare, which are laid out in baracks for the officers. Beſides theſe there are other baracks ſufficient to contain 1000 men; a powder magazine bomb-proof; a grand arſenal, capable of containing 8000 ſtand of arms; and other apartments for the ſame uſe, which can contain 22,000 more: ſo that 30,000 ſtand of arms may be conveniently lodged in this caſtle.—On the eaſt ſide of the ſquare above mentioned, were formerly royal apartments; in one of which king James VI. was born, and which is ſtill ſhown to thoſe who viſit the caſtle. In another, the regalia of Scotland were depoſited on the 26th of March 1707, and are ſaid to be ſtill kept there; but they are never ſhown to any body. Hence a ſuſpicion has ariſen that they have been carried to London; which is the more confirmed, as the keeper of the jewel-office in the tower of London ſhows a crown, which he calls that of Scotland; and it is certain that the door of what is called the *Crown-room* has not been publicly known to be opened ſince the union.

The governor of the caſtle is generally a nobleman, whoſe place is worth about 1000l. a-year; and that of deputy-governor, 500l. This laſt reſides in the houſe appointed for the governor, as the latter never inhabits it. There is alſo a fort-major, a ſtore-keeper, maſter gunner, and chaplain; but as this laſt does not reſide in the caſtle, worſhip is ſeldom performed in the chapel. The parliament-houſe was formerly included in the great ſquare on the top, and the royal gardens were in the marſh afterwards called the *North-loch*; the king's ſtables being on the ſouth ſide, where the houſes ſtill retain the name, and the place where the barns were ſtill retain the name of Caſtle-barns.

The caſtle is defended by a company of invalids, and four or five hundred men belonging to ſome marching regiment, though it can accommodate 1000, as above-mentioned; and this number has been ſometimes kept in it. Its natural ſtrength of ſituation was not ſufficient to render it impregnable, even before the invention of artillery, as we have already obſerved; much leſs would it be capable of ſecuring it againſt the attacks of a modern army well provided with cannon. It could not, in all probability, withſtand, even for a few hours, a well directed bombardment: for no part but the powder-magazine is capable of reſiſting theſe deſtructive machines; and the ſplinters from the rock on which the caſtle is built, could not fail to render them ſtill more formidable. Beſides, the water of the well, which is very bad, and drawn up from a depth of 100 feet, is apt to ſubſide on the continued diſcharge of artillery, which produces a concuſſion in the rock.

2. *The Palace of Holyrood-houſe.* This, though much neglected, is the only royal habitation in Scotland that is not entirely in ruins. It is a handſome ſquare of 230 feet in the inſide, ſurrounded with piazzas. The front, facing the weſt, conſiſts of two double towers joined by a beautiful low building, adorned with a double baluſtrade above. The gateway in the middle is decorated with double ſtone columns, ſupporting a cupola in the middle, repreſenting an imperial crown, with a clock underneath. On the right hand is the great ſtaircaſe which leads to the council chamber and the royal apartments. Theſe are large and ſpacious, but unfurniſhed: in one of them the Scotch peers meet to elect 16 of their number to repreſent them in parliament. The gallery is on the left hand, and meaſures 150 feet by 27½. It is adorned with the ſuppoſed portraits of all the kings of Scotland. In the apartments of the duke of Hamilton, which he poſſeſſes as hereditary keeper of the palace, queen Mary's bed of crimſon damaſk, bordered with green fringes and taſſels, is ſtill to be ſeen, but almoſt reduced to rags. Here alſo ſtrangers are ſhown a piece of wainſcot hung upon hinges, which opens to a trap-ſtair communicating with the apartments below. Through this paſſage Darnley and the other conſpirators ruſhed in to murder the unhappy Rizzio. Towards the outward door of theſe apartments are large duſky ſpots on the floor, ſaid to be occaſioned by Rizzio's blood, which could never be waſhed out. In the lodgings aſſigned to lord Dunmore is a picture by Van Dyke, eſteemed a maſterly performance, of king Charles I. and his queen going a-hunting. There are likewiſe the portraits of their preſent majeſties at full length by Ramſay. The lodgings above the royal apartments are occupied by the duke of Argyle as heritable maſter of the houſehold.

The front of this palace is two ſtories high; the roof

roof flat; but at each end the front projects, and is ornamented with circular towers at the angles. Here the building is much higher, and the reſt of the palace is three ſtories in height. The north-weſt towers were built by James V. for his own reſidence: his name is ſtill to be ſeen below a nitch in one of theſe towers. During the minority of queen Mary, this palace was burned by the Engliſh; but ſoon after repaired and enlarged beyond its preſent ſize. At that time it conſiſted of five courts, the moſt weſterly of which was the largeſt. It was bounded on the eaſt by the front of the palace, which occupied the ſame ſpace it does at preſent; but the building itſelf extended further to the ſouth. At the north-weſt corner was a ſtrong gate, with Gothic pillars, arches, and towers, part of which was not long ago pulled down. Great part of the palace was burnt by Cromwell's ſoldiers; but it was repaired and altered into the preſent form after the Reſtoration. The fabric was planned by Sir William Bruce a celebrated architect, and executed by Robert Mylne maſon. The environs of the palace afford an aſylum for inſolvent debtors; and adjoining to it is an extenſive park, all of which is a ſanctuary.

The abbey church was formerly called the *monaſtery of Holyrood-houſe*, and built by king David I. in 1128. He gave it the name of *Holyrood-houſe*, in memory, as is ſaid, of his deliverance from an enraged hart, by the miraculous interpoſition of a croſs from heaven. This monaſtery he gave to the canons regular of St Auguſtine: on whom he alſo beſtowed the church of Edinburgh caſtle, with thoſe of St Cuthbert's, Corſtorphin, and Libberton, in the ſhire of Mid-Lothian, and of Airth in Stirlingſhire; the priories of St Mary's iſle in Galloway, of Blantyre in Clydeſdale, of Rowadill in Roſs, and three others in the Weſtern Iſles. To them he alſo granted the privilege of erecting a borough between the town of Edinburgh and the church of Holyrood-houſe. From theſe canons it had the name of the *Canongate*, which it ſtill retains. In this new borough they had a right to hold markets. They had alſo portions of land in different parts, with a moſt extenſive juriſdiction, and right of trial by duel, and fire and water ordeal. They had alſo certain revenues payable out of the exchequer and other funds, with fiſhings, and the privilege of erecting mills on the water of Leith, which ſtill retain the name of *Canon-mills*. Other grants and privileges were beſtowed by ſucceeding ſovereigns; ſo that it was deemed the richeſt religious foundation in Scotland. At the Reformation, its annual revenues were, 442 bolls of wheat, 640 bolls of bear, 560 bolls of oats, 500 capons, two dozen of hens, as many ſalmon, 12 loads of ſalt; beſides a great number of ſwine, and about 250 l. ſterling in money. At the Reformation, the ſuperiority of North Leith, part of the Pleaſance, the barony of Broughton, and the Canongate, was veſted in the earl of Roxburgh; and were purchaſed from him by the town-council of Edinburgh in 1636. In 1544, the church ſuffered conſiderably by the invaſion of the Engliſh; but was ſpeedily repaired. At the Reſtoration, king Charles II. ordered the church to be ſet apart as a chapel-royal, and prohibited its uſe as a common pariſh church for the future. It was then fitted up in a very elegant manner. A throne was erected for the ſovereign, and 12 ſtalls for the knights of the order of the thiſtle: but as maſs had been celebrated in it in the reign of James VII. and it had an organ, with a ſpire, and a fine chime of bells on the weſt ſide, the Preſbyterians at the revolution entirely deſtroyed its ornaments, and left nothing but the bare walls.—Through time, the roof of the church became ruinous; on which the duke of Hamilton repreſented its condition to the barons of exchequer, and craved that it might be repaired. This requeſt was complied with: but the architect and maſon who were employed, covered the roof with thick flag-ſtones, which ſoon impaired the fabric; and on the 2d of December 1768, the roof fell in. Since that time, no attempt has been made to repair it, and it is now entirely fallen to ruin.

The ruins of this church, however, are ſtill ſufficient to diſcover the excellency of the workmanſhip. Here ſome of the king's of Scotland are interred; and an odd kind of curioſity has been the occaſion of expoſing ſome bones ſaid to be thoſe of lord Darnley and a counteſs of Roxburgh who died ſeveral hundred years ago. Thoſe ſaid to belong to the former were very large, and the latter had ſome fleſh dried upon them. The chapel was fitted up in the elegant manner above mentioned by James VII. but ſuch was the enthuſiaſm of the mob, that they not only deſtroyed the ornaments, but tore up even the pavement, which was of marble.

To the eaſtward of the palace is the bowling-green, now entirely in diſorder; and behind it is a field called *St Ann's Yards*. Beyond this is a piece of ground called *the King's Park*; which undoubtedly was formerly overgrown with wood, though now there is not a ſingle tree in it. It is about three miles in circumference; and was firſt incloſed by James V. It contains the rocky hills of *ARTHUR's Seat* and Saliſbury Craigs, which laſt afford an inexhauſtible ſtone quarry; and upon the north ſide of the hill ſtands an old ruinous chapel, dedicated to St Anthony. The ſtones are uſed in building, as well as for paving the ſtreets and high-ways. The park was mortgaged to the family of Haddington for a debt due to them; and by the preſent earl has been divided into a number of incloſures by ſtone-dykes raiſed at a conſiderable expence. A good number of ſheep and ſome black cattle are fed upon it; and it is now rented at 1500 l. annually.

3. *St Giles's Church* is a beautiful Gothic building, meaſuring in length 206 feet. At the weſt end, its breadth is 110; in the middle, 129; and at the eaſt end, 76 feet. It has a very elevated ſituation, and is adorned with a lofty ſquare tower; from the ſides and corners of which riſe arches of figured ſtone-work: theſe meeting with each other in the middle, complete the figure of an imperial crown, the top of which terminates in a pointed ſpire. The whole height of this tower is 161 feet.

This is the moſt ancient church in Edinburgh. From a paſſage in an old author called *Simeon Dunelmenſis*, ſome conjecture it to have been built before the year 854; but we do not find expreſs mention made of it before 1359. The tutelar ſaint of this church, and of Edinburgh, was St Giles, a native of Greece. He lived in the ſixth century, and was deſcended of an illuſtrious family. On the death of his parents, he

Edinburgh.

gave all his eſtate to the poor; and travelled into France, where he retired into a wilderneſs near the conflux of the Rhone with the ſea, and continued there three years. Having obtained the reputation of extraordinary ſanctity, various miracles were attributed to him; and he founded a monaſtery in Languedoc, known long after by the name of *St Giles's.*—In the reign of James II. Mr Preſton of Gorton, a gentleman whoſe deſcendents ſtill poſſeſs an eſtate in the county of Edinburgh, got poſſeſſion of the arm of this ſaint; which relic he bequeathed to the church of Edinburgh. In gratitude for this donation, the magiſtrates granted a charter in favour of Mr Preſton's heirs, by which the neareſt heir of the name of Preſton was entitled to carry it in all proceſſions. At the ſame time, the magiſtrates obliged themſelves to found an altar in the church of St Giles's, and appoint a chaplain for celebrating an annual maſs for the ſoul of Mr Preſton; and likewiſe, that a tablet, containing his arms, and an account of his pious donation, ſhould be put up in the chapel.—St Giles's was firſt ſimply a pariſh-church, of which the biſhop of Lindisfarn or Holy Iſland, in the county of Northumberland, was patron. He was ſucceeded in the patronage by the abbot and canons of Dunfermline, and they by the magiſtrates of Edinburgh. In 1466, it was erected into a collegiate church by James III.—At the Reformation, the church was, for the greater convenience, divided into ſeveral parts. The four principal ones are appropriated to divine worſhip, the leſſer ones to other purpoſes. At the ſame time the religious utenſils belonging to this church were ſeized by the magiſtrates. They were,—St Giles's arm, enſhrined in ſilver, weighing five pounds three ounces and an half; a ſilver chalice, or communion-cup, weighing 23 ounces; the great *euchariſt* or communion-cup, with *golden weike and ſtanes;* two cruets of 25 ounces; a golden bell, with a heart, of four ounces and a half; a golden unicorn; a golden pix, to keep the hoſt; a ſmall golden heart, with two pearls; a diamond ring: a ſilver chalice, patine, and ſpoon, of 32 ounces and a half: a communion-table-cloth of gold brocade; *St Giles's coat*, with a little piece of red velvet which hung at his feet; a round ſilver *euchariſt:* two ſilver cenſers, of three pounds fifteen ounces; a ſilver ſhip for incenſe; a large ſilver croſs, with its baſe, weighing ſixteen pounds thirteen ounces and a half; a triangular ſilver lamp; two ſilver candleſticks, of ſeven pounds three ounces; other two, of eight pounds thirteen ounces; a ſilver chalice gilt, of 20½ ounces; a ſilver chalice and croſs, of 75 ounces; beſides the prieſts robes, and other veſtments, of gold brocade, crimſon velvet embroidered with gold, and green damaſk.—Theſe were all ſold, and part of the money applied to the repairs of the church; the reſt was added to the funds of the corporation.

In the ſteeple of St Giles's church are three large bells brought from Holland in 1621; the biggeſt weighing 2000 lb. the ſecond 700, and the third 500. There are alſo a ſet of muſic bells, which play every day between one and two o'clock, or at any time in the caſe of rejoicings. The principal diviſion is called the *High Church*, and has been lately repaired and new ſeated. There is a very elegant and finely ornamented ſeat for his majeſty, with a canopy ſupported by four Corinthian pillars decorated in high taſte. This ſeat is uſed by the king's commiſſioner during the time the General Aſſembly ſits. On the right hand is a ſeat for the lord high conſtable of Scotland, whoſe office it is to keep the peace within doors in his majeſty's preſence; it being the duty of the earl marſhal to do the ſame without. The ſeats belonging to the lords of council and ſeſſion are on the right of the lord high conſtable; and on the left of the throne was a ſeat for the lord high chancellor of Scotland; but that office being now aboliſhed, the ſeat is occupied by others. On the left of this ſit the barons of exchequer; and, to the left of them, the lord provoſt, magiſtrates, and town-council. The pulpit, king's ſeat, and galleries, are covered with crimſon velvet with gold and ſilk fringes.

Edinb

The aiſle of St Giles's church is fitted up with ſeats for the general aſſembly who meet here; and there is a throne for his majeſty's commiſſioner with a canopy of crimſon ſilk damaſk, having the king's arms embroidered with gold, preſented by the late lord Cathcart to his ſucceſſor in office. In this church is a monument dedicated to the memory of lord Napier, baron of Merchiſton, well known as the inventor of logarithms; a ſecond to the earl of Murray, regent of Scotland during the minority of James VI.; and a third to the great marquis of Montroſe.

4. *The Parliament Houſe*, in the great hall of which the Scottiſh parliament uſed to aſſemble, is a magnificent building. The hall is 123 feet long and 42 broad, with a fine arched roof of oak, painted and gilded. In this the lawyers and agents now attend the courts, and ſingle judges ſit to determine cauſes in the firſt inſtance, or to prepare them for the whole court, who ſit in an inner room formerly appropriated to the privy-council. In a nich of the wall is placed a fine marble ſtatue of preſident Forbes, erected at the expence of the faculty of advocates. There are alſo full length portraits of king William III. queen Mary his conſort, and queen Anne, all done by Sir Godfrey Kneller; alſo of George I. John duke of Argyle, and Archibald duke of Argyle, by Mr Aikman of Cairney.

Above ſtairs are the court of exchequer and treaſury chamber, with the different offices belonging to that department; and below is one of the moſt valuable libraries in Great Britain, belonging to the faculty of advocates. Beſides 30,000 printed volumes, there are many ſcarce and valuable manuſcripts, medals, and coins: here is alſo an entire mummy in its original cheſt, preſented to the faculty (at the expence of 300 l.) by the earl of Morton, late preſident of the royal ſociety. As theſe rooms are immediately below the hall where the parliament ſat, they are ſubject to a ſearch by the lord high conſtable of Scotland ever ſince the gun-powder plot: and this is ſpecified in the gift from the city to the faculty. This library was founded, in the year 1682, by Sir George Mackenzie lord advocate. Among other privileges, it is intitled to a copy of every book entered in ſtationer's hall. Before the great door is a noble equeſtrian ſtatue of Ch. II. the proportions of which are reckoned exceedingly juſt. Over the entrance are the arms of Scotland, with Mercy and Truth on each ſide for ſupporters.

The court of ſeſſion, the ſupreme tribunal in Scotland, conſiſts of 15 judges, who ſit on a circular bench, clothed in purple robes turned up with crimſon velvet. Six of theſe are lords of the juſticiary, and go the circuit

cuit twice a-year; but, in that capacity, they wear ſcarlet robes turned up with white ſattin.

5. *The Tolbooth* was erected in 1561, not for the purpoſes merely of a priſon, but likewiſe for the accommodation of the parliament and other courts; but it has ſince become ſo very unfit for any of theſe purpoſes, that it is now propoſed to pull it down and rebuild it in ſome other place, eſpecially as it is very inconvenient in its preſent ſituation on account of its incumbering the ſtreet. The provoſt is captain of the tolbooth, with a gaoler under him: and the latter has a monopoly of all the proviſions for the priſoners; a circumſtance which muſt certainly be conſidered as a grievous oppreſſion, thoſe who are leaſt able to purchaſe them being thus obliged to do ſo at the higheſt price. There is a chaplain who has a ſalary of 30l. a-year.

6. There is a Hall in the Writers Court belonging to the clerks to his majeſty's ſignet, where there is alſo an office for the buſineſs of the ſignet. The office of keeper of the ſignet is very lucrative, and he is allowed a depute and clerks under him. Before any one enters into this ſociety he muſt attend the college for two years, and ſerve five years as an apprentice to one of the ſociety. There is a good library belonging to this hall, which is rapidly increaſing, as every one who enters muſt pay 10 l. towards it. He pays alſo 100 l. of apprentice-fee, and 100l. when he enters.

7. *The Exchange* is a large and elegant building, with a court of about 90 feet ſquare in the middle. On the north ſide are piazzas where people can walk under cover, the other three ſides being laid out in ſhops; but the merchants have never made uſe of it to meet in, ſtill ſtanding in the ſtreet as formerly. The back part of the building is uſed for the general cuſtomhouſe of Scotland, where the commiſſioners meet to tranſact buſineſs. They have above 20 offices for the different departments, to which the acceſs is by a hanging ſtair 60 feet in height. In looking over the window before he aſcends this ſtair, a ſtranger is ſurpriſed to find himſelf already 40 feet from the ground, which is owing to the declivity on which the exchange is built. For the cuſtomhouſe rooms the city receives a rent of 1l. *per* day.

The Truſtees Office for the improvement of fiſheries and manufactures in Scotland is in the ſouth-weſt corner of the exchange; the fund under their management being part of the equivalent money given to Scotland at the Union. This is diſtributed in premiums amongſt thoſe who appear to have made any conſiderable improvement in the arts.

7. *The North Bridge*, which forms the main paſſage of communication betwixt the Old and New Towns, was founded, as has already been obſerved, in 1763 by Provoſt Drummond; but the contract for building it was not ſigned till Auguſt 21ſt 1765. The architect was Mr William Mylne, who agreed with the town-council of Edinburgh to finiſh the work for 10,140 l. and to uphold it for 10 years. It was alſo to be finiſhed before Martinmas 1769: but on the 3d of Auguſt that year, when the work was nearly completed, the vaults and ſide-walls on the ſouth fell down, and five people were buried in the ruins. This misfortune was occaſioned by the foundation having been laid, not upon the ſolid earth, but upon the rubbiſh of the houſes which had long before been built on the north ſide of the high-ſtreet, and which had been thrown out into the hollow to the northward. Of this rubbiſh there were no leſs than eight feet between the foundation of the bridge and the ſolid earth. Beſides this deficiency in the foundation, an immenſe load of earth which had been laid over the vaults and arches in order to raiſe the bridge to a proper level, had no doubt contributed to produce the cataſtrophe above mentioned.—The bridge was repaired, by pulling down ſome parts of the ſide-walls, and afterwards rebuilding them; ſtrengthening them in others with chain-bars; removing the quantity of earth laid upon the vaults, and ſupplying its place with hollow arches, &c. The whole was ſupported at the ſouth end by very ſtrong buttreſſes and counterforts on each ſide; but on the north it has only a ſingle ſupport.—The whole length of the bridge, from the High-ſtreet in the Old Town to Prince's-ſtreet in the New, is 1125 feet; the total length of the piers and arches is 310 feet. The width of the three great arches is 72 feet each; of the piers, 13½ feet; and of the ſmall arches, each 20 feet. The height of the great arches, from the top of the parapet to the baſe, is 68 feet; the breadth of the bridge within the wall over the arches is 40 feet, and the breadth at each end 50 feet.—On the ſouthern extremity of this bridge ſtands the General Poſt Office for Scotland; a neat plain building, with a proper number of apartments for the buſineſs, and a houſe for the ſecretary.

The communication betwixt the two towns by means of this bridge, though very complete and convenient for ſuch as lived in certain parts of either, was yet found inſufficient for thoſe who inhabited the weſtern diſtricts. Another bridge being therefore neceſſary, it was propoſed to fill up the valley occaſionally with the rubbiſh dug out in making the foundations of houſes in the New Town; and ſo great was the quantity, that this was accompliſhed ſo as to be fit for the paſſage of carriages in little more than four years and an half.

8. *The South Bridge* is directly oppoſite to the other, ſo as to make but one ſtreet, croſſing that called the *High-ſtreet* almoſt at right angles. It conſiſts of 19 arches of different ſizes: but only one of them is viſible, *viz.* the large one over the Cowgate; and even this is ſmall in compariſon with thoſe of the North Bridge, being no more than 30 feet wide and 31 feet high. On the ſouth it terminates at the Univerſity on one hand, and the Royal Infirmary on the other. The Tron Church, properly called *Chriſt Church*, ſtands at the northern extremity, facing the High-ſtreet, and in the middle of what is now called *Hunter's Square*, in memory of the late worthy chief magiſtrate who planned theſe improvements, but did not live to ſee them executed. On the weſt ſide of this ſquare the Merchant Company have built a very handſome hall for the occaſional meetings of their members. This bridge was erected with a deſign to give an eaſy acceſs to the great number of ſtreets and ſquares on the ſouth ſide, as well as to the country on that quarter from whence the city is ſupplied with coals. The ſtreet on the top is ſuppoſed to be as regular as any in Europe; every houſe being of the ſame dimenſions, excepting that between every two of the ordinary conſtruction there is one with a pediment on the top, in order to prevent

that faſtneſs of appearance which would otherwiſe take place. So great was the rage for purchaſing ground on each ſide of this bridge for building, that the areas ſold by public auction at 50l. *per* foot in front. By this the community will undoubtedly be conſiderable gainers; and the proprietors hope to indemnify themſelves for their extraordinary expence by the vaſt ſale of goods ſuppoſed to attend the ſhops in that part of the town; though this ſeems ſomewhat more dubious than the former.

9. *The Concert Hall*, called alſo *St Cecilia's Hall*, ſtands in Niddery's-ſtreet; and was built in 1762, after the model of the great opera-theatre in Parma. The plan was drawn by Sir Robert Mylne, architect of Blackfriars bridge. The muſical room is of an oval form, the ceiling being a concave elliptical dome, lighted from the top by a lanthorn. The ſeats are ranged in the form of an amphitheatre; and are capable of containing 500 perſons, beſides leaving a large area in the middle of the room. The orcheſtra is at the upper end, and is terminated by an elegant organ.

The muſical ſociety was firſt inſtituted in the year 1728. Before that time, ſeveral gentlemen had formed a weekly club at a tavern kept by one Steil, a great lover of muſic, and a good ſinger of Scots ſongs. Here the common enertainment conſiſted in playing on the harpſichord and violin the concertos and ſonatas of Handel, juſt then publiſhed. The meeting, however, ſoon becoming numerous, they inſtituted, in the year above mentioned, a ſociety of 70 members, for the purpoſe of holding a weekly concert. The affairs of the ſociety are regulated by a governor, deputy-governor, treaſurer, and five directors, who are annually choſen by the members. The meetings have been continued ever ſince that time on much the ſame footing as at firſt, and the number of members is now increaſed to 200. The weekly concerts are on Friday; the tickets being given gratis by the directors, and attention paid in the firſt place to ſtrangers. Oratorios are occaſionally performed throughout the year; and the principal performers have alſo benefit concerts. The band are excellent in their ſeveral departments; and ſeveral of the members are alſo good performers, and take their part in the orcheſtra. There are always many applications on the occaſion of a vacancy by the death of any of the members or otherwiſe; and ſuch is generally the number of candidates, that it is no eaſy matter to get in.

10. *The Univerſity*. In the year 1581, a grant was obtained from king James VI. for founding a college or univerſity within the city of Edinburgh; and the citizens, aided by various donations from well diſpoſed perſons, purchaſed a ſituation for the intended new college, conſiſting of part of the areas, chambers, and church of the collegiate provoſtry and prebends of the Kirk-a-field, otherwiſe called *Templum et Præfectura Sanctæ Mariæ in campis*, lying on the ſouth ſide of the city. Next year, a charter of confirmation and erection was obtained alſo from king James VI. from which the college to be built did afterwards derive all the privileges of an univerſity.

In 1583, the provoſt, magiſtrates, and council, the patrons of this new inſtitution, prepared the place in the beſt manner they could for the reception of teachers and ſtudents; and in the month of October the ſame year, Robert Rollock, whom they had invited from a profeſſorſhip in St Salvator's College in the univerſity of St Andrew's, began to teach in the new college of Edinburgh. Other profeſſors were ſoon after elected; and in the year 1586, Rollock was appointed principal of the college, and the following year alſo profeſſor of divinity, immediately after he had conferred the degree of M. A. on the ſtudents who had been under his tuition for four years. The offices of principal and profeſſor of divinity remained united till the year 1620.

In the 1617, king James VI. having viſited Scotland after his acceſſion to the crown of England, commanded the principal and regents of the college of Edinburgh to attend him in Stirling caſtle; and after they had there held a ſolemn philoſophical diſputation in the royal preſence, his majeſty was ſo much ſatisfied with their appearance, that he deſired their college for the future might be called *The College of King James*, which name it ſtill bears in all its diplomas or public deeds.

For ſeveral years the college conſiſted only of a principal, who was alſo profeſſor of divinity, with four regents or profeſſors of philoſophy. Each of theſe regents inſtructed one claſs of ſtudents for four years, in Latin, Greek, ſchool logic, mathematics, ethics, and phyſics, and graduated them at the concluſion of the fourth courſe. A profeſſor of humanity or Latin was afterwards appointed, who prepared the ſtudents for entering under the tuition of the regents; alſo a profeſſor of mathematics, and a profeſſor of Hebrew or Oriental languages. It was not till about the year 1710 that the four regents began to be confined each to a particular profeſſion; ſince which time they have been commonly ſtyled *Profeſſors of Greek, Logic, Moral, Philoſophy, and Natural Philoſophy*.—The firſt medical profeſſors inſtituted at Edinburgh, were Sir Robert Sibbald and Doctor Archibald Pitcairn, in the year 1685[*]. Theſe, however, were only titular profeſſors; and for 30 years afterwards, a ſummer-lecture on the officinal plants, and the diſſection of a human body once in two or three years, completed the whole courſe of medical education at Edinburgh.—In 1720, an attempt was made to teach the different branches of phyſic regularly; which ſucceeded ſo well, that, ever ſince, the reputation of the univerſity as a ſchool for medicine hath been conſtantly increaſing, both in the iſland of Britain, and even among diſtant nations.

The college is endowed with a very fine library, founded in 1580 by Mr Clement Little advocate, who bequeathed it to the town-council. They ordered a houſe to be built for it in the neighbourhood of St Giles's church, where it was for ſome time kept under the care of the eldeſt miniſter of Edinburgh, but was afterwards removed to the college. This collection is enriched, as well as others of a ſimilar kind, by receiving a copy of every book entered in Stationer's hall, according to the ſtatute for the encouragement of authors. Beſides this, the only fund it has is the money paid by all the ſtudents at the univerſity, except thoſe of divinity, upon their being matriculated; and a ſum of 5l. given by each profeſſor at his admiſſion. The amount of theſe ſums is uncertain, but has been eſtimated at about 150l. annually. The ſtudents of

---

[*] See LEGE *Phyſi*

of divinity, who pay nothing to this library, have one belonging to their own particular department.

Here are ſhown two ſkulls, one almoſt as thin as paper, pretended to be that of the celebrated George Buchanan, and, by way of contraſt, another ſaid to have been that of an idiot, and which is exceſſively thick. Here alſo are preſerved the original proteſt againſt the council of Conſtance for burning John Huſs and Jerom of Prague in 1417; the original contract of queen Mary with the dauphin of France, and ſome valuable coins and medals. There are alſo ſeveral portraits; particularly of Robert Pollock the firſt principal of the univerſity, king James VI. Lord Napier the inventor of logarithms, John Knox, principal Carſtairs, Mr Thomſon the author of the Seaſons, &c. The muſeum contains a good collection of natural curioſities, the number of which is daily increaſing. The anatomical preparations are worth notice, as are alſo thoſe belonging to the profeſſor of midwifery.

The celebrity of this college has been greatly owing to the uniform attention of the magiſtracy in filling up the vacant chairs with men of known abilities in their reſpective departments. Greatly to their honour, too, they have been no leſs attentive to the inſtituting of new profeſſorſhips from time to time as the public ſeemed to demand them. At preſent (anno 1790), the Senatus Academicus conſiſts of the following members, arranged according to the different faculties.

### *Faculty of* THEOLOGY.

William Robertſon, D. D. Principal of the College.
Andrew Hunter, D. D. Profeſſor of Divinity.
Thomas Hardy, D. D. Regius Profeſſor of Church-Hiſtory.
James Robertſon, D. D. Profeſſor of Oriental Languages, and Emeritus Secretary and Librarian.

### *Faculty of* LAW.

Robert Dick, Advocate, Profeſſor of Civil Law.
Allan Maconochie, Advocate, Profeſſor of Public Law.
Alexander Fraſer Tytler, Advocate, Profeſſor of Univerſal Civil Hiſtory, and of Greek and Roman Antiquities.
David Hume, Advocate, Profeſſor of Scots Law.

### *Faculty of* MEDICINE.

Alexander Monro, M. D. Profeſſor of Medicine, and of Anatomy and Surgery.
James Gregory, M. D. Profeſſor of the Practice of Phyſic.
Joſeph Black, M. D. Profeſſor of Medicine and Chemiſtry.
Francis Home, M. D. Profeſſor of Medicine and Materia Medica.
Andrew Duncan, M. D. Profeſſor of the Theory of Phyſic.
Daniel Rutherford, M. D. Profeſſor of Medicine and Botany.
Alexander Hamilton, M. D. Profeſſor of Midwifery.

### *Faculty of* ARTS.

George Stewart, LL. D. Emeritus Profeſſor of Humanity.
Adam Ferguſſon, LL. D. Emeritus Profeſſor of Moral Philoſophy, and joint Profeſſor of Mathematics.
Hugh Blair, D. D. Emeritus Profeſſor of Rhetoric and Belles Lettres.
Andrew Dalziel, A. M. Profeſſor of Greek, and Secretary and Librarian.
John Robiſon, A. M. Profeſſor of Natural Philoſophy.
Dugald Stewart, A. M. Profeſſor of Moral Philoſophy.
John Hill, LL. D. Profeſſor of Humanity.
John Bruce, A. M. Joint Profeſſor of Logic.
John Walker, D. D. Regius Profeſſor of Natural Hiſtory, and Keeper of the Muſeum.
William Greenfield, A. M. Profeſſor of Rhetoric and Belles Lettres.
John Playfair, A. M. Profeſſor of Mathematics.
Robert Blair, M. D. Regius Profeſſor of Practical Aſtronomy.
James Finlayſon, A. M. Joint Profeſſor of Logic.
Andrew Coventry, M. D. Profeſſor of Agriculture.
Andrew Fife, Principal Janitor and Macer.
William Stewart, under Janitor.

*N. B.* There are only about 50 burſers in this univerſity, and theſe do not exceed 12l. *per annum*.

The number of ſtudents during the laſt ſeſſion of the college, from October 10. 1789 to May 6. 1790, was nearly as follows:

| | |
|---|---|
| Students of Divinity | 130 |
| ———— Law | 100 |
| ———— Phyſic | 440 |
| General Claſſes | 420 |
| In all | 1090 |

The old buildings being very mean, and unfit for the reception of ſo many profeſſors and ſtudents, and quite unſuitable to the dignity of ſuch a flouriſhing univerſity, as well as inconſiſtent with the improved ſtate of the city, the Lord Provoſt, Magiſtrates, and Council, ſet on foot a ſubſcription for erecting a new ſtructure, according to a deſign of Robert Adam, Eſq; architect. Part of the old fabric has in conſequence been pulled down, and the new building is already in conſiderable forwardneſs. The foundation ſtone was laid on Monday the 16th of November, with great ſolemnity, by the Right Hon. Francis Lord Napier, grand maſter maſon of Scotland, in the preſence of the Right Hon. the Lord Provoſt, Magiſtrates, and Town-Council of the city of Edinburgh, with the Principal, Profeſſors, and Students of the univerſity of Edinburgh, a number of Nobility and Gentry, and the Maſters, Officers, and Brethren, of all the lodges of free maſons in the city and neighbourhood, who marched in proceſſion from the Parliament-Houſe down the High-Street. After the different maſonic ceremonials were performed, two cryſtal-bottles, caſt on purpoſe at the glaſs-houſe of Leith, were depoſited in the foundation-ſtone. In one of theſe were put different coins of the preſent reign, each of them being previouſly enveloped in cryſtal, in ſuch an ingenious manner, that the legend on the coins could be diſtinctly read without breaking the cryſtal. In the other bottle were depoſited ſeven rolls of vellum, containing a ſhort account of the original foundation and preſent ſtate of the univerſity, together with ſeveral other papers, in particular the different newſpapers, containing advertiſements relative to the college, &c. and a liſt of the names of the Principal and Profeſſors, alſo of the preſent Lord Provoſt and Magiſtrates, and Officers of the grand lodge of Scotland. The bottles being carefully ſealed up, were covered with a plate of copper wrapt in block tin; and upon the under ſide of the copper were engraved the arms of the city of Edinburgh and the univerſity; likewiſe the arms of the Right Hon. Lord Napier, grand maſter maſon of Scotland. Upon the upper ſide, a Latin inſcription, of which the following is a copy:

ANNUENTE DEO OPT. MAX.
REGNANTE GEORGIO III. PRINCIPE
MUNIFICENTISSIMO;
ACADEMIÆ EDINBURGENSIS
ÆDIBUS,
INITIO QUIDEM HUMILLIMIS,
ET JAM, POST DUO SECULA, PENE RUINOSIS;
NOVI HUJUS ÆDIFICII,
UBI COMMODITATI SIMUL ET ELEGANTIÆ,
TANTO DOCTRINARUM DOMICILIO
DIGNÆ,
CONSULERETUR,
PRIMUM LAPIDEM POSUIT,
PLAUDENTE INGENTI OMNIUM ORDINUM
FREQUENTIA,
VIR NOBILISSIMUS
FRANCISCUS DOMINUS NAPIER,
REIPUB. ARCHITECTONICÆ APUD SCOTOS
CURIO MAXIMUS:
XVI. KAL. DECEMB.
ANNO SALUTIS HUMANÆ MDCCLXXXIX.
ÆRÆ ARCHITECTONICÆ IↃↃIↃCCLXXXIX.
CONSULE THOMA ELDER,
ACADEMIÆ PRÆFECTO GULIELMO
ROBERTSON,
ARCHITECTO ROBERTO ADAM.
Q. F. F. Q. S.

The eaſt and weſt fronts of this pile are to extend 255 feet, and the ſouth and north 358. There are to be houſes for the principal and ſix or ſeven of the profeſſors. The library is to be a room of 160 feet in length; the muſeum for natural curioſities is to be of the ſame extent; and the dimenſions of the hall for degrees and public exerciſes are about 90 feet by 30. There are likewiſe to be an elegant and moſt convenient anatomical theatre; a chemical laboratory; and large rooms for inſtruments and experiments for the profeſſors of mathematics, natural philoſophy, and agriculture. The whole when finiſhed, if not the moſt ſplendid ſtructure of the ſort in Europe, will however be the completeſt and moſt commodious; and it will do the utmoſt honour to the genius of the architect and to the munificence of the public. About L. 16,000 is already ſubſcribed; and there is no doubt that the aid of parliament will be granted to complete the work.

The botanical garden belonging to the univerſity is ſituated at the diſtance of about a mile, on the road between Edinburgh and Leith. It conſiſts of about five acres of ground; and is furniſhed with a great variety of plants, many of them brought from the moſt diſtant quarters of the globe. The profeſſor is botaniſt to the king, and receives a ſalary of 120l. annually for the ſupport of the garden. A monument, to the memory of the celebrated botaniſt Linnæus, was erected here by the late Dr Hope, who firſt planned the garden, and brought it to perfection.

The univerſity of Edinburgh, like the others in this kingdom, ſends one member to the General Aſſembly of the church of Scotland; and the widows of the profeſſors have a right to the funds of thoſe of miniſters, the profeſſors being truſtees on that fund along with the preſbytery of Edinburgh.

11. *The Royal Infirmary* was firſt thought of by the college of phyſicians in 1725. A fiſhing company happening to be diſſolved at that time, the partners contributed ſome of their ſtock towards the eſtabliſhment of the infirmary. A ſubſcription was alſo ſet on foot, and application made to the General Aſſembly to recommend the ſame throughout their juriſdiction. This was readily complied with, and the aſſembly paſſed an act for that purpoſe; but very little regard was paid to it by the clergy. Notwithſtanding this, however, 2000l. being procured, a ſmall houſe was opened for the reception of the ſick poor in Auguſt 1729. In 1736, the contributors towards the infirmary were erected into a body corporate by royal ſtatute; and after this the contributions increaſed very conſiderably: by which means the managers were enabled to enlarge their ſcheme from time to time; and at laſt to undertake the preſent magnificent ſtructure, the foundation of which was laid in 1738. During 25 years, when this inſtitution was in its infancy, Lord Hopetoun beſtowed upon it an annuity of 400l. In 1750, Doctor Archibald Ker bequeathed to this incorporation 200l. a-year in the iſland of Jamaica. In 1755, the lords of the treaſury made a donation to it of 8000l. which had been appointed for the ſupport of invalids. In return for this, the managers of the infirmary conſtantly keep 60 beds in readineſs for the reception of ſick ſoldiers. This year alſo ſick ſervants began to be admitted into the infirmary, and a ward was fitted up for their reception.

This inſtitution, however, was more indebted to George Drummond, Eſq; than to any other perſon. He was ſeven times choſen lord provoſt of Edinburgh; and always directed his attention to the improvement of the city, particularly to that of the royal infirmary. So ſenſible were the managers of their obligations to him, that, in their hall, they erected a buſt of him with this inſcription, "George Drummond, to whom this country is indebted for all the benefit which it derives from the Royal Infirmary."—In 1748, the ſtock of the infirmary amounted to 5000l; in 1755, to 7076l. beſides the eſtate left by Doctor Ker; in 1764, to 23,426l.; and in 1778, to 27,074l.

The royal infirmary is attended by two phyſicians choſen by the managers, who viſit their patients daily in preſence of the ſtudents. All the members of the college of ſurgeons are alſo obliged to attend in rotation, according to ſeniority. If any ſurgeon declines attendance, he is not allowed to appoint a depute; but the patients are committed to the care of one of four aſſiſtant ſurgeons, choſen annually by the managers.—From the year 1762 to 1769, there were admitted 6261 patients; which number added to 109 who were in the hoſpital at the commencement of the year 1762, made, in all, 6370. Of theſe, 4395 were cured; 358 died; the reſt were either relieved, diſmiſſed incurable, for irregularities, or by their own deſire, or remained in the hoſpital. - From 1770 to 1775, the patients annually admitted into the infirmary were, at an average, 1567; of whom 63 died. In 1776, there were admitted 1668, of whom 57 died; and in 1777, the number admitted was 1593, and of deaths 52. In the year 1786, there were admitted 1822 patients: Of theſe 1354 were cured; 166 relieved; 84 died; the reſt were either relieved, diſmiſſed incurable, for irregularities, or by their own deſire.

The building conſiſts of a body and two wings, each of them three ſtories high, with an attic ſtory and garrets, and a very elegant front. The body is 210 feet long, and 36 broad in the middle, but at the ends only 24 feet broad. There is a buſt of king George II. in a Roman dreſs, above the great door. The wings are 70 feet long, and 24 broad. In the centre is a large ſtair-caſe, ſo wide that ſedan chairs may be carried up. In the different wards, 228 patients may be accommodated, each in a different bed. There are cold and hot baths for the patients, and alſo for the citizens; and to theſe laſt the patients are never admitted.

Beſides the apartments neceſſary for the ſick, there are others for the officers and ſervants belonging to the houſe. There are likewiſe rooms for the managers, a conſulting room for the phyſicians and ſurgeons, a waiting-room for the ſtudents, and a theatre that will hold upwards of 200 people for performing chirurgical operations. There is a military ward, ſupported by the intereſt of the 8000l. already mentioned; and in conſequence of which a ſmall guard is always kept at the infirmary. The wards for ſick ſervants are ſupported by collections at the church doors. Beſides the attendance of the royal college of ſurgeons by rotation, as has already been mentioned, there are two phyſicians belonging to the houſe, who are elected by the managers, and have a ſmall ſalary; there is likewiſe a houſe-ſurgeon and apothecary. Students who attend the infirmary pay 3l. 3s. annually, which brings in a revenue of about 500l. towards defraying the expence of the houſe. Two wards are ſet apart for the patients whoſe caſes are ſuppoſed to be moſt intereſting; and the phyſicians give lectures upon them.

12. *The Public Diſpenſary* was founded by Dr Duncan in 1776, for the poor whoſe diſeaſes are of ſuch a nature as to render their admiſſion into the infirmary either unneceſſary or improper. Here the patients receive advice gratis four days in the week; a regiſter is kept of the diſeaſes of each, and of the effects produced by the medicines employed. All patients not improper for diſpenſary treatment are admitted on the recommendation of the elder or church-warden of the pariſh where they reſide. The phyſicians officiate and give lectures gratis; ſo that the apothecary who lodges in the houſe, and the medicines, are the only expences attending this uſeful inſtitution. The expence of the whole is defrayed by public contributions, and from a ſmall annual fee paid by the ſtudents who attend the lectures. It is under the direction of a preſident, two vice-preſidents, and 20 directors, elected annually from among the contributors. One guinea intitles a contributor to recommend patients and be a governor for two years, and five guineas gives the ſame privilege for life.

13. *The High School.* The earlieſt inſtitution of a grammar-ſchool in Edinburgh ſeems to have been about the year 1519. The whole expence beſtowed upon the firſt building of this kind amounted only to about 40l. Sterling. Another building, which had been erected for the accommodation of the ſcholars in 1578, continued, notwithſtanding the great increaſe of their number, to be uſed for that purpoſe till 1777. The foundation of the preſent new building was laid on the 24th of June that year by Sir William Forbes, Grand Maſter of the Free Maſons. The total length of this building is 120 feet from ſouth to north; the breadth in the middle 36, at each end 38 feet. The great hall where the boys meet for prayers, is 68 feet by 30. At each end of the hall is a room of 32 feet by 20, intended for libraries. The building is two ſtories high, the one 18, the other 17, feet in height. The expence of the whole when finiſhed is reckoned at 4000l.

There is a rector and four maſters, who teach from 4 to 500 ſcholars annually. The ſalaries are trifling, and the fees depend upon the reputation they have obtained for teaching; and as this has been for ſome years very conſiderable, the rector's place is ſuppoſed to be worth not leſs than 400l. *per annum*, a maſter's about half that ſum. There is a janitor, whoſe place is ſuppoſed to be worth about 70l. a-year. His buſineſs is to take care of the boys on the play-ground; and there is a woman who lives on the ſpot as under janitor, whoſe place may be worth about 25 l. annually. There is a library, but not large, as each of the boys pays only one ſhilling annually to its ſupport.

There are four eſtabliſhed Engliſh ſchools in Edinburgh; the maſters of which receive a ſmall ſalary, upon expreſs condition that they ſhall not take above five ſhillings per quarter from any of their ſcholars. There are likewiſe many other private ſchools in Edinburgh for all languages; and, in general, every kind of education is to be had here in great perfection and at a very cheap rate.

14. *The Mint* is kept up by the articles of union, with all the offices belonging to it, though no money is ever ſtruck here. It ſtands in the Cowgate, a little to the weſt of the Engliſh church; but is in a ruinous ſtate, though ſtill inhabited by the different officers, who have free houſes; and the bell-man enjoys his ſalary by regularly ringing the bell. This place, as well as the abbey of Holyrood-houſe, is an aſylum for debtors.

15. *The Engliſh Chapel* ſtands near the Cowgate port, and was founded on the 3d of April 1771. The foundation-ſtone was laid by general Oughton, with the following inſcription: *Edifici ſacr. Eccleſiæ epiſc. Angliæ, primum poſuit lapidem J. Adolphus Oughton, in architectonicæ Scotiæ repub. curio maximus, militum præfectus, regnante Georgio III. tertio Apr. die, A. D.* MDCCLXXI. It is a plain handſome building, neatly fitted up in the inſide, and ſomewhat reſembling the church of St Martin's in the Fields, London. It is 90 feet long, 75 broad, and ornamented with an elegant ſpire of conſiderable height. It is alſo furniſhed with an excellent bell, formerly belonging to the chapel royal at Holyrood-houſe, which is permitted to be rung for aſſembling the congregation; an indulgence not granted to the Preſbyterians in England. The expence of the building was defrayed by voluntary ſubſcription;

and, to the honour of the country, people of all perſuaſions contributed to this pious work. It has already coſt 7000l. and will require 1000l. more to finiſh the portico. This church is built in a ſingular manner, viz. from ſouth to north, and the altar-piece ſtands on the eaſt ſide. Three clergymen officiate here, of whom the firſt has 150l. the other two 100l. each. The altar-piece is finely decorated, and there is a good organ.

There is another Epiſcopal chapel, but ſmall, in Black-fryars wynd, which was founded by Baron Smith in the year 1722. There are alſo ſome meetings of the Epiſcopal church of Scotland, who adhere to their old forms, having ſtill their biſhops and inferior clergy. For ſome time theſe were ſubjected to penal laws, as they refuſed to take the oath to government, or mention the preſent royal family in their public prayers: but of late they have conformed, and had their conduct approved of by his Majeſty; ſo that now every denomination of Chriſtians in Britain pray for the royal family on the throne.

16. *Heriot's Hoſpital* owes its foundation to George Heriot, goldſmith to James VI. who acquired by his buſineſs a large fortune. At his death, he left the magiſtrates of Edinburgh 23,625l. 10s. "for the maintenance, relief, and bringing up of ſo many poor and fatherleſs boys, freemens ſons of the town of Edinburgh," as the above ſum ſhould be ſufficient for. This hoſpital is finely ſituated on the weſt end of the ſouth ridge, almoſt oppoſite to the caſtle, and is the moſt magnificent building of the kind in Edinburgh. It was founded in July 1628, according to a plan (as is reported) of Inigo Jones; but the work being interrupted by the civil wars, it was not finiſhed till the year 1650. The expence of the building is ſaid to have been upwards of 30,000l (A): and the hoſpital is now poſſeſſed of an income of about 3000l. a-year; though this cannot be abſolutely aſcertained, as the rents are paid in grain, and of courſe muſt be fluctuating.

It ſtands on a riſing ground to the ſouth-weſt of the city, and is a ſquare of 162 feet without, having a court 94 feet ſquare in the inſide, with piazzas on three of the ſides. There is a ſpire with a clock over the gateway, and each corner of the building is ornamented with turrets; but notwithſtanding the magnificent appearance of the outſide, the inner part is far from being convenient. There is a ſtatue of the founder over the gateway, in the dreſs of the times, and a very good painting of him in the governor's room, with a picture of the late treaſurer Mr Carmichael. There is a chapel 61 feet long and 22 broad, which is now repairing in ſuch a manner as will make it worthy of notice. When Cromwell took poſſeſſion of Edinburgh after the battle of Dunbar, he quartered his ſick and wounded ſoldiers in this hoſpital. It was applied to the ſame purpoſe till the year 1658, when general Monk, at the requeſt of the governors, removed the ſoldiers; and on the 11th of April 1659, it was opened for the reception of boys, 30 of whom were admitted into it. The Auguſt after, they were increaſed to 40; and in 1661, to 52. In 1753 the number was raiſed to 130, and in 1763 to 140; but ſince that time it has decreaſed.—In this hoſpital the boys are inſtructed in reading, writing, arithmetic, and a knowledge of the Latin tongue. With ſuch as chooſe to follow any kind of trade, an apprentice-fee of 30l. is given when they leave the hoſpital; and thoſe who chooſe an academical education, have an annuity of 10l. a-year beſtowed on them for four years. The whole is under the overſight of the treaſurer, who has under him a houſe-governor, houſe-keeper, and ſchool-maſters.

17. *Watſon's Hoſpital* has its name from the founder George Watſon, who was at firſt clerk to Sir William Dick provoſt of Edinburgh in 1676, then accountant of the bank of Scotland; after that he became receiver of the city's impoſt on ale, treaſurer to the Merchant's Maiden Hoſpital, and to the ſociety for propagating Chriſtian knowledge. Dying a bachelor in 1723, he left 12,000l. for the maintenance and education of the children and grand-children of decayed members of the merchant company of Edinburgh. The ſcheme, however, was not put in execution till the year 1738, when the ſum originally left had accumulated to 20,000l. The preſent building was then erected, in which about 60 boys are maintained and educated. It is much leſs magnificent than Heriot's hoſpital, but the building is far from being deſpicable. It ſtands to the ſouthward of the city at a ſmall diſtance from Heriot's hoſpital, and was erected at the expence of 5000l.: its preſent revenue is about 1700l. It is under the management of the maſter, aſſiſtants, and treaſurer of the Merchant Company, four old bailies, the old dean of guild, and the two miniſters of the old church. The boys are genteelly clothed and liberally educated. Such as chooſe an univerſity education are allowed 10l. *per annum* for five years: thoſe who go to trades have 20l. allowed them for their apprentice fee; and at the age of 25 years, if they have behaved properly, and not contracted marriage without conſent of the governors, they receive a bounty of 50l. The boys are under the immediate inſpection of the treaſurer, ſchool-maſter, and houſe-keeper.

18. *The Merchants Maiden Hoſpital* was eſtabliſhed by voluntary contribution about the end of the laſt century, for the maintenance of young girls, daughters of the merchants burgeſſes of Edinburgh. The governors were erected into a body corporate, by act of parliament, in 1707. The annual revenue amounts to 1350l. Seventy girls are maintained in it; who, upon leaving the houſe, receive 3l. 6s. 8d. excepting

---

(A) It is to be obſerved, that money then bore 10l. *per cent.* intereſt.—The above ſums are taken from Mr Arnot's Hiſtory of Edinburgh, who ſubjoins the following note. "Where Maitland had collected his moſt erroneous account of George Heriot's effects, we do not know. He makes the ſum received, out of Heriot's effects, by the governors of the hoſpital, to be 43,608l. 11s. 3d. being almoſt the double of what they really got. This blunder has been the cauſe of many unjuſt murmurings againſt the magiſtrates of Edinburgh, and even the means of ſpiriting up law-ſuits againſt them."

a few who are allowed 8l. 6s. 8d. out of the funds of the hoſpital. The profits ariſing from work done in the houſe are alſo divided among the girls, according to their induſtry.

19. *The Trades Maiden Hoſpital* was founded in the year 1704 by the incorporations of Edinburgh, for the maintenance of the daughters of decayed members, on a plan ſimilar to that of the merchants hoſpital. To this, as well as to the former, one Mrs Mary Erſkine, a widow gentlewoman, contributed ſo liberally, that ſhe was by the governors ſtyled *joint foundreſs* of the hoſpital. Fifty girls are maintained in the houſe, who pay of entry-money 1l. 13s. 4d.; and, when they leave it, receive a bounty of 5l. 11s. 1½d. The revenues are eſtimated at 600l. a-year.

20. *The Orphan Hoſpital* was planned in 1732 by Andrew Gairdner merchant, and other inhabitants. It was promoted by the ſociety for propagating Chriſtian knowledge, by other ſocieties, by voluntary ſubſcriptions, and a collection at the church-doors.—In 1733, the managers hired a houſe, took in 30 orphans, maintained them, gave them inſtructions in reading and writing, and taught them the weaving buſineſs. In 1735, they were erected into a body corporate by the town of Edinburgh: and, in 1742, they obtained a charter of erection from his late majeſty, appointing moſt of the great officers of ſtate in Scotland, and the heads of the different ſocieties in Edinburgh, members of this corporation; with powers to them to hold real property to the amount of 1000l. a-year. The revenue is inconſiderable; but the inſtitution is ſupported by the contributions of charitable perſons. Into this hoſpital orphans are received from any part of the kingdom. None are admitted under ſeven, nor continued in it after 14, years of age. At preſent (1790) about 140 orphans are maintained in it.

The orphan hoſpital is ſituated to the eaſt of the north bridge; and is a handſome building, conſiſting of a body and two wings, with a neat ſpire, furniſhed with a clock and two bells. The late worthy Mr Howard admits, that this inſtitution is one of the moſt ueſeful charities in Europe, and is a pattern for all inſtitutions of the kind. The funds have been conſiderably increaſed, and the building greatly improved, through the attention and exertions of Mr Thomas Tod the preſent treaſurer.

21. *The Trinity Hoſpital.* This was originally founded and amply endowed by king James II.'s queen. At the Reformation, it was ſtripped of its revenues; but the regent afterwards beſtowed them on the provoſt of Edinburgh, who gave them to the citizens for the uſe of the poor. In 1585, the town-council purchaſed from Robert Pont, at that time provoſt of Trinity college, his intereſt in theſe ſubjects; and the tranſaction was afterwards ratified by James VI. The hoſpital was then repaired, and appointed for the reception of poor old burgeſſes, their wives, and unmarried children, not under 50 years of age. In the year 1700, this hoſpital maintained 54 perſons; but, ſince that time, the number has decreaſed.—The revenue conſiſts in a real eſtate of lands and houſes, the groſs rent of which are 762l. a-year; and 5500l. lent out in bonds at 4 per cent.

This hoſpital is ſituated at the foot of Leith-wynd, and maintains about 50 of both ſexes, who are comfortably lodged, each having a room for themſelves. They are ſupplied with roaſt or boiled meat every day for dinner, have money allowed them for clothes, and likewiſe a ſmall ſum for pocket-money. There is a ſmall library for their amuſement, and they have a chaplain to ſay prayers. There are ſome out-penſioners who have 6l. a-year, but theſe are diſcouraged by the governors. The funds are under the management of the town-council.

22. *The Charity Workhouſe* was erected in 1743 by voluntary contribution. It is a large plain building, on the ſouth ſide of the city. Here the poor are employed, and are allowed twopence out of every ſhilling they earn. The expence of this inſtitution is ſuppoſed not to be leſs than 4000l. annually; as about 700 perſons of both ſexes, including children, are maintained here, each of whom cannot be reckoned to coſt leſs than 4l. 10s. *per annum;* and there are beſides 300 out-penſioners. The only permanent fund for defraying this expence is a tax of two *per cent.* on the valued rents of the city, which may bring in about 600l. annually; and there are other funds which yield about 400l. The reſt is derived from collections at the church doors and voluntary contributions; but as theſe always fall ſhort of what is requiſite, recourſe muſt frequently be had to extraordinary collections. The ſum ariſing from the rents of the city, however, is conſtantly increaſing; but the members of the College of Juſtice are exempted from the tax.

There are two other charity workhouſes in the ſuburbs, much on the ſame plan with that now deſcribed; one in the Canongate, and the other in St Cuthbert's or Weſt Kirk pariſh.

To this account of the charitable eſtabliſhments in Edinburgh, we ſhall add that of ſome others; which, though not calculated to decorate the city by any public building, are perhaps no leſs deſerving of praiſe than any we have mentioned. The firſt is that of Captain William Horn; who left 3500l. in truſt to the magiſtrates, the annual profits to be divided on Chriſtmas day to poor out-day labourers, who muſt at that ſeaſon of the year be deſtitute of employment; five pounds to be given to thoſe who have large families, and one half to thoſe who have ſmaller.

Another charity is that of Robert Johnſton, L.L.D. of London, who in 1640 left 3000l. to the poor of this city; 1000l. to be employed in ſetting them to work, another 1000l. to clothe the boys in Heriot's Hoſpital, and the third 1000l. to burſers at the univerſity.

About the beginning of this century John Strachen left his eſtate of Craigcrook, now upwards of 300l. a-year, in truſt to the preſbytery of Edinburgh, to be by them diſpoſed of in ſmall annual ſums to poor old people not under 65 years of age, and to orphans not above 12.

There is beſides a ſociety for the ſupport of the induſtrious poor, another for the indigent ſick, and there are alſo many charity-ſchools.

Having thus given an account of the moſt remarkable edifices belonging to Old Edinburgh, we ſhall now proceed to thoſe of the New Town. This is terminated on the eaſt ſide by the Calton-hill, round which there is a pleaſant walk, and which affords one of the fineſt proſpects that can be imagined, varying remarkably almoſt at every ſtep. On this hill is a burying-ground, which contains a fine monument to the memory of David Hume the hiſtorian.—On the top is an Obſervatory, the ſcheme for building which was firſt adopted in the year 1736; but the diſturbance occaſioned by the Porteous mob prevented any thing from being done towards the execution of it at that time. The Earl of Morton afterwards gave 100 l. for the purpoſe of building an obſervatory, and appointed Mr M'Laurin profeſſor of mathematics, together with the principal and ſome profeſſors of the univerſity, truſtees for managing the ſum. Mr M'Laurin added to the money above mentioned the profits ariſing from a courſe of lectures which he read on experimental philoſophy; which, with ſome other ſmall ſums, amounted in all to 300 l.: but Mr M'Laurin dying, the deſign was dropped.—Afterwards the money was put into the hands of two perſons who became bankrupt; but a conſiderable dividend being obtained out of their effects, the principal and intereſt, about the year 1776, amounted to 400 l. A plan of the building was made out by Mr Craig architect; and the foundation-ſtone was laid by Mr Stodart, lord provoſt of Edinburgh, on the 25th of Auguſt 1776. About this time, however, Mr Adam architect happening to come to Edinburgh, conceived the idea of giving the whole the appearance of a fortification, for which its ſituation on the top of the Calton-hill was very much adapted. Accordingly a line was marked out for incloſing the limits of the obſervatory with a wall conſtructed with buttreſſes and embraſures, and having Gothic towers at the angles. Thus the money deſigned for the work was totally exhauſted, and the obſervatory ſtill remains unfiniſhed; nor is there any appearance of its being ſoon completed either by voluntary ſubſcription or any other way.

23 Proceeding to the weſtward, the firſt remarkable building is the *Theatre*, which ſtands oppoſite to the Regiſter Office, in the middle of Shakeſpeare Square. The building is plain on the outſide, but elegantly fitted up within, and is generally open three days in the week, and when full will draw about 150 l. a-night; ſo that the manager generally finds himſelf well rewarded when he can procure good actors.

Entertainments of the dramatic kind came very early into faſhion in this country. They were at firſt only repreſentations of religious ſubjects, and peculiarly deſigned to advance the intereſts of religion; the clergy being the compoſers, and Sunday the principal time of exhibition. In the 16th century, the number of playhouſes was ſo great, that it was complained of as a nuiſance, not only in Edinburgh, but throughout the kingdom. They ſoon degenerated from their original inſtitution; and the plays, inſtead of being calculated to inſpire devotion, became filled with all manner of buffoonery and indecency.—After the Reformation, the Preſbyterian clergy complained of theſe indecencies; and being actuated by a ſpirit of violent zeal, anathematiſed every kind of theatrical repreſentation whatever. King James VI. compelled them to paſs from their cenſures againſt the ſtage; but in the time of Charles I. when fanaticiſm was carried to the utmoſt length at which perhaps it was poſſible for it to arrive, it cannot be ſuppoſed that ſtage plays would be tolerated.—It ſeems, however, that amuſements of this kind were again introduced at Edinburgh about the year 1684, when the Duke of York kept his court there. His reſidence at Edinburgh drew off one half of the London company, and plays were acted in Edinburgh for ſome little time. The misfortunes attending the Duke of York, however, and the eſtabliſhment of the Preſbyterian religion (the genius of which is unfavourable to amuſements of this kind), ſoon put a ſtop to the progreſs of the ſtage, and no theatrical exhibition was heard of in Edinburgh till after the year 1715. The firſt adventurer was Signora Violante, an Italian, remarkable for feats of ſtrength, tumbling, &c. In this way ſhe firſt exhibited in a houſe at the foot of Carrubber's Cloſe, which has ſince been employed by different ſectaries for religious purpoſes. Meeting with good ſucceſs, ſhe ſoon invited a company of comedians from London; and theſe being alſo well received, Edinburgh continued for ſome years to be entertained with the performances of a ſtrolling company, who viſited it annually. Becoming at laſt, however, obnoxious to the clergy, they were in 1727 prohibited by the magiſtrates from acting within their juriſdiction. But this interdict was ſuſpended by the Court of Seſſion, and the players continued to perform as uſual.

Still, however, theatrical entertainments were but rare. The town was viſited by itinerant companies only once in two or three years. They performed in the Taylor's Hall in the Cowgate; which, when the houſe was full, would have drawn (at the rate of 2 s. 6d. for pit and boxes, and 1 s. 6d. for the gallery) 40l. or 45 l. a-night. About this time an act of parliament was paſſed, prohibiting the exhibition of plays, except in a houſe licenſed by the king. Of this the preſbytery of Edinburgh immediately laid hold; and at their own expence brought an action on the ſtatute againſt the players. The cauſe was by the Court of Seſſion decided againſt the players; who thereupon applied to parliament for a bill to enable his majeſty to licenſe a theatre in Edinburgh. Againſt this bill petitions were preſented in 1739 to the houſe of commons by the magiſtrates and town-council, the principal and profeſſors of the univerſity, and the dean of guild and his council; in conſequence of which, the affair was dropped. All this oppoſition, however, contributed in reality to the ſucceſs of the players; for the ſpirit of party being excited, a way of evading the act was eaſily found out, and the houſe was frequented more than uſual, inſomuch that Taylor's Hall was found inſufficient to contain the number of ſpectators.

The comedians now fell out among themſelves, and a new playhouſe was erected in the Canongate in the year 1746. The conſequence of this was, that the old one in Taylor's Hall became entirely deſerted, and through bad conduct the managers of the new theatre ſoon found themſelves greatly involved. At laſt, a riot enſuing through diſſenſions among the performers, the playhouſe was totally demoliſhed.—When the extenſion of the royalty over the ſpot where the New Town is built was obtained, a clauſe was likewiſe added to the bill, enabling his majeſty to licenſe a theatre in Edinburgh. This was obtained, and thus the oppoſition of the clergy for ever ſilenced. But notwithſtanding

this,

this, the high price paid by the managers to the patentee, being no leſs than 500 guineas annually, prevented them effectually from decorating the houſe as they would otherwiſe have done, or even from always retaining good actors in their ſervice; by which means the ſucceſs of the Edinburgh theatre has not been ſo great as might have been expected.

Not far from this building, an amphitheatre was opened in 1790, on the road to Leith, for equeſtrian exhibitions, pantomime entertainments, dancing, and tumbling. The circus is 60 feet diameter; and in the forenoon ladies and gentlemen are taught to ride. The houſe will hold about 1500 people.

24. *The Regiſter Office.* This work was firſt ſuggeſted by the late Earl of Morton, lord-regiſter of Scotland, with a view to prevent the danger which attended the uſual method of keeping the public records. In former times, indeed, theſe ſuffered from a variety of accidents. Edward I. carried off or deſtroyed moſt of them, in order to prevent any marks of the former independency of the nation from remaining to poſterity. Afterwards Cromwell ſpoiled this nation of its records, moſt of which were ſent to the tower of London At the time of the Reſtoration, many of them were ſent down again by ſea; but one of the veſſels was ſhipwrecked, and the records brought by the other have ever ſince been left in the greateſt confuſion.—The Earl of Morton taking this into conſideration, obtained from his majeſty a grant of 12,000l. out of the forfeited eſtates, for the purpoſe of building a regiſter-office, or houſe for keeping the records, and diſpoſing them in proper order. The foundation was laid on the 27th of June 1774, by Lord Frederic Campbell lord-regiſter, Mr Montgomery of Stanhope lord advocate, and Mr Miller of Barſkimming lord juſtice-clerk; three of the truſtees appointed by his majeſty for executing the work. The ceremony was performed under a diſcharge of artillery, in preſence of the judges of the courts of ſeſſion and exchequer, and in the ſight of a multitude of ſpectators. A braſs plate was put into the foundation-ſtone with the following inſcription: CONSERVANDIS TABULIS PUBLICIS POSITUM EST, ANNO M.DCC LXXIV, MUNIFICENTIA OPTIMI ET PIETISSIMI PRINCIPIS GEORGII TERTII. In a glaſs vaſe hermetically ſealed, which is alſo placed in the foundation-ſtone, are depoſited ſpecimens of the different coins of his preſent majeſty.

The front of the building directly faces the bridge, extends from eaſt to weſt 200 feet, and is 40 feet back from the line of Prince's-ſtreet. In the middle of the front is a ſmall projection of three windows in breadth. Here is a pediment, having in its centre the arms of Great Britain, and the whole is ſupported by four Corinthian pilaſtres. At each end is a tower projecting beyond the reſt of the building, having a Venetian window in front, and a cupola on the top. The front is ornamented from end to end with a beautiful Corinthian entablature. In the centre of the building is a dome of wooden work covered with lead. The inſide forms a ſaloon 50 feet diameter and 80 high, lighted at top by a copper window 15 feet in diameter. Round the whole is a hanging gallery of ſtone, with an iron baluſtrade, which affords conveniency for preſſes in the walls for keeping the records. The whole number of apartments is 97; all of which are vaulted beneath, and warmed with fire-places. This building, which is the moſt beautiful of Mr Adams's deſigns, has been executed in a ſubſtantial manner, in about 16 years, at the expence of near 40,000l. and is one of the principal ornaments of the city. A ſerjeant's guard is placed here from the caſtle, for the further protection of the records. It is intended to place a ſtatue of his preſent Majeſty in the front of the building, with the lion and unicorn above the centinels boxes. The lord-regiſter has the direction of the whole, and the principal clerks of Seſſion are his deputes. Theſe have a great number of clerks under them for carrying on the buſineſs of the Court of Seſſion. The lord-regiſter is a miniſter of ſtate in this country. He formerly collected the votes of the parliament of Scotland, and ſtill collects thoſe of the peers at the election of 16 to repreſent them in parliament.

25. On the eaſt ſide of St Andrew's Square ſtands the *General Exciſe Office*, built by the late Sir Laurence Dundas for his own reſidence, but ſold by his ſon for the above purpoſe. It is a very handſome building, with a pediment in front ornamented with the king's arms, and ſupported by four Corinthian pilaſtres; and, in conjunction with the two corner houſes, has a fine effect.

26. *St Andrew's Church* ſtands on the north ſide of George's Street. It is of an oval form; and has a very neat ſpire of 186 feet in height, with a chime of eight bells, the firſt and only one of the kind in Scotland. It has alſo a handſome portico in front.

27. Oppoſite to St Andrew's church is the *Phyſicians Hall*, deſigned for the meetings of the faculty, and which has a portico reſembling that of the church.

28. Farther to the weſtward, on the ſouth ſide, ſtand the *Aſſembly-rooms*, which though a heavy looking building on the outſide, are nevertheleſs extremely elegant and commodious within. The largeſt is 100 feet long and 40 broad, being exceeded in its dimenſions by none in the iſland, the large one at Bath excepted. Weekly aſſemblies are held here for dancing and card-playing, under the direction of a maſter of ceremonies; admiſſion-tickets five ſhillings each.

29 Religious eſtabliſhments.

It now remains only to ſpeak ſomething of the religious and civil eſtabliſhments of this metropolis. The higheſt of the former is the General Aſſembly of the Church of Scotland, who meet here annually in the month of May, in an aiſle of the church of St Giles fitted up on purpoſe for them. The throne is filled by a commiſſioner from his majeſty, but he neither debates nor votes. He calls them together, and diſſolves them at the appointed time in the name of the king; but they call and diſſolve themſelves in the name of the Lord Jeſus Chriſt. This aſſembly conſiſts of 350 members choſen out of the various preſbyteries throughout the kingdom; and the debates are often very intereſting and eloquent. This is the ſupreme eccleſiaſtical court in Scotland, to which appeals lie from the inferior ones.

The eccleſiaſtical court next in dignity to the aſſembly is the Synod of Lothian and Tweeddale, who meet in the ſame place in April and November; and next to them is the Preſbytery of Edinburgh. Theſe meet on the laſt Wedneſday of every month, and are truſtees on the fund for miniſters widows. They have a hall in Scott's cloſe, where there is a good picture of Dr Webſter by Martin, which was put up at the expence of the truſtees, out of gratitude for the trouble he took in planning and fully eſtabliſhing the fund.

The Society for Propagating Chriſtian Knowledge in the Highlands and Iſlands of Scotland, was eſtabliſhed a body corporate by queen Anne in the year 1709, for the purpoſe of erecting ſchools to inſtruct poor children in the principles of Chriſtianity, as well as in reading and writing. The ſociety have a hall in Warriſton's cloſe where their buſineſs is tranſacted. From time to time they have received large contributions, which have always been very properly applied; and for much the ſame purpoſe his majeſty gives 1000 l. annually to the general aſſembly of the church of Scotland, which is employed by a committee of their number for inſtructing the poor Highlanders in the principles of the Chriſtian religion.

The Earſe church at Edinburgh was built about 20 years ago by ſubſcription for the ſame laudable purpoſe. Great numbers of people reſort to the metropolis from the Highlands, who underſtand no other language but their own, and conſequently have no opportunity of inſtruction without it; and a moſt remarkable proof of the benefit they have received from it is, that though the church is capable of holding 1000 people, yet it is not large enough for thoſe who apply for ſeats. The miniſter has 100 l. *per annum* ariſing from the ſeat-rents, and holds communion with the church of Scotland. The eſtabliſhment was promoted by William Dickſon dyer in Edinburgh.

30 Political conſtitution.

With regard to the political conſtitution of Edinburgh, the town-council have the direction of all public affairs. The *ordinary* council conſiſts only of 25 perſons; but the *council ordinary and extraordinary*, of 33. The whole is compoſed of merchants and tradeſmen, whoſe reſpective powers and intereſts are ſo interwoven, that a balance is preſerved between the two bodies. The members of the town-council are partly elected by the members of the 14 incorporations, and they partly chooſe their own ſucceſſors. The election is made in the following manner: Firſt a liſt or *leet* of ſix perſons is made out by each incorporation; from which number, the deacon belonging to that incorporation muſt be choſen. Theſe liſts are then laid before the ordinary council of 25, who "ſhorten the *leets*," by expunging one half of the names from each; and from the three remaining ones the deacon is to be choſen. When this election is over, the new deacons are preſented to the ordinary council, who chooſe ſix of them to be members of their body, and the ſix deacons of laſt year then walk off. The council of 25 next proceed to the election of three merchant and two trades counſellors. The members of council, who now amount to 33 in number, then make out *leets*, from which the lord provoſt, dean of guild, treaſurer, and bailies muſt be choſen. The candidates for each of theſe offices are three in number; and the election is made by the 30 members of council already mentioned, joined to the eight *extraordinary* council-deacons.

The lord provoſt of Edinburgh, who is ſtyled *right honourable*, is high ſheriff, coroner, and admiral, within the city and liberties, and the town, harbour, and road of Leith. He has alſo a juriſdiction in matters of life and death. He is preſes of the convention of royal boroughs, colonel of the trained bands, commander of the city-guard and of Edinburgh jail. In the city he has the precedency of all the great officers of ſtate and of the nobility; walking on the right hand of the king or of his majeſty's commiſſioner; and has the privilege of having a ſword and mace carried before him. Under him are four magiſtrates called *bailies*, whoſe office is much the ſame with that of aldermen in London. There is alſo a dean of guild, who has the charge of the public buildings, and without whoſe warrant no houſe nor building can be erected within the city. He has a council to conſult with, a nominal treaſurer, who formerly had the keeping of the town's money, which is now given to the chamberlain. Theſe ſeven are elected annually; who with the ſeven of the former year, three merchants and two trades counſellors, and 14 deacons or preſes of incorporated trades, making in all 33, form the council of the city, and have the ſole management and diſpoſal of the city revenues; by which means they have the diſpoſal of places to the amount of 20,000 l. annually. Formerly the provoſt was alſo an officer in the Scots parliament. The magiſtrates are ſheriffs-depute and juſtices of the peace; and the town council are alſo patrons of all the churches in Edinburgh, patrons of the univerſity, and electors of the city's repreſentative in parliament. They have beſides a very ample juriſdiction both civil and criminal. They are ſuperiors of the Canongate, Portſburgh, and Leith; and appoint over theſe certain of their own number, who are called *baron bailies:* but the perſon who preſides over Leith has the title of *admiral*, becauſe he hath there a juriſdiction over maritime affairs. The baron bailies appoint one or two of the inhabitants of their reſpective diſtricts to be their ſubſtitutes, and theſe are called *reſident bailies*. They hold courts in abſence of the baron-bailies, for petty offences, and diſcuſſing civil cauſes of little moment.

31 Town guard.

No city in the world affords greater ſecurity to the inhabitants in their perſons and properties than Edinburgh. Robberies are here very rare, and a ſtreet-murder hardly known in the memory of man; ſo that a perſon may walk the ſtreets at any hour of the night in perfect ſecurity. This is in a great meaſure owing to the *town-guard*. This inſtitution originated from the conſternation into which the citizens were thrown after the battle at Flowden. At that time, the town-council commanded the inhabitants to aſſemble in defence of the city, and every fourth man to be on duty each night. This introduced a kind of perſonal duty for the defence of the town, called *watching and warding*; by which the trading part of the inhabitants were obliged in perſon to watch alternately, in order to prevent or ſuppreſs occaſional diſturbances. This, however, becoming in time extremely inconvenient, the town-council, in 1648, appointed a body of 60 men to be raiſed; the captain of which was to have a monthly pay of 11 l. 2s. 3d. two lieutenants of 2l. each, two ſerjeants of 1 l. 5s. and the private men of 15s. each. No regular fund was eſtabliſhed for defraying this expence; the conſequence of which was, that the old method of watching and warding was reſumed: but the people on whom this ſervice devolved were now become ſo relaxed in their diſcipline, that the magiſtrates were threatened with having the king's troops

troops quartered in the city if they did not appoint a ſufficient guard. On this 40 men were raiſed in 1679, and in 1682 the number was increaſed to 108. After the revolution, the town-council complained of the guard as a grievance, and requeſted parliament that it might be removed. Their requeſt was immediately granted, and the old method of watching and warding was renewed. This, however, was now ſo intolerable, that the very next year they applied to parliament for leave to raiſe 126 men for the defence of the city, and to tax the citizens for their payment. This being granted, the corps was raiſed which ſtill continues under the name of the *town-guard*. At preſent the eſtabliſhment conſiſts of three officers and about 90 men, who mount guard by turns. The officers have a lieutenant's pay; the ſerjeants, corporals, drummers, and common ſoldiers, the ſame with thoſe of the army. Their arms are the ſame with thoſe of the king's forces; but when called upon to quell mobs, they uſe Lochaber-axes, a part of the ancient Scottiſh armour now in uſe only among themſelves.

The militia or trained band of the city conſiſt of 16 companies of 100 men each. They were in uſe to turn out every king's birth-day; but only the officers now remain, who are choſen annually. They conſiſt of 16 captains and as many lieutenants; the provoſt, as has already been mentioned, being the colonel.

The town-guard are paid chiefly by a tax on the trading people; theſe being the only perſons formerly ſubject to watching and warding. This tax, however, amounts only to 1250l. and as the expence of the guard amounts to 1400l. the magiſtrates are obliged to defray the additional charge by other means.

The number of inhabitants in the city of Edinburgh is ſomewhat uncertain, and has been very variouſly calculated. By a ſurvey made in the year 1775, it appears that the number of families in the city, Canongate, and other ſuburbs, and the town of Leith, amounted to 13,806. The difficulty therefore is to fix the number of perſons in a family. Dr Price fixes this number at $4\frac{1}{15}$; Mr Maitland, at $5\frac{1}{4}$; and Mr Arnot, at 6: ſo that, according to this laſt gentleman, the whole number of inhabitants is 82,836; to which he thinks 1400 more may be added for thoſe in the garriſon, hoſpitals, &c. There are in Edinburgh 14 incorporations, capable of chooſing their own deacons, viz. The royal college of ſurgeons; the corporations of goldſmiths, ſkinners, furriers, hammermen, wrights and maſons, taylors, bakers, butchers, ſhoemakers, weavers, waukers, bonnet-makers, and merchant-company. The revenue of the city, ariſing partly from duties of different kinds, and partly from landed property, is eſtimated at about 10,000l. per annum.

The markets of Edinburgh are plentifully ſupplied with all ſorts of proviſions. Freſh butcher-meat, as well as fowl and fiſh, if the weather permit, may be had every day; and no city can be better ſupplied with garden ſtuffs. The Edinburgh ſtrawberries particularly are remarkably large and fine. A remarkable inſtance of the plenty of proviſions with which Edinburgh is ſupplied was obſerved in the year 1779, when ſeveral large fleets, all of them in want of neceſſaries, arrived in the Forth, to the amount of about 500 ſail, and having on board at leaſt 20,000 men; yet the increaſed conſumption of proviſions, which certainly enſued upon the arrival of ſo many ſtrangers, made not the leaſt increaſe in the rate of the markets, inſomuch that ſeveral victualling ſhips ſent down by the navy-board returned without opening their hatches. The city-mills are let to the corporation of bakers in Edinburgh; and the bread made in the city is remarkable for its goodneſs.

Edinburgh is ſupplied with water brought for ſome miles in pipes, and lodged in two reſervoirs, from whence it is diſtributed through the city both to public wells and private families. A revenue accrues to the town from the latter, which muſt undoubtedly increaſe in proportion as the city extends in magnitude.

There are but few merchants in Edinburgh, moſt of them reſiding at the port of Leith; ſo that the ſupport of the city depends on the conſumption of the neceſſaries as well as the ſuperfluities of life. There are five different ſorts of people on whom the ſhopkeepers, publicans, and different trades depend: 1. The people of the law, who are a very reſpectable body in the city. 2. The number of young people of both ſexes who come to town for their education, many of the parents of whom come along with them. 3. The country gentlemen, gentlemen of the army and navy, and people who have made their fortunes abroad, &c. all of whom come to attend the public diverſions, or to ſpend their time in ſuch a manner as is moſt agreeable to them. 4. The vaſt concourſe of travellers from all parts. 5. Moſt of the money drawn for the rents of country gentlemen is circulated among the bankers or other agents.

At Edinburgh there are excellent manufactures of linen and cambrics; there are alſo manufactures of paper in the neighbourhood, and printing is carried on very extenſively. But for ſome time the capital branch about Edinburgh has been building: which has gone on, and ſtill continues to do ſo, with ſuch rapidity, that the city has been increaſed exceedingly in its extent; and it is not uncommon to ſee a houſe built in a few months, and even inhabited before the roof is quite finiſhed.

EDITOR, a perſon of learning, who has the care of an impreſſion of any work, particularly that of an ancient author: thus, Eraſmus was a great editor; the Louvain doctors, Scaliger, Petavius, F. Sirmond, biſhop Walton, Mr Hearne, Mr Ruddiman, &c. are likewiſe famous editors.

EDOM, or ESAU, the ſon of Iſaac and brother of Jacob. The name of Edom, which ſignifies *red*, was given him, either becauſe he ſold his birth-right to Jacob for a meſs of red pottage, or by reaſon of the colour of his hair and complexion. Idumea derives its name from Edom, and is often called in ſcripture the land of Edom. See the next article.

EDOM, or IDUMÆA (anc. geog.), a diſtrict of Arabia Petræa; a great part alſo of the ſouth of Judæa was called Idumæa, becauſe occupied by the Idumæans, upon the Jewiſh captivity, quite to Hebron. But the proper Edom or Idumæa appears not to have been very extenſive, from the march of the Iſraelites, in which they compaſſed it on the ſouth eaſtwards, till they

they came to the country of the Moabites. Within this compaſs lies mount Hor, where Aaron died; marching from which the Iſraelites fought with king Arad the Canaanite, who came down the wilderneſs againſt them (Moſes). And this is the extent of the *Idumæa Propria,* lying to the ſouth of the Dead Sea; but in Solomon's time extending to the Red Sea (1 Kings ix. 26.)

EDMUND I. and II. See *(Hiſtory of)* ENGLAND.

1 Definition.

EDUCATION may be defined, that ſeries of means by which the human underſtanding is gradually enlightened, and the diſpoſitions of the human heart are formed and called forth between earlieſt infancy and the period when we conſider ourſelves as qualified to take a part in active life, and, ceaſing to direct our views ſolely to the acquiſition of new knowledge or the formation of new habits, are content to act upon the principles which we have already acquired.

2 Particulars comprehended under the definition.

This comprehends the circumſtances of the child in regard to local ſituation, and the manner in which the neceſſaries and conveniences of life are ſupplied to him; the degree of care and tenderneſs with which he is nurſed in infancy; the examples ſet before him by parents, preceptors, and companions; the degree of reſtraint or licentiouſneſs to which he is accuſtomed; the various bodily exerciſes, languages, arts, and ſciences, which are taught him, and the method and order in which they are communicated; the moral and religious principles which are inſtilled into his mind; and even the ſtate of health which he enjoys during that period of life.

3 Various modes of education have prevailed.

In different periods of ſociety, in different climates, and under different forms of goverment, various inſtitutions have naturally prevailed in the education of youth; and even in every different family, the children are educated in a different manner, according to the differences in the ſituation, diſpoſitions, and abilities, of the parents. The education of youth being an object of the higheſt importance, has not only engaged the anxious care of parents, but has likewiſe often attracted the notice of the legiſlator and the philoſopher. What our readers have therefore a right to expect from us on this article is, 1ſt, That we give an account of ſome of the moſt remarkable inſtitutions for the education of youth which have been legally eſtabliſhed or have accidentally prevailed among various nations and in various periods of ſociety. 2dly, That we alſo give ſome account of the moſt judicious and the moſt fanciful plans which have been propoſed by thoſe authors who have written on the ſubject of education. And, laſtly, that we venture to preſent them with the reſult of our own obſervations and recollections on this important head.

4 Plan.

5 Education in a ſavage ſtate.

In the infancy of ſociety, very little attention can be paid to the education of youth. Before men have riſen above a ſavage ſtate, they are almoſt entirely the creatures of appetite and inſtinct. The impulſe of appetite hurries them to propagate their ſpecies. The power of inſtinctive affection is often, though not always, ſo ſtrong as to compel them to preſerve and nurſe the fruit of their embraces. But even when their wants are not ſo urgent, nor their hearts ſo deſtitute of feeling, as to prompt them to abandon their new-born infants to the ferocity of wild beaſts or the ſeverity of the elements, yet ſtill their uncomfortable and precarious ſituation, their ignorance of the laws of nature, their deficiency of moral and religious principles, and their want of dexterity or ſkill in any of the arts of life, all theſe together muſt render them unable to regulate the education of their children with much attention or ſagacity. They may relate to them the wild inconſiſtent tales in which all their notions concerning ſuperior beings and all their knowledge of the circumſtances and tranſactions of their anceſtors are contained; they may teach them to bend the bow, to point their arrows, to hollow the trunk of a tree into a canoe, and to trace the almoſt imperceptible path of an enemy or a wild beaſt over dreary mountains or through intricate foreſts: but they cannot impreſs their minds with juſt ideas concerning their ſocial relations, or concerning their obligations to a Supreme Being, the framer and upholder of nature: they teach them not to repreſs their irregular appetites, nor to reſtrain the ſallies of paſſion when they exceed juſt bounds or are improperly directed; nor can they inform their underſtandings with very accurate or extenſive views of the phenomena of nature. Beſides, they know not how far implicit obedience to his parents commands is to be required of the boy or youth, nor how far he ought to be left to the guidance of his own reaſon or humour. Among ſavages the influence of parental authority ſoon expires, nor is the parent ſolicitous to maintain it. As the eagle expels his young from his lofty neſt as ſoon as they become able to ſupport themſelves in the air; ſo the ſavage generally ceaſes to care for his child, or aſſume any power over him, as ſoon as he becomes capable of procuring the means neceſſary for his own ſubſiſtence. Savages being ſcarce connected by any ſocial ties, being unacquainted with the reſtraint of civil laws, and being unable to contribute in any great degree to the maintenance or protection of one another; each individual among them, as ſoon as he attains that degree of ſtrength and dexterity which may enable him to procure the neceſſaries of life, ſtands ſingle and alone, independent on others, and ſcorning to ſubmit to their commands. The parent, conſcious of his inability to confer any important benefits on his child, after he has advanced even a very ſhort way towards manhood, no longer endeavours to controul his actions; and the child, proud of his independence, ſcarce ſubmits to aſk his parent's advice. And even before reaching this period of independence, ſo few are the benefits which parents can beſtow (being confined to ſupplying the neceſſaries of life, and communicating the knowledge of a very few of the rudeſt ſimpleſt arts), that children regard them with little deference, nor do *they* always inſiſt on implicit ſubmiſſion. Want of natural affection, and conſciouſneſs of ſuperior ſtrength, often prompt the parent to abuſe the weakneſs of his child. Yet though ſmall the ſkill with which the ſavage can cultivate the underſtanding or form the diſpoſitions of his child, though few the arts which he can teach him, and though not very reſpectful or ſubmiſſive the obedience or deference which he requires; yet is there one quality of mind which the ſavage is more careful to inſpire than thoſe parents who are directed in educating their children by all the lights of civilized ſociety. That quality is indeed abſolutely neceſſary to fit the ſavage for his ſituation; without it, the day on which he ceaſed

ceaſed to enjoy the protection of his parents would moſt probably be the laſt day of his life: That quality is Fortitude. We may perhaps think, that the hardſhips to which the young ſavage is from the period of his birth unavoidably expoſed, might be enough to inſpire him with fortitude; but, as if theſe were inſufficient, other means are applied to inſpire him with what the Stoics have regarded as the firſt of virtues. He is compelled to ſubmit to many hardſhips unneceſſary, but from a view to this. Children are there called to emulate each other in bearing the ſevereſt torments. Charlevoix relates, that he has ſeen a boy and girl bind their arms together, place a burning coal between them, and try who could longeſt endure without ſhrinking the pain to which they thus expoſed themſelves.

Still, however, the young ſavage owes his education rather to nature and to the circumſtances in which he is placed, and the accidents which befal him, than to the kindneſs or prudence of his parents. Nature has endowed him with certain powers of underſtanding, ſentiments, ſenſations, and bodily organs; he has been placed in certain circumſtances, and is expoſed to a certain train of events; and by theſe means chiefly, not by the watchful induſtry of inſtructors, does he become ſuch as he appears when he has reached the years of maturity.

But man was not deſigned by his wiſe and beneficent Creator to remain long in a ſavage ſtate; the principles of his nature incline him to ſocial life. Reaſon, diſtinguiſhing the ſuperior advantages to be enjoyed in ſociety, concurs with the ſocial principle in his breaſt, in prompting him to ſeek the company and converſation of others of the human race. When men enter into ſociety, they always unite their powers and talents, in a certain degree, for the common advantage of the ſocial body. In conſequence of this, laws come in time to be inſtituted; new arts are invented; progreſs is made in the knowledge of nature; moral duties are better underſtood and defined; juſter ideas are gradually acquired of all our ſocial relations; friendſhip, love, filial, parental, and conjugal affection, all are heightened and refined. All theſe advantages do not inſtantly reſult from mens entering into a ſocial ſtate; the improvement of the human mind, and the civilization of ſociety, are gradual and progreſſive: But as it is natural for men to unite in a ſocial ſtate, ſo it is no leſs natural for ſociety to be gradually improved and civilized till it attain an high degree of perfection and refinement.

8

When men have attained to ſuch knowledge and improvement as to be intitled to a more honourable appellation than that of ſavages, one part of their improvements generally conſiſts in their becoming more judicious and attentive in directing the education of their youth. They have now acquired ideas of dependence and ſubordination; they have arts to teach and knowledge to communicate; they have moral principles to inſtil; and have formed notions of their relation and obligations to ſuperior powers, which they are deſirous that their children ſhould alſo entertain. Their affection to their offspring is now alſo more tender and conſtant. We obſerve at preſent in that ſtate of ſociety in which we live, that the poor who can ſcarce earn for themſelves and their children the neceſſaries of life, are generally leſs ſuſceptible of parental affection, in all its anxious tenderneſs, than the rich, or thoſe whom Providence hath placed in eaſy circumſtances; and we may make uſe of this fact in reaſoning concerning the different degrees of the ſame affection felt by the ſavage and the member of a civilized ſociety. The ſavage may be conſidered as the poor man, who with difficulty procures the neceſſaries of life even for himſelf; the other, as the man in affluent circumſtances, who is more at leiſure to liſten to the voice of tender and generous affection.

In this improved ſtate of ſociety, the education of youth is viewed as an object of higher importance. The child is dearer to his parent; and the parent is now more capable of cultivating the underſtanding and rectifying the diſpoſitions of his child. His knowledge of nature, and his dexterity in the arts of life, give him more authority over a child than what the ſavage can poſſeſs. Obedience is now enforced, and a ſyſtem of education is adopted; by means of which the parent attempts to form his child for acting a part in ſocial life. Perhaps the legiſlature interferes; the education of the youth is regarded as highly worthy of public concern; it is conſidered that the fooliſh fondneſs or the unnatural caprice of parents may, in the riſing generation, blaſt the hopes of the ſtate.

9
Public eſtabliſhments for education among the ancients.

In reviewing ancient hiſtory, we find that this actually took place in ſeveral of the moſt celebrated governments of antiquity. The Perſians, the Cretans, and the Lacedemonians, were all of them too anxious to form their youth for diſcharging the duties of citizens to entruſt the education of the children ſolely to the parents. Public eſtabliſhments were formed among thoſe nations, and a ſeries of inſtitutions enacted, for carrying on and regulating the education of their youths: Not ſuch as our European univerſities, in which literary knowledge is the ſole object of purſuit, the ſtudent is maintained ſolely at his parents expence, and attends only if his parents think proper to ſend him; but of a very different nature, and on a much more enlarged plan.

10
Among the ancient Perſians.

The Perſians, according to the elegant and accurate account delivered by Xenophon in the beginning of his Cyropædia, divided the whole body of their citizens into four orders; the boys, the youth, the full-grown men, and thoſe who were advanced beyond that period of life during which military ſervice was required. For each of theſe orders particular halls were appropriated. Each of them was ſubjected to the inſpection of twelve rulers. The adults and the ſuperannuated were required to employ themſelves in the performance of particular duties, ſuitable to their age, their abilities, and their experience; while the boys and the youth were engaged in ſuch a courſe of education as ſeemed likely to render them worthy and uſeful citizens.

The boys were not employed, in their places of inſtruction, in acquiring literary accompliſhments; for to ſuch the Perſians were ſtrangers. They went thither to learn juſtice, temperance, modeſty; to ſhoot the bow, and to lanch the javelin. The virtues and the bodily exerciſes were what the Perſians laboured to teach their children. Theſe were the direct, and not ſubordinate, purpoſes of their ſyſtem of education. The maſters uſed to ſpend the greateſt part of the day in diſpenſing juſtice to their ſcholars; who carried before them actions for thefts, robberies, frauds, and other ſuch grounds of complaint againſt one another.—Such were the means by which the Perſians endeavoured to inſtil, even in early youth, a regard for the laws of natural equity, and for the inſtitutions of their country. Till the age of 16 or 17, the boys were buſied in acquiring thoſe parts of education. At that period they ceaſed to be conſidered as boys, and were raiſed to the order of the youths. After they entered this order, the ſame views were ſtill attended to in the carrying on of their education. They were ſtill enured to bodily labour. They were to attend the magiſtrates, and to be always ready to execute their commands. They were led out frequently to the chace; and on ſuch expeditions they were always headed by the king, as in time of war. Here they were taught to expoſe themſelves fearleſsly to danger; to ſuffer, without repining or complaint, hunger, thirſt, and fatigue; and to content themſelves with the coarſeſt, ſimpleſt fare, for relieving the neceſſities of nature. In ſhort, whether at home or out on ſome hunting expedition, they were conſtantly employed in acquiring new ſkill and dexterity in military exerciſes, new vigour of mind and body, and confirmed habits of temperance, fortitude, abſtinence, patience, patriotiſm, and noble integrity. After ſpending ten years in this manner, their courſe of education was completed; they were admitted into the claſs of the adults, and were eſteemed qualified for public offices. It muſt not eſcape our notice, that the citizens were not compelled to ſend their children to paſs through this courſe of education in the public halls; but none except ſuch as paſſed through this courſe of education were capable of civil power, or admitted to participate in public offices or public honours.

Such are the outlines of that ſyſtem of education which Xenophon repreſents as publicly eſtabliſhed among the Perſians. Were we able to preſerve in a tranſlation all the manly and graceful ſimplicity of that enchanting author, we would have offered to the peruſal of our readers the paſſage in which he has deſcribed it; but conſcious of being inadequate to that taſk, we have preſumed only to extract the information which it contains.

11 Remarks on Xenophon's account of Perſian education.

Perhaps, however, this ſyſtem of education did not ſubſiſt preciſely as the eloquent diſciple of Socrates deſcribes it among that rude and ſimple people. On other occaſions he has commemorated ſuch inſtances of their barbarity, as would tempt us to think them incapable of ſo much order and ſo much wiſdom. Perhaps, as the diſcoverers of the new world have ſometimes conferred on the inhabitants of that hemiſphere, in the accounts of them with which they entertained their friends in Europe, amazing degrees of moral and political wiſdom, of ſkill and dexterity in the arts, of induſtry and valour, which thoſe uncivilized children of nature were afterwards found not to poſſeſs; ſo the Athenian philoſopher has alſo aſcribed to the Perſians prudence and attention in regulating the education of their youth beyond what people in ſo rude a ſtate can poſſibly exert.

But if we examine into the principles on which this ſyſtem of education proceeds, without concerning ourſelves whether it once actually prevailed among the Perſians, or is the production of the fine imagination of Xenophon, we will find it peculiarly ſuitable for a nation juſt emerging from the rudeneſs and ignorance of barbarity to a knowledge of ſocial and civil relations, and of the duties connected with ſuch relations. They have ſacrificed their independence to obtain the comfort and ſecurity of a ſocial ſtate. They now glory in the appellation of citizens, and are deſirous to diſcharge the duties incumbent on a citizen. They muſt inform their children in the nature of their ſocial relations, and impreſs them with habits of diſcharging their ſocial duties; otherwiſe the ſociety will ſoon be diſſolved, and their poſterity will fall back into the ſame wild miſerable ſtate from which they have emerged. But perhaps the circumſtances, or abilities, or diſpoſitions of individuals, render them unequal to this weighty taſk. It becomes therefore naturally an object of public care. The whole ſocial body find it neceſſary to deliberate on the moſt proper means for diſcharging it aright. A plan of education is then formed; the great object of which is, to fit the youth for diſcharging the duties of citizens. Arts and ſciences are hitherto almoſt wholly unknown: and all that can be communicated to the youth is only a ſkill in ſuch exerciſes as are neceſſary for their procuring ſubſiſtence, or defending themſelves againſt human enemies or beaſts of prey; and habits of performing thoſe duties, the neglect of which muſt be fatal to the ſociety or the individual.

Such is the ſyſtem of education which we have ſurveyed as eſtabliſhed among the Perſians; and perhaps we may now be leſs ſuſpicious than before of Xenophon's veracity. It appears natural for a people who have reached that degree of civilization in which they are deſcribed, and have not yet advanced farther, to inſtitute ſuch an eſtabliſhment. Some ſuch eſtabliſhment alſo appears neceſſary to prevent the ſociety from falling back into their former barbarity. It will prevent their virtue and valour from decaying, though it may perhaps at the ſame time prevent them from making any very rapid progreſs in civilization and refinement. Yet the induſtry, the valour, the integrity, and the patriotiſm which it inſpires, muſt neceſſarily produce ſome favourable change in their circumſtances; and that change in their circumſtances will be followed by a change in their ſyſtem of education.

Amo Cre

The Cretans, too, the wiſdom of whoſe laws is ſo much celebrated in the records of antiquity, had a public eſtabliſhment for the education of their youth. Minos, whom they revered as their great legiſlator, was alſo the founder of that eſtabliſhment. Its tendency was ſimilar to that of the courſe of education purſued among the Perſians,—to form the ſoldier and the citizen. We cannot preſent our readers with a very particular or accurate account of it; but ſuch as we have been able to procure from the beſt authorities we think it our duty to lay before them.

The Cretans were divided into three claſſes; the boys, the youth, and the adults. Between ſeven and ſeventeen years of age, the boy was employed in learning to ſhoot the bow, and in acquiring the knowledge of his duties as a man and a citizen, by liſtening to the converſation of the old men in the public halls, and obſerving their conduct. At the age of ſeven, he was conducted to the public halls to enter on this courſe of education. He was taught to expoſe himſelf boldly to danger and fatigue; to aſpire after ſkill and dexterity in the uſe of arms and in the gymnaſtic exerciſes; to repeat the laws and hymns in honour of the gods. At the age of ſeventeen he was enrolled among the youth. Here his education was ſtill continued on the ſame plan. He was to exerciſe himſelf among his equals in hunting, wreſtling, and the military exerciſes; and while thus engaged, his ſpirits were rouſed and animated by ſtrains of martial muſic played on ſuch inſtruments as were then in uſe among the inhabitants of Crete. One part of the education of the Cretan youth, in which they were particularly deſirous to excel, was the Pyrrhic dance; which was the invention of a Cretan, and conſiſted of various military evolutions performed to the ſound of inſtruments.

Such were the principles and arts in which the Cretan legiſlature directed the youth to be inſtructed. This courſe of education could not be directed or ſuperintended by the parent. It was public, and carried on with a view to fit the boy for diſcharging the duties of a citizen when he ſhould attain to manhood.

3 earks on Cretan ation. It is eaſy to ſee, that ſuch a ſyſtem of education muſt have been inſtituted in the infancy of ſociety, before many arts had been invented, or the diſtinctions of rank had ariſen; at a time when men ſubſiſted in a conſiderable degree by hunting, and when the intercourſe of nations was on ſuch a footing, that war, inſtead of being occaſional, was the great buſineſs of life. Such a ſyſtem of life would then naturally take place even though no ſage legiſlator had ariſen to regulate and enforce it.

14 ng the demo- s. Lycurgus, the celebrated lawgiver of Lacedemon, thought it neceſſary to direct the education of youth in a particular manner, in order to prepare them for paying a ſtrict obedience to his laws. He regarded children as belonging more properly to the ſtate than to their parents, and wiſhed that patriotiſm ſhould be ſtill more carefully cheriſhed in their breaſts than filial affection. The ſpirit of his ſyſtem of education was pretty ſimilar to that of thoſe which we have juſt viewed as ſubſiſting among the Perſians and the Cretans.

As ſoon as a boy was born, he was ſubmitted to the inſpection of the elders of that tribe to which his parents belonged. If he was well ſhaped, ſtrong, and vigorous, they directed him to be brought up, and aſſigned a certain portion of land for his maintenance. If he was deformed, weak, and ſickly, they condemned him to be expoſed, as not being likely ever to become an uſeful citizen. If the boy appeared worthy of being brought up, he was entruſted to the care of his parents till he attained the age of ſeven years; but his parents were ſtrictly charged not to ſpoil either his mind or his bodily conſtitution by fooliſh tenderneſs. Probably, too, the ſtate of their manners was at that time ſuch as not to render the injunction peculiarly neceſſary.

At the age of ſeven, however, he was introduced to a public claſs, conſiſting of all the boys of the ſame age. Their education was committed to maſters appointed by the ſtate; and what was chiefly inculcated on them in the courſe of it, was ſubmiſſive obedience and reſpect to their ſuperiors; quickneſs and brevity in their converſation, and replies to ſuch queſtions as were put to them; dexterity and addreſs in performing what was commanded them, and firmneſs and patience in bearing every pain or hardſhip to which they might be expoſed. One of the means uſed to form them to habits of activity and addreſs, was to permit, nay, to direct them to commit little acts of theft; which, if they performed them ſo dexterouſly as to avoid detection, they might afterwards boaſt of as noble exploits: but if detected in ſuch enterpriſes, the aukward artleſs boy was expoſed both to puniſhment and diſgrace. To avoid the puniſhment and diſgrace incurred by being detected in an act of theft, the Spartan boy would often ſuffer with unſhrinking fortitude the ſevereſt torments. It is related of one of them, that rather than be diſcovered with a young fox under his cloak, which he had ſtolen, he ſuffered the little animal to tear open his bowels. Not content with beholding the children ſuffer by ſubmitting voluntarily to ſuch hardſhips, the Spartans alſo endeavoured to form them to fortitude, by whipping them on their religious feſtivals, ſometimes with ſuch ſeverity that they expired under the laſh. The Lacedemonian youth were alſo taught ſuch bodily exerciſes, and the uſe of ſuch warlike weapons, as were neceſſary to render them expert and ſkilful ſoldiers.

15 Remarks. They too, as well as the Cretans and Perſians, among whom we have ſeen that ſomewhat ſimilar modes of education prevailed, were to be citizens and ſoldiers; not huſbandmen, mechanics, artiſts, merchants, &c. Therefore the mode of education eſtabliſhed among them was ſimple and uniform. Its aim was, to make them acquainted with the nature of their ſocial duties, and to form them to ſuch vigour of body and ſuch firmneſs of mind as might render them fit for the ſtation in which they were to be placed, and adequate to the part which they were to act. This eſtabliſhment for education was perfectly conſiſtent with the other parts of that legiſlature which was inſtituted by Lycurgus. Youth educated among the Lacedemonias could hardly fail to become worthy members of that ſingular republic. Let us not however regard the Spartans as *ſingularly* inhumane in their treatment of youth. Let us reaſcend, in imagination, to that period in the progreſs of ſociety from rudeneſs to refinement, to which they had attained when Lycurgus aroſe among them. What were then their circumſtances, their arts and manners, their moral principles, and military diſcipline? Not very different from thoſe which the laws of Lycurgus rendered ſo long ſtationary among them. He, no doubt, rectified ſome abuſes, and introduced greater order and equality. But man is not to be ſo eaſily metamorphoſed into a new form. As you cannot, at once, raiſe an acorn to a venerable oak; ſo neither will you be able to change the ſavage, at once, into the citizen. All the art or wiſdom of Lycurgus, even though aſſiſted by all the influence of the prophetic Apollo, could never have eſtabliſhed his laws among his countrymen, had not their character and circumſtances previouſly diſpoſed them to receive them. But, grant this, and you muſt, of conſequence, allow, that what to us may appear cruel and inhumane, muſt have affected their feelings in a different manner. The change introduced in the treatment of youth by the eſtabliſh-

ment of this ſyſtem of education was probably recommended by its being more humane than what before prevailed. Corrupted as are our manners, and effeminate our modes of education; yet we would not perhaps act wiſely in laying them aſide, to adopt in their ſtead thoſe of ancient Sparta. But the Spartan education was peculiarly well fitted to form citizens for the republic of Lycurgus; it was happily adapted to that ſtate of ſociety in which it was introduced. And, if we ſhould enquire by what means Lycurgus was enabled to fix the arts, the manners, and in ſhort the civilization of his country, for ſo long a period in a ſtationary ſtate; we would perhaps find reaſon to aſcribe that effect, to the public eſtabliſhment which he inſtituted for the education of youth; to his confining the Spartan citizens to the profeſſion of arms, and aſſigning all ſervile offices to the Helots; and to his prohibiting the uſe of gold and ſilver. Among theſe however his eſtabliſhment for education occupies the chief place. Never was any ſtate adorned with more patriotic citizens than thoſe of Sparta. With them every private affection ſeemed to be ſwallowed up by the *amor patriæ:* the love of their country was at leaſt their ruling paſſion. Pœdaretes being rejected when he offered himſelf a candidate for a ſeat among the council of three hundred, returned home, rejoicing that there were in Sparta no fewer than three hundred whom his countrymen found reaſon to regard as better citizens than himſelf. This was not a ſeeming joy, aſſumed to conceal the pain which he ſuffered from the diſappointment; it was heartfelt and ſincere. Such were the effects of their ſyſtem of education.

16
Education among the other nations of antiquity.

When we turn our eyes from the Perſians, the Cretans, and the Spartans, to the other nations of antiquity; we no where behold ſo regular a ſyſtem of public education. Among the Athenians and the Romans, the laws did not deſcend to regulate in ſo particular a manner the management of the youth These nations gradually emerged from a ſtate of the rudeſt barbarity, to that poliſhed, enlightened, and civilized ſtate which rendered them the glory and the wonder of the heathen world: but in no part of their progreſs from the one ſtate to the other do we find any ſuch eſtabliſhment ſubſiſting among them. So various, however, are the circumſtances which form and diverſify the character of nations, that we cannot reaſonably conclude, becauſe no ſuch eſtabliſhments exiſted among the Athenians and Romans, that therefore their exiſtence was unnatural among thoſe nations who poſſeſſed them. But though the education of youth was managed in a different manner among theſe and moſt other nations in the ancient world, than by public eſtabliſhments, which detached children from the care of their parents; yet ſtill it was every where regarded as an object of the higheſt importance. As the manners of mankind gradually improved to a ſtate of refinement; as the invention of arts, and the diſcovery of ſcience gradually introduced opulence and luxury; connubial, parental, and filial affection gradually acquired greater ſtrength and tenderneſs. Of conſequence, children experienced more of their parents care; and that care was directed to form them for acting a becoming part in life. According to the circumſtances of each nation, the arts which they cultivated, and the form of government under which they lived; the knowledge which they ſought to communicate to their children, and the habits which they endeavoured to impreſs upon them, were different from thoſe of other nations: And again, according to the different circumſtances, tempers, abilities. and diſpoſitions of parents, even the children of each family were brought up in a manner different from that in which thoſe of other families were managed. The Athenians, the Romans, the Carthaginians, conducted each of them the education of their youth in a different manner, becauſe they had each different objects in view. But having conſidered the moſt ſingular eſtabliſhments for education which prevailed in the ancient world, it ſeems unneceſſary for us to deſcend to a particular account of the manner which every nation, or fantaſtic individual, thought proper to purſue in bringing up their youth. It will probably be more uſeful and entertaining to our readers, if we next preſent them with a view of ſome of the moſt judicious or fanciful plans of education which have been propoſed by the writers on that ſubject.

17
Quinctilian.

One of the moſt reſpectable writers on education among the ancients, is the celebrated Quinctilian. He taught rhetoric in Rome during the reign of Domitian and under ſeveral of the other emperors. When he retired from the exerciſe of his employment as a teacher of rhetoric, he ſpent his leiſure in the compoſition of a treatiſe, not merely on rhetoric, but on the moſt proper means for educating a boy ſo as to render him both an eloquent orator and a good man.

In that valuable treatiſe, he enters into a minute detail of all that appears to him moſt likely to conduce to thoſe important ends.

As ſoon as the boy enters the world, he would have the greateſt care to be uſed in ſelecting thoſe who are to be placed about him. Let his nurſe have no impediment of ſpeech. It will be happy for him, if his parents be perſons of ſenſe and learning. Let his tutor, at leaſt, poſſeſs theſe qualifications. As ſoon as he attains the diſtinct uſe of his organs of ſpeech, let him be initiated in the firſt elements of literature. For as he is capable of diſtinguiſhing and remembering at a vety early age; ſo his faculties cannot poſſibly be employed in a more advantageous manner. And even at this early period of life, let maxims of prudence and the firſt principles of morals be inculcated upon his mind by the books which are put into his hands, and even by the lines which he copies in learning the art of writing. The Greek language was to the Romans in the days of Quinctilian, what the Latin and Greek and French are to us at preſent, an acquiſition held indiſpenſably neceſſary to thoſe who aſpired to a liberal education; and Quinctilian judges it proper that the boy ſhould begin his application to letters with the Greek language in preference to his mother tongue.

This judicious writer next examines a queſtion which has been often agitated, Whether a domeſtic or a public education is liable to the feweſt inconveniences, and likely to be attended with the greateſt advantages? And he is of opinion, that in a domeſtic education the boy is in danger of being corrupted by injudicious fondneſs and evil example; is not rouſed by the ſpur of emulation; and is deprived of proper oppurtunities for acquiring a juſt idea of his own powers, or that ac-

activity and dexterity which he will afterwards find ſo neceſſary when he comes to act a part in life: While in a public education, which was preferred by ſome of the moſt renowned nations of antiquity, the morals are not greatly expoſed to corruption, emulation is rouſed, friendſhips are formed, all the powers of the mind are called forth to act with new vigour, and the youth is prepared for performing his part on the great theatre of the world. Quinctilian, therefore, wiſhes that parents would place their children in public ſeminaries of education.

When a boy is committed to a maſter's care, the maſter's attention muſt be firſt directed to diſcover his diſpoſitions and the extent of his capacity. Of his capacity he will form a favourable judgment, not from his ſprightlineſs, nor even from his quickneſs of apprehenſion; but from his modeſty, docility, and virtuous diſpoſitions. If the boy poſſeſs theſe laſt qualifications, the maſter will rejoice in him, as likely to give him ſatisfaction and do him honour. According to his temper and diſpoſitions, let the boy be treated with mildneſs or ſeverity; but never let ſeverity extend to blows. Let the boy be allured and led, by the moſt artful and inſinuating treatment, to do his duty; there will then be no occaſion to puniſh him for neglecting it.

As Quinctilian's profeſſed object was, not merely to give general directions for forming the heart and cultivating the underſtanding, but to form a particular character in life, the ſcholar and the orator; he finds it neceſſary to enter into minute details concerning the manner in which the boy is to be inſtructed in ſpeaking, writing, grammar, and compoſition; of which it does not appear neceſſary for us to take particular notice in this place. Muſic and geometry, he thinks, ought to make a part of the young orator's ſtudies; as being uſeful to render him accurate in reaſoning, and capable of reliſhing the beauties of the poets. He is alſo of opinion, that the boy ſhould not be confined to one branch of ſtudy, without being allowed to attempt others till he have made himſelf maſter of that. Let ſeveral parts of literature engage his attention by turns: let him dedicate a conſiderable portion of his time to them. He may thus acquire habits of induſtrious application which will remain with him through life.

With the tender attention of a good man, this ſenſible and elegant writer ſtill accompanies his pupil through the courſe of his ſtudies; anxiouſly inſiſts that he be placed under a maſter diſtinguiſhed for purity of morals, and for no mean abilities in his profeſſion; directs his memory to be ſtored with the nobleſt paſſages of the poets, orators, and hiſtorians; and carefully diſcuſſes and refutes thoſe opinions which repreſent genius as above induſtry. The remaining part of his work being employed on the principles of rhetoric, without containing any thing on the ſubject of education in general, it is not neceſſary that we ſhould here preſent an analyſis of it to our readers. But ſince Quinctilian was ſo diſtinguiſhed, not only as a rhetorician, but as an inſtructor of youth, and diſplays ſo much good ſenſe and ſo ſolid a judgment, formed on long experience, in whatever he advances on the ſubject of education; we could not, without extreme negligence, omit taking notice of him under this article, and affording our readers an opportunity of being inſtructed by liſtening to his ſentiments on this head.

18
Milton's treatiſe on education.

The name of John Milton is ſo much revered in Britain, that his ſentiments on any ſubject are intereſting to Britons. His life was dedicated to ſtudy: During a part of it, he was employed in the taſk of inſtructing youth; and among his other works we find a treatiſe on education. He had himſelf been educated according to that plan which has long been eſtabliſhed in the Engliſh univerſities; but with that mode of education he was not ſatisfied. The object of his directions is chiefly to form the ſcholar. He conſidered himſelf as qualified to exhibit a model of "a better education, in extent and comprehenſion far more large, and yet of time far ſhorter, and of attainment far more certain, than any that had yet been in practice." The following is the ſubſtance of his treatiſe.

As the end of learning is to cultivate our underſtandings, and to rectify our diſpoſitions; therefore the deſign of our applying to the ſtudy of languages cannot be merely that we may commit to memory the words of which they conſiſt, or that we may acquire a knowledge of their analogy and ſtructure; but that we may enrich our minds with the treaſures of wiſdom which they contain. But in the preſent modes of education this deſign does not appear to be kept in view. The learner of Latin is burdened with rules, and themes, and verſes, and orations; but no care is taken to make him maſter of the valuable knowledge which the claſſics contain. And when he advances a little farther, he is driven into the thorny paths of logic and metaphyſics. So, when his ſtudies are completed, and he is conſidered as having received a liberal education, he is almoſt as deſtitute of real knowledge as when he firſt entered a ſchool.

But to render learning truly beneficial, inſtead of the ſchool and univerſity education which youth at preſent receive; let the place of both ſchool and univerſity be ſupplied by an academy, in which they may acquire all that is taught at either, except law and phyſic. Let the academy afford accommodation for 150 perſons; 20 of whom may be ſervants and attendants. As many academies as are neceſſary may be afterwards erected on the model of this one. Let the youth who are introduced into this academy begin their ſtudies with learning the principal rules of grammar from ſome good elementary book. In their pronunciation of Latin, let them be taught to follow the pronunciation of the Italians; as that of the Engliſh is indiſtinct, and unſuitable to the genius of the language. Next, read to them ſome entertaining book on education; ſuch as, the three firſt books of Quinctilian in Latin, and Cebes, Plutarch, or ſome other of the Socratic diſcourſes, in Greek; and be careful to ſeize every opportunity of inſpiring them, by ſeaſonable lectures and explanations, with love for learning, admiration of great and virtuous characters, and a diſpoſition to cheerful obedience. At the ſame time, but at a different hour of the day, let them be inſtructed in the rules of arithmetic and the elements of geometry. Between ſupper and bed-time inſtruct them in the principles of religion and the ſacred hiſtory. From the writers on education let your pupils paſs to the authors on agriculture, to Cato, Varro, and Columella. Be-

Educa

fore half theſe authors be read, they cannot but be pretty well qualified to read moſt of the proſe authors in the Latin language; and they may now, with great propriety, learn the uſe of the globes, and make themſelves acquainted with the ancient and modern maps. Let them, about the ſame time, begin the ſtudy of the Greek tongue, and proceed in it as in the Latin: they will not fail to overcome, in a ſhort time, all the difficulties of grammar; after which they will have acceſs to all the treaſures of natural knowledge to be found in Ariſtotle and Theophraſtus. In the ſame manner they may make themſelves acquainted with Vitruvius, Seneca, Mela, Celſus, Pliny, and Solinus. And having thus paſſed through the principles of arithmetic, geometry, aſtronomy, and geography, with a general compact of phyſics; let them next turn their attention to mathematics, in which they may begin with the practical branch of trigonometry, which will ſerve as an introduction to fortification, architecture, and navigation. To teach them the knowledge of nature, and inſtruct them in the arts of life, let them have the aſſiſtance and inſtructions, not merely of maſters who are acquainted only with books, but of men whoſe ſkill has been obtained by actual practice, even of artiſts and mechanics. Next, let the poets obtain their attention; and they will now read them with eaſe and pleaſure. From the poets let your pupils proceed to the moraliſts; and, after acquainting themſelves with them, they may be allowed the entertainment of ſome of the beſt Greek, Latin, and Italian, dramatic compoſitions. From theſe let them proceed to politics: let them here ſtudy the law of Moſes, the admirable remains of the ancient lawgivers of Greece, the Roman tables, edicts, and pandects, concluding with the inſtitutions of their mother country. Now let them be more particularly inſtructed in the principles of theology; for by this time they may have acquired the Hebrew language, together with the Chaldee and the Syriac dialect, and may therefore read the ſcriptures in their original language. When their minds are thus furniſhed, they will be able to enter into the ſpirit of the nobleſt hiſtorians and poets. To get by heart, and repeat in a proper manner, paſſages from the writings of ſome of theſe, will have the happieſt effects in elevating their genius. Let this ſtately edifice be crowned with logic and rhetoric. Far different would be the effects of ſuch a courſe of education, from thoſe produced by any which is at preſent purſued. We ſhould then ſee abler writers, more eloquent ſpeakers, and wiſer ſtateſmen. Similar to this, probably, was the courſe taught in the famous ſchools of Pythagoras, Plato, Iſocrates, and Ariſtotle. This would unite the advantages of an Athenian and a Spartan education: for our pupils ſhould be taught the exerciſes of wreſtling and fencing, and the whole military diſcipline.

19
Remarks.

Such are the ideas of our admired Milton on the ſubject of education. An enthuſiaſtic admirer of the ſciences, arts, and inſtitutions of Greece and Rome; from his religious and political principles, no friend to the univerſities; it was natural for a man of his learning and ingenuity, in an age of innovation, and influenced by ſuch prejudices, to form ſuch a project as that which we have ſurveyed. He ſeems not to have reflected, that it is neceſſary for children to be long occupied in obtaining a familiar acquaintance with words, before they can gain from books any knowledge of things; overlooking this circumſtance, and perceiving plainly that the mode of education which then prevailed confined the attention of youth almoſt wholly to words, he could not but regard the ſcheme which he propoſed as likely to produce very happy effects. His obſervation, that the appearances of external nature are among the firſt objects which attract the attention of youth, which he communicates by directing his pupils to peruſe the writers on agriculture and natural hiſtory as near the beginning of their ſtudies as poſſible; if not altogether juſt, yet muſt be allowed to be nearly ſo. Perhaps human actions and paſſions, and the ſeries of events which happen around us, are, by the time at which we begin our application to learning, the objects which moſt frequently and ſtrongly engage our attention: But the appearances of external nature are at leaſt the next object of our regard.

Educati

20
Locke'
Treati
educat

Mr Locke, to whoſe abilities and noble deſire to be uſeful to the world his country is ſo much indebted, has written, among other things, on the education of youth. He was capable of thinking for himſelf; but more deſirous of rendering himſelf uſeful, than of being admired for ſingularity. He is, therefore, an author to whom we ought to liſten, at leaſt, with reſpectful attention. If Quinctilian and Milton had been employed as teachers of youth, Mr Locke had been converſant with the world, had inquired into the principles of human nature, and had no doubt endeavoured to examine without prejudice the effects of thoſe modes of education of which he diſapproves. When we conſider, that, to render himſelf uſeful to the riſing generation, he could deſcend from the heights of ſcience to tranſlate the fables of Æſop, and to perform other humble taſks in literature, which a philoſopher of leſs benevolence and virtue would have diſdained; we cannot but look with veneration and gratitude on ſo exalted a character. In his Treatiſe on Education, the two great objects which Mr Locke keeps in view are, 1ſt, To preſerve and ſtrengthen the bodily conſtitution; 2dly, To inform the underſtanding with uſeful knowledge, and to cheriſh good diſpoſitions in the heart.

21
Bodily
ſtitut

In his directions on the firſt of theſe heads, he ſeems extremely anxious to prevent parents and others in whoſe hands children are placed, from injuring them by ill-directed tenderneſs. Plain fare, ſimple and light cloathing, abſtinence from phyſic and from ſtrong liquors, he earneſtly recommends as the moſt judicious means for preſerving and confirming the health of the child. In all his gratifications let the ſtricteſt moderation be obſerved. If you permit him to indulge pretty freely in ſleep, at leaſt cauſe him to get up at an early hour in the morning. In one thing, however, few parents will be willing to comply with Mr Locke's advice. He not only directs that the child's feet be frequently bathed in cold water; but even expreſſes a wiſh, that his ſhoes were always kept in ſuch a condition as to admit water freely. This he thinks likely to fortify the conſtitution of the body in ſuch a manner, as to render him leſs liable, in the courſe of life, to ſuch diſeaſes as ariſe from any unuſual expoſure to wetneſs or cold, than others whoſe feet have been more carefully kept dry. Though he had proſecuted his ſtudies with a deſign to enter into the profeſſion of phyſic, yet ſo unfavourable an opinion did he entertain of the effects produced by medical preparations on the human conſtitution, that he earneſtly inſiſts on the parent to beware of adminiſtering any of them to his child. From the deſire which Mr Locke diſcovers to have children expoſed to hardſhips, and reſtrained from indulgence, in order to confirm the health and invigorate the conſtitution, we may conjecture him to have been an admirer of that ſevere mode of education which uſually prevails in the earlier periods of the exiſtence of ſociety. He ſeems to have thought, that if a boy be brought up like a Huron or a Spartan, he muſt neceſſarily become robuſt and healthy; without reflecting, that of thoſe children who are ſubjected to ſuch a courſe of education, too great a proportion are unable to ſurvive it: ſuch is the natural delicacy of the human frame.

When he turns his attention to the cultivating of the underſtanding, and the forming of the diſpoſitions, Mr Locke ſtill deſervedly claims the regard of the parent and the preceptor. With a virtuous indignation he reprobates that negligence and folly by which we generally corrupt the heart and ſpoil the temper of children, even in the period of infancy; ſo as to render them incorrigible when they advance farther in life. Their appetites are pampered, all their deſires are gratified; and if we are at any time diſpoſed to refuſe what they aſk, they have an all-powerful engine to compel our compliance with their wiſhes. They aſſail us with tears; and we then yield to their requeſts, however hurtful to themſelves or inconvenient to us. We often ſtudiouſly inſtruct them in vicious tricks, and call forth their evil paſſions. At ſo early an age, their rage or cunning can ſcarcely injure us; and we reflect not that habits of peeviſhneſs and deceit muſt be peculiarly hurtful to themſelves.

But though all the fooliſh deſires of children ought not to be gratified, and though we ſhould carefully avoid leading them into any bad habit; yet it is not neceſſary nor prudent to treat them with harſhneſs or ſeverity. Let them be formed to obedience from their earlieſt years: let them be accuſtomed to ſubmit implicitly to the direction of thoſe on whom they depend. But beware of ſouring their temper and depreſſing their ſpirits by harſhneſs: and on the other hand, remember, that it is no leſs improper to give the boy a habit of neglecting his duty except when he is allured to it by the hopes of reward. As he advances towards manhood, and attains the uſe of reaſon; you may admit him to greater familiarity, and allow him to follow his own inclinations more than at an earlier period: and if, inſtead of indulging all his freaks in childhood, you have carefully accuſtomed him to obedience and ſubmiſſion, without enforcing theſe by improper means, he will now be able to regulate his conduct with ſome degree of prudence.

But while caution is to be uſed in beſtowing rewards and inflicting puniſhments; ſtill rewards and puniſhments are indiſpenſably neceſſary in the management of the child. Inſpire your boy with a ſenſe of ſhame, and with a generous thirſt for praiſe. Careſs and honour him when he does well; treat him with neglect when he acts amiſs. This conduct will produce much better effects than if you were at one time to chide and beat him; at another, to reward him with a profuſion of ſweetmeats and playthings.

Think not that children are to be taught propriety of conduct by loading their memory with rules, directing them how to act on every particular occaſion. Burden them not with rules, but impreſs them with habits.

Be not deſirous of forming them at too early an age, to all that politeneſs and propriety of manners which you wiſh to diſtinguiſh them when they become men. Let them be taught an eaſy, graceful carriage of body: but give yourſelf no concern, though they now and then blunder againſt the punctilios of good-breeding; time will correct their aukwardneſs.

With regard to that important queſtion, whether children ought to be ſent to a public ſchool, or are likely to be better trained up in a domeſtic education? ſo impoſſible is it for one maſter to extend his attention to a number of boys, and ſo likely is the contagion of vice to be caught among the crowd of a public ſchool, that a private ſeems more favourable than a public education to virtue, and ſcarce leſs favourable to learning.

When you reſolve to give your ſon a domeſtic education, be careful to regulate that domeſtic education in a judicious manner. Keep him at a diſtance from evil example: chooſe the moſt favourable ſeaſons for communicating inſtruction: ſtrictly enforce obedience; but never by blows, except in caſe of obſtinacy which you find otherwiſe incurable. If his engagements in life prevent the parent from ſuperintending and directing his ſon's education perſonally, let him commit him to the care of a virtuous and judicious tutor. Let the tutor be rather a man of experience in the world than of profound learning; for it is more neceſſary that the pupil be formed for conducting himſelf with prudence in the world, and be fortified againſt thoſe temptations to which he will be expoſed when he enters upon active life, than that his head be ſtuffed with Latin and logic.

Here Mr Locke, notwithſtanding that his own mind was ſtored with the treaſures of Grecian and Roman literature, takes occaſion to declare himſelf pretty freely againſt that application to ancient learning, which was then indiſpenſably required in the education of youth. He conſiders languages and philoſophy as rather having a tendency to render the youth unfit for acting a prudent and becoming part in life, than forming for it: and he therefore inſiſts that theſe ſhould be but in a ſubordinate degree the objects of his attention.

Let the tutor encourage the child under his care to a certain degree of familiarity; let the pupil be accuſtomed to give his opinon on matters relative to himſelf: let him be taught juſtice, by finding injuſtice to others prejudicial to himſelf; let him be taught liberality, by finding it advantageous; let him be rendered ſuperior to teazing his parents or tutor with complaints, by finding his complaints unfavourably received. That you may teach him to reſtrain every fooliſh or irregular deſire, be ſure never to indulge his wiſhes, ſave when you find the indulgence proper for him, and convenient for yourſelf. Curioſity, however, is a principle which ought to be induſtriouſly rouſed in the breaſt of the child, and cheriſhed there by meeting always the readieſt gratification. However you may oppoſe the boy's inclinations in other things, yet refuſe him not a proper portion of recreation: let him indulge in play, while he continues to play with keenneſs and activity; but ſuffer him not to loiter about in liſtleſs indolence. To reſtrain your child from fool-hardy courage, point out to him the dangers to which it expoſes him: to raiſe him above timorous cowardice, and inſpire him with manly fortitude; accuſtom him from the earlieſt period of life to an acquaintance with ſuch things as he is moſt likely to be afraid of: ſubject him now and then to pain, and expoſe him to danger; but let ſuch trials be judiciouſly conducted.

Idleneſs or curioſity ſometimes leads children to cruelty in their treatment of ſuch animals as are placed within their power. Dogs, cats, birds, and butterflies, often ſuffer from their inhumanity. But when they ſeem inclined to ſuch cruelty, let them be carefully watched, and let every means be uſed to awake their hearts to generous ſenſibility. Allow them to keep tame birds, dogs, &c. only on condition of their uſing them with tenderneſs. Perhaps this unhappy diſpoſition to cruelty is occaſioned, or at leaſt foſtered, by people's laughing when they behold the impotent efforts of children to do miſchief; and often going ſo far as even to encourage them in maltreating thoſe creatures which are within their reach. We entertain them, too, with ſtories of fighting and battles; and repreſent characters diſtinguiſhed for atrocious acts of inhumanity as great and illuſtrious. But let ſuch practice be carefully refrained from, if you wiſh to inſpire your child with generous and humane ſentiments. Teach him gentleneſs and tenderneſs, not only to brute animals, but alſo to ſervants and companions.

Curioſity is to be rouſed and cheriſhed in the breaſt of the child: but by what means? Anſwer his inquiries readily: though his queſtions be put in aukward language, let not that hinder you from attending to the objects of them. Curioſity is natural to the human mind; and if you repreſs not the curioſity of the child, he will often be moved by its impulſe to the purſuit of knowledge. Let him find his eagerneſs in the purſuit of knowledge, a ſource of applauſe and eſteem. Avoid the folly of thoſe who ſport with the credulity of children, by anſwering their queſtions in a ludicrous or deceitful manner.

You muſt, however, not only liſten with obliging attention to his queſtions, and ſtrive to gratify his curioſity; but even whenever he attempts to reaſon on ſuch ſubjects as are offered to his obſervation, be careful to encourage him: praiſe him if he reaſons with any degree of plauſibility; even if he blunders, beware of ridiculing or laughing at him. With regard to the boy's play-things: while you indulge him freely in innocent diverſions. give him ſuch play-things as may be neceſſary in the amuſements in which he engages, provided they be ſuch as he cannot make himſelf; but it will be ſtill better for him to exerciſe his dexterity and ingenuity in making them himſelf.

After throwing out theſe things concerning the general principles on which education ſhould be carried on, Mr Locke next proceeds to thoſe particular parts of knowledge in which he thinks every young gentleman ought to be inſtructed. In virtue, wiſdom, breeding, and learning, he comprehends all that is neceſſary to enable his pupil to act a reſpectable part in life.

In forming the boy to virtue, the firſt thing to be done, is to inform him of the relation ſubſiſting between human creatures and a ſupreme independent Being, their creator, preſerver, and governor; and to teach him, that obedience and worſhip are due to that Being. But when you inform the child of the exiſtence of an inviſible Being, beware of impreſſing his mind with any notions concerning ſpirits or goblins, which may render him incapable of bearing darkneſs or ſolitude. In infancy our minds are, by the indiſcretion of thoſe about us, generally impreſſed with ſuch prejudices concerning a thouſand frightful forms, ever ready to aſſail or haunt us under the ſhade of night, that we become incapable of manly fortitude during the courſe of life: the ſoldier who will boldly face death in the field of battle, ſhall perhaps tremble and take to flight at the ruſtling of a few leaves, or the grunting of a hog in the dark. But were the imaginations of children not crazed with wild ſtories concerning ſpirits and hobgoblins, darkneſs would be no more alarming to them than light. After informing the child of the exiſtence of a Deity, and teaching him to pray to him; next labour to impreſs his mind with a veneration for truth, and habituate him to a ſtrict adherence to it on every occaſion. Endeavour alſo to render him gentle and good-natured.

The beſt means you can uſe to teach him wiſdom or prudence in conducting himſelf in the ordinary buſineſs and intercourſe of life, is to teach him to deſpiſe the mean ſhifts of cunning. The reſt muſt be learned by actual experience in life.

The decencies of life, comprehended under the word Good Breeding, form no inconſiderable part of a good education. In teaching theſe, two things are to be attended to: Inſpire the youth with a diſpoſition to pleaſe and oblige all with whom he is converſant; next, teach him how to expreſs that diſpoſition in a becoming manner. Let boiſterous roughneſs, haughty contempt of others, cenſoriouſneſs, impertinent raillery, and a ſpirit of contradiction, be baniſhed from his temper and behaviour. At the ſame time, beware of leading him to regard the mere forms of intercourſe as a matter of the higheſt importance. Remember that genuine good-breeding is only an eaſy and graceful way of expreſſing good ſenſe and benevolence in his converſation and deportment.

Mr Locke, when he comes to give his opinion concerning thoſe parts of learning which are proper to be taught a young gentleman, and the manner in which they ought to be communicated, adviſes to initiate the child in the art of reading, without letting him know that he is engaged about a matter of any importance, or learning an accompliſhment which you are ſolicitous that he ſhould acquire. Preſent it to him in the form of an amuſement, or teach him to conſider it as an high honour to be permitted to learn his alphabet; otherwiſe he will turn from it with diſguſt. When by inſinuating arts you have allured him to apply to reading, put into his hands ſuch books as are plain, entertaining, and inſtructive. Inſiſt not on his reading over the bible: inſtead of gaining any advantage from an indiſcriminate

peruſal

peruſal of it at this period of life, he is likely to acquire the moſt confuſed notions of religion, and an indifference for the ſacred volume during the reſt of life; yet it may be highly proper to cauſe him to peruſe ſome of its beautiful hiſtorical paſſages, and to familiarize him with its elegant and ſimple moral precepts. After learning to read his mother-tongue, the boy's attention ought to be next directed to the art of writing. The eaſieſt way to teach him that art, is to get a plate engraved, after the model of any hand which you think moſt proper for his imitation. With this plate get a number of copies caſt with red ink; the letters of theſe the learner may trace with his pen filled with black ink: and he will thus in a ſhort time, and without much trouble to you or himſelf, acquire a decent hand. As drawing is uſeful on many occaſions in life; if the boy be not naturally incapable of acquiring it, he may with great propriety dedicate ſome part of his time and attention to that art.

When the ſcholar has attained a tolerable degree of ſkill in writing, and in reading and ſpeaking his native language, he muſt next begin an acquaintance with other languages. Among theſe, the firſt object of his ſtudy will naturally be the Latin. Yet let none waſte their time in attempting to acquire a knowledge of Latin, but ſuch as are deſigned for ſome of the learned profeſſions, or for the life of a gentleman without a profeſſion. To theſe laſt it may be uſeful; to others it is wholly unſerviceable. But in learning the Latin tongue, a much happier method than burdening and perplexing him with rules of grammar, would be to make him ſpeak it with a tutor who were ſufficiently maſter of it for that purpoſe. Thus might he ſpend that time which is uſually occupied in acquiring this language, in learning ſome other neceſſary branches of education. But if you cannot conveniently have the boy taught the language by the way of converſation, let the introductory books be accompanied with an Engliſh verſion, which he may have eaſy recourſe to for the explanation of the Latin. Never perplex him with grammatical difficulties. Reflect that, at his age, it is impoſſible to enter into the ſpirit of thoſe things. Render every thing as eaſy and pleaſing as poſſible; for the attention will not fail to wander, even though you labour not to render the taſk diſagreeable. Skill in grammar may be uſeful; but it is to thoſe whoſe lives are to be dedicated to the ſtudy of the dead languages: that knowledge which the gentleman and the man of the world may have occaſion to derive from the treaſures contained in the ancient languages, may be acquired without a painful ſtudy of proſody or ſyntax. As the learning of any language is merely learning words; if poſſible, let it be accompanied with the acquiſition of ſome real knowledge of things; ſuch as the nature of plants, animals, &c. their growth and propagation. But if you cannot or will not give your boy a private education, and are ſtill reſolved to ſend him to ſchool, to be whipped through the uſual courſe of Greek and Latin; at leaſt act with ſo much good ſenſe and humanity, as to inſiſt that he be not burdened and tormented with the compoſition of Latin themes and verſes. Neither let his memory be oppreſſed with whole pages and chapters from the claſſics. Such ridiculous exerciſes have no tendency, whatever prejudice may urge to the contrary, to improve him either in the knowledge of languages or of nature.

Mr Locke ſeems to wiſh that the French language, which in his days had attained to higher refinement and a more regular analogy than any of the other modern languages of Europe;—he ſeems to wiſh that the French were learned along with the Latin: and he wiſhes the ſtudy of theſe languages to be accompanied with the ſtudy of arithmetic, geography, hiſtory, and chronology. Let theſe branches of knowledge be communicated to the learner in one of the two languages; and he will thus acquire the language with greater facility. He next points out the advantages of the branches of knowledge which he recommends as proper to be learned together with the languages; but on that head he ſays nothing ſingular. One method which he recommends for facilitating the ſtudy of language is, to put into the youth's hands, as ſoon as he has acquired a tolerable knowledge of chronology, ſome of the moſt entertaining Latin hiſtorians: the intereſting nature of the events which they relate will not fail to command his attention, in ſpite of the difficulty which he muſt find in making out their meaning. The Bible and Tully's Offices will be his beſt guides in the ſtudy of ethics. The law of nature and nations, as well as the civil and political inſtitutions of his country, will form to him an important object, which he ought to ſtudy with the moſt careful attention. Rhetoric and logic, though generally regarded as objects of great importance in a liberal education, can neither of them contribute much, with all their rules and terms, to render him an acute reaſoner or an eloquent ſpeaker; and it is therefore unneceſſary for him to honour them with very particular attention. Tully and Chillingworth will be more beneficial in teaching him to reaſon and to perſuade, than all the treatiſes on rhetoric and logic which he can poſſibly peruſe, or all the lectures on thoſe arts which he can gain opportunities to hear. In every art and every ſcience, practice and experience are infinitely better than rules. Natural philoſophy, as contributing to inſpire the breaſt with warmer ſentiments of devotion, and ſerving alſo to many uſeful purpoſes in life, ought to make a part in the young gentleman's ſtudies. But the humble experimental writers on that ſubject are to be put into his hands in preference to the lofty builders of ſyſtems. As for Greek, our pupil is not to be a profeſſed ſcholar, but a gentleman and a man of the world; and therefore it does not appear neceſſary that Greek ſhould make a part in the ſyſtem of his education. But in none of theſe ſtudies will the pupil ever attain any proficiency, unleſs he be accuſtomed to method and regularity in the proſecution of them. In languages, let him gradually aſcend from what is ſimpleſt to what is moſt difficult: in hiſtory, let him follow the order of time; in philoſophy, that of nature.

Dancing, as contributing to eaſe and gracefulneſs of carriage, ought to make a part in our young gentleman's education. Fencing and riding being faſhionable, cannot well be denied him. As he is likely, in the courſe of life, to have ſome leiſure hours on his hands, and to be ſometimes diſpoſed to active recreation, let him learn ſome mechanical trade, with the exerciſe of which he may agreeably fill up ſome of thoſe hours. If he is to poſſeſs any property, let him not be unſkilled in the management of accounts. Travel, inſtead of being uſeful, appears more likely to be hurtful to the underſtanding and morals of the traveller, unleſs deferred to a later period than that at which young men are uſually ſent out to complete their education by traverſing through foreign countries.

Here Mr Locke concludes his work with obſerving, that he does not offer it to the world as a full or comprehenſive treatiſe on the ſubject of education; but merely as the outlines of what occurred to him as moſt proper to be obſerved in breeding up a young gentleman not intended for any learned profeſſion or mechanical employment, but for acting a reſpectable part in life at the head of a competent hereditary fortune.

23
Remarks.

In conſidering the ſentiments of this reſpectable philoſopher on the ſubject of education, we perceive, that as he was, on the one hand, ſuperior to thoſe prejudices which render us incapable of diſtinguiſhing the defects or abſurdities of any cuſtom or inſtitution which has long prevailed; ſo, on the other hand, he was free from that ſilly vanity which diſpoſes thoſe who are ſubject to its influence to affect novelty and ſingularity of ſentiment on every ſubject which they conſider. Though a member of one of the univerſities, he heſitates not to declare himſelf againſt a very laborious attention to claſſical learning; and his reaſoning is, through the whole of his treatiſe, rather plain and ſolid than ſubtle or refined.

Yet, however we reſpect the ſoundneſs of his underſtanding or the benevolence of his intentions, we cannot avoid obſerving, that his opinions are not always ſuch as experience juſtifies. He had no doubt taken notice of ſome inſtances in which the too great anxiety of parents about the preſervation of their children's health was the very means of rendering their conſtitution feeble and tender through the courſe of life; and from that circumſtance might be led to propoſe thoſe expedients which he mentions for preſerving the health and ſtrengthening the conſtitution of children. But a little more obſervation or inquiry would have eaſily convinced him, that ſome of his expedients, inſtead of ſtrengthening the child's conſtitution, would in all probability ſhorten his days.

He had perhaps ſeen ſome of the heroes of claſſical literature, who were familiar with Demoſthenes and Cicero, and had Homer and Virgil at their fingers ends,—he had ſeen ſome of thoſe gentlemen ſo overloaded with their cargo of Greek and Latin as to be unfit for the ordinary buſineſs and intercourſe of life; and ſuch inſtances might tempt him to forget the advantages which he himſelf, and a long ſeries of philoſophers, patriots, and ſtateſmen, with whoſe names the annals of our country are adorned, had derived from a regular claſſical education. But as we are afterwards to deliver our own ſentiments on this ſubject, we will not here extend our obſervations on Mr Locke to a greater length.

24
Rouſſeau

An author more diſtinguiſhed than Mr Locke, for tenderneſs of ſentiment, ſingularity, eloquence, and whim, has preſented the public with a work on the ſubject of education, in which he, with unexampled boldneſs, inveighs againſt all the eſtabliſhed modes, as well as reprobates whatever had been advanced by former writers on the ſubject; and, at the ſame time, delineates a plan of education which he would perſuade us is infinitely ſuperior to thoſe which he explodes. This writer is the amiable and pathetic Rouſſeau: And tho' he be often vain, paradoxical, and whimſical; yet the charm of genius and ſentiment which adorns his writings will at leaſt engage our attention while he unfolds his opinions.

man
men
child
infan

He ſets out with obſerving, that our buſineſs in the bringing up of children ſhould be, to ſecond and to call forth nature; and that, inſtead of this, we almoſt always oppoſe her intentions and operations. As ſoon as the child ſees the light, he is wrapped in ſwathing bands. His limbs are thus reſtrained from that free motion which is neceſſary to their growth and vigour; and even the internal parts of his frame are rendered incapable of their proper functions. Mothers are too proud or indolent, or too fond of gaiety and diſſipation, to ſubmit to the taſk of nurſing their own children. The poor infants are committed to ſome hireling nurſe, who not being attached to them by natural affection, treats them with negligence or inhumanity. But is that mother capable of any delicacy of ſentiment, who can permit another to ſuckle her child, and to ſhare with her, or perhaps wholly ſupplant her, in the filial affection of that child?

Again, when parents undertake the care of their infant children, they often injure them by miſtaken tenderneſs. They pamper them with delicate meats, cover them with warm clothes, and anxiouſly keep them at a diſtance from all that has the appearance of danger: not attending to the economy of nature, who ſubjects us in infancy to a long train of epidemical diſtempers, and expoſes us during the ſame period to innumerable dangers; the deſign of which doubtleſs is, to teach us a prudent concern for our own ſafety, and to ſtrengthen and confirm our conſtitutions.

A child no ſooner enters into life, than it begins to cry; and during a great part of infancy continues frequently to ſhed tears. We either attempt to ſoothe it into good nature, or ſeek to ſilence it by harſher means; and it is thus we infuſe into its infant mind thoſe evil paſſions which we afterwards preſume to impute to nature.

As the mother generally diſdains to nurſe her own child, ſo the father is ſeldom at leiſure to take any ſhare in the management of his education: he is put into the hands of a tutor. But that tutor whoſe time and attention can be purchaſed for money is unworthy of the charge. Either be yourſelf your ſon's preceptor, or gain a friend whoſe friendſhip to you ſhall be his ſole motive to undertake the taſk.

me
mil
ring
cy.

After a few preliminary obſervations to the above purport, our author introduces his Emilius; in whoſe education he delineates that plan which he prefers. The preceptor whom he would aſſign Emilius muſt be young; and muſt dedicate his attention to Emilius alone, from the time when his pupil enters the world till he attain the full age of manhood. Emilius, to receive the full benefit of his preceptor's ſyſtem of education, and to afford full ſcope to it, muſt poſſeſs a genius of the middle claſs; no prodigy of parts, nor ſingularly dull; he muſt have been born to affluent circumſtances and an elevated rank in life. His preceptor is inveſted with the rights, and takes upon him the obligations, of both father and mother. Emilius is, when put into

into the hands of his preceptor, a well-ſhaped, vigorous, and healthy child The firſt care of the preceptor is to provide him with a nurſe, who, as he is new born, muſt be newly delivered : it is of ſtill higher importance that ſhe be clean, healthy, virtuous, and of mild diſpoſitions. While ſuckling her charge, ſhe ſhall feed plentifully, chiefly on a vegetable diet. The child muſt be frequently bathed, in cold water if poſſible ; if you begin with warm, however, uſe it by degrees colder and colder, till at length he is able to bear it entirely cold. He is not to be wrapped in ſwaddling-clothes or rollers, or bound with ſtay-bands ; but put in good warm blankets and in a roomy cradle : Let him ſtretch and move his limbs at freedom, and crawl about on hands and knees at his pleaſure. The greateſt care muſt now be taken to prevent the child from contracting any habits whatever : Suffer him not to uſe one arm more than another, or to eat or ſleep at ſtated hours. Prepare him for the enjoyment of liberty, by preſerving to him the exerciſe of his natural abilities, unfettered by any artificial habits.

As ſoon as the child begins to diſtinguiſh objects, let his education begin. Some objects are naturally agreeable, others frightful. Accuſtom him to look upon any object that may come in his way without being affrighted. Children are at firſt ignorant of local relations, and learn to diſtinguiſh them only by experience ; and while Emilius is yet an infant, incapable of ſpeaking or walking, he may be aſſiſted in acquiring the knowledge of theſe.

In his feeble helpleſs condition, the child muſt feel many wants and much uneaſineſs ; tears are the language which nature has given him to make known his diſtreſſes and wants. When the child cries, it would be much more prudent and humane to examine what he ſuffers or ſtands in need of, than, as is uſually done, to rock or ſing him aſleep ; or, when theſe means ſucceed not, to threaten or uſe him brutally.

In managing children, as nature has endowed them with no ſuperfluous powers, we ought not to confine them from the free uſe of thoſe which they are able to exert. It is our duty to ſupply their deficiency both of mental and bodily powers ; but while we are ready to adminiſter on every occaſion to their real wants, we muſt beware of gratifying their caprice or unreaſonable humours. In order to diſtinguiſh between their natural and fantaſtic wants, we muſt ſtudy the language and ſigns by which they expreſs their wiſhes and emotions. Though crying be the means which nature has given infants to enable them to procure relief or aſſiſtance, yet when they cry they are not always in need of either. They often cry from obſtinacy or habits of peeviſhneſs. But if, inſtead of attempting to ſoothe them by diverting their attention to other objects, we would on ſuch occaſions entirely neglect them, they would ſoon ceaſe to indulge in ſuch fits of crying.

When children begin to ſpeak, we are uſually anxious about their language and articulation, and are every moment correcting their blunders. But inſtead of hoping to teach them purity or correctneſs of ſpeech by ſuch means as theſe, let us be careful to ſpeak eaſily and correctly before them, and allow them to expreſs themſelves in the beſt manner they can. By ſuch means we will be much more likely to obtain our wiſhes in this matter. When they ſpeak, let us not liſten with ſuch ſolicitude as to relieve them from the neceſſity of uſing an open diſtinct articulation.

When the child attains the power of expreſſing himſelf in artificial language, he may then be conſidered as having reached the ſecond period of infancy. He needs not now to make known his wants by tears, and ſhould therefore be diſcouraged from the uſe of them. Let his tears be entirely neglected. He now begins to run about, and you are anxious to prevent him from hurting himſelf ; but your anxiety can only render him peeviſh or timid. Remove him from any very alarming danger, and then ſuffer him to run about at his pleaſure. He will now and then bleed, and hurt himſelf ; but he will become bold, lively, and cheerful.

27
Subjection to authority.

In regulating the conduct of your child, let him know that he is dependant ; but require not of him an implicit ſubmiſſion to your will. Let his unreaſonable deſires be oppoſed only by his natural inability to gratify them, or by the inconveniences attending the gratification. When he aſks what is neceſſary or reaſonable, let him inſtantly obtain it ; when he aſks what is unreaſonable or improper, lend a deaf ear to all his intreaties and demands. Beware of teaching him to eſtabliſh his authority over you by means of the forms of politeneſs. A child will ſcarce take the trouble to addreſs you with *If you pleaſe*, unleſs he has been made to regard theſe as a ſet of magic ſyllables, by the uſe of which he may ſubject every perſon to his will. His *If you pleaſe* then means *I pleaſe ; pray*, with him, ſtands for *do*. Though you put in his mouth the words of humility, his tone and air are thoſe of authority that *will* be obeyed.

Sacrifice not the preſent happineſs of your child for the ſake of any diſtant advantage.

Be not too anxious to guard him againſt natural evil. The liberty which he enjoys while he is now and then permitted to expoſe himſelf to blows, or cold, or wetneſs, is more than a ſufficient compenſation for all that he thus ſuffers.

28
Ideas of moral obligation.

Seek not to impreſs him with ideas of *duty* or *obligation*. Till children reach the years of diſcretion, they are incapaple of any notions of the diſtinctions of morality. Avoid therefore even the uſe of the terms by which theſe are expreſſed in their hearing. While they continue to be affected only by ſenſible objects, ſeek not to extend their ideas beyond the ſphere of ſenſation. Try all the powers of language, uſe the plaineſt and moſt familiar methods you can contrive ; you ſhall ſtill be unable to give the boy at this age any juſt ideas of the diſtinction between right and wrong. He may readily conceive, that for one ſet of actions you will puniſh him, and that by another he will obtain your approbation ; but farther than this his ideas of *right* and *wrong*, of *virtue* and *vice*, cannot yet be carried.

The powers of the human mind are gradually unfolded. At firſt, the infant is capable only of perception ; by and by, his inſtincts and paſſions begin to exert their force ; at length, as he advances towards manhood, reaſon begins to act, and he becomes able to feel the beauty of virtue and the deformity of vice.

But though you ſeek not to regulate his conduct by by notions of *duty*, yet let him feel the yoke of neceſſity. Let him know, that as he is weaker than you, he muſt not, therefore, expect that you ſhould be ſubject to his will; and that, as he has neither ſkill nor ſtrength to control the laws of nature, and make every object around him bend to his pleaſure, he cannot hope to obtain the gratification of all his wiſhes. Thus you teach him virtue before he knows what virtue is; and call forth his reaſon without miſleading or perverting it. Let him feel his impotence; but forbid him not to think, that if he had power there would be no reaſon why he might not at pleaſure even turn the world upſide down.

Hitherto you have given your pupil no verbal inſtructions, nor muſt you yet attempt to inſtruct him by any other means than experience; let all his knowledge be literally of his own acquiſition.

Let not the parent who has obſerved the conduct of children brought up in the uſual way be afraid that, if his child ſhould be treated like our pupil, he would become ſtupid and vicious. Nature ſends not human beings into the world with a prediſpoſition to vice: we ſow the ſeeds of it in the infant heart; and by our abſurd modes of treatment, we alſo enfeeble and pervert the powers of the underſtanding.

But from the hour of his birth till he attain the age of twelve, the education of Emilius ſhall be purely negative. Could we but bring him up healthy and robuſt, and entirely ignorant, till that period, the eyes of his underſtanding would then be open to every leſſon: free from the influence of habit and prejudice, his paſſions would not then oppoſe us; and we might render him the wiſeſt and moſt virtuous of men. If we can but loſe time, if we can but advance without receiving any impreſſions whatever, our gains are unſpeakable. Nature gives the powers of every mind ſome particular direction: but that particular bias, impreſſed by the hand of nature, cannot be diſtinguiſhed before the period we have mentioned; and if you counteract nature, inſtead of ſeconding her views, the conſequences cannot but be highly unfavourable both to the heart and the underſtanding of your pupil.

Perhaps, in the midſt of ſociety, it may be difficult to bring up our pupil without giving him ſome idea of the relations between man and man, and of the morality of human actions. Let that, however, be deferred as long as poſſible.

Were Emilius to witneſs a ſcene of anger, and to aſk the cauſe of the appearances which he beheld, he ſhould be told that the perſons were affected with a fit of ſudden illneſs. We might thus perhaps prevent the unhappy effects of ſuch an example.

The firſt moral notions which ſhould be communicated to the child are thoſe of property. To communicate the ideas of property to our pupil, we will direct him to take poſſeſſion of ſomething; for inſtance, of a piece of ground belonging to ſome other perſon, and in a ſtate of cultivation. Let him cultivate this ſpot of ground anew, ſow it with ſeeds, and look eagerly forward to the time of harveſt in the hopes of reaping the fruit of his labours. In the mean time, let the proprietor of the ground take notice of what is done, deſtroy your pupil's riſing crop, and complain of the injuſtice done him. While the boy laments his loſs and the diſappointment of his hopes, in all the bitterneſs of grief, let the proprietor of the ground ſtill inſiſt on the injury done him, and complain of what he ſuffers by the purpoſe for which he himſelf had cultivated and ſown the ground being fruſtrated. Our pupil, now ſenſible of the reaſonableneſs of the other's claims, will deſiſt from his lamentations, and only beg to have ſome other ſpot aſſigned him which he may cultivate at his pleaſure without offending any perſon. This he will juſtly conſider as his own property, to the productions of which raiſed by his own labour he has an excluſive right, and in the occupying of which none ought to moleſt him. In ſome ſuch manner as this may the nature of property, the idea of which eaſily refers in this inſtance to the firſt occupier, and afterwards the exchange of property, be explained to him.

Another inſtance of the manner in which the pupil is now to be managed may not be improper in this place. He is poſſibly ſo rude and boiſterous as to ſpoil or break whatever is within his reach. Be not angry with him, however, if he break the utenſils which he has conſtant need of; be in no haſte to ſupply him with others in their room; let other things be removed out of his way: if he break the windows of his apartment, let him be expoſed night and day to the cold; complain not of the inconvenience yourſelf, but order matters ſo that he may feel it. After ſome time, let them be mended up; and if he break them again, change your method. Tell him calmly, "Theſe windows are mine; I took care to have them put there; and I will prevent their being again broken, by confining you in a dark room." Let all his endeavours to avoid this prove ineffectual. Let him be actually confined, and be liberated only on propoſing and agreeing to the condition of breaking no more windows. When he propoſes this condition, be ready to liſten to him; obſerve that it is well thought on, and that it is a pity he did not think of it ſooner. Conſider this engagement between you as ſacred; treat him as before, and you cannot fail to attain the end in view.

The moral world now opens to us: But no ſooner are we able to diſtinguiſh between right and wrong, than we become deſirous to conceal thoſe inſtances in which we act wrong. Lying is therefore a vice of which your pupil is now apt to be guilty: you cannot always prevent, but you can puniſh; but let the puniſhments which you inflict appear to the child only the natural conſequences of his conduct. If he is in any inſtance convicted of a lie, let his aſſertions no longer gain credit. By this means, ſooner than by precepts, or any other ſpecies of puniſhment, will you be able to reclaim him from the habit of lying.

The methods generally taken to render children virtuous are prepoſterous and fooliſh. To render them generous and charitable, we give them money, and bid them beſtow it in alms, while we ourſelves give nothing; but the parent or maſter, and not the child, ſhould beſtow the alms. Example might produce the wiſhed-for effect. Beſides, children are ſtrangers to the value of money. A gingerbread cake is more to them than an hundred guineas. Though you teach them to give away money, till you perſuade them to part readily with thoſe things which they value moſt, you do not inſpire them with generoſity. Would you make them liberal by ſhowing them that the moſt liberal is always beſt provided for? this is to teach covetouſneſs, not liberality. Example is the only means by which you can, at this period, hope to teach your pupil any of the virtues.

The only leſſon of morality that can with any propriety be inculcated on children, is to injure no perſon. Even the poſitive precept of doing good, muſt be conſidered as ſubordinate to this negative one of doing no harm. The moſt virtuous and the moſt exalted of characters, is the man who does the leaſt harm to his fellow-creatures.

In a public education, it will be neceſſary to attempt the communication of moral inſtruction at an earlier period than in a private one. In a private education, it will always be beſt to allow the moral powers of children to ripen as much as poſſible before you endeavour to inform and direct them by precepts.

There is an inequality among geniuſes; and fond mothers and fathers may be diſpoſed to plead for exceptions in favour of ſuch of their children as they view with a partial eye. "This boy's mind is more capacious, his powers are riper, than thoſe of others." But however great the ſeeming diſparity of geniuſes may be, it is at bottom but inconſiderable. Let the age of children be therefore regarded as a common meaſure by which their treatment is to be regulated.

However quick and tenacious the memories of children may ſeem, they can derive little advantage from the exertions of memory till ſuch time as judgment begins to act. All the knowledge that they acquire in the courſe of the uſual ſyſtem of education, is merely the knowledge of words. The languages, geography, chronology, in ſhort all that they are taught, and called to diſplay ſo oſtentatiouſly at this period of life, ſerve no other purpoſe than to fill their minds with words.

29 H y, he far er to bout in- the ds of s.

Hiſtory is eſteemed a proper thing to be put into the hands of children. But except you wiſh to confine their attention to the external and phyſical actions, it is almoſt nothing they can acquire by the peruſal of it. And if diveſted of the moral diſtinctions of actions, of the workings of the paſſions, and the complication of intereſts, what is there to render hiſtory entertaining? We may indeed eaſily teach them to repeat the words *kings*, *emperors*, *wars*, *conqueſts*, *revolutions*, *laws*: but of the things which you uſe theſe words to denote, you will find they are hitherto incapable of forming any clear ideas.

But the mere knowledge of words is not ſcience; make your pupil acquainted with things, and he will not fail to acquire their names. Emilius muſt never be ſet to get any compoſition by heart, not even fables: be careful to place before him thoſe ſcenes and objects, the images of which it may be uſeful for him to have impreſſed on his memory; but by no other means ſeek to aſſiſt him to improve that faculty.

Emilius ſhall not even learn to read till he attain the age of twelve: for, before that period, it can be of no benefit to him; and the labour would only make him unhappy during that period of life which is naturally the golden part of our days. But when he has attained the proper age, matters ſhall be ſo ordered, that he ſhall find his ignorance of letters an inconvenience. A card ſhall be ſent him, which being unable to read, he will apply to ſome of thoſe about him. They may be unwilling to oblige him, or otherwiſe engaged. If, at length, it is read to him, that may be when it is now too late to take advantage of ſome agreeable invitation which it contained. This may be two or three times repeated. At length he becomes eager to learn to read; and accompliſhes that almoſt without aſſiſtance.

The principle on which we proceed, is to leave the pupil almoſt wholly under his own direction, ſeemingly at leaſt; to lead him to acquire new accompliſhments, ſolely from the deſire of increaſing his powers, and extending his influence; and humbly to follow nature, not to force her.

As we are deſirous of cultivating his underſtanding, the means which we employ for that purpoſe is, to cultivate thoſe abilities on which it depends; he is always active and in motion. Let us firſt make him a man in point of health and vigour, and he will ſoon become a man in underſtanding.

By our conſtant attention to the welfare of children, we render it unneceſſary for them to attend to it themſelves. What occaſion has your ſon or pupil to obſerve whether the aſpect of the ſky threaten rain, when he knows that you will take care to have him ſheltered from a ſhower? or to regulate the length of his excurſions, when he is ſure that you will not ſuffer him to loſe his dinner?

While matters are ſo ordered that Emilius thinks himſelf ſubject only to his own will, though all his motions are regulated according to your pleaſure; inſtead of becoming fantaſtic and capricious, he inſenſibly acquires the habit of keeping utility in view in all his actions.

The firſt objects which engage the attention of children are the appearances of the material world around them: our firſt ſtudy is a kind of experimental philoſophy; our inſtruments and inſtructors are our hands, our feet, and our eyes. By exerciſing theſe bodily organs, the boy will acquire more real knowledge even in the period of childhood, than if we ſhould dedicate nine-tenths of his time to books, from the age of ſix to ſixty. All who have examined, with any ſagacity, the characters, circumſtances, and manners of the ancients, have agreed in attributing to their gymnaſtic exerciſes that ſuperior ſtrength of body and mind which renders them objects of admiration to the moderns.

Our pupil's clothes cannot be too light and eaſy. If tight and cloſe, they fetter and confine his joints and limbs, and likewiſe obſtruct the circulation of the blood; if accuſtomed to warm clothing, he will ſoon become incapable of bearing cold.

30 Expoſure and exerciſe.

In every thing let him be habituated to what is plain and hardy. Let his bed be coarſe and hard, his clothes plain, his fare ſimple. Infants muſt be freely indulged in ſleep: but as Emilius is now advanced beyond infancy, he muſt be accuſtomed at times to go to bed late and get up early, to be ſometimes haſtily waked from ſleep; and thus to prepare himſelf for what he may afterwards have occaſion to ſubmit to in the courſe of life.

As this period is in a particular manner that of exerciſe, and Emilius is encouraged to take as much exerciſe as he chooſes; we muſt endeavour to prompt, but without ſeeming to direct him to ſuch as are moſt proper. Swimming, though not generally attended to, is yet one of the firſt which a boy ought to learn. It may, in many occaſions in life, be of the greateſt advantage, by enabling us to ſave our own life or the life of others. Emilius ſhall be taught to ſwim; he ſhall be taught whatever can really enlarge the ſphere of his power: "could I teach him to fly in the air, I would make him an eagle; if to bear the fire, a ſalamander."

To exerciſe the ſenſes is not merely to make uſe of them; it is to learn to judge by them. Call not your pupil to exert all his ſtrength on every occaſion; but let him learn to judge of the truth of the information which he receives from one ſenſe, by having recourſe to the evidence of another.

It is not impoſſible to improve the ſenſes to an higher degree of perfection than that which they uſually attain. Blind men generally poſſeſs the ſenſe of touch in a more exquiſite degree, than we who have alſo eyes to guide and inform us. But they acquire this ſuperior delicacy and acuteneſs of ſenſation, only by their finding it neceſſary to have more frequent recourſe to the information of that ſenſe. Here is then a wide field for improvement and agreeable exerciſe to our pupil.

31 Darkneſs and ghoſts.

What a variety of uſeful diverſions might he be led to entertain himſelf with in the courſe of the night. The hours of darkneſs are generally hours of terror, not only to men, but alſo to the brute animals. Even reaſon, knowledge, and courage, are not always ſufficient to render us ſuperior to the terror which darkneſs inſpires.

This timidity is uſually attributed to the tales of ghoſts and goblins with which we are frightened in infancy. But it originates from another cauſe; our ignorance of what is paſſing around us, and our inability to diſtinguiſh objects during that period of darkneſs. The paſſion of fear was implanted by nature in the human breaſt, in order that it might ſerve to put us on our guard againſt danger. But in conſequence of our being ſubject to the influence of that paſſion, when we are ignorant of what ſurrounds us, imagination calls up dangers on all hands. And ſuch is the cauſe from which our terror in darkneſs naturally ariſes.

But the only way to free our pupil from this tyranny of imagination, is to oppoſe to it the power of habit. A bricklayer or tyler is never giddy on looking down from the roofs of houſes. Neither will our pupil be alarmed by the terrors of darkneſs, if he be accuſtomed to go frequently abroad under night. It is eaſy to contrive a number of little amuſements, the agreeableneſs of which may, for a time, overcome our pupil's averſion for darkneſs; and thus may a habit be at length impreſſed.

Let us give yet another inſtance of the means by which children may be led to do what we wiſh, without our impoſing any reſtraint on their will. Suppoſe Emilius is lazy and inactive, and we wiſh to make him learn to run. When walking out with the young ſluggard after dinner, I would ſometimes put a couple of his favourite cakes in my pocket: of theſe each of us ſhould eat one in the courſe of our walk. After ſome time I would ſhow him I had put a third cake in my pocket. This he would not fail to aſk after finiſhing his own: no, ſays I, I can eat it myſelf, or we will divide it;—or ſtay, we had better let theſe two little boys there run a race for it. Accordingly I propoſe the race to the boys; who readily accept the conditions, and one of them carries off the prize. After ſeeing this ſeveral times repeated, Emilius begins to think himſelf qualified to obtain the third cake as well as any of the little boys, and to look upon running as an accompliſhment of ſome conſequence. He ſeeks an opportunity of being permitted to enter the liſts. He runs; and after being two or three times outſtripped, is at length ſucceſsful, and in a ſhort time attains an undoubted ſuperiority.

32 Drawi

As children naturally imitate almoſt whatever they behold, they are often diſpoſed to attempt drawing. In this our pupil might be indulged, not merely for the ſake of the art, but to give him a ſteady hand and a good eye. But he ſhould draw from nature, not from other drawings or from prints. Were he to draw the likeneſs of a horſe, he ſhould look at the animal: if to attempt a repreſentation of a houſe, he ſhould view the houſe itſelf. In this method he will, no doubt, ſcratch for a long time without producing any likeneſs: but he will acquire what we propoſed as the ends of his attempting to draw; namely, ſteadineſs of hand and juſtneſs of ſight, by this method, ſooner than by any others.

33 Geome

Geometry, when taught in the uſual way, is certainly above the capacity of children; they cannot go along with us in our reaſonings: Yet they are not totally incapable of acquiring even this difficult ſcience; if, when they are proſecuting their amuſements, you lead them inſenſibly to obſerve the properties of the circle, the triangle, and the ſquare, and place them now and then in circumſtances when they may have occaſion to apply their knowledge of theſe to real uſes in life.

A child has been taught the various relations between the outlines, ſurfaces, and contents of bodies, by having cakes ſet before him, cut into all manner of regular ſolids; by which means he was led to maſter the whole ſcience of Archimedes, by ſtudying which form contained the greateſt quantity.

There is a period between infancy and the age of puberty at which the growth and improvement of our faculties exceed the increaſe of our deſires. About 12 or 13, when the appetite for the ſex has not yet begun to make itſelf felt, when unnatural wants are yet unknown, no falſe appetites yet acquired; at that period, though weak as a man, as a child the youth is ſtrong.

This interval, when the individual is able to effect more than is neceſſary for the gratification of his wiſhes, contains the moſt precious moments of his life, which ought to be anxiouſly filled up in an uſeful manner. This is the beſt time for employment, for inſtruction, for ſtudy.

Now, let us begin to conſider what is uſeful; for, hitherto, we have only inquired what was neceſſary. In entering on our ſtudies, we will make no account of any but ſuch as inſtinct directs us to purſue: thoſe which the pedants and the pretended philoſopher are im-ation.

impelled to purſue ſolely from the deſire of attracting the admiration of mankind, are unworthy of our notice.

The earth which we inhabit, and the ſun by whoſe beams we are enlightened, are the firſt objects which claim our attention. We will therefore direct the attention of our pupil to the phenomena of nature. We will lead him to the knowledge of geography, not by maps, ſpheres, and globes: we will lead Emilius out on ſome beautiful evening to behold the ſetting ſun. Here we take particular notice of ſuch objects as mark the place of his going down. Next morning we viſit the ſpot to contemplate the riſing of the glorious luminary. After contemplating for ſome time the ſucceſſive appearances which the ſcene before us aſſumes, and making Emilius obſerve the hills and the other ſurrounding objects, I ſtand ſilent a few moments, affecting to be occupied in deep meditation: At laſt I addreſs him thus: “I am thinking, that, when the ſun ſet laſt night, it went down yonder; whereas this morning, you ſee he is riſen on the oppoſite of the plain here before us. What can be the meaning of this?” I ſay nothing more at this time, but rather endeavour to direct his attention to other objects.

This is our firſt leſſon in coſmography.

Our laſt obſervation was made about Midſummer; we will next view the riſing ſun on ſome fine morning in the middle of winter. This ſecond obſervation ſhall be made on the very ſame ſpot which we choſe for the former. When Emilius and I perceive the ſun now emerging above the horizon, we are ſtruck at the change of the place of his riſing.—By ſuch leſſons as theſe may the pupil be gradually taught a real, not a ſeeming, acquaintance with the relative motions of the ſun and the planets and with geography.

4
ts du-
he ſe-
period
ild-

During the firſt period of childhood, the great object of our ſyſtem of education was to ſpend our time as idly as poſſible, in order that we might avoid employing it to an ill purpoſe: but our views are now changed with our pupil's progreſs in life; and we have ſcarce enough of time for the accompliſhment of our neceſſary purſuits. We therefore proceed as quickly as poſſible in making ourſelves acquainted with the nature of the bodies around us, and the laws by which their motions and appearances are regulated. We keep to this ſtudy at preſent, as being neceſſary for the moſt important purpoſes in life, and as being the moſt ſuitable to the preſent ſtate of our pupil's powers. We ſtill begin with the moſt common and obvious phenomena of nature, regarding them as mere facts; and, advancing from theſe, we come to generalize by degrees.

As ſoon as we are ſo far advanced as to be able to give our pupil an idea of what is meant by the word *uſeful*, we have attained a conſiderable influence over his future conduct. On every occaſion after this a frequent queſtion between us will be, Of what uſe is that? This ſhall be the inſtrument by means of which I ſhall now be able to render him abſolutely ſubmiſſive to my wiſhes. However, I will allow him to make uſe of it in his turn, and will be careful not to require of him to do or learn any thing the utility of which he cannot comprehend.

Education.

35
Robinſon Cruſoe.

Books only teach people to talk about what they do not underſtand. Emilius ſhall have as little recourſe as poſſible to books for inſtruction. Yet if we can find a book in which all the natural wants of man are diſplayed in a manner ſuitable to the underſtanding of a child, and in which the means of ſatisfying thoſe wants are gradually diſplayed with the ſame eaſe and ſimplicity; ſuch a book will be worthy of his moſt attentive ſtudy. There is ſuch a book to be found; but it is neither Ariſtotle, nor Pliny, nor Buffon; it is Robinſon Cruſoe. Emilius ſhall have the adventures of Robinſon put into his hands: he ſhall imitate his example; even affect his dreſs; and, like Robinſon, learn to provide for himſelf without the aid of others.

Another employment of Emilius at this period ſhall be, to viſit the ſhops of various artiſans; and when he enters a ſhop, he ſhall never come out without lending a hand to the work, and underſtanding the nature and the reaſon of what he ſees going forward.

Still, however, we are careful to afford not a hint concerning thoſe ſocial relations the nature of which he is not yet able to comprehend.

The value and importance of the various arts are ordinarily eſtimated, not according to their real utility, but by a very injudicious mode of eſtimation: Thoſe which contribute in a particular manner to the gratification of the fantaſtic wiſhes of the rich, are preferred to thoſe which ſupply the indiſpenſable neceſſaries of life. But Emilius ſhall be taught to view them in a different light. Robinſon Cruſoe ſhall teach him to value the ſtock of a petty ironmonger above that of the moſt magnificent toy-ſhop in Europe. Let us eſtabliſh it as a maxim, that we are to lead our pupil to form juſt notions of things for himſelf, not to dictate to him ours. He will eſtimate the works both of nature and art by their relation to his own convenience; and will therefore regard them as more precious than gold—a ſhoemaker or a maſon, as a man of more importance than the moſt celebrated jeweller in Europe.

The intercourſe of the arts conſiſts in the reciprocal exchange of induſtry; that of commerce, in the exchange of commodities; and that of money, in the exchange of bills and caſh. To make our pupil comprehend the nature of theſe, we have now only to generalize and extend to a variety of examples thoſe ideas of the nature of property, and of the exchange of property, which we formerly communicated to him. The nature of money, as bearing only a conventional value, which it derives from the agreement of men to uſe it as a ſign for facilitating commerce, may be now explained to Emilius, and will be eaſily comprehended by him. But go no farther: ſeek not yet to explain to the child in what manner money has given riſe to the numerous chimeras of prejudice and caprice; nor how countries which abound moſt in gold and ſilver, come to be the moſt deſtitute of real wealth.

Still our views are directed to bring up our pupil in ſuch a manner that he may be qualified to occupy any place in the order of ſociety into which even the caprice of fortune can throw him. Let us make him a man; not a ſlave, a lord, or a monarch. How much ſuperior the character of a king of Syracuſe turned ſchoolmaſter at Corinth, of a king of Macedon become a notary at Rome, to an unhappy Tarquin incapable of ſupporting himſelf in a ſtate of independence when expelled from his kingdom!

36 The propriety of making a young man, in whatever ſphere of life, learn a trade.

Whatever be our ſituation in the world, we can contribute nothing but our perſonal abilities to ſociety. To exert them is therefore the indiſpenſable duty of every one who enjoys the advantages of a ſocial ſtate; and to cultivate them in our pupil to the beſt purpoſe, ought to be the great aim of every courſe of education. Emilius has already made himſelf familiar with all the labours of huſbandry; I can therefore bid him cultivate the land which he inherits from his father. But if it ſhould be loſt, what ſhall be his reſource? He ſhall learn a trade, that he may be provided againſt ſuch an accident. And he ſhall not be a politician, a painter, a muſician, or an architect; to gain employment for his talents in any of theſe arts, would coſt him no leſs trouble than to regain his loſt eſtate. He ſhall learn ſome ſimple mechanical art: he will then need only to ſtep into the firſt ſhop he ſees open, to perform his day's labour, and receive his wages.

It may be here proper to take notice of a miſtake into which people generally fall in determining the trade or profeſſion in which they are to place their children. Some accident diſpoſes the child to declare himſelf for a particular employment: the parent regards that as the employment to which his talents are fitted by the deſign of nature; and permits him to embrace it without inquiring whether another would have been more ſuitable or advantageous. But becauſe I am pleaſed with my occupation, I am not on that account neceſſarily qualified for it. Inclinations do not confer abilities. It requires more careful and accurate obſervation than is generally imagined, to diſtinguiſh the particular taſte and genius with which nature has endowed the mind of a child. We view him careleſsly, and of conſequence we are apt to miſtake caſual inclination for original diſpoſition.

But Emilius needs not now to heſitate about the occupation which he is to chooſe. It is to be ſome mechanical employment. All the diſtinction we have now to make is, to prefer one that is cleanly and not likely to be injurious to his health. We ſhall make choice of that of a joiner. We cannot dedicate all our time to the trade; but at leaſt for two days in the week we will employ ourſelves in learning our trade. We will have no workſhop erected for our convenience, nor will we have a joiner to wait on us in order to give us the neceſſary inſtructions: but for the two days in every week which we dedicate to the purpoſe of learning a trade, we will go to our maſter's workſhop; we will riſe before him in the morning; work according to his orders; eat at his table; and, after doing ourſelves the honour of ſupping with his family, return to our own hard mattreſſes at night. We ſhall be treated only according to the merit of our performances. Our maſter ſhall find fault with our work when clumſily or negligently done, and be pleaſed with it only when well executed.

37 New ideas ſuggeſted to Emilius by his application to a trade.

While my pupil has been accuſtomed to bodily exerciſe and manual labour, his education has been hitherto conducted in ſuch a manner as to give him inſenſibly a taſte for reflection and meditation. Before he has been long a workman, therefore, he will begin to become more ſenſible of that inequality of ranks which takes place in the order of ſociety. He will therefore take notice of his own dependence, and of my apparent wealth, and will be deſirous to know why I contribute not my perſonal exertions to ſociety. I put off the queſtion with telling him, that I beſtow my ſuperfluous wealth on him and the poor; and will take to make a bench or table every week, that I may not be quite uſeleſs to the public.

38 Progre that E lius ha made b fore th age of berty.

And now when about to enter the moſt critical period of life, when juſt on the brink of that age at which the heart and blood begin to feel the impulſe of a new appetite, what progreſs has our pupil made? what knowledge has he acquired? All his ſcience is merely phyſical. Hitherto he has ſcarce acquired any ideas of moral relations; but the eſſential relations between men and things he has attentively ſtudied. He knows the general qualities of certain bodies; but upon thoſe qualities he has not attempted to reaſon. He has an idea of abſtract ſpace, by means of geometrical figures; of abſtract quantity, by means of algebraical ſigns. He has no deſire to find out the eſſence of things; their relations alone intereſt him. He values nothing external but from its relation to himſelf. The general conſent of mankind, or the caprice of cuſtom, have not yet given any thing a value in his eyes; utility alone is his meaſure of eſtimation. He is laborious, temperate, patient, reſolute, and bold. His imagination never exaggerates danger. He ſcarce knows as yet what death is; but ſhould it approach him, he is prepared to ſubmit to neceſſity. He is virtuous in every thing relative merely to himſelf. He is prepared to become a virtuous member of ſociety as ſoon as he ſhall be made acquainted with the nature of his ſocial relations. He is free from vice and error as far as is poſſible for human nature. He conſiders himſelf as unconnected with others; requires nothing from any perſon, and thinks none has a right to require any thing of him. Sure a youth arrived thus at his fifteenth year has not miſpent the period of his infancy.

39 New m ſures to adopte his edu tion at age.

But now our pupil has reached the moſt critical period of life. He now feels the influence of the paſſion for the ſex; and as ſoon as we become ſubject to the influence of that paſſion, we are no longer unſocial beings. The want of a miſtreſs ſoon produces the want of a friend.

As hitherto we have been careful not to force or anticipate nature, ſo even now our attention muſt be directed to divert the impulſes of that dangerous appetite which now begins to make itſelf felt. To confine the growing paſſions within proper limits, let it be our care to defer as long as poſſible the time at which they begin to diſplay themſelves. For this purpoſe, let us cautiouſly guard our words and actions in the preſence of our pupil. Let us be careful to give him no premature inſtructions.

To excite and cheriſh that ſenſibility of mind which now firſt begins to ſhow itſelf, to extend the care of the youth beyond himſelf, and to intereſt him in the welfare of his fellow creatures; let us be careful to put ſuch objects in his way as have a tendency to call forth and refine the feelings. It is not poſſible for the human heart to ſympathiſe with thoſe who are happier than ourſelves: our ſympathy is moved only by the ſight of miſery. We pity in others only thoſe diſtreſ-

ſes

ſes to which we ourſelves are liable; and our pity for the misfortunes of others is meaſured, not by the quantity of the evil, but by the ſuppoſed ſenſibility of the ſufferer. Let theſe obſervations ſerve to direct us in what manner we are to form the minds of children to humanity and compaſſion.

In proſecution of our deſign, to retard rather than accelerate the growth of the paſſions, let us, when that critical period which we have ſo much feared comes on, ſeclude him as much as poſſible from the intercourſe of ſociety, where ſo many objects appear to inflame the appetites. Let us be circumſpect in the choice of his companions, his employment, his pleaſures. Let all our care be directed to nouriſh his ſenſibility without inflaming his deſires. As his moral powers now begin to unfold themſelves; in cultivating them, let us proceed not by way of lecture, or by directing his attention to books, but ſtill by leading him to acquire experience. At length the period will arrive for communicating to him ſome religious inſtruction. When he knows the nature of his relations to ſociety, he may be informed of his relation to and dependence upon a Deity.

[The creed of the Savoyard curate, containing thoſe ſentiments concerning religious matters which Rouſſeau ſeems to propoſe as the moſt proper to be inculcated on his pupil, comes next in the order of the work; but it does not appear to be ſo cloſely connected with the ſubject of education as to render it proper for us to give a view of it in this place. The ſentiments which he there advances, the reaſonings which he urges, are evidently hoſtile to revealed religion; and the power of his eloquence has adorned ſlight and ſuperficial arguments with ſuch a charm, that even the ſterneſt believer, if not abſolutely deſtitute of taſte and feeling, muſt read them with delight.]

And now, notwithſtanding all my arts, I can no longer keep back that moment which I have endeavoured to defer to as late a period as poſſible. As ſoon as I perceive that it has certainly arrived, I no longer treat Emilius as my pupil or diſciple, but as my friend. His affections are now expanded beyond himſelf; his moral powers have begun to exert themſelves, and have received ſome cultivation; he alſo is become capable of religious ſentiments, and inſtructed in the nature of his relation to a ſupreme Being. Beſides, it is now requiſite, if we conſider the period to which nature has conducted him, that he ſhould no longer be treated as a ſimple child. Hitherto ignorance has been his guardian, but now he muſt be reſtrained by his own good ſenſe.

Now is the time for me to give him in my accounts; to ſhow him in what manner his time and mine have been employed; to acquaint him with his ſtation and mine, with our obligations to each other, his moral relations, the engagements he has entered into with regard to others, the degree of improvement which he has attained, the difficulties he will hereafter meet with, and the means by which he may ſurmount them: —in a word, to point out to him his critical ſituation, and the new perils which ſurround him; and to lay before him all the ſolid reaſons which ſhould engage him to watch with the utmoſt attention over his conduct, and to be cautious of indulging his youthful deſires.

40
Means employed to preſerve the purity of his manners.

Books, ſolitude, idleneſs, a ſedentary and effeminate life, the company of women and young people, are what he muſt carefully avoid at this age. He has learned a trade, he is not unſkilled in agriculture; theſe may be means, but not our only means, for preſerving him from the impulſe of ſenſual deſire. He is now too familiar with theſe: he can exerciſe them without taking the trouble to reflect; and while his hands are buſy, his head may be engaged about ſomething quite different from that in which he is employed. He muſt have ſome new exerciſe which may at once fix his attention and cauſe him to exert his bodily powers. We can find none more ſuitable for this purpoſe than hunting. Now, therefore, Emilius ſhall eagerly join in the chace; and though I do not wiſh him to acquire that cruelty of diſpoſition and ferocity of temper which uſually diſtinguiſh thoſe who dedicate their lives to that barbarous diverſion, yet at preſent it may have the happieſt effects in ſuſpending the influence of the moſt dangerous of paſſions.

When I have now conducted my pupil ſo far; have informed him of what I have done for him, and of the difficulty of his ſituation; and have reſigned my authority into his hands; he is ſo ſenſible of the dangers to which he is expoſed, and of the tender ſolicitude with which I have watched over him, that he ſtill wiſhes to continue under my direction. With ſome feigned difficulty I again reſume the reins. My authority is now eſtabliſhed. I may command obedience; but I endeavour to guard againſt the neceſſity of uſing it in this manner.

To preſerve him from indulging in licentious pleaſures, I let him know that nature has deſigned us for living in a ſtate of marriage, and invite him to go in ſearch of a female companion. I will deſcribe to him the woman whom he is to conſider as worthy of his attachment in the moſt flattering colours. I will array her in ſuch charms, that his heart ſhall be hers before he has once ſeen her. I will even name her: her name ſhall be Sophia. His attachment to this imaginary fair one will preſerve him from all the allurements of unlawful love. Beſides, I take care to inſpire him with ſuch reverence for himſelf, that, notwithſtanding all the fury of his deſires, he will not condeſcend to purſue the enjoyments of debauchery. And though I may now ſometimes entruſt him to his own care, and not ſeek to confine him always under my eye; yet ſtill I will be cautious to watch over his conduct with careful circumſpection.

But as Emilius is to be ſhortly introduced to his Sophia, it may perhaps be proper for us to inquire into her character, and in what manner ſhe has been brought up.

41
Diſtinctive characters of the two ſexes.

There is a natural difference between the two ſexes. The difference in the ſtructure of their bodies ſhows them to be deſtined by nature for different purpoſes in life, and muſt neceſſarily occaſion a diſtinction between their characters. It is vain to aſk which of them merits the pre-eminence: each of them is peculiarly fitted to anſwer the views of nature. Woman is naturally weak and timid, man ſtrong and courageous; the one is a dependent, the other a protector. As the guardian of her virtue, and a reſtraint on her deſires, woman is armed with native modeſty. Reaſon is the guide and governor of man. When a man and a wo-

Education man are united by conjugal vows, a violation of thoſe vows is evidently more criminal in the woman than in the man. The wife ought to be anſwerable for the genuineneſs of the offspring with which ſhe has been entruſted by nature. It is no doubt barbarous and wicked for the huſband to defraud his wife of the only reward which ſhe can receive for the ſevere duties of her ſex: but the guilt of the faithleſs wife is ſtill more atrocious; and the conſequences of her infidelity are ſtill more unhappy.

But if nature has eſtabliſhed an original diſtinction between the characters of the two ſexes; has formed them for different purpoſes, and aſſigned them different duties; it muſt follow, that the education of the one ſex ought to be conducted in a manner different from that of the other. The abilities common to the two ſexes are not equally divided between them; but if that ſhare which nature has diſtributed to woman be ſcantier than what ſhe has beſtowed on man, yet the deficiency is more than compenſated by the qualities peculiar to the female. When the woman confines herſelf to aſſert her proper rights, ſhe has always the advantage over man; when ſhe would uſurp thoſe of the other ſex, the advantage is then invariably againſt her.

But we require not that woman ſhould be brought up in ignorance. Let us conſider the delicacy of her ſex, and the duties which ſhe is deſtined to perform; and to theſe we may accommodate the education which we beſtow upon her. While boys like whatever is attended with motion and noiſe, girls are fond of ſuch decorations as pleaſe the eye. Dolls are the favourite plaything of the ſex in their infant years. This is an original taſte, of the exiſtence of which we have the plaineſt evidence. All therefore that we ought to do is, to trace and bring it under proper regulation. Allow the girl to decorate her baby in whatever manner ſhe pleaſes; while employed about that, ſhe will acquire ſuch ſkill and dexterity in thoſe arts which are peculiar to her ſex, that with ſcarce any difficulty ſhe will acquire needle-work, embroidery, and the art of working lace. Her improvements may even be extended as far as deſigning, an art ſomewhat connected with taſte in dreſs; but there is no reaſon that their ſkill in this art ſhould be carried farther than to the drawing of foliage, fruits, flowers, drapery, and ſuch parts of the art as bear ſome relation to dreſs. Always aſſign reaſons for the employment which you give to young girls, but be ſure you keep them conſtantly buſy. They ought to be accuſtomed to laborious induſtry, as well as to bear the abridgment of their liberty. Uſe every art to prevent their work from becoming diſagreeable to them. For that purpoſe, let the mother be careful to make herſelf agreeable. A girl who loves her mother or her aunt, will work cheerfully by them all day; while ſhe to whom her mother is not dearer than all the world beſides, ſeldom turns out well. Never ſuffer girls, even at their diverſions, to be entirely free from reſtraint, nor allow them to run from one amuſement to another. If you now and then detect your daughter uſing a little artifice to excuſe herſelf from obedience, reflect that artifice is, in a certain degree, natural to the fair ſex; and as every natural inclination, when not abuſed, is upright and good, why ſhould it not be cultivated? In order to give girls proper notions of dreſs, let them be taught to conſider ſplendor and elegance of dreſs as deſigned only to conceal the natural defects of the perſon; and to regard it as the nobleſt triumph, the higheſt praiſe, of beauty, to ſhine with unborrowed luſtre in the ſimpleſt attire. Forbid not young women to acquire thoſe arts which have a tendency to render them agreeable. Why refuſe them the indulgence of learning to dance, to ſing, and to ſtudy ſuch other accompliſhments as afterwards enable them to entertain their huſbands? Girls are more diſpoſed to prattle, and at an earlier age, than boys. We may now and then find it neceſſary to reſtrain their volubility. But the proper queſtion to them on ſuch occaſions is not, as to boys, *Of what uſe is this?* but, *What effects will this produce?* At this early period, when they are yet ſtrangers to the diſtinction between good and evil, and therefore unable to form a juſt judgment concerning any perſon's conduct, we ought to reſtrain them carefully from ſaying what may be diſagreeable to thoſe with whom they converſe.

Girls are no leſs incapable than boys of forming diſtinct notions of religion at an early age. Yet, and even for that very reaſon, religious inſtruction ſhould be communicated to them much ſooner than to the youth of the other ſex. Were we to wait the period when their mental faculties arrive at maturity, we might perhaps loſe the happieſt time, from our inability to make a right diſtinction. Since a woman's conduct is ſubject to public opinion, her belief ought therefore to depend, not on reaſon, but on authority. Every girl ought to follow the religion of her mother, every married woman that of her huſband. They cannot derive a rule of faith from their own inquiry. Let us therefore ſeek, not ſo much to inſtruct them in the reaſons of our belief, as to give them clear diſtinct notions of thoſe articles which we require them to believe. Be more careful to inſtruct her in thoſe doctrines which have a connection with morality, than in thoſe myſterious articles which we are required to believe, though we cannot comprehend them.

Such are the principles on which the education of Emilius's unknown miſtreſs has been conducted.

[Notwithſtanding the merit of that part of this treatiſe in which the author entertains us with the courtſhip between his Emilius and Sophia, it does not appear to be ſo intimately connected with the ſubject of education as to render it proper for us to preſent our readers with a view of it. We therefore paſs over the courtſhip, to give a view of our author's ſentiments concerning the advantages to be derived from travelling, and the manner in which it ought to be directed.]

4 Emili ſuch d miſtre

When Emilius has formed a firm attachment to Sophia, and by his aſſiduities has been ſo fortunate as to gain her affections, his great wiſh now is, to be united with her in the bonds of marriage. But as he is ſtill young, is but imperfectly acquainted with the nature of thoſe duties incumbent on him as a member of a particular ſociety, and is even ignorant of the nature of laws and government, I muſt ſeparate him from his Sophia, and carry him to gain a knowledge of theſe things, and of the character and circumſtances of mankind, in various countries, and under various forms of civil government, by travelling. Much has been ſaid con-

4 Trave

concerning the propriety of ſending young people to travel, in order to complete their education. The multiplicity of books is unfavourable to real knowledge. We read with avidity, and think that by reading we render ourſelves prodigiouſly wiſe. But we impoſe on ourſelves : the knowledge which we acquire from books is a falſe ſpecies of knowledge, that can never render us truly wiſe.

To obtain real knowledge, you muſt obſerve nature with your own eyes, and ſtudy mankind. But to gain this knowledge by travelling, it is not neceſſary that we ſhould traverſe the univerſe. Whoever has ſeen ten Frenchmen, has beheld them all ; and whoever has ſurveyed and compared the circumſtances and manners of ten different nations, may be ſaid to know mankind.

To pretend that no advantages may be derived from travelling, becauſe ſome of thoſe who travel return home without having gained much real improvement, would be highly unreaſonable. Young people who have had a bad education, and are ſent on their travels without any perſon to direct or ſuperintend their conduct, cannot be expected to improve by viſiting foreign countries. But they whom nature has adorned with virtuous diſpoſitions, who have been ſo happy as to receive a good education, and go abroad with a real deſign of improvement, cannot but return with an increaſe of virtue and wiſdom. In this manner ſhall Emilius conduct his travels. To induce him to improve in the moſt attentive manner that time which he ſhould ſpend in travelling, I would let him know, that as he had now attained an age at which it might be proper for him to form ſome determination with regard to the plan of his future life, he ought therefore to look abroad into the world, to view the various orders in ſociety, to examine the various circumſtances of mankind, under different forms of government, and in different parts of the globe ; and to chooſe his country, his ſtation, and his profeſſion. With theſe views ſhould Emilius ſet out on his travels ; and with theſe views, in the courſe of our travels, we ſhould inquire into the origin of ſociety and government, into the nature of thoſe principles by means of which men are united in a ſocial ſtate, into the various circumſtances which have given riſe to ſo many different forms of government, and into the neceſſary relation between government and manners. Our ſtay in the great towns ſhould be but ſhort : for as in them corruption of manners has riſen to a great height, and diſſipation reigns, a long ſtay in any great town might be fatal to the virtuous diſpoſitions of Emilius. Yet his attachment to Sophia would alone be ſufficient to ſave him from the dangers to which his virtue is expoſed. A young man muſt either be in love, or be a debauchee. Inſtances may be pointed out in which virtue has been preſerved without the aid of love ; but to ſuch inſtances I can give little credit.

44
ern
h his
al-, and
riage.

Emilius, however, may now return to his Sophia. His underſtanding is now much more enlightened than when he ſet out on his travels. He is now acquainted with ſeveral forms of government, their advantages and defects, with the characters of ſeveral different nations, and with the effects which difference in circumſtances may be expected to produce on the characters of nations. He has even been ſo fortunate as to get acquainted with ſome perſons of merit in each of the countries which he has viſited. With theſe advantages gained, and with affection unchanged and unabated, he returns to his Sophia. After having made him acquainted with the languages, the natural hiſtory, the government, the arts, cuſtoms, and manners, of ſo many countries, Emilius eagerly informs me that the period which we had deſtined for our travels is now expired. I aſk, What are then his purpoſes for life? He replies, that he is ſatisfied with the circumſtances in which nature has placed him, and with my endeavours to render him independent on fortune, and wiſhes only for his Sophia to be happy. After giving him a few advices for the regulation of his conduct in life, I conduct him to his Sophia, and behold him united with her in marriage. I behold him happy ; with affectionate gratitude he bleſſes me as the author of his happineſs ; and I thus receive the reward of all the pains with which I have conducted his education.

45
Remarks.

Such are the outlines of the ſyſtem of education propoſed by this ſingular and original genius. For originality of thought, affecting ſentiment, enchanting deſcription, and bold vehement eloquence, this book is one of the nobleſt pieces of compoſition, not only in the French language, but even in the whole compaſs of ancient and modern literature. The irregularity of his method, however, renders it a very difficult taſk to give an abridged view of his work. He conducts his pupil, indeed, from infancy to manhood : But inſtead of being barely a ſyſtem of education, his work is beſides a treaſure of moral and philoſophical knowledge. He has choſen a path, and follows it from the bottom to the ſummit of the hill : yet whenever a flower appears on the right or left hand, he eagerly ſteps aſide to pluck it ; and ſometimes, when he has once ſtepped aſide, a new object catches his eye and ſeduces him ſtill farther. Still, however, he returns. His obſervations are in many places looſely thrown together, and many things are introduced, the want of which would by no means have injured either the unity or the regularity of his work. If we attempt to review the principles on which he proceeds in reprobating the prevalent modes of education, and pointing out a new courſe, his primary and leading one ſeems to be, that we ought to watch and ſecond the deſigns of nature, without anticipating her. As the tree bloſſoms, the flowers blow and the fruit ripens each at a certain period ; ſo there is a time fixed in the order of nature for the ſenſitive, another for the intellectual, and another for the moral powers of man to diſplay themſelves. We in vain attempt to teach children to reaſon concerning truth and falſehood, concerning right and wrong, before the proper period arrive : We only confound their notions of things, and load their memories with words without meaning ; and thus prevent both their reaſoning and moral powers from attaining that ſtrength and acuteneſs of which they are naturally capable. He attempts to trace the progreſs of nature, and to mark in what manner ſhe gradually raiſes the human mind to the full uſe of all its faculties. Upon the obſervations which he has made in tracing the gradual progreſs of the powers of the human mind towards maturity, his ſyſtem is founded.

As it is impoſſible to communicate to the blind any juſt ideas of colours, or to the deaf of ſounds ; ſo it muſt be acknowledged, that we cannot poſſibly communicate

municate to children ideas which they have not faculties to comprehend. If they are, for a certain period of life, merely ſenſitive animals, it muſt be folly to treat them during that period as rational and moral beings. But is it a truth that they are, during any part of life, guided ſolely by inſtinct, and capable only of ſenſation? Or, how long is the duration of that period? Has nature unkindly left them to be, till the age of twelve, the prey of appetite and paſſion? So far are the facts of which we have had occaſion to take notice, concerning the hiſtory of infancy and childhood, from leading to ſuch a concluſion, that to us it appears undeniable that children begin to reaſon very ſoon after their entrance into life. When the material world firſt opens on their ſenſes, they are ignorant of the qualities and relations of ſurrounding objects: they know not, for inſtance, whether the candle which they look at be near or at a diſtance; whether the fire with which they are agreeably warmed may alſo affect them with a painful ſenſation. But they remain not long in this ſtate of abſolute ignorance. They ſoon appear to have acquired ſome ideas of the qualities and relative ſituation of bodies. They cannot, however, acquire ſuch ideas, without exerting reaſoning powers in a certain degree. Appearances muſt be compared, and inferences drawn, before knowledge can be gained. It is not ſenſation alone which informs us of the relative diſtances of bodies; nor can ſenſation alone teach us, that the ſame effects which we have formerly obſerved will be again produced by the ſame cauſe.

But if children appear capable of reaſoning at a very early period, they appear alſo to be at a very early period ſubject to the influence of the paſſions: they are angry or pleaſed, merry or ſad, friends or enemies, even while they hang at the breaſt; inſtead of being ſelfiſh, they are naturally liberal and ſocial. And if we obſerve them with candid attention, we will find that the paſſions do not diſplay themſelves ſooner than the moral ſenſe. As nature has wiſely ordered, that we ſhould not ſee, and hear, and feel, without being able to compare and draw inferences from our perceptions; ſo it is a no leſs certain and evident law of nature, that the paſſions no ſooner begin to agitate the human breaſt, than we become able to diſtinguiſh the beauty and the deformity of virtue and vice. The child is not only capable of gratitude and attachment to the perſon who treats him with kindneſs; he is alſo capable of diſtinguiſhing between gratitude and ingratitude, and of viewing each with proper ſentiments. He cries when you refuſe to gratify his deſires; but he boldly inſiſts that he is injured when you uſe him cruelly or unjuſtly. It is indeed impoſſible to attend to the conduct of children during infancy, without being convinced that they are, even then, capable of moral diſtinctions. So little are they acquainted with artificial language, that we and they do not then well underſtand each other. But view their actions; conſider thoſe ſigns by which nature has taught them to expreſs themſelves. Our limbs, our features, and our ſenſes, are not gradually and by piecemeal beſtowed as we advance towards maturity; the infant body comes not into the world mutilated or defective: why then, in point of mental abilities, ſhould we be for a while brutes, without becoming rational and moral beings till the fulneſs of time be accompliſhed? All the differences between the phenomena of manhood and thoſe of infancy and childhood may be accounted for, if we only reflect, that when children come into the world, they are totally unacquainted with all the objects around them; with the appearances of nature, and the inſtitutions of ſociety; that they are ſent into the world in a feeble ſtate, in order that the helpleſſneſs occaſioned by their ignorance may attract the notice and gain the aſſiſtance of thoſe who are able to help them; and that they attain not full ſtrength in the powers either of mind or body, nor a ſufficient acquaintance with nature, with artificial language, and with the arts and inſtitutions of ſociety, till they arrive at manhood.

Even Rouſſeau, notwithſtanding the art with which he lays down his ſyſtem, cannot avoid acknowledging indirectly, on ſeveral occaſions, that our ſocial diſpoſitions, our rational and our moral powers, diſplay themſelves at an earlier period than that at which he wiſhes us to begin the cultivation of them.

But though the great outlines of his ſyſtem be merely theory, unſupported by facts, nay plainly contradictory to facts; yet his obſervations on the impropriety or abſurdity of the prevalent modes of education are almoſt always juſt, and many of the particular directions which he gives for the conducting of education are very judicious. He is often fanciful, and often deviates from the common road, only to ſhow that he is able to walk in a ſeparate path. Yet why ſhould he be oppoſed with ſo much virulence, or branded with ſo many reproachful epithets? His views are liberal and extenſive: his heart ſeems to have glowed with benevolence: his book contains much obſervation of human actions; diſplays an intimate acquaintance with the motives which ſway the human heart; and if not a perfect ſyſtem for education, is yet ſuperior to what any other writers had before done upon the ſubject. It is ſurely true, that we ourſelves often call forth evil paſſions in the breaſts of children, and impreſs them with bad habits: it is no leſs true that we put books in their hands, and load their memory with words, when we ought rather to direct their attention to things, to the phenomena of nature, and the ſimpleſt arts of life. The form in which he has choſen to communicate his ſentiments on the ſubject of education renders the peruſal of it more pleaſing, and his precepts more plain, than they would otherwiſe have been: it is nearly that dramatic form with which we are ſo much delighted in ſome of the nobleſt compoſitions of the ancients.

After viewing the public eſtabliſhments for education which exiſted in ſome of the moſt renowned ſtates of antiquity; and after liſtening to the ſentiments of the experienced Quinctilian, the learned Milton, the judicious Locke, and the bold fanciful Rouſſeau, on this intereſting ſubject; it may now be proper to lay before the reader our own ſentiments concerning the education of youth under a few diſtinct heads.

Indeed, if we were diſpoſed to give abridgments of all the books which have been written on the ſubject of education, or even to hint at all the various modes which have been recommended by teachers or theoriſts, we might ſwell this article to an amazing ſize: Nay, were we only to take notice of the many elegant and ſenſible writers who have of late endeavoured to call the attention of the public to this ſubject, we might extend it to an immoderate length. A Kames, a Prieſtley,

ley, a Knox, a Madame de Sillery, and a Berquin, might well attract and fix our attention. But as, among ſuch a crowd of writers, every thing advanced by each cannot be original; and even of thoſe things which are original only a certain, and that perhaps even a moderate, proportion, can be juſt and judicious; and as they often either borrow from one another, or at leaſt agree in a very friendly manner, though in ſome things they profeſs a determined hoſtility; therefore we ſhall content ourſelves with having taken notice of four of the moſt reſpectable writers on the ſubject.

In preſenting to our readers the reſult of our own obſervations and reflections, we ſhall throw our thoughts nearly under the following heads. The management of children from their birth till they attain the age of five or ſix; from that period till the age of puberty; and from that age till manhood; private and public education; religion and morals; the languages; natural philoſophy; the education of people of rank and fortune; education of perſons deſigned for a mercantile employment, and for the other humbler occupations in active life not particularly connected with literature; education of the female ſex; foreign travel; knowledge of the world; and entrance into active life. We do not pretend to be able to include under theſe heads every thing worthy of notice in the ſubject of education: but under theſe we will be able to comprehend almoſt every thing of importance that has occurred to us on the ſubject.

## I. *On the Management of Infants from the Time of their Birth till they attain the Age of five or ſix.*

The young of no other animal comes into the world in ſo helpleſs a ſtate, or continues ſo long to need aſſiſtance, as that of the human ſpecies. The calf, the lamb, and the kid, are vigorous and lively at the inſtant of their birth; require only, for a very ſhort period, nouriſhment and protection from their reſpective dams; and ſoon attain ſuch degrees of ſtrength and activity as to become entirely independent. The infancy of the oviparous animals is not of longer continuance: And, indeed, whatever department of the animal world we may chooſe to ſurvey, we ſtill find that no ſpecies is ſubject to the ſame ſevere laws as man during the firſt period of life.

46 Man compared to the animals in reſpect to the helpleſſneſs of infancy.

Yet the character and the views of man are ſo very different from thoſe of the other animals, that a more careful attention to theſe may perhaps induce us to regard this ſeeming ſeverity rather as an inſtance of the peculiar kindneſs of the Author of nature. From every obſervation which has been hitherto made on the powers and operations of the inferior animals, we are led to conſider them as guided and actuated chiefly, if not ſolely, by inſtinct, appetite, and ſenſation: their views extend not beyond the preſent moment; nor do they acquire new knowledge or prudence as they advance in life. But the character of the human race is much more exalted. We have alſo powers and organs of ſenſation, inſtincts and appetites; but theſe are the moſt ignoble parts of our nature: our rational faculties and moral powers elevate us above the brutes, and advance us to an alliance with ſuperior beings. Theſe rational faculties and moral powers render us capable of ſocial life, of artificial language, of art, of ſcience, and of religion. Now, were one of the ſpecies to come into the world full grown, poſſeſſed of that bodily ſtrength and vigour which diſtinguiſhes manhood, his ignorance would ſtill render him inadequate to the duties of life; nay, would even render him unable to procure means for his ſubſiſtence: while his manly appearance would deprive him of the compaſſion and benevolent aſſiſtance of others; and his ſtrength and vigour would alſo render him leſs docile and obedient than is neceſſary, in order that he may receive inſtruction in the duties and arts of life. Again, were the period of infancy as ſhort to the human ſpecies as to the other animals; were we to be no longer ſubjected to a parent's authority, or protected by his care, than the bird or the quadruped; we ſhould be expoſed to the dangers and difficulties of the world before we had acquired ſufficient knowledge or prudence to conduct us through them, before we had gained any acquaintance with the ordinary phenomena of nature, or were able to uſe the language or practiſe the arts of men in a ſocial ſtate.

Since, then, it is by the benevolence of nature that we are feeble and helpleſs at our entrance into life, and that our progreſs towards maturity is ſlow and gradual; ſince nature has deſtined us to be for a conſiderable time under the care and authority of our parents; and ſince the manner in which we are managed during that early part of life has ſo important an influence on our future character and conduct: it is therefore incumbent on parents to direct that tenderneſs, which they naturally feel for their offspring, in ſuch a manner as to ſecond the views of nature.

47 Dreſs of infants.

When children come into the world, inſtinct directs them to receive nouriſhment from the breaſt, and to claim attention to their pains and wants by crying. We attend to their ſigns, and ſtrive to render them as eaſy as we can. They are waſhed, clothed with ſuch garments as we think moſt ſuitable, and ſuckled either by their mother or by ſome other woman who is conſidered as proper for the purpoſe. The abſurd mode of ſwaddling up infants in ſuch a manner as to confine them almoſt from all motion, and leave ſcarce a limb at liberty, which has been ſo often exclaimed againſt and repreſented as highly injurious to the ſymmetry and vigour of the human frame, is now almoſt entirely laid aſide; and therefore we need not raiſe our voice againſt it. Still, however, there are certainly too many pins and bandages uſed in the dreſs of infants: theſe are unfavourable to the circulation of the blood, impede the growth, and often occaſion thoſe tears and that peeviſhneſs which we raſhly attribute to the natural ill-humour of the poor creatures. Their dreſs ought to be looſe and cool, ſo as to preſs hard on no joint, no vein nor muſcle; and to leave every limb at liberty. If too heavy and cloſe, it may occaſion too copious a perſpiration, and at the ſame time confine the matter perſpired on the ſurface of the ſkin; than which nothing can be more prejudicial to the health of the child. It may alſo, however, be too thin and cool: for as moderate warmth is neceſſary to the vegetation of plants; ſo it is no leſs neceſſary for promoting the growth of animals: and, therefore, though the dreſs of infants ought to be looſe and eaſy, yet ſtill it ſhould be moderately warm.

48 Nurſes.

It is common for mothers in affluent or even in comfortable circumſtances, to forego the pleaſure of nurſing their own children, that they may avoid the fatigues with which it is attended. This practice has long prevailed in various ages and among various nations: it has been often reprobated with all the warmth of paſſion, and all the vehemence of eloquence, as diſhonourable, inhuman, contradictory to the deſigns of nature. and deſtructive of natural affection: yet ſtill it prevails; fathers and mothers are ſtill equally deaf to the voice of nature and the declamations of philoſophers. Indeed, in a luxurious age, ſuch a practice may be naturally expected to prevail. In ſuch an age, they who are poſſeſſed of opulence generally perſuade themſelves, that, to be happy, is to ſpend their time wholly amid diverſions and amuſements, without deſcending to uſeful induſtry, or troubling themſelves about the ordinary duties of life. Influenced by ſuch notions, they think it proper for them to manage their family affairs, and to nurſe and educate their children, by proxy; nay, to do for themſelves nothing that another can perform for them. It is vain to make a furious oppoſition to theſe abſurd notions; the falſe views of happineſs, the pride and the indolence produced by luxury, will ſtill be too powerful for us. We muſt not hope to perſuade the mother, that to receive the careſſes, to behold the ſmiles, and to mark the bodily and mental powers of her child in their gradual progreſs towards maturity, would be more than a ſufficient compenſation for all the fatigues which ſhe would undergo in nurſing and watching over him in his infant years. We need not mention, that the mutual affection between a mother and her child, which is partly the effect of inſtinct, depends alſo, in no inconſiderable degree, on the child's ſpending the period of infancy in its mother's arms; and that when ſhe ſubſtitutes another in her place, the child naturally transfers its affection to the perſon who performs to it the duties of a mother. We need not urge theſe, nor the various other reaſons which ſeem to recommend to every mother the province of ſuckling her own children, and watching over their infant years; for we will either not be heard, or be liſtened to with contempt. Yet we may venture to ſuggeſt, that if the infant muſt be committed to a ſtranger, ſome degree of prudence may be employed in ſelecting the perſon to whom he is to be entruſted. Her health, her temper, and her manner of ſpeaking, muſt be attended to. A number of other qualifications are alſo to be required in a nurſe: but it is rather the buſineſs of the phyſician to give directions with regard to theſe. If her habit of body be any way unhealthy, the conſtitution of the infant that ſucks her milk cannot but be injured: if her temper be rough or peeviſh, the helpleſs child ſubjected to her power will be often harſhly treated; its ſpirit will be broken, and its temper ſoured: if her pronunciation be inarticulate or too rapid, the child may acquire a bad habit when it firſt begins to exert its vocal organs, which will not be eaſily corrected.

49
Influence of treatment in infancy on the abilities and diſpoſitions.

In the milder ſeaſons of the year, infants ought to be frequently carried abroad. Not only is the open air favourable to health, but the freſhneſs, the beauty, the variety, and the lively colours of the ſcenes of nature, have the happieſt effects on the temper, and have even a tendency to enliven and invigorate the powers of the mind. At this period, the faculties of the underſtanding and the diſpoſitions of the heart generally acquire that particular bias, and thoſe diſtinguiſhing features, which characterize the individual during the future part of his life, as quick or dull, mild or paſſionate; and which, though they be generally attributed to the original conformation of the mind by the hand of nature, yet are owing rather to the circumſtances in which we are placed, and the manner in which we are treated, during the firſt part of life.

When children begin to walk, our fondneſs diſpoſes us to adopt many expedients to aſſiſt them. But theſe ſeem to be improper. It is enough for us to watch over them ſo as to guard them from any danger which they might otherwiſe incur by their firſt attempts to move about. Thoſe who adviſe us not to be too anxious to preſerve children from thoſe ſlight hurts to which they are expoſed from their diſpoſition to activity, before they have acquired ſufficient ſtrength or caution, certainly give a judicious piece of advice which ought to be liſtened to. By being too attentive to them, we teach them to be careleſs of themſelves; by ſeeming to regard every little accident which befals them as a moſt dreadful calamity, we inſpire them with timidity, and prevent them from acquiring manly fortitude. When children begin to liſp out a few words or ſyllables, the pleaſure which we feel at hearing them aim at the uſe of our language, diſpoſes us to liſten to them with ſuch attention as to relieve them from the neceſſity of learning an open diſtinct articulation. Thus we teach them to expreſs themſelves in a rapid, indiſtinct, and heſitating manner, which we often find it difficult, ſometimes even impoſſible, to correct, when they are farther advanced. Would we teach them a plain diſtinct articulation, we ought not only to ſpeak plainly and diſtinctly in their preſence, but alſo to diſregard their queſtions and requeſts, if not expreſſed with all the openneſs and diſtinctneſs of pronunciation of which they are capable.

Man is naturally an imitative animal. Scarce any of our natural diſpoſitions is diſplayed at an earlier period than our diſpoſition to imitation. Childrens firſt amuſements are dramatic performances, imitative of the arts and actions of men. This is one proof among others, that even in infancy our reaſoning faculties begin to diſplay themſelves; for we cannot agree with ſome philoſophers, that children are actuated and guided ſolely by inſtinct in their attempts at imitation.

However that be, the happieſt uſe might be made of this principle which diſcovers itſelf ſo early in the infant mind. Whatever you wiſh the child to acquire, do in his preſence in ſuch a manner as to tempt him to imitate you. Thus, without ſouring his mind by reſtraint during this gay innocent period of life, you may begin even now to cultivate his natural powers. Were it impoſſible at this time to communicate any inſtruction to the boy, without baniſhing that ſprightly gaiety which naturally diſtinguiſhes this happy age, it would be beſt to think only how he might loſe his time in the leaſt diſadvantageous manner. But this is far from being neceſſary. Even now the little creature is diſpoſed to imitation, is capable of emulation, and feels a deſire to pleaſe thoſe whoſe kindneſs has gained his affection. Even now his ſentiments and conduct may be influenced by rewards when prudently beſtowed, and by puniſhments when judiciouſly inflicted. Why then ſhould we heſitate to govern him

Education.

ain by the ſame principles, by which the laws of God and ſociety aſſert their influence on our own ſentiments and conduct? Indeed, the imprudent manner in which children are too generally managed at this early period, would almoſt tempt us to think it impoſſible to inſtruct them, as yet, without injuring both their abilities and diſpoſitions. But this is owing ſolely to the careleſsneſs, ſtupidity, or capricious conduct of thoſe under whoſe care they are placed.

Is implicit obedience to be exacted of children? and at what period of life ſhould we begin to enforce it? As children appear to be capable both of reaſoning and of moral diſtinctions at a very early age; and as they are ſo weak, ſo inexperienced, ſo ignorant of the powers of ſurrounding bodies, and of the language, inſtitutions, and arts of men, as to be incapable of ſupporting or conducting themſelves without direction or aſſiſtance; it ſeems therefore proper that they be required even to ſubmit to authority. To the neceſſity of nature both they and we muſt on many occaſions ſubmit. But if the will of a parent or tutor be always found ſcarce leſs unalterable than the neceſſity of nature, it will always meet with the ſame reſpectful ſubmiſſive reſignation. It may not perhaps be always proper to explain to children the reaſons for which we require their obedience: becauſe, as the range of their ideas is much leſs extenſive than ours; as they do not well underſtand our language, or comprehend our modes of reaſoning; and as they are now and then under the influence of paſſion and caprice, as well as people who are farther advanced in life; we are therefore likely to fail in making them comprehend our reaſons, or in convincing them that they are well-grounded. And as it is proper to exact obedience of children; ſo we ſhould begin to require it as ſoon as they become capable of any conſiderable degree of activity. Yet we muſt not confine them like ſlaves, without allowing them to ſpeak, to look, or to move, but as we give the word. By ſuch treatment we could expect only to render them peeviſh and capricious. It will be enough, at firſt, if we let them know that obedience is to be hexacted; and if we reſtrain them only where, if left at liberty, they would be expoſed to imminent danger.

If then, at ſo early a time of life as before the age of five or ſix, it is poſſible to render children obedient, and to communicate to them inſtruction; what arts, or what learning, ought we to teach them at that period? To give a proper anſwer to this queſtion, is no eaſy matter. It ſeems at firſt difficult to determine, whether we ought yet to initiate them in letters. But as their apprehenſion is now quick, and their memory pretty tenacious, there cannot be a more favourable time for this very purpoſe. As ſoon as they are capable of a diſtinct articulation, and ſeem to poſſeſs any power of attention, we may with the greateſt propriety begin to teach them the alphabet. The moſt artful, alluring methods may be adopted to render the horn-book agreeable; or we may uſe the voice of authority, and command attention for a few minutes; but no harſhneſs, no ſeverity, and ſcarce any reſtraint. At the ſame time, it will be proper to allow the little creatures to run much about in the open air, to exerciſe their limbs, and to cultivate thoſe ſocial diſpoſitions which already begin to appear, by playing with their equals.

Such are the thoughts which have ſuggeſted themſelves to us concerning the management of children in mere infancy. What an amiable little creature would the boy or girl be, who were brought up in a manner not inconſiſtent with the ſpirit of theſe few hints? Behold him healthy and vigorous, mild, ſprightly, and cheerful: He is ſubmiſſive and docile, yet not dull or timid; he appears capable of love, of pity, and of gratitude. His mind is hitherto, however, almoſt wholly uninformed: he is acquainted but with a few of the objects around him; and knows but little of the language, manners, and inſtitutions of men: but he feels the impulſe of an ardent curioſity, and all the powers of his mind are alive and active.

### II. *On the Management of Children between the Age of five or ſix and the Age of puberty.*

At this period it may be proper, not only to exact obedience, and to call the child's attention for a few minutes now and then to thoſe things of which the knowledge is likely to be afterwards uſeful to him; but we may now venture to require of him a regular ſteady application, during a certain portion of his time, to ſuch things as we wiſh him to learn. Before this time it would have been wrong to confine his attention to any particular taſk. The attempt could have produced no other effect than to deſtroy his natural gaiety and cheerfulneſs, to blunt the native quickneſs of his powers of apprehenſion, and to render hateful that which you wiſhed him to acquire. Now, however, the caſe is ſomewhat different: The child is not yet ſenſible of the advantages which he may derive from learning to read, for inſtance; or even though he were able to foreſee all the advantages which he will obtain by ſkill in the art of reading through the courſe of life; yet is it the character of human nature, at every ſtage of life, to be ſo much influenced by preſent objects in preference to future views, that the ſenſe of its utility alone would not be ſufficient to induce him to apply to it. Even at the age of 12, of 20, of 50; nay, in extreme old age, when reaſon is become very perſpicacious, and the paſſions are mortified; ſtill we are unable to regulate our conduct ſolely by views of utility. Nothing could be more abſurd, therefore, than to permit the child to ſpend his time in fooliſh tricks, or in idleneſs, till views of utility ſhould prompt him to ſpend it in a different manner. No; let us begin early to habituate him to application and to the induſtrious exertion of his powers. By endowing him with powers of activity and apprehenſion, and rendering him capable of purſuing with a ſteady eye thoſe objects which attract his deſires, nature plainly points out to us in what manner we ought to cultivate his earlier years. Beſides, we can command his obedience, we can awaken his curioſity, we can rouſe his emulation, we can gain his affection, we can call forth his natural diſpoſition to imitation, and we can influence his mind by the hope of reward and the fear of puniſhment. When we have ſo many means of eſtabliſhing our authority over the mind of the boy without tyranny or uſurpation; it cannot ſurely be difficult, if we are capable of any moderation and prudence, to cultivate his powers by making him begin at this period to give regular application to ſomething that may afterwards be uſeful.

51
A knowledge of words and of things muſt be learnt at the ſame time.

And if the boy muſt now begin to dedicate ſome portion of his time regularly to a certain taſk, what taſk will be moſt ſuitable? Even that to which children are uſually firſt required to apply; continue teaching him to read. Be not afraid that his abilities will ſuffer from an attention to books at ſo early an age. Say not that it is folly to teach him words before he have gained a knowledge of things. It is neceſſary, it is the deſign of nature, that he ſhould be employed in acquiring a knowledge of things, and gaining an acquaintance with the vocal and written ſigns by which we denote them, at the ſame time. Theſe are intimately connected; the one leads to the other. When you view any object, you attempt to give it a name, or ſeek to learn the name by which men have agreed to diſtinguiſh it: in the ſame manner, when the names of ſubſtances or of qualities are communicated to us, we are deſirous of knowing what they ſignify. At the ſame time, ſo imperfect is the knowledge of nature which children can acquire from their own unaſſiſted obſervation, that they muſt have frequent recourſe to our aſſiſtance before they can form any diſtinct notions of thoſe objects and ſcenes which they behold. Indeed language cannot be taught, without teaching that it is merely a ſyſtem of ſigns, and explaining what each particular ſign is deſigned to ſignify. If, therefore, language is not only neceſſary for facilitating the mutual intercourſe of men, but is even uſeful for enabling us to obtain ſome knowledge of external nature, and if the knowledge of language has a natural tendency to advance our knowledge of things; to acquaint ourſelves with it muſt therefore be regarded as an object of the higheſt importance: it muſt alſo be regarded as one of the firſt objects to which we ought to direct the attention of children. But the very ſame reaſons which prove the propriety of making children acquainted with thoſe artificial vocal ſigns which we uſe to expreſs our ideas of things, prove alſo the propriety of teaching them thoſe other ſigns by which we expreſs theſe in writing. It is poſſible indeed, nay it frequently happens, that we attempt to inſtruct children in language in ſo improper a manner as to confound their notions of things, and to prevent their intellectual powers from making that improvement of which they are naturally capable: but it is alſo poſſible to initiate them in the art of reading, and in the knowledge of language, with better auſpices and happier effects. The knowledge of language may be conſidered as the key by which we obtain acceſs to all the ſtores of natural and moral knowledge.

52
Confinement, how far proper

Though we now agree to confine our pupil to a certain taſk, and have determined that his firſt taſk ſhall be to learn to read; yet we do not mean to require that he be confined to this taſk during the greateſt part of the day, or that his attention be ſeriouſly directed to no other object. To ſubject him to too ſevere reſtraint would produce the moſt unfavourable effects on his genius, his temper, and his diſpoſitions. It is in conſequence of the injudicious management of children, while they are ſometimes ſuffered to run riot, and at other times cruelly confined like priſoners or ſlaves; it is in conſequence of this, that we behold ſo many inſtances of peeviſhneſs, caprice, and invincible averſion to all ſerious application at this period of life. But were a due medium obſerved, were reſtraint duly tempered with liberty and indulgence, nothing would be more eaſy than to diſpoſe children to cheerful obedience, and to communicate to them inſtruction at this age. That part of their time which they are left to enjoy at liberty, they naturally dedicate to their little ſports. The favourite ſports of boys are generally active; thoſe of girls, ſedentary. Of each we may take advantage, to prepare them for the future employments of life. However, neither are the amuſements of boys invariably active, nor thoſe of girls always ſedentary; for, as yet, the manners and diſpoſitions of the two ſexes are diſtinguiſhed rather by habit or accident than by nature. The diſpoſition to activity which characterizes children, is no leſs favourable to health than to their improvement in knowledge and prudence; their active ſports have a tendency to promote their growth and add new vigour to their limbs. Perhaps, even at this time, children might be enticed to learn the elements of natural philoſophy and natural hiſtory amid their amuſements and ſports. Birds, butterflies, dogs, and other animals, are now favourite objects of their care; their curioſity is powerfully rouſed by the appearance of any ſtrange object; and many of the ſimpleſt experiments of natural philoſophy are ſo pleaſing, that they cannot fail to attract the attention even of thoſe who are leaſt under the influence of curioſity. Yet it would be improper to inſiſt on their attention to theſe things as a taſk: if we can make them regard them as amuſements, it will be well; if not, we muſt defer them to ſome happier ſeaſon. They might alſo, by proper management, be led to acquire ſome ſkill in the arts. They build mimic houſes, and fill them with ſuitable furniture; they conſtruct little boats, and ſail them; they will fence in little gardens, and cultivate them; and we even ſee them imitate all the labours of the huſbandman. Such is the pleaſure which man naturally feels in exerting his powers, and in acting with deſign. Let us encourage this diſpoſition. Theſe are the moſt ſuitable amuſements in which they can engage.

As the boy's attention to literary objects is ſtill ſuppoſed to be continued, he will ſoon be able to read with ſome correctneſs and facility. It becomes an object of importance, and of no ſmall difficulty, to determine what books are to be put into his hands, and in what manner his literary education is to be conducted. After the child is made acquainted with the names and powers of the letters, with their combination into ſyllables, and with the combination of theſe again into words, ſo that he can read with tolerable facility; it will be proper that the pieces of reading which are put into his hands be ſuch as are deſcriptive of the actions of men, of the ſcenes of external nature, and of the forms and characters of animals. With theſe he is already in ſome degree acquainted: theſe are the objects of his daily attention; beyond them the range of his ideas does not yet extend; and therefore other ſubjects will be likely to render his taſk diſagreeable to him. Beſides, our preſent object is to teach him words: in order to teach him words, we muſt let him know their ſignification; but till he have acquired a very conſiderable knowledge of language, till he have gained a rich fund of ſimple ideas, it will be impoſſible for him to read or to hear with underſtanding on any other ſubject but theſe. And let us not as yet be particularly ducion.

ticularly anxious to communicate to him religious or moral inſtruction, otherwiſe than by our example, and by cauſing him to act in ſuch a manner as we think moſt proper. Our great buſineſs at preſent is, to make him acquainted with our language, and to teach him in what manner we uſe it to expreſs our ideas. By his own obſervation, and by our inſtruction, he will ſoon become capable of comprehending all that we wiſh to communicate: But let us not be too haſty; the boy cannot long view the actions of mankind, and obſerve the economy of the animal and the vegetable world, without becoming capable of receiving both religious and moral inſtruction when judiciouſly communicated.

ng.

As ſoon as the pupil can read and ſpell with tolerable facility, and has acquired ſufficient ſtrength of arm and fingers to hold a pen, it may be proper to initiate him in the art of writing. If this art is not made diſagreeable by the manner in which his application to it is required, he will learn it without difficulty. Childrens natural diſpoſition to imitate, particularly whatever depends on manual operation, renders this art peculiarly eaſy and pleaſing to them when they are not harſhly forced to apply to it, nor ſuffered to get into a habit of performing their taſk with haſte and negligence.

t.

It requires indeed the moſt cautious prudence, the niceſt delicacy, and the moſt artful addreſs, to prevail with children to give a cheerful and attentive application to any appointed taſk. If you are too ſtern and rigid in enforcing application, you may ſeemingly obtain your object: the child ſits motionleſs, and fixes his eye on his book or copy; but his attention you cannot command; his mind is beyond your reach, and can elude your tyranny; it wanders from the preſent objects, and flies with pleaſure to thoſe ſcenes and objects in which it has found delight. Thus you are diſappointed of your purpoſe; and, beſides, inſpire the child with ſuch averſion both to you and to thoſe objects to which you wiſh him to apply, that perhaps at no future period will he view learning otherwiſe than with diſguſt.

5
eneſs.

Again, gentleneſs, and the arts of inſinuation, will not always be ſucceſsful. If you permit the child to apply juſt when he pleaſes; if you liſten readily to all his pretences and excuſes; in ſhort, if you ſeem to conſider learning as a matter not of the higheſt importance, and treat him with kindneſs while he pays but little attention and makes but ſlow progreſs; the conſequences of your behaving to him in this manner will be ſcarce leſs unfavourable than thoſe which attend imprudent and unreaſonable ſeverity. It is, however, ſcarce poſſible to give particular directions how to treat children ſo as to allure them to learning, and at the ſame time to command their ſerious attention. But the prudent and affectionate parent and the judicious tutor will not be always unſucceſsful; ſince there are ſo many circumſtances in the condition of children, and ſo many principles in their nature, which ſubject them to our will.

57
me-
c.

The principles of arithmetic ought to make a part in the boy's education as ſoon as his reaſoning powers appear to have attained ſuch ſtrength and quickneſs that he will be able to comprehend them. Arithmetic affords more exerciſe to the reaſoning powers of the mind than any other of thoſe branches of learning to which we apply in our earlier years: and if the child's attention be directed to it at a proper period, if he be allowed to proceed ſlowly, and if care be taken to make him comprehend fully the principles upon which each particular operation proceeds, it will contribute much to increaſe the ſtrength and the acuteneſs of the powers of his underſtanding.

Education.

Where the learned languages are regarded as an object worthy of attention, the boy is generally initiated in them about this time, or perhaps earlier. We have reſerved to a ſeparate head the arguments which occur to us for and againſt the practice of inſtructing children in the dead languages; and ſhall therefore only obſerve in this place, that the ſtudy of them ought not to engroſs the learner's attention ſo entirely as to exclude other parts of education.

58
Practical mathematics.

From arithmetic our pupil may proceed to the practical branches of the mathematics: And in all of theſe, as well as in every other branch of learning, what you teach him will be beſt remembered and moſt thoroughly underſtood, if you afford him a few opportunities of applying his leſſons to real uſe in life. Geometry and geography are two moſt important branches of education; but are often taught in ſuch a manner, that no real benefit is derived from the knowledge of them. The means which Rouſſeau propoſes for initiating young people in theſe and in ſeveral other of the arts and ſciences are excellent; and if judiciouſly applied, could hardly fail of ſucceſs.

While boys are engaged in theſe and in the languages, they may alſo attend to and cultivate the bodily exerciſes; ſuch as dancing, fencing, and horſemanſhip. Each of theſe exerciſes is almoſt abſolutely neceſſary for one who is deſigned to have intercourſe with the world; and beſides, they have a tendency to render the powers of the body active and vigorous, and even to add new courage and firmneſs to the mind.

59
Firſt exerciſes in compoſition.

When our pupil has acquired ſome knowledge of his own and of the learned languages, has gained ſome ſkill in the principles of arithmetic and of practical mathematics, and has received ſome inſtruction in the principles of morality and religion, or even before this time, it will be proper to begin him to the practice of compoſition. Themes, verſions, and letters, the firſt exerciſes in compoſition which the boy is uſually required to perform, none of them ſeems happily calculated for leading him to increaſe his knowledge, or to acquire the power of expreſſing himſelf with eaſe and elegance. Without enlarging on the impropriety or abſurdity of theſe exerciſes, we will venture to propoſe ſomething different, which we cannot help thinking would conduce more effectually to the end in view. It has been already obſerved, that the curioſity of children is amazingly eager and active, and that every new object powerfully attracts their regard: but they cannot view any object without taking notice of its moſt obvious qualities; any animal, for inſtance, without taking notice of its ſhape, its colour, its ſeeming mildneſs or ferocity; and they are generally pretty ready to give an account of any thing extraordinary which they have obſerved. How eaſy then would it be to require them to write down an account of any new object expoſed to their obſervation?

tion? The taſk would not be difficult; and every new piece of compoſition which they preſented to us would add ſo much to their knowledge of nature. We might even require ſuch ſpecimens of their accuracy of obſervation and ſkill in language, at times when they enjoyed no opportunities of beholding new or ſurpriſing objects; a tree, a flower, a field, a houſe, an animal, any other ſimple object, ſhould be the ſubject of their exerciſe. After ſome time, we might require them to deſcribe ſomething more various and complex. They might give an account of ſeveral objects placed in a relative ſituation; as, a ſtream, and the vale through which it flows; or, a bird, and the manner in which it conſtructs its neſt; or, of one object ſucceſſively aſſuming various appearances, as the bud, the flower, the apple. Human actions are daily expoſed to their obſervation, and powerfully attract their attention. By and by, therefore, their taſk ſhould be to deſcribe ſome action which had lately paſſed in their preſence. We need not purſue this hint farther; but, if we miſtake not, by theſe means young people might ſooner, and much more certainly, be taught to expreſs themſelves with eaſe and correctneſs in writing, than by any of the exerciſes which they are at preſent cauſed to perform with a view to that. Beſides, they would at the ſame time acquire much more real knowledge. The ſtudy of words would then be rendered truly ſubſervient to their acquiring a knowledge of things.

We cannot deſcend to every particular of that ſeries of education in which we wiſh the boy to be engaged from that period when he firſt becomes capable of ſerious application till he reach the age of puberty. It is not neceſſary that we ſhould, after having given abſtracts of what has been offered to the world by ſo many reſpectable writers on the ſubject.

The few hints which we have thrown out will be ſufficient to ſhow, in general, in what manner we wiſh the youth's education to be conducted during this period. Let the parent and the tutor bear in mind, that much depends on their example, with regard to the diſpoſitions and manners of the youth; and let them carefully ſtrive to form him to gentleneſs, to firmneſs, to patient induſtry, and to vigorous courage: let them, if poſſible, keep him at a diſtance from that contagion with which the evil example of worthleſs ſervants and play-fellows will be likely to infect him. Now is the time for ſowing the ſeeds of piety and virtue: if carefully ſown now, they will ſcarce fail to grow up, and bear fruit in future life.

### III. *From Puberty to Manhood.*

This age is every way a very important period in human life. Whether we conſider the change which now takes place in the bodily conſtitution, or the paſſion which now firſt begins to agitate the breaſt, ſtill we muſt regard this as a critical ſeaſon to the youth. The buſineſs of thoſe to whoſe care he is ſtill entruſted, is to watch over him ſo as to prevent the paſſion for the ſex from hurrying him to ſhameful and vicious indulgence, and from ſeducing him to habits of frivolity and indolence; to prevent him from becoming either the ſhameleſs rake, or the trifling coxcomb. Though ſo furious is the impulſe of that appetite which now fires the boſom and ſhoots through the veins of the youth, that to reſtrain him from the exceſſes to which it leads can be no eaſy taſk; yet if his education has been hitherto conducted with prudence, if he is fond of manly exerciſes, active, ſober, and temperate, and ſtill influenced by modeſty and the ſenſe of ſhame; even this may through the bleſſing of heaven be accompliſhed. It is impoſſible to give better directions than thoſe of Rouſſeau for this purpoſe. Let the young man know his ſituation; ſet before him in a ſtriking light the virtue which he may practiſe by reſtraining appetite, and the frightful fatal vices into which he may be hurried. But truſt not to precept, nor to any views which you can lay before him, either of the diſgracefulneſs and the pernicious conſequences of vice, or of the dignity and the happy fruits of virtue. Something more muſt be done. Watch over him with the attention of an Argus; engage him in the moſt active and fatiguing ſports. Carefully keep him at a diſtance from all ſuch company, and ſuch books, as may ſuggeſt to his mind ideas of love, and of the gratification at which it aims. But ſtill all your precautions will not counteract the deſigns of nature; nor do you wiſh to oppoſe her deſigns. The youth under your care muſt feel the impulſe of deſire, and become ſuſceptible of love. Let him then fix his affections on ſome virtuous young woman. His attachment to her will raiſe him above debauchery, and teach him to deſpiſe brutal pleaſures: it will operate as a motive to diſpoſe him to apply to ſuch arts, and to purſue ſuch branches of knowledge, as may be neceſſary for his farther eſtabliſhment in the world. The good ſenſe of Rouſſeau on this head renders it leſs neceſſary for us to enlarge on it; eſpecially as we are to treat of ſome articles ſeparately which regard the management of youth at this period.

### IV. *Religion and Morals.*

In pointing out the general plan of education which appears to us the moſt proper to be purſued in order to form a virtuous and reſpectable member of ſociety, we took but ſlight notice of the important objects of religion and morals. At what period, and in what manner, ought the principles of religion and morality to be inſtilled into the youthful mind? It has been before obſerved, that children are capable of reaſoning and of moral diſtinctions even at a very early age. But they cannot then comprehend our reaſonings, nor enter into our moral diſtinctions; becauſe they are ſtrangers to our language, and to the artificial manner in which we arrange our ideas when we expreſs them in converſation or in writing. It follows, then, that as ſoon as they are ſufficiently acquainted with our language, it muſt be proper to communicate to them the principles and precepts of morality and religion. Long before this time, they are diligent and accurate obſervers of human actions. For a ſhort period it is merely the external act which they attend to and obſerve: ſoon, however, they penetrate farther; conſcious themſelves of reflection and volition, they regard us alſo as thinking beings; conſcious of benevolent and of unfriendly diſpoſitions, they regard us as acting with deſign, and as influenced by paſſion: naturally imitative animals, they are diſpoſed in their conduct to follow the example which we ſet before them. By our example we may teach them piety and virtue long before it can be proper to offer them religious or moral inſtruction in a formal manner.

We

We cannot preſume to determine at what particular period children ought to be firſt informed of their relations to God and to ſociety, and of the duties incumbent on them in conſequence of thoſe relations. That period will be different to different children, according to the pains which have been taken, and the means which have been employed, in cultivating their natural powers. Perhaps even where the moſt judicious maxims of education have been adopted, and have been purſued with the happieſt effects, it cannot be ſooner than the age of eight or nine. But even before this period much may be done. Show the child your reverence for religion and virtue; talk in his preſence, and in the plaineſt, ſimpleſt terms, though not directly to him, of the exiſtence of God the creator, the preſerver, and the governor of the world; ſpeak of the conſtant dependance of every creature on the gracious care of that Being; mention with ardour the gratitude and obedience which we owe to him as our great parent and beſt benefactor: next, ſpeak of the mutual relations of ſociety; of the duties of children and parents, of maſters and ſervants, of man to man. At length, when his mind is prepared by ſuch diſcourſes which have paſſed in his preſence without being addreſſed to him, you may begin to explain to him in a direct manner the leading doctrines of religion. He will now be able to comprehend you, when you addreſs him on that important ſubject: the truths which you communicate will make a powerful impreſſion on his mind; an impreſſion which neither the corruption and diſſipation of the world, nor the force of appetite and paſſion, will ever be able to efface.

61 bit. Some writers on this ſubject have aſſerted, that youth are incapable of any juſt ideas of religion till they attain a much more advanced age; and have inſiſted, that, for this reaſon, no attempts ſhould be made to communicate to them the articles of our creed in their earlier years. This doctrine, both from its novelty and from its pernicious tendency, has provoked the keeneſt oppoſition. It has, however, been oppoſed rather with keenneſs than with acuteneſs or ſkill. Its opponents ſeem to have generally allowed that children are incapable of reaſoning and of moral diſtinctions; but they have aſcribed wonderful effects to habit. Enrich the memories of children, ſay they, with the maxims of morality, and with the doctrines of religion; teach them prayers, and call them to engage in all the ordinances of religion. What though they comprehend not the meaning of what they learn? What though they underſtand not for what purpoſe you bid them repeat their prayers, nor why you confine them on the Lord's day from their ordinary amuſements? Their powers will at length ripen, and they will then ſee in what they have been employed, and derive the higheſt advantage from the irkſome taſks to which you confined them. You have formed them to habits which they will not be able to lay aſide: After this they cannot but be religious at ſome period of life, even though you have inſpired them with a diſguſt for the exerciſes of religion. Thoſe good people have alſo talked of the priniciple of *the aſſociation of ideas.* As no man ſtands alone in ſociety, ſay they; ſo no one idea exiſts in the mind ſingle and unconnected with others: as you are connected with your parents, your children, your friends, your countrymen; ſo the idea of a tree, for inſtance, is connected with that of the field in which it grows, of the fruit which it bears, and of contiguous, diſſimilar, and reſembling objects. When any one ſet of related ideas have been often preſented to the mind in connection with one another, the mind at length comes to view them as ſo intimately united, that any particular one among them never fails to introduce the reſt. Reviſit the ſcenes in which you ſpent your earlieſt years; the ſports and companions of your youth naturally ariſe to your recollection. Have you applied to the ſtudy of the claſſics with reluctance and conſtraint, and ſuffered much from the ſeverity of parents and tutors for your indifference to Greek and Latin? you will, perhaps, never through the courſe of life ſee a grammar ſchool, without recollecting your ſufferings, nor look on a Virgil or Homer without remembering the ſtripes and confinement which they once occaſioned to you. In the ſame manner, when religious principles are impreſſed on the mind in infancy in a proper manner, an happy aſſociation is formed which cannot fail to give them a powerful influence on the ſentiments and conduct in future life. But if we have advanced to manhood before being informed of the exiſtence of a Deity, and of our relation to him; the principles of religion, when communicated, no longer produce the ſame happy effects: the heart and the underſtanding are no longer in the ſame ſtate; nor will the ſame aſſociations be formed.

62 Dr Prieſtley's opinion concerning aſſociation of *ideas.*

This doctrine of *the aſſociation of ideas* has been adduced by an ingenious writer, diſtinguiſhed for his diſcoveries in natural philoſophy, and for his labours in controverſial divinity, as an argument in behalf of the propriety of inſtructing youth in the principles of religion even in their earlieſt years. We admire, we eſteem, the ſpirit which has prompted him to diſcover ſo much concern for the intereſts of the riſing generation; but at the ſame time we will not conceal our opinion, that even this argument ought to be urged with caution. Many of the phenomena of human nature may indeed be explained, if we have recourſe to the principle of *aſſociation.* The influence of any principle, religious or moral, depends in a great meaſure on the ideas and images which, in conſidering it, we have been accuſtomed to aſſociate with it in our minds. But what are the ideas or images moſt likely to be aſſociated by children with the doctrines and duties of religion, if we call them to liſten to the one and perform the other at too early a period? Will they be ſuch as may aſſiſt the influence of religion on their ſentiments and conduct in the future part of life? Obſerve the world: Are thoſe who, in infancy, have been moſt rigidly compelled to get their catechiſms by rote, either the moſt pious or the beſt informed in religious matters? Indeed, when we conſider what has been ſaid of the influence of habit, and of the aſſociation of ideas, we cannot help thinking, that any arguments which on the preſent occaſion may be adduced from either of theſe, tend directly to prove, not that we ought to pour in religious inſtruction into the minds of children, without conſidering whether they be qualified to receive it; but, on the contrary, that we ought cautiouſly to wait for and catch the proper ſeaſon;—that ſeaſon when the youthful mind, no longer a ſtranger to our language, our ſentiments, our views of nature, or our manner of reaſoning, will be able to go along with us, when we talk to him of a ſupreme Being, of our condition as dependant and accountable creatures, of truth, benevolence, and juſtice.

We flatter ourſelves, then, that our readers will readily agree with us, 1ſt, That the moral and reaſoning powers of children begin to diſplay themſelves at a very early age, even in infancy. 2dly, That as ſoon as they have made themſelves acquainted with the moſt obvious appearances of nature, and have gained a tolerable knowledge of our language and our manner of arranging our ideas in reaſoning, we may with the greateſt propriety begin to inſtruct them in the principles of religion. 3dly, That the moſt careful and judicious obſervation is neceſſary to enable us to diſtinguiſh the period at which children become capable of receiving religious inſtruction; becauſe, if we either attempt to communicate to them theſe important truths too early, or defer them till towards manhood, we may fail of accompliſhing the great end which we have in view.

63
Catechiſms.

If we can be ſo fortunate as to chooſe the happieſt ſeaſon for ſowing the firſt ſeeds of piety in the infant mind, our next care will be to ſow them in a proper manner. We muſt anxiouſly endeavour to communicate the principles of religion and morality, ſo as they may be eaſieſt comprehended by the underſtanding of the learner, and may make the deepeſt impreſſion on his heart. It would be a matter of the greateſt difficulty to give particular directions on this head. The diſcretion of the parent or tutor muſt here be his guide. We are afraid that ſome of the catechiſms commonly taught are not very happily calculated to ſerve the purpoſe for which they are intended. Yet we do not wiſh that they ſhould be neglected while nothing more proper is introduced in their room. In inſtructing children in the firſt principles of religion, we muſt beware of arraying piety in the gloomy garb, or painting her with the forbidding features, in which ſhe has been repreſented by anchorites, monks, and puritans. No; let her aſſume a pleaſing form, a cheerful dreſs, and an inviting manner. Deſcribe the Deity as the affectionate parent, the benefactor, and though the impartial yet the merciful judge of mankind. Exhibit to them Jeſus Chriſt, the generous friend and ſaviour of the poſterity of Adam, who with ſuch enchanting benevolence hath ſaid, "Suffer little children to come unto me." Repreſent to them his yoke as eaſy, and his burden as light. Inſiſt not on their ſaying long prayers or hearing tedious ſermons. If poſſible, make the doctrines of religion to appear to them as glad tidings, and its duties as the moſt delightful of taſks.

## V. *The Languages.*

64
Prejudice againſt cl ſical educ tion.

Is the time uſually ſpent in learning the languages uſefully occupied? What advantages can our Britiſh youth derive from an acquaintance with the languages and the learning of Greece and Rome? Would we liſten to many of the fathers, the mothers, and the polite tutors of the preſent age, they will perſuade us, that the time which is dedicated to grammar-ſchools, and to Virgil, Cicero, Homer, and Demoſthenes, is fooliſhly thrown away; and that no advantages can be gained from the ſtudy of claſſical learning. They wiſh their children and pupils to be not merely ſcholars; they wiſh them to acquire what may be uſeful and ornamental when they come to mingle with the world; and for this purpoſe, they think it much better to teach their young people to ſmatter out French, to dance, to fence, to appear in company with invincible aſſurance, and to dreſs in ſuch a manner as may attract the attention of the ladies. Beſides, the tenderneſs and humanity of thoſe people are amazing. They are ſhocked at the idea of the ſufferings which boys undergo in the courſe of a claſſical education. The confinement, the ſtripes, the harſh language, the burdens laid on the memory, and the pain occaſioned to the eyes, during the dreary period ſpent in acquiring a knowledge of Greek and Latin, affect them with horror when they think of them as inflicted on children. They therefore give the preference to a plan of education in which leſs intenſe application is required and leſs ſeverity employed.

65
Prejudice for it.

But, again, there are others who are no leſs warm in their eulogiums on a claſſical education, and no leſs induſtrious in recommending the ſtudy of Greek and Latin, than thoſe are eager in their endeavours to draw neglect on the poliſhed languages of antiquity. With this ſecond claſs, if an adept in Greek and Latin, you are a great and learned man; but without thoſe languages, contemptible for ignorance. They think it impoſſible to inſpire the youthful mind with generous or virtuous ſentiments, to teach the boy wiſdom, or to animate him with courage, without the aſſiſtance of the ancient philoſophers, hiſtorians, and poets. Indeed their ſuperſtitious reverence for the ancient languages, and for thoſe writers whoſe compoſitions have rendered Greece and Rome ſo illuſtrious, leads them to aſcribe many other ſtill more wonderful virtues to a claſſical education.

With which of theſe parties ſhall we join? or ſhall we mediate between them? Is it improper to call youth to the ſtudy of the languages? Is it impoſſible to communicate any uſeful knowledge without them? Or are they, though highly uſeful, yet not always indiſpenſably neceſſary?

66
Utility of claſſical learning t wards the improvement of our moth tongue.

We have formerly taken notice of one circumſtance in favour of a claſſical education, to which it may be proper to recal the attention of our readers. We obſerved, that the cultivation of claſſical learning has a favourable influence on the living languages. It has a tendency to preſerve their purity from being debaſed, and their analogy from becoming irregular. In ſtudying the dead languages, we find it neceſſary to pay more attention to the principles of grammar than in acquiring our mother-tongue. We learn our native language without attending much to its analogy and ſtructure. Of the numbers who ſpeak Engliſh through the Britiſh dominions, but few are ſkilled in the inflexion of its nouns and verbs, or able to diſtinguiſh between adverbs and conjunctions. Deſirous only of making their meaning underſtood, they are not anxious about purity or correctneſs of ſpeech. They reject not an expreſſion which occurs to them, becauſe it is barbarous or ungrammatical. As they grew up they learned to ſpeak from their mothers, their nurſes, and others about them: they were ſoon able to make known their wants, their wiſhes, and their obſervations,

tions, in words. Satisfied with this, or called at a very early period to a life of humble induſtry, they have continued to expreſs themſelves in their mother-tongue without acquiring any accurate knowledge of its general principles. If theſe people find occaſion to expreſs themſelves in writing, they are ſcarce more ſtudious of correctneſs and elegance in writing than in ſpeaking; or, though they may aſpire after thoſe properties, yet they can never attain them. But ſuch writers or ſpeakers can never refine any language, or reduce it to a regular analogy. Neither can they be expected to diſtinguiſh themſelves as the guardians of the purity and regularity of their native tongue, if it ſhould before have attained an high degree of perfection. But they who, in learning a language different from their native tongue, have found it neceſſary to pay particular attention to the principles of grammar, afterwards apply the knowledge of grammar which they have thus acquired in uſing their mother-tongue; and by that means become better acquainted with its ſtructure, and learn to write and ſpeak it with more correctneſs and propriety. Beſides, the languages of Greece and Rome are ſo highly diſtinguiſhed for their copiouſneſs, their regular analogy, and for various other excellencies, which render them ſuperior to even the chief of modern languages, that the ſtudy of them has a natural tendency to improve and enrich modern languages. If we look backwards to the 15th century, when learning began to revive in Europe, and that ſpecies of learning which began firſt to be cultivated was claſſical literature, we find that almoſt all the languages then ſpoken in Europe were wretchedly poor and barbarous. Knowledge could not be communicated, nor buſineſs tranſacted, without calling in the aid of Latin. Claſſical learning, however, ſoon came to be cultivated by all ranks with enthuſiaſtic eagerneſs. Not only thoſe deſigned to purſue a learned profeſſion, and men of fortune whoſe object was a liberal education without a view to any particular profeſſion; but even the lower ranks, and the female ſex, keenly ſtudied the languages and the wiſdom of Greece and Rome. This avidity for claſſical learning was followed by many happy effects. But its influence was chiefly remarkable in producing an amazing change on the form of the living languages. Theſe ſoon became more copious and regular; and many of them have conſequently attained ſuch perfection, that the poet, the hiſtorian, and the philoſopher, can clothe their thoughts in them to the greateſt advantage. Could we derive no new advantage from the ſtudy of the ancient languages, yet would they be worthy of our care, as having contributed ſo much to raiſe the modern languages to their preſent improved ſtate. But they can alſo conduce to the preſervation and ſupport of thoſe noble ſtructures which have been reared by their aſſiſtance. The intercourſe of nations, the affectation of writers, the gradual introduction of provincial barbariſms, and various other cauſes, have a tendency to corrupt and debaſe even the nobleſt languages. By ſuch means were the languages of Greece and Rome gradually corrupted, till the language uſed by a Horace, a Livy, a Xenophon, and a Menander, was loſt in a jargon unfit for the purpoſes of compoſition. But if we would not diſdain to take advantage of them, the claſſical works in thoſe languages might prevent that which we uſe from experiencing ſuch a decline. He who knows and admires the excellencies of the ancient languages, and the beauties of thoſe writers who have rendered them ſo celebrated, will be the firm enemy of barbariſm, affectation, and negligence, whenever they attempt to debaſe his mother-tongue. We venture therefore to aſſert, that when the poliſhed languages of antiquity ceaſe to be ſtudied among us, our native tongue will then loſe its purity, regularity, and other excellencies, and gradually decline till it be no longer known for the language of Pope and of Addiſon; and we adduce it as an argument in behalf of claſſical learning, that it has contributed ſo much to the improvement of the living languages, and is almoſt the only means that can prevent them from being corrupted and debaſed.

67
For inuring to induſtry.

In thoſe plans of education of which the ſtudy of the dead languages does not make a part, proper means are ſeldom adopted for impreſſing the youthful mind with habits of induſtry: nor do the judgment, the memory, and the other powers of the mind, receive equal improvement, as they paſs not through the ſame exerciſes as in a claſſical education. Let us enter thoſe academies where the way to a complete education leads not through the thorny and rugged paths of claſſical literature; let us attend to the exerciſes which the polite teachers cauſe their pupils to perform. Do they inſiſt on laborious induſtry or intenſe application? No; they can communicate knowledge without requiring laborious ſtudy. They profeſs to allow their pupils to enjoy the ſweets of idleneſs, and yet render them prodigies of learning. But are their magnificent promiſes ever fulfilled? Do they indeed cultivate the underſtandings of the young people intruſted to their care? They do not: their care is never once directed to this important object. To adorn them with ſhowy and ſuperficial qualities, is all that thoſe gentlemen aim at. Hence, when their pupils come to enter the world and engage in the duties of active life, they appear deſtitute of every manly qualification. Though they have attained the age and grown up to the ſize of manhood, their underſtandings are ſtill childiſh and feeble: they are capricious, unſteady, incapable of induſtry or fortitude, and unable to purſue any particular object with keen, unremitting perſeverance. That long ſeries of ſtudy and regular application, which is requiſite in order to attain ſkill in the ancient languages, produces much happier effects on the youthful mind. The power of habit is univerſally felt and acknowledged. As he who is permitted to trifle away the earlieſt part of his life in idleneſs or in frivolous occupations, can ſcarce be expected to diſplay any manly or vigorous qualities when he reaches a more mature age; ſo, on the contrary, he whoſe earlier days have been employed in exerciſing his memory and furniſhing it with valuable treaſures, in cultivating his judgment and reaſoning powers by calling the one to make frequent diſtinctions between various objects, and the other to deduce many inferences from the compariſon of the various objects preſented to the underſtanding, and alſo in ſtrengthening and improving the acuteneſs of his moral powers by attending to human actions and characters, and diſtinguiſhing between them, as virtuous or vicious, as mean or glorious: he who has thus cultivated his powers, may be naturally expected to diſtinguiſh himſelf when he comes to perform his part in active life, by prudence, activity, firmneſs, perſeverance, and moſt of the other noble qualities which can adorn a human character. But in the courſe of a claſſical education, the powers of the mind receive this cultivation; and therefore theſe happy effects may be expected to follow from it. The repetitions which are required afford improving exerciſe to the memory, and ſtore it with the moſt valuable treaſures: the powers of the underſtanding are employed in obſerving the diſtinctions between words; in tracing words to the ſubſtances and qualities in nature which they are uſed to repreſent; in comparing the words and idioms of different languages, and in tracing the laws of their analogy and conſtruction; while our moral faculties are at the ſame time improved, by attending to the characters which are deſcribed, and the events and actions which are related, in thoſe books which we are directed to peruſe in order to acquire the ancient languages. We aſſert therefore, that the ſtudy of the ancient languages is particularly uſeful for improving and ſtrengthening all the powers of the mind; and, by that means, for preparing us to act our part in life in a becoming manner: and this our readers will readily agree with us in conſidering as a weighty argument in behalf of that plan of education.

68
Fund of uſeful and elegant knowledge which ancient authors afford.

But if, after all, claſſical learning is ſtill to be given up, where ſhall we find the ſame treaſures of moral wiſdom, of elegance, and of uſeful hiſtorical knowledge, which the celebrated writers of Greece and Rome afford? Will you content yourſelf with the modern writers of Italy, France, and England? Or will you deign to ſurvey the beauties of Homer and Virgil through the medium of a tranſlation? No ſurely; let us penetrate to thoſe ſources from which the modern writers have derived moſt of the excellencies which recommend them to our notice; let us diſdain to be impoſed upon by the whims or the ignorance of a tranſlator.

*Juvat integros accedere fontes.*

Farther, claſſical learning has long been cultivated among us; and both by the ſtores of knowledge which it has conveyed to the mind, and the habits which it has impreſſed, has contributed in no ſmall degree to form many illuſtrious characters. In reviewing the annals of our country, we will ſcarce find an eminent politician, patriot, general, or philoſopher, during the two laſt centuries, who did not ſpend his earlier years in the ſtudy of the claſſics.

Yet though we have mentioned theſe things in favour of claſſical literature, and were we to deſcend to minute particulars might enumerate many more facts and circumſtances to recommend it; we mean not to argue that it is abſolutely impoſſible to be a wiſe, a great, or a good man, unleſs you are ſkilled in Greek and Latin. Means may, no doubt, be adopted to inſpire the young mind with virtuous diſpoſitions, to call forth the powers of the youthful underſtanding, and to impreſs habits of induſtry and vigorous perſeverance, without having recourſe to the diſcipline of a grammar ſchool. But we cannot help thinking, for the reaſons which we have ſtated to our readers, that a claſſical education is the moſt likely to produce theſe happy effects.

As we are afterwards to take particular notice of the courſe of education moſt ſuitable for thoſe who are to occupy the humble ſtations in ſociety, we ſhall not here inquire whether it be proper to introduce them to an acquaintance with the Greek and Latin claſſics.

### VI. *On the Education of People of Rank and Fortune.*

69
Duties o people rank.

THOSE whom the kindneſs of Providence has placed in an elevated ſtation, and in affluent circumſtances, ſo that they ſeem to be born rather to the enjoyment of wealth and honours than to act in any particular profeſſion or employment, have notwithſtanding a certain part aſſigned them to perform, and many important duties to fulfil. They are members of ſociety, and enjoy the protection of the civil inſtitutions of that ſociety to which they belong; they muſt therefore contribute what they can to the ſupport of thoſe inſtitutions. The labours of the induſtrious poor are neceſſary to ſupply them with the luxuries of life; and they muſt know how to diſtribute their wealth with prudence and generoſity among the poor. They enjoy much leiſure; and they ought to know how to employ their leiſure hours in an innocent and agreeable manner. Beſides, as their circumſtances enable them to attract the regard and reſpect of thoſe who are placed in inferior ſtations, and as the poor are ever ready to imitate the conduct of their ſuperiors; it is neceſſary that they endeavour to adorn their wealth and honours by the moſt eminent virtues, in order that their example may have an happy influence on the manners of the community.

Their education ought therefore to be conducted with a view to theſe ends. After what we have urged in favour of a claſſical education, our readers will naturally preſume that we regard it as highly proper for a man of fortune. The youth who is deſtined to the enjoyment of wealth and honours, cannot ſpend his earlier years more advantageouſly than in gaining an acquaintance with the elegant remains of antiquity. The benefits to be derived from claſſical learning are peculiarly neceſſary to him. Care muſt be taken to preſerve him from acquiring an haughty, fierce, imperious temper. The attention uſually paid to the children of people of fortune, and the fooliſh fondneſs with which they are too often treated, have a direct tendency to inſpire them with high notions of their own importance, and to render them paſſionate, overbearing, and conceited. But if their temper acquire this bias even in childhood, what may be expected when they advance towards manhood, when their attention is likely to be oftener turned to the dignity and importance of that rank which they occupy, and to the pitiful humility of thoſe beneath them? Why, they are likely to be ſo proud, inſolent, reſentful, and revengeful, as to render themſelves diſagreeable and hateful to all who know them; and beſides, to be incapable of thoſe delightful feelings which attend humane, benevolent, and mild diſpoſitions. Let the man of fortune, therefore, as he is concerned for the future happineſs and dignity of his child, be no leſs careful to prevent him from being treated in ſuch a manner as to be inſpired with haughtineſs, caprice, and inſolence, than to prevent his mind from being ſoured by harſh and tyrannical uſage.

70
How to form the temper o a young man of f tune.

The manly exerciſes, as they are favourable to the health, the ſtrength, and even the morals; ſo they are highly

highly worthy of engaging the attention of the young gentleman. Dancing, fencing, running, horſemanſhip, the management of the muſket, and the motions of military diſcipline, are none of them unworthy of occupying his time, at proper ſeaſons. It is unneceſſary to point out the advantages which he may derive from dancing; theſe ſeem to be pretty generally underſtood. Perhaps our men of fortune would be aſhamed to make uſe of their legs for running; but occaſions may occur, on which even this humble accompliſhment may be uſeful. Though we wiſh not to ſee the young man of fortune become a jockey; yet to be able to make a graceful appearance on horſeback, and to manage his horſe with dexterity, will not be unworthy of his ſtation and character. If times of public danger ſhould ariſe, and the ſtate ſhould call for the ſervices of her ſubjects againſt any hoſtile attack, they whoſe rank and fortune place them in the moſt eminent ſtations will be firſt expected to ſtand forth; but if unacquainted with thoſe exerciſes which are connected with the military art, what a pitiful figure muſt they make in the camp, or on the field of battle?

71
aw.

As the man of fortune may perhaps enjoy by hereditary right, or may be called by the voice of his fellow-citizens, to a ſeat among the legiſlative body of his country; he ought in his youth to be carefully inſtructed in the principles of her political conſtitution, and of thoſe laws by which his own rights and the rights of his fellow-citizens are determined and ſecured.

72
loſophy.

Natural philoſophy, as being both highly uſeful and entertaining, is well worthy of the attention of all who can afford to appropriate any part of their time to ſcientific purſuits; to the man of fortune, a taſte for natural philoſophy might often procure the moſt delightful entertainment. To trace the wonders of the planetary ſyſtems, to mark the proceſs of vegetation, to examine all the properties of that fine element which we breathe, to trace the laws by which all the different elements are confined to their proper functions, and above all to apply the principles of natural philoſophy in the cultivation of the ground, are amuſements which might agreeably and innocently occupy many of the leiſure hours of the man who enjoys a ſplendid and independent fortune.

73
and
als.

Neither do we ſuppoſe civil hiſtory and the principles of morals to be overlooked. Without being acquainted with theſe, how could any juſt or accurate knowledge of the laws and political conſtitution of his country be acquired by the young gentleman? Hiſtory expoſes to our obſervation the fortune and the actions of other human beings, and thus ſupplies in ſome meaſure the place of experience; it teaches prudence, and affords exerciſe to the moral ſenſe. When hiſtory condeſcends to take notice of individuals, they are almoſt always ſuch as have been eminent for virtue, for abilities, or for the rank which they held in life; to the rich and great it ought to ſpeak with peculiar efficacy, and they ought to be carefully invited to liſten to its voice.

Such then is the manner in which we wiſh the education of young men of rank and fortune to be conducted, in order that they may be prepared for enjoying their opulence and honours with becoming dignity. Let them be early inured to habits of vigorous induſtry and perſevering firmneſs, by paſſing through a regular courſe of claſſical learning in a free ſchool; let them play and converſe with their equals, and not be permitted to form high ideas of their own importance, nor to domineer over ſervants or inferiors: Let them be carefully inſtructed in the principles of morality and religion: Let them be taught the manly exerciſes: Let them be carefully informed of the nature of the political conſtitution of their country, and of the extent of thoſe civil and political rights which it ſecures to them and their fellow-citizens: Let them be called to trace the annals of mankind through the records of hiſtory; to mark the appearances and operations of nature, and to amuſe themſelves by purſuing theſe to their general cauſes. We ſay nothing of cauſing the young man of fortune to learn ſome mechanical art: We think ſkill in a mechanical art might now and then afford him an innocent and pleaſing amuſement; but we do not conſider it as abſolutely neceſſary, and therefore do not inſiſt on his acquiring it. With thoſe accompliſhments we hope he might become an uſeful member of ſociety, might adorn the rank and fortune to which he is born, and might find wealth and high ſtation a bleſſing, not a curſe. It is peculiarly unfortunate for our age and country, that people of rank and fortune are not ſo ſtudious that their children acquire theſe as the more ſuperficial accompliſhments.

### VII. *On the Education of People deſigned for a Mercantile Employment, and for the humbler Occupations in Life not particularly connected with Literature.*

74
Elegant literature.

WERE modern literature in a leſs flouriſhing ſtate; were the Engliſh and French languages adorned with fewer eminent poetical, hiſtorical, and philoſophical compoſitions; we might perhaps inſiſt on it as neceſſary to give the boy, who is deſigned for a mercantile employment, a claſſical education. At preſent this does not appear abſolutely neceſſary; yet we do not preſume to forbid it as improper. Even the merchant will ſcarce find reaſon to repent his having been introduced to the acquaintance of Plato and Cicero. But ſtill, if the circumſtances of the parent, or any other juſt reaſon, ſhould render it inconvenient to ſend the young man who is intended for trade to a free ſchool to ſtudy the ancient languages, means may be eaſily adopted to make up for his loſs. Confine him not to writing and accounts alone. Theſe, though particularly uſeful to the merchant, have no great power to reſtrain the force of evil paſſions, or to inſpire the mind with generous and virtuous ſentiments. Though you burden him not with Latin and Greek, yet ſtrive to inſpire him with a taſte for uſeful knowledge and for elegant literature. Some of the pureſt and moſt elegant of our poets, the excellent periodical works which have appeared in our language, ſuch as the Spectator, the Adventurer, the Mirror, and the compoſitions of our Britiſh hiſtorians, together with ſome of the beſt tranſlations of the claſſics which we poſſeſs; theſe you may with great propriety put into his hands. They will teach him how to think and reaſon juſtly, and to expreſs himſelf in converſation or in writing with correctneſs and elegance: they will refine and poliſh his mind, and raiſe him above low and groſs pleaſures. And as no man, who has any occaſion to ſpeak or write, ought to be entirely ignorant of the principles of grammar, you will therefore

therefore be careful to inſtruct the young man who is deſigned for a mercantile occupation in the grammar of his mother-tongue.

75 Integrity.

A ſacred regard to his engagements, and an honeſty which may prevent him from taking undue advantages or exacting unreaſonable profits, are the virtues which a merchant is moſt frequently called to exerciſe: punctuality and integrity are the duties moſt particularly incumbent on the mercantile profeſſion. Temptations will now and then ariſe to ſeduce the merchant to the violation of theſe. But if ſuperior to every ſuch temptation, he is one of the moſt illuſtrious characters, and is likely to be one of the moſt ſucceſsful merchants. From his earlieſt years, then, labour to inſpire the child whom you intend for trade with a ſacred regard for truth and juſtice: let him be taught to view deceit and fraud, and the violation of a promiſe, with abhorrence and diſdain. Frugality is a virtue which, in the preſent age, ſeems to be antiquated or proſcribed. Even the merchant often appears better ſkilled in the arts of profuſion than in thoſe of parſimony. The miſer, a character at no time viewed as amiable, is at preſent beheld with double deteſtation and contempt. Yet, notwithſtanding theſe unfavourable circumſtances, fear not to impreſs on the young merchant habits of frugality. Let him know the folly of beginning to ſpend a fortune before he have acquired it. Let him be taught to regard a regular attention to confine his expences within due bounds, as one of the firſt virtues which can adorn his character.

76 Induſtry.

Frugality and induſtry are ſo cloſely connected, that when we recommend the one of them to the merchant, we will be naturally underſtood to recommend the other alſo. It is eaſy to ſee, that, without induſtrious application, no man can reaſonably expect to meet with ſucceſs in the occupation in which he engages: and if the merchant thinks proper to leave his buſineſs to the management of clerks and ſhop-keepers, it is not very probable that he will quickly accumulate a fortune. It is, therefore, no leſs neceſſary, that he who is intended for trade be early accuſtomed to habits of ſober application, and be carefully reſtrained from volatility and levity, than that he be inſtructed in writing, arithmetic, and keeping of accounts.

With theſe virtues and qualifications the merchant is likely to be reſpectable, and not unſucceſsful, while he continues to proſecute his trade; and if, by the bleſſing of Providence, he be at length enabled to accumulate a moderate fortune, his acquaintance with elegant literature, and the virtuous habits which he has acquired, will enable him to enjoy it with taſte and dignity. Indeed, all the advantages which a man without taſte, or knowledge, or virtue, can derive from the poſſeſſion of even the moſt ſplendid fortune, are ſo inconſiderable, that they can be no adequate reward for the toil which he undergoes, and the mean arts which he practiſes in acquiring it. At the head of a great fortune a fool can only make himſelf more ridiculous, and a man of a wicked and vicious character more generally abhorred, than if fortune had kindly concealed their crimes and follies by placing them in a more obſcure ſtation.

77 Education of perſons in the loweſt ranks.

A conſiderable part of the members of ſociety are placed in ſuch circumſtances, that it is impoſſible for them to receive the advantages of a liberal education. The mechanic and the huſbandman, who earn a ſubſiſtence by their daily labour, can ſeldom afford, whatever parental fondneſs may ſuggeſt, to favour their children with many opportunities of literary inſtruction. Content if they can provide them with food and raiment till ſuch time as they acquire ſufficient ſtrength to labour for their own ſupport, parents in thoſe humble circumſtances ſeldom think it neceſſary that they ſhould concern themſelves about giving their children learning. Happily it is not requiſite that thoſe who are deſtined to ſpend their days in this low ſphere ſhould be furniſhed with much literary or ſcientific knowledge. They may be taught to read their mother tongue, to write, and to perform ſome of the moſt common and the moſt generally uſeful operations of arithmetic: for without an acquaintance with the art of reading, it will ſcarce be poſſible for them to acquire any rational knowledge of the doctrines and precepts of religion, or of the duties of morality; the invaluable volume of the ſacred ſcriptures would be ſealed to them: we may allow them to write, in order that they may be enabled to enjoy the ſweet ſatisfaction of communicating accounts of their welfare to their abſent friends; and, beſides, both writing and arithmetic are neceſſary for the accompliſhment of thoſe little tranſactions which paſs among them. It would be hard, if even the loweſt and pooreſt were denied theſe ſimple and eaſily acquired branches of education; and happily that degree of ſkill in them which is neceſſary for the labourer and the mechanic may be atained without greater expence than may be afforded by parents in the meaneſt circumſtances. Let the youth who is born to paſs his days in this humble ſtation be carefully taught to conſider honeſt patient induſtry as one of the firſt of virtues: let him be taught to regard the ſluggard as one of the moſt contemptible of characters: teach him contentment with his lot, by letting him know that wealth and honour ſeldom confer ſuperior happineſs: Yet ſcruple not to inform him, that if he can raiſe himſelf above the humble condition to which he was born, by honeſt arts, by abilities virtuouſly exerted, he may find ſome comfort in affluent circumſtances, and may find reaſon to rejoice that he has been virtuous, induſtrious, and active. In teaching him the principles of religion, be careful to ſhow him religion as intimately connected with morality: teach him none of thoſe myſterious doctrines, whoſe ſole tendency is to foſter that enthuſiaſm which naturally prevails among the vulgar, and to perſuade them that they may be pious without being virtuous. Labour to inſpire him with an invincible abhorrence for lying, fraud, and theft. Inſpire him with an high eſteem for chaſtity, and with an awful regard to the duties of a ſon, an huſband, and a father. Thus may he become reſpectable and happy, even in his humble ſtation and indigent circumſtances; a character infinitely ſuperior, in the eyes of both God and man, to the rich and great man who miſemploys his wealth and leiſure in ſhameful and vicious purſuits.

## VIII. *On the Education of the Female Sex.*

The abſtracts which we have given of ſome of the moſt celebrated and original treatiſes on education, as well as our own obſervations on this ſubject, have been hitherto either relative to the education of both the ſexes, or directed chiefly to the education of the male ſex. But as there is a natural difference between the characters of the two ſexes, and as there are certain duties peculiar to each of them; it is eaſy to ſee that the education of the boy and that of the girl cannot, ought not, to be conducted preciſely in the ſame manner. And ſince the duties of the female ſex are ſo important to ſociety, and they form ſo conſiderable a part of our ſpecies; their education, therefore, merits the higheſt attention.

78
nilarity the cha-ſters of th ſexes the firſt riod of :.

In infancy, the inſtincts, the diſpoſitions, and the faculties of boys and girls ſeem to be nearly the ſame. They diſcover the ſame curioſity, and the ſame diſpoſition to activity. For a while they are fond of the ſame ſports and amuſements. But by and by, when we begin to make a diſtinction in their dreſs; when the girl begins to be more confined to a ſedentary life under her mother's eye, while the boys are permitted to ramble about without doors; the diſtinction between their characters begins to be formed, and their taſte and manners begin to become different. The boy now imitates the arts and the active amuſements of his father; digs and plants a little garden, builds a houſe in miniature, ſhoots his bow, or draws his little cart; while the girl, with no leſs emulation, imitates her mother, knits, ſews, and dreſſes her doll. They are no longer merely children: the one is now a girl; the other a boy. This taſte for female arts, which the girl ſo eaſily and naturally acquires, has been judiciouſly taken notice of by Rouſſeau, as affording an happy opportunity for inſtructing her in a very conſiderable part of thoſe arts which it is proper to teach her. While the girl is buſied in adorning her doll, ſhe inſenſibly becomes expert at needle-work, and learns how to adjuſt her own dreſs in a becoming manner. And therefore, if ſhe be kindly treated, it will not be a matter of difficulty to prevail with her to apply to theſe branches of female education. Her mother or governeſs, if capable of managing her with mildneſs and prudence, may teach her to read with great facility. For being already more diſpoſed to ſedentary application than the boy of the ſame age, the confinement to which ſhe muſt ſubmit in order to learn to read will be leſs irkſome to her. Some have pretended that the reaſoning powers of girls begin to exert themſelves ſooner than thoſe of boys. But, as we have already declared our opinion, that the reaſoning powers of children of both ſexes begin to diſplay themſelves at a very early period; ſo we do not believe that thoſe of the one ſex begin to appear, or attain maturity, ſooner than thoſe of the other. But the different occupations and amuſements in which we cauſe them to engage from their earlieſt years, naturally call forth their powers in different manners, and perhaps cauſe the one to imitate our modes of ſpeaking and behaviour ſooner than the other. However, as we wiſh both boys and girls to learn the art of reading at a very early age, even as ſoon as they are capable of any ſerious application; ſo we wiſh girls to be taught the art of writing, arithmetic, and the principles of religion and morals, in the ſame order in which theſe are inculcated on boys.

We need not point out the reaſons which induce us to regard theſe as accompliſhments proper for the female ſex: they ſeem to be generally conſidered as not only ſuitable, but neceſſary. It is our moſt important privilege, as beings placed in a ſituation different from that of the inferior animals, that we are capable of religious ſentiments and religious knowledge; it therefore becomes us to communicate religious inſtruction with no leſs aſſiduity and care to the youth of the female ſex than to thoſe of our own. Beſides, as the care of children during their earlier years belongs in a particular manner to the mother; ſhe, therefore, whom nature has deſtined to the important duties of a mother, ought to be carefully prepared for the proper diſcharge of thoſe duties, by being accurately inſtructed, in her youth, in ſuch things as it will be afterwards requiſite for her to teach her children.

79
Erudition, how far becoming in ladies.

Ladies have ſometimes diſtinguiſhed themſelves as prodigies of learning. Many of the moſt eminent geniuſes of the French nation have been of the female ſex. Several of our countrywomen have alſo made a reſpectable figure in the republic of letters. Yet we cannot approve of giving girls a learned education. To acquire the accompliſhments which are more proper for their ſex, will afford ſufficient employment for their earlier years. If they be inſtructed in the grammar of their mother-tongue, and taught to read and ſpeak it with propriety; be taught to write a fair hand, and to perform with readineſs the moſt uſeful operations of arithmetic: if they be inſtructed in the nature of the duties which they owe to God, to themſelves, and to ſociety; this will be almoſt all the literary inſtruction neceſſary for them. Yet we do not mean to forbid them an acquaintance with the literature of their country. The periodical writers, who have taught all the duties of morality, the decencies of life, and the principles of taſte, in ſo elegant and pleaſing a manner, may with great propriety be put into the hands of our female pupil. Neither will we deny her the hiſtorians, the moſt popular voyages and travels, and ſuch of our Britiſh poets as may be put into her hands without corrupting her heart or inflaming her paſſions. But could our opinion or advice have ſo much influence, we would endeavour to perſuade our countrymen and countrywomen to baniſh from among them the noveliſts, thoſe panders of vice, with no leſs determined ſeverity than that with which Plato excludes the poets from his republic, or that with which the converts to Chriſtianity, mentioned in the Acts, condemned their magical volumes to the flames. Unhappily, novels and plays are almoſt the only ſpecies of reading in which the young people of the preſent age take delight; and nothing has contributed more effectually to bring on that diſſoluteneſs of manners which prevails among all ranks.

80
Ornamental accompliſhments.

But we will not diſcover ſo much auſterity as to expreſs a wiſh that the education of the female ſex ſhould be confined ſolely to ſuch things as are plain and uſeful. We forbid not thoſe accompliſhments which are merely ornamental, and the deſign of which is to render them amiable in the eyes of the other ſex. When we conſider the duties for which they are deſtined by nature, we find that the art of pleaſing conſtitutes no inconſiderable part of theſe; and it would be wrong, therefore, to deny them thoſe arts, the end of which is to enable them to pleaſe. Let them endeavour to acquire taſte in dreſs: to dreſs in a neat graceful manner, to ſuit colours to her complexion, and the figure of her clothes to her ſhape, is no ſmall accompliſhment for a young woman. She who is rigged out by the taſte and dexterity of her maid and her milliner, is nothing better than a doll

Education.

81 Dancing.

ſent abroad to public places as a ſample of their handywork Dancing is a favourite exerciſe; nay, we might almoſt call it the favourite ſtudy of the fair ſex: So many pleaſing images are aſſociated with the idea of dancing; dreſs, attendance, balls, elegance and grace of motion irreſiſtible, admiration, and courtſhip: and theſe are ſo early inculcated on the young by mothers and maids, that we need not be ſurpriſed if little Miſs conſider her leſſon of dancing as a matter of much more importance than either her book or ſampler. And indeed, though the public in general ſeem at preſent to place too high a value on dancing; and though the undue eſtimation which is paid to it ſeems owing to that taſte for diſſipation, and that rage for public amuſements, which naturally prevail amid ſuch refinement and opulence; yet ſtill dancing is an accompliſhment which both ſexes may cultivate with conſiderable advantage. It has an happy effect on the figure, the air, and the carriage; and we know not if it be not favourable even to dignity of mind: Yet, as to be even a firſt-rate poet or painter, and to value himſelf on his genius in theſe arts, would be no real ornament to the character of a great monarch; ſo any very ſuperior ſkill in dancing muſt ſerve rather to diſgrace than to adorn the lady or the gentleman. There are ſome arts in which, though a moderate degree of ſkill may be uſeful or ornamental, yet ſuperior taſte and knowledge are rather hurtful, as they have a tendency to ſeduce us from the more important duties which we owe to ourſelves and to ſociety. Of thoſe, dancing ſeems to be one: It is ſaid of a certain Roman lady, by an eloquent hiſtorian, "that ſhe was more ſkilled in dancing than became a modeſt and virtuous woman."

82 Muſic.

Muſic, alſo, is an art in which the youth of the female ſex are pretty generally inſtructed; and if their voice and ear be ſuch as to enable them to attain any excellence in vocal muſic, it may conduce greatly to increaſe their influence over our ſex, and may afford a pleaſing and elegant amuſement to their leiſure hours. The harpſichord and the ſpinnet are inſtruments often touched by female hands; nor do we preſume to forbid the ladies to exerciſe their delicate fingers in calling forth the enchanting ſounds of theſe inſtruments. But ſtill, if your daughter have no voice or ear for muſic, compel her not to apply to it.

83 Drawing.

Drawing is another accompliſhment which generally enters into the plan of female education. Girls are uſually taught to aim at ſome ſcratches with a pencil: but when they grow up, they either lay it totally aſide, or elſe apply to it with ſo much aſſiduity as to neglect their more important duties. We do not conſider ſkill in drawing, any more than ſkill in poetry, as an accompliſhment very neceſſary for the ladies; yet we agree with Rouſſeau, that as far as it can contribute to improve their taſte in dreſs, it may not be improper for them to purſue it. They may very properly be taught to ſketch and colour flowers; but we do not wiſh them to forget or lay aſide this as ſoon as the drawing-maſter is diſmiſſed: let them retain it to be uſeful through life. Though pride can never be lovely, even in the faireſt female form; yet ought the young woman to be carefully impreſſed with a due reſpect for herſelf. This will join with her native modeſty to be the guardian of her virtue, and to preſerve her from levity and impropriety of conduct.

Educat

Such are the hints which have occurred to us on the education proper for the female ſex, as far as it ought to be conducted in a manner different from that of the male.

### IX. *Public and private Education.*

One queſtion uſually diſcuſſed by the writers on this ſubject has not hitherto engaged our attention. It is, Whether it be moſt proper to educate a young man privately, or ſend him to receive his education at a public ſchool? This queſtion has been ſo often agitated, and by people enjoying opportunities of receiving all the information which experience can furniſh on the ſubject, that we cannot be expected to advance any new argument of importance on either ſide. Yet we may ſtate what has been urged both on the one and the other.

8 Argu for pri educat

They who have conſidered children as receiving their education in the houſe and under the eye of their parents, and as ſecluded in a great meaſure from the ſociety of other children, have been ſometimes led to conſider this ſituation as particularly favourable for their acquiring uſeful knowledge, and being formed to virtuous habits. Though we reap many advantages from mingling in ſocial life, yet in ſociety we are alſo tainted with many vices to which he who paſſes his life in ſolitary retirement is a ſtranger. At whatever period of life we begin to mix with the world, we ſtill find that we have not yet acquired ſufficient ſtrength to reſiſt thoſe temptations to vice with which we are there aſſailed. But if we are thus ready to be infected with the contagion of vice, even at any age, no other argument can be neceſſary to ſhow the propriety of confining children from thoſe dangerous ſcenes in which this infection is ſo eaſily caught. And whoever ſurveys the ſtate of morals in a public ſchool with careful and candid attention, even though it be under the management of the moſt virtuous, judicious, and aſſiduous teachers, will find reaſon to acknowledge, that the empire of vice is eſtabliſhed there not leſs fully than in the great world. Nothing, therefore, can be more negligent or inhuman, than for parents to expoſe their children to thoſe ſeductions which a great ſchool preſents, at a time when they are ſtrongly diſpoſed to imitate any example ſet before them, and have not yet learned to diſtinguiſh between ſuch examples as are worthy of imitation, and thoſe which ought to be beheld with abhorrence. Even when under the parent's eye, from intercourſe with ſervants and viſitors their native innocence is likely to ſuffer conſiderably. Yet the parent's care will be much more likely to preſerve the manners of his child uncorrupted in his own houſe, than any aſſiduity and watchfulneſs of his teachers in a ſchool.

The morals and diſpoſitions of a child ought to be the firſt objects of our concern in conducting his education: but to initiate him in the principles of uſeful knowledge is alſo an important object; and it will be happy, if in a private education virtue be not only better ſecured, but knowledge alſo more readily acquired, than in a public. But this actually happens. When one or two boys are committed to the care of a judicious tutor, he can watch the moſt favourable ſeaſons for communicating inſtruction; he can awake curioſity and command attention by the gentle arts of inſinuation: though he ſtrive not to inflame their breaſts with emulation, which leads often to envy and inveterate hatred ; yet he will ſucceed in rendering learning pleaſing, by other means leſs likely to produce unfavourable effects on the temper and diſpoſitions of his pupils. As his attention is not divided among a number, he can pay more regard to the particular diſpoſitions and turn of mind of each of his pupils : he can encourage him who is modeſt and ſlow, and repreſs the quickneſs and volatility of the other ; and he can call forth and improve their powers, by leading them at one time to view the ſcenes of nature and the changes which ſhe ſucceſſively undergoes through the varying ſeaſons ; at another, to attend to ſome of the moſt entertaining experiments of natural philoſophy ; and again alluring them artfully to their literary exerciſes. With theſe he may mix ſome active games ; and he may aſſume ſo much of the fondneſs of the parent, as to join in them with his little pupils. Theſe are certainly circumſtances favourable both to the happineſs and to the literary improvement of youth ; but they are peculiar to a private education. Beſides, in a private education, as children ſpend more of their time with grown up people than in a public ; thoſe, therefore, who receive a domeſtic education, ſooner acquire our manner of thinking, of expreſſing ourſelves, and of behaving, in our ordinary intercourſe with one another. For the very ſame reaſon for which girls are often obſerved to be capable of prudence and propriety of behaviour at an earlier age than boys, thoſe boys who receive a family education will begin ſooner to think and act like men, than thoſe who paſs their earlier days in a public ſeminary. And though you educate your ſon at home, there is no reaſon why he ſhould be more accuſtomed to domineer over his inferiors, or to indulge a capricious or inhumane diſpoſition, than if he were brought up among fifty boys, all of the ſame age, ſize, and rank, with himſelf. He may alſo, in a private education, exerciſe his limbs with the ſame activity as in a public one. He cannot, indeed, engage in thoſe ſports for which a party of companions is neceſſary ; but ſtill there are a thouſand objects which will call forth his activity : if in the country, he will be diſpoſed to fiſh, to climb for bird-neſts, to imitate all that he ſees performed by labourers and mechanics : in ſhort, he will run, leap, throw and carry ſtones, and keenly exert himſelf in a variety of exerciſes, which will produce the moſt favourable effects on the powers both of his mind and body. It may indeed be poſſible for you to oppoſe the deſigns of nature ſo effectually, if you take pains for that purpoſe, as to repreſs the natural activity of your child or pupil, and cauſe him to pine away his time in liſtleſs indolence ; but you will thus do violence to his diſpoſitions, as well as to thoſe inſtincts which nature has for wiſe purpoſes implanted in his breaſt. And the bad conſequences which may reſult from this management are not to be conſidered as the natural effects of a domeſtic education, but as the effects of an education careleſsly or imprudently conducted.

But there is another conſideration which will perhaps be ſtill more likely than any of thoſe which we have hitherto urged, to prevail with the fond parent to give his child a private education. As the infant who is abandoned by its mother to the care of an hireling nurſe, naturally transfers its affection from the unnatural parent to the perſon who ſupplies her room and performs the duties incumbent upon her ; ſo the boy who is baniſhed from his parent's houſe at a time when he has ſcarce begun to know the relation in which he ſtands to his father and mother, brothers or ſiſters, ſoon ceaſes to regard them with that fondneſs which he had contracted for them from living in their company and receiving their good offices. His reſpect, his affection, and his kindneſs, are beſtowed on new objects, perhaps on his maſter or his companions ; or elſe his heart becomes ſelfiſh and deſtitute of every tender and generous feeling ; and when the gentle and amiable affections of filial and fraternal love are thus, as it were, torn up by the roots, every evil paſſion ſprings up, with a rapid growth, to ſupply their place. The boy returns afterwards to his father's houſe : but he returns as a ſtranger ; he is no longer capable of regarding his parents and relations with the ſame tenderneſs of affection. He is now a ſtranger to that filial love which ſprings up in the breaſt of the child who is conſtantly ſenſible of the tender care of his parents, and ſpends his earlier years under their roof, in ſuch a manner as to appear the effect of inſtinct rather than of habit. Selfiſh views are now the only bond which attaches him to his parents and relations ; and by coming under their influence at ſo early a period of life, he is rendered for ever incapable of all the moſt amiable virtues which can adorn human nature. Let the parent, therefore, who loves his child, and wiſhes to obtain from him a mutual return of affection, beware of excluding him from his houſe, and devolving the ſole charge of him upon another, in his childhood.

Theſe views repreſent a private education as the moſt favourable to virtue, to knowledge, and to the mutual affection which ought always to unite the parent and his child. But let us now liſten to the arguments which are uſually urged in behalf of a public education.

85
Arguments for public education.

In the firſt place, it has been aſſerted, that a public education is much more favourable than a private to the pupil's improvement in knowledge, and much more likely to inſpire him with an ardour for learning. In a private education, with whatever aſſiduity and tenderneſs you labour to render learning agreeable to your pupil, ſtill it will be but an irkſome taſk. You may confine him to his books but for a very ſhort ſpace in the courſe of the day, and allow him an alternation of ſtudy and recreation. Still, however, you will never be able to render his books the favourite objects of his attention. He will apply to them with reluctance and careleſs indifference : even while he ſeems engaged on his leſſon, his mind will be otherwiſe occupied ; it will wander to the ſcenes where he purſues his diverſions, and to thoſe objects which have attracted his deſires. If the period during which you require his application be extremely ſhort ; during the firſt part of it, he will ſtill be thinking of the amuſements from which you have called him, and regretting his confinement ; during the laſt, he will fondly anticipate the moment when he is to be ſet at liberty, and think of new amuſements. Again, if you confine him during a longer period, ſtill more unfavourable effects will follow. Peeviſhneſs, dulneſs, and a determined averſion to all that bears the name of literature, will

be

be naturally impreſſed on his mind by ſuch treatment. How can it be otherwiſe? Books poſſeſs ſo few of thoſe qualities which recommend any object to the attention of children, that they cannot be naturally agreeable. They have nothing to attract and detain the eye, the ear, or any of the ſenſes; they preſent things with which children are unacquainted, and of which they know not the value: children cannot look beyond the letters and words, to the things which theſe repreſent; and even though they could, yet is it much more pleaſing to view ſcenes and objects as they exiſt originally in nature, than to trace their images in a faint and imperfect repreſentation. It is vain, therefore, to hope that children will be prevailed with to pay attention to books by means of any allurements which books can of themſelves preſent. Other means muſt be uſed; but thoſe in a private education you cannot command. In a public ſeminary, the ſituation of maſters with reſpect to their pupils is widely different. When a number of boys meet together in the ſame ſchool, each of them ſoon begins to feel the impulſe of a principle which enables the maſter to command their attention without difficulty, and prompts them to apply with cheerful ardour to taſks which would otherwiſe be extremely irkſome. This principle is a generous emulation, which animates the breaſt with the deſire of ſuperior excellence, without inſpiring envy or hatred of a competitor. When children are prudently managed in a great ſchool, it is impoſſible for them not to feel its impulſe. It renders their taſks ſcarce leſs agreeable than their amuſements, and directs their activity and curioſity to proper objects. View the ſcholar at a public ſchool, compoſing his theme, or turning over his dictionary; how alert! how cheerful! how indefatigable! He applies with all the eagerneſs, and all the perſeverance, of a candidate for one of the moſt honourable places in the temple of fame. Again, behold and pity that poor youth who is confined to his chamber with no companion but his tutor; none whoſe ſuperiority can provoke his emulation, or whoſe inferiority might flatter him with thoughts of his own excellence, and thus move him to preſerve by induſtrious application the advantages which he has already gained. His book is before him; but how languid, how liſtleſs his poſture! how heavy and dull his eye! Nothing is expreſſed in his countenance but dejection or indignation. Examine him concerning his leſſon; he replies with confuſion and heſitation. After a few minutes obſervation, you cannot fail to be convinced that he has ſpent his time without making any progreſs in learning; that his ſpirits are now broken, his natural cheerfulneſs deſtroyed, and his breaſt armed with invincible prejudices againſt all application in the purſuit of literary knowledge. Beſides, in a ſchool there is ſomething more than emulation to render learning leſs diſagreeable than it naturally is to children. The ſlighteſt obſervation of life, or attention to our own conduct in various circumſtances, will be ſufficient to convince us, that whenever mankind are placed in circumſtances of diſtreſs, or ſubjected to any diſagreeable reſtraint, that which a ſingle perſon bears with impatience or dejection will make a much leſs impreſſion on his mind if a number of companions be joined with him in his ſuffering or reſtraint. It is eſteemed a piece of much greater ſeverity to confine a priſoner in a ſolitary cell, than when he is permitted to mix with others in the ſame uncomfortable ſituation. A journey appears much leſs tedious to a party of travellers, than to him who beats the path alone. In the ſame manner, when a number of boys in a great ſchool are all buſied on the ſame or on ſimilar taſks, a ſpirit of induſtry and perſeverance is communicated from one to another over the whole circle; each of them inſenſibly acquires new ardour and vigour; even though he feel not the ſpur of emulation, yet, while all are buſy around him, he cannot remain idle. Theſe are facts obvious to the moſt careleſs obſerver.

Neither are public ſchools ſo unfavourable to the virtue of their members as they have been repreſented to be. If the maſters are men of virtue and prudence, careful to ſet a good example before their pupils, attentive to the particular character and behaviour of each individual among them, firm to puniſh obſtinate and incorrigible depravity, and even to expel thoſe who are more likely to injure the morals of others than to be reclaimed themſelves, and at the ſame time eager to applaud and to encourage amiable and virtuous diſpoſitions wherever they appear; under the government of ſuch maſters, a public ſchool will not fail to be a ſchool of virtue. There will no doubt be particular individuals among the pupils of ſuch a ſeminary, whoſe morals may be corrupt and their diſpoſitions vicious; but this, in all probability, will ariſe from the manner in which they were managed before entering the ſchool, or from ſome other circumſtances, rather than from their being ſent for their education to a public ſchool. Again, at a public ſchool young people enjoy much greater advantages for preparing them to enter the world, than they can poſſibly be favoured with if brought up in a private and ſolitary manner. A great ſchool is a miniature repreſentation of the world at large. The objects which engage the attention of boys at a ſchool are different from thoſe which occupy their parents; the views of the boys are leſs extenſive, and they are not yet capable of proſecuting them by ſo many baſe and mean arts: but, in other reſpects, the two ſcenes and the actors upon them nearly reſemble each other; on both you behold contending paſſions, oppoſite intereſts, weakneſs, cunning, folly, and vice. He therefore who has performed his part on the miniature ſcene, has rehearſed as it were for the greater; if he has acquitted himſelf well on the one, he may be alſo expected to diſtinguiſh himſelf on the other; and even he who has not diſtinguiſhed himſelf at ſchool, at leaſt enters the world with ſuperior advantages when viewed in compariſon with him who has ſpent his earlier days in the ignorance and ſolitude of a private and domeſtic education. Beſides, when a number of boys meet at a public ſeminary of education, ſeparated from their parents and relations; nearly of the ſame age, engaged in the ſame ſtudies, and fond of the ſame amuſements; they naturally contract friendſhips with one another which are more cordial and ſincere than any that take place between perſons farther advanced in life. A friendſhip is often formed between two boys at ſchool which continues through life, and is productive of the happieſt conſequences to each of them. While at ſchool, they mutually aſſiſt and encourage each other in their learning; and their mutual affection renders their taſks leſs burdenſome

denſome than they might otherwiſe find them. As they advance in life, their friendſhip ſtill continues to produce happy effects on their ſentiments and conduct: perhaps they are mutually uſeful to each other by intereſt or by perſonal aſſiſtance in making their way in the world; or when they are engaged in the cares and buſtle of life, their intercourſe and correſpondence with each other may contribute much to conſole them amid the vexations and fatigues to which they may be expoſed.

Such are the chief arguments uſually adduced in favour of a public education. When we compare them with thoſe which have been urged to recommend a private education, we will perhaps find that each has its peculiar advantages. A public education is the more favourable to the acquiſition of knowledge, to vigour of mind, and to the formation of habits of induſtry and fortitude. A private education, when judiciouſly conducted, will not fail to be peculiarly favourable to innocence and to mildneſs of diſpoſition; and notwithſtanding what has ſometimes been advanced by the advocates for a public education, it is ſurely better to keep youth at a diſtance from the ſeductions of vice till they be ſufficiently armed againſt them, than to expoſe them to them at an age when they know not to what dangers they lead, and are wholly unable to reſiſt them. Were we to give implicit credit to the ſpecious talk of the two parties, either a private or a public education would form characters more like to angels than to thoſe men whom we ordinarily meet in the world: but they ſpeak with the ardour of enthuſiaſts; and therefore we muſt liſten with caution both to the facts which they adduce, and to the inferences which they draw. Could we, without expoſing children to the contagion of a great town, procure for them the advantages of both a public and a private education at the ſame time, we would by this means probably ſucceed beſt in rendering them both reſpectable ſcholars and good men. If we may preſume to give our opinion freely, we would adviſe parents never, except when ſome unavoidable neceſſity of circumſtances obliges them, to expel their children from under their own roof till they be advanced beyond their boyiſh years: let the mother nurſe her own child; let her and the father join in ſuperintending its education: they may then expect to be rewarded, if they have acted their parts aright, by commanding the gratitude, the affection, and the reſpect of their child, while he and they continue to live together. Let matters be ſo ordered, that the boy may reſide in his father's houſe, and at the ſame time attend a public ſchool: but let the girl be educated wholly under her mother's eye.

## X. *On Travel.*

87
avel con-
ered in
neral.

ANOTHER queſtion which has been often diſcuſſed comes here under our review. The philoſophers of ancient Greece travelled in ſearch of knowledge. Books were then ſcarce, and thoſe few which were to be obtained were no very rich treaſuries of uſeful information. The rhapſodies of a poet, the rude legends of ſome ill-informed and fabulous hiſtorian, or the theories of fanciful philoſophers, were all that they could afford. Thales, Lycurgus, Solon, Plato, travelled, ſeeking that knowledge among more civilized nations which they could not find in their native country. In the courſe of their travels, they heard the lectures of celebrated philoſophers; conſulted the prieſts, who were the guardians of the traditions of antiquity, concerning the nature and origin of thoſe traditions; and obſerved the inſtitutions of thoſe nations which were moſt renowned for the wiſdom of their legiſlature. When they ſet out to viſit foreign countries, they ſeem to have propoſed to themſelves a certain end; and by keeping that end ſteadily in view during the courſe of their travels, they gained ſuch improvement as to be able on their return to command the veneration of their countrymen by means of the knowledge which they were enabled to communicate. Many beſides the philoſophers of ancient Greece have travelled for improvement, and have ſucceeded in their views. But ancient hiſtory does not relate to us, that travelling was conſidered by the Greeks or Romans as neceſſary to finiſh the education of their young men of fortune before they entered the ſcenes of active life. It is true, after Greece became a province of the Roman empire, and the Romans began to admire the ſcience and elegance of Greece, and to cultivate Grecian literature, the young noblemen of Rome often repaired to Rhodes and Athens to complete their ſtudies under the maſters of philoſophy and eloquence who taught in thoſe cities. But they went thither with the ſame views with which our youth in modern times are ſent to free ſchools and univerſities, not to acquire knowledge by the obſervation of nature, of the inſtitutions, manners, and cuſtoms of nations; but merely to hear lectures, read books, and perform exerciſes. In modern times, a few men of reflection and experience have now and then travelled for improvement: but the greateſt part of our travellers, for a long time, were enthuſiaſtic devotees who went in pilgrimage to viſit the ſhrine or relics of ſome favourite ſaint; ſoldiers, who wandered over the earth to deſtroy its inhabitants; or merchants, whoſe buſineſs as factors between widely diſtant countries and nations led them to brave every danger in traverſing from one corner of the globe to another. But ſince the nations of modern Europe have begun to emerge from rudeneſs, ignorance, and ſervile depreſſion, they have formed one great commonwealth, the members of which are ſcarce leſs intimately connected with each other than were the ſtates of ancient Greece. The conſequence of this mutual connection and dependence is, that almoſt all the nations of Europe have frequent intercourſe with one another; and as ſome of them are and have long been more enlightened and refined than others, thoſe nations who have attained the higheſt degrees of civilization and refinement have naturally attracted the admiration and homage of the reſt. Their language has been ſtudied, their manners and arts have been adopted, and even their dreſs has been imitated. Other nations have thronged to pay the homage due to their ſuperior merit, and to ſtudy under them as maſters. Hence has ariſen the practice which at preſent prevails among us of ſending our youth to complete their education by travelling, before we introduce them to active life, or require them to engage in buſineſs. Formerly young men were not ſent to travel till after they had proceeded through the forms of a regular education, and had at leaſt attained ſuch an age that they were no longer to be conſidered as mere boys. But the progreſs of luxury, the deſire of parents to introduce their children into the world at an early age that they may early attain to wealth and honours, and various other cauſes, have gradually introduced the practice of ſending mere boys to foreign countries, under pretence of affording them opportunities of ſhaking off prejudices, of ſtoring their minds with truly uſeful knowledge, and of acquiring thoſe graceful manners and that manly addreſs which will enable them to acquit themſelves in a becoming manner when they are called to the duties of active life. How much travelling at ſuch an early age contributes to fulfil the views of parents, a ſlight ſurvey of the ſenate-houſe, the gambling-houſes, the race courſe, and the cockpit, will readily convince the ſagacious obſerver.

But we wiſh to foſter no prejudices againſt neighbouring nations; we entertain no ſuch prejudices in favour of Britain, as to wiſh to confine our countrymen within the ſea-girt iſle. Let us inquire, what advantages may be gained by travelling, and at what age it may be moſt proper to ſet out in purſuit of thoſe advantages.

88
Travel neceſſary to the acquiſition of knowledge.

After all that bookiſh men have urged, and notwithſtanding all that they may continue vehemently to urge, in behalf of the knowledge to be derived from their beloved books; it muſt ſtill be acknowledged, that books can teach us little more than merely the language of men. Or, if we ſhould grant that books are of higher importance, and that language is the leaſt valuable part of the knowledge which they teach, yet ſtill we need to beware that they lead us not aſtray; it is better to examine nature with the naked eye, than to view her through the ſpectacles of books. Neither the theories or experiments of philoſophers, nor the narratives of travellers, nor the relations of hiſtorians, though ſupported by a numerous train of authorities, are worthy of implicit credit. You retire from the world, confine yourſelf for years to your cloſet, and read volume after volume, hiſtorians, philoſophers, and poets; at laſt you fancy that you have gained an immenſe ſtore of knowledge: But leave your retirement, return into the world, compare the knowledge which you have treaſured up with the appearances of nature; you will find that you have laboured in vain, that it is only the ſemblance of knowledge which you have acquired, and will not ſerve for a faithful guide in life, nor even enable you to diſtinguiſh yourſelf for literary merit. Compare the relations of travellers with one another; how ſeldom do they agree when they deſcribe the ſame ſcenes and the ſame people! Turn your attention to the moſt reſpectable hiſtorians, compare their accounts of the ſame events; what diſagreement! what contrariety! Where ſhall truth be found? Liſten to the cool, the candid philoſophers; what contradictory theories do they build on the ſame ſyſtem of facts!

We agree, then, that it is better to ſeek knowledge by actual obſervation and experiment, than to receive it at ſecond-hand from the information of others. He who would gain an acquaintance with the beauties of external nature, muſt view them with his own eyes; he who would know the operations of the human underſtanding, muſt reflect upon what paſſes in his own mind; he who would know the cuſtoms, opinions, and manners of any people, muſt mingle with them, muſt obſerve their conduct, and liſten to their converſation. The arts are acquired by actual practice; the ſciences by actual obſervation in your own perſon, and by deducing inferences from your obſervations.

If therefore to extend our knowledge can contribute in any degree to render us happier, wiſer, or better; travelling, as being more favourable to knowledge than the ſtudy of books, muſt be highly advantageous. Get well acquainted with your own country; with the manners, the cuſtoms, the laws, and the political ſituation of your countrymen: Get alſo a knowledge of books; for books would not be altogether uſeleſs, though they could ſerve no other purpoſe but to teach us the language in which mankind expreſs themſelves: And then, if your judgment have attained maturity; if curioſity prompt you; if your conſtitution be robuſt and vigorous, and your ſpirits lively; you may imitate the Solons, Homers, and Platos of old, and viſit foreign countries in ſearch of knowledge, and with a view to bring home ſomething which may be of real utility to yourſelf and your country. You will, by this time, be ſo much maſter of the language of your own country, that you will not loſe it while you are learning the languages of foreign nations; your principles of taſte and of right and wrong will be ſo formed and fixed, that you will not deſpiſe any inſtitution or cuſtom or opinion merely becauſe it prevails not in your own country; nor yet will you be ready to admire and adopt any thing, merely becauſe it prevails among a foreign nation who are diſtinguiſhed for profound and extenſive knowledge, or for elegance of taſte and manners. No; you will diveſt yourſelf of every prejudice, and judge only by the fixed unalterable principles which determine the diſtinction between right and wrong, between truth and falſehood, between beauty and deformity, ſublimity and meanneſs. Your object will not be to learn exotic vices, to mingle in frivolous amuſements, or to form a catalogue of inns. Your views, your inquiries, will have a very different direction. You will attend to the ſtate of the arts, of the ſciences, of morals, manners, and government; you will alſo contemplate with eager delight, the grand or beautiful ſcenes of nature, and examine the vegetable productions of the various regions through which you paſs, as well as the different tribes of animals which inhabit them; you will obſerve what bleſſings the beneficence of nature has conferred on the inhabitants of each particular diviſion of the globe, and how far the ingenuity and induſtry of man have taken advantage of the kindneſs of nature. Thus ſurveying the face of the earth, and conſidering how advantages and diſadvantages are balanced with each other through every various region and climate from one extremity of the globe to another; you will admire and revere that impartiality with which the Author of nature has diſtributed his benefits to the whole human race. When from the chilly climes and ſtubborn ſoil of the north, you turn your eyes to the fertile, genial regions of the ſouth, where every tree is loaded with exquiſite fruits, and every vegetable is nouriſhing and delicious; you will be pleaſed to find, that the inhabitants of the north, by their ſuperior ingenuity and vigour, are able to raiſe themſelves to circumſtances no leſs comfortable and reſpectable than thoſe which the nations inhabiting between the tropics enjoy: when you behold the French ſhaking off the yoke of deſpotiſm, and aſpiring to the ſweets of liberty as well as their Britiſh neighbours; you will be pleaſed to ſee, that the natural gaiety and cheerfulneſs of the former nation render them not incapable of the energy of the latter. You will be pleaſed to view the remains of antiquity, and the noble monuments of art; but you will think it below you to trifle away your time in gazing at palaces and churches, and collecting ruſty medals and fragments of marble; you will ſeek the ſociety of eminent men, and eagerly cultivate an acquaintance with the moſt diſtinguiſhed artiſts and men of ſcience who adorn the nations among whom you may happen to ſojourn: Knowing that the knowledge which is to be acquired in great towns, is by no means an adequate compenſation for the vicious habits which you are liable to contract in them; and beſides, that the luxuries, the arts, the manners, the virtues, and the vices of all great towns are nearly the ſame, ſo that when you have ſeen one, you have ſeen all others; you will avoid taking up your reſidence for any conſiderable time in any of the great towns through which you have occaſion to paſs in the courſe of your travels. The traveller who has attained the previous accompliſhments which we have mentioned as neceſſary, who ſets out with the views which we have ſuppoſed him to entertain, and who conducts his travels in this manner, cannot fail to return home enriched with much uſeful knowledge; he cannot but derive more real improvement from travelling, than he could have gained by ſpending the ſame period of time in ſolitary ſtudy: when he returns to his native country, he will appear among his countrymen as more than a philoſopher; a ſage, and a benefactor. His knowledge is ſo extenſive and accurate, his views are ſo liberal and enlarged, and he is ſo ſuperior to prejudices, without being the enemy of any uſeful eſtabliſhments, that he will be enabled to command univerſal eſteem, by performing his part in life with becoming dignity and propriety, and perhaps to render his name illuſtrious, and his memory dear to future times, by ſome important ſervices to the community to which he belongs, or even to mankind in general.

But though we have thus far, and we hope for obvious and ſolid reaſons, decided in favour of travelling, as being more likely than a ſolitary application to books, to furniſh the mind with uſeful and ornamental knowledge; yet we do not ſee that our Britiſh youth either take care to furniſh themſelves with the previous knowledge which we conſider as indiſpenſably neceſſary in order to prepare them for travelling with advantage, or ſet out with proper views, or proſecute their travels in a prudent judicious manner. After receiving a very imperfect education, in which religious and moral inſtruction are almoſt wholly neglected, and no means are uſed to inſpire the youthful mind with ſolid, virtuous, manly qualities; but every art is tried to make the young man appear learned, while his mind is deſtitute of all uſeful information, and to teach him to aſſume the confidence of manhood before he has attained even to a moderate degree of ſenſe and prudence;—after an education conducted in this manner, and with theſe views, the ſtripling is ſent abroad to view the world, and is expected to return home a finiſhed character, an ornament and a comfort to his parents and all his connexions. He is hitherto unacquainted, perhaps, even with the ſimple events of the hiſtory of his native country; and either totally ignorant of claſſical literature, or but very ſuperficially inſtructed in it. He has not yet viewed with a diſcerning eye the manners and cuſtoms prevailing among his countrymen; he knows not the nature of the government under which he lives, nor the ſpirit of thoſe laws by which his civil conduct muſt be regulated. He has no fixed principles; no clear, diſtinct views. But to ſupply all his wants of this nature, he is put into the hands of a travelling governor, who is to be entirely ſubmiſſive to his will, and yet to ſerve him both for eyes and intellect. This governor is generally either ſome macaroni officer, who is conſidered as well bred, and thought to know the world; or elſe, perhaps, ſome cringing ſon of literature, who having ſpent much time among his books, without acquiring ſuch ſtrength or dignity of mind as to raiſe him above frivolity of manners and converſation or pitiful fawning arts, is therefore regarded as happily qualified for this important charge. This reſpectable perſonage and his pupil are ſhipped off for France, that land of elegant diſſipation, frivolity, and faſhion. They travel on with eager impatience, till they reach the capital. There the young man is induſtriouſly introduced to all the gay ſcenes which Paris can diſplay. He is, at firſt, confounded; by and by his ſenſes are faſcinated; new deſires are awaked in his breaſt; all around him he ſees the ſons of diſſipation wallowing in debauchery, or the children of vanity fluttering about like ſo many gawdy inſects. The poor youth has no fixed principles: he has not been taught to regard vanity as ridiculous, or to turn from vice with abhorrence. No attempt is made to allure him to thoſe objects, an attention to which can alone render travelling truly beneficial. Hitherto his mind had been left almoſt wholly uncultivated; and now the ſeeds of vice are plentifully ſown in it. From one great town he is conveyed to another, till he viſit almoſt every place in Europe where profligacy of manners has attained to any uncommon height. In this happy courſe of education he probably continues to purſue improvement till he is well acquainted with moſt of the poſt roads, the principal inns, and the great towns at leaſt in France and Italy; and perhaps till he has worn out his conſtitution, and rendered his mind totally incapable of any generous ſentiments or ſober reflection. He then reviſits his native country, to the inexpreſſible happineſs of his parents, who now eagerly long to embrace their all-accompliſhed child. But how miſerably are the poor folks diſappointed, when they find his conſtitution waſted, his underſtanding uninformed, his heart deſtitute of every manly or generous ſentiment; and perceive him to poſſeſs no accompliſhment, but ſuch as are merely ſuperficial? Perhaps, however, his parents are prevented by their partiality both for their child and for the means which they have adopted in conducting his education, from viewing his character and qualifications in a true light. Perhaps they overlook all his defects, or conſider them as ornaments, and regard their dear ſon as the mirror of perfection. But, unfortunately, though they be blind to the hideous deformity of the monſter which they have formed, they cannot hinder it from being conſpicuous to others; though they may view their ſon's character as amiable and reſpectable, they cannot render it uſeful, they cannot prevent it from being hurtful to ſociety. Let this youth whoſe education has been thus wiſely conducted, let him be placed at the head of an opulent fortune, advanced to a ſeat in the legiſlative body of his country, or called to act in any public character; how will he diſtinguiſh himſelf? As the virtuous patriot, the honeſt yet able ſtateſman, the ſkilful general, or the learned upright judge? How will he enjoy his fortune? Will he be the friend of the poor, the ſteady ſupporter of the laws and conſtitution under whoſe protection he lives? Will he ſhow himſelf capable of enjoying *otium cum dignitate?* If we reaſon by the uſual laws of probability, we cannot expect that he ſhould: and if we obſerve the manners and principles of our men of wealth and high birth who have been brought up in this manner, we find our reaſonings confirmed.

Such are the opinions which candid obſervation leads us to entertain with regard to the advantages which may be gained by travelling.

He whoſe mind has been judiciouſly cultivated, and who has attained to maturity of judgment, if he ſet out on his travels with a view to obtain real improvements, and perſiſt invariably in the proſecution of that view, cannot but derive very great advantages from travelling.

But again, thoſe young men whoſe minds have not been previouſly cultivated by a judicious education, who ſet out without a view to the acquiſition of real knowledge, and who wander among foreign nations, without attention to any thing but their luxuries, their follies, and their vices, thoſe poor young men cannot gain any real improvement from their travels.

Our countrymen, who travel for improvement, do not appear to derive ſo much advantage from their travels as were to be wiſhed, becauſe they generally receive too ſuperficial an education, ſet out at too early a period of life, and direct not their views to objects of real utility and importance.

## XI. *On Knowledge of the World, and Entrance into Life.*

90 Unhappy effects of a too early introduction into the world.

MUCH has been ſaid concerning the utility of a knowledge of the world, and the advantage of acquiring it at an early period of life. But thoſe who have the moſt earneſtly recommended this knowledge of the world, have generally explained themſelves in ſo inaccurate a manner concerning it, that it is difficult to underſtand what ideas they affix to it. They ſeem to wiſh, that, in order to acquire it, young people may be early made acquainted with all the vices and follies of the world, introduced into polite company, carried to public places, and not confined even from the gaming table and the ſtews. Some knowledge of the world may, no doubt, be gained by theſe means. But it is ſurely dearly purchaſed; nor are the advantages which can be derived from it ſo conſiderable, as to tempt the judicious and affectionate parent to expoſe his child to the infection of vanity, folly, and vice, for their ſake. Carry a boy or girl into public life at the age of fourteen or fifteen; ſhow them all the ſcenes of ſplendid vanity and diſſipation which adorn London or Paris; tell them of the importance of dreſs, and of the ceremonies of good breeding and the forms of intercourſe; teach them that faſhionable indifference and aſſurance which give the *ton* to the manners of our fine gentlemen and fine ladies of the preſent age. What effects can you expect the ſcenes into which you introduce them, and the myſteries which you now teach them, to produce on the minds of the children? They have a direct tendency to inſpire them with a taſte for vanity, frivolity, and diſſipation. If you wiſh them to be like the fooliſh, the diſſipated, and the gay, you are likely to obtain your purpoſe; but if, on the contrary, your views are to prepare them for diſcharging the duties of life, you could not adopt more improper means: for though they be well acquainted with all thoſe things on which you place ſo much value, yet they have not thereby gained any acceſſion of uſeful knowledge. They are not now more able than before to eſtimate the real value of objects; nay, their judgement is now more liable than before to be miſled in eſtimating the value of the objects around them. Luxury, vanity, and faſhion, have ſtamped on many things an ideal value. By mingling at an early age in thoſe ſcenes of the world where luxury, vanity, and faſhion, reign with arbitrary ſway, young people are naturally impreſſed with all thoſe prejudices which theſe have a tendency to inſpire. Inſtead of acquiring an uſeful knowledge of the world, they are rendered incapable of ever viewing the world with an unprejudiced and diſcerning eye. If poſſible, therefore, we ſhould rather labour to confine young people from mingling in the ſcenes of gay and diſſipated life till after they have attained maturity of age and judgment. They will then view them in a proper light, and perhaps be happy enough to eſcape the infectious contagion of vice.

91 What knowle of the world m be ſafel commu cated to young ple.

But there is another and a more valuable knowledge of the world, which we ought induſtriouſly to communicate to them as ſoon as they are capable of receiving it. As ſoon as they are made thoroughly acquainted with the diſtinctions between right and wrong, between virtue and vice, between piety and impiety, and have become capable of entering into our reaſonings; we ought then to inform them concerning the various eſtabliſhments and inſtitutions which exiſt in ſociety; concerning the cuſtoms, opinions, and manners of mankind; and concerning the various degrees of ſtrength or weakneſs of mind, of ingenuity or dullneſs, of virtuous or vicious qualities, which diſcriminate thoſe characters which appear in ſociety. We ought alſo to ſeize every opportunity which may be preſented of exemplifying our leſſons by inſtances in real life. We muſt point out to them thoſe circumſtances which have led mankind to place an undue value on ſome objects, while they appretiate others much below their real utility and importance. Thus let us fortify their judgements againſt that impreſſion which the dazzling novelty of the ſcene, and the force of paſſion, will be apt to produce; and communicate to them a knowledge of the world, without expoſing them imprudently to the contagion of its vices and follies.

When at length the period arrives at which they muſt be emancipated from ſubjection, and committed to the guidance of their own conſcience and reaſon, and of thoſe principles which we have laboured to inculcate on their minds; let us warn them of the dangers to which they are about to be expoſed; tell them of the glory and the happineſs to which they may attain; inſpire them, if poſſible, with diſdain for folly, vanity, and vice, whatever dazzling or enchanting forms they may aſſume; and then diſmiſs them to enrich their minds with new ſtores of knowledge by viſiting foreign nations; or, if that ſhould be inconvenient, to enter immediately on the duties of ſome uſeful employment in active life.

EDULCORATION, properly ſignifies the rendering ſubſtances more mild. Chemical edulcoration conſiſts almoſt always in taking away acids and other ſaline ſubſtances; and this is effected by waſhing the bodies to which they adhere in a large quantity of water. The waſhing of diaphoretic antimony, powder of algaroth, &c. till the water comes off quite pure and inſipid, are inſtances of chemical edulcoration.—In pharmacy, juleps, potions, and other medicines, are ſaid to be *edulcorated*, by adding ſugar of ſyrup.

EDWARD, the name of ſeveral kings of England. See (*Hiſtory of*) ENGLAND.

EDWARDS, (George), fellow of the royal and antiquarian ſocieties, was born at Stratford, a hamlet belonging to Weſtham in Eſſex, on the 3d of April 1694. After having ſpent ſome time at ſchool, he was put apprentice to a tradeſman in Fenchurch ſtreet. His maſter, who was eminent both for his piety and ſkill in the languages, treated him with great kindneſs; but about the middle of his apprenticeſhip, an accident happened which totally put a ſtop to the hopes of young Edwards's advancing himſelf in the way of trade. Dr Nicolas, a perſon of eminence in the phyſical world, and a relation of his maſter's, happened to die. The Doctor's books were removed to an apartment occupied by Edwards, who eagerly employed all his leiſure hours, both in the day and great part of the night, in peruſing thoſe which treated of natural hiſtory, ſculpture, painting, aſtronomy, and antiquities. The reading of theſe books entirely deprived him of any inclination for mercantile buſineſs he might have formerly had, and he reſolved to travel into foreign countries. In 1716, he viſited moſt of the principal towns in Holland, and in about a month returned to England. Two years after, he took a voyage to Norway, at the invitation of a gentleman who was diſpoſed to be his friend, and who was nephew to the maſter of the ſhip in which he embarked. At this time Charles XII. was beſieging Frederickſhall; by which means our young naturaliſt was hindered from making ſuch excurſions into the country as otherwiſe he would have done, for the Swedes were very careful to confine ſuch ſtrangers as could not give a good account of themſelves. But notwithſtanding all his precaution, he was confined by the Daniſh guard, who ſuppoſed him to be a ſpy employed by the enemy to get intelligence of their deſigns. However, by obtaining teſtimonials of his innocence, a releaſe was granted. In 1718 he returned to England, and next year viſited Paris by the way of Dieppe. During his ſtay in this country he made two journeys of 100 miles each; the firſt to Chalons in Champagne, in May 1720; the ſecond on foot, to Orleans and Blois; but an edict happening at that time to be iſſued for ſecuring vagrants, in order to tranſport them to America, as the banks of the Miſſiſſippi wanted population; our author narrowly eſcaped a weſtern voyage. On his arrival in England, Mr Edwards cloſely purſued his favourite ſtudy of natural hiſtory, applying himſelf to drawing and colouring ſuch animals as fell under his notice. A ſtrict attention to natural, more than pictureſque beauty, claimed his earlieſt care: birds firſt engaged his particular attention; and having purchaſed ſome of the beſt pictures of theſe ſubjects, he was induced to make a few drawings of his own; which were admired by the curious, who encouraged our young naturaliſt to proceed, by paying a good price for his early labours. Among his firſt patrons and benefactors may be mentioned James Theobalds, Eſq; of Lambeth; a gentleman zealous for the promotion of ſcience. Our artiſt, thus unexpectedly encouraged, increaſed in ſkill and aſſiduity; and procured, by his application to his favourite purſuit, a decent ſubſiſtence and a large acquaintance. However, he remitted his induſtry in 1731; when, in company with two of his relations, he made an excurſion to Holland and Brabant, where he collected ſeveral ſcarce books and prints, and had an opportunity of examining the original pictures of ſeveral great maſters at Antwerp, Bruſſels, Utrecht, and other cities. In December 1733, by the recommendation of the great Sir Hans Sloane, Bart. preſident of the College of Phyſicians, he was choſen librarian, and had apartments in the college. This office was peculiarly agreeable to his taſte and inclination, as he had the opportunity of a conſtant recourſe to a valuable library, filled with ſcarce and curious books on the ſubject of natural hiſtory, which he ſo aſſiduouſly ſtudied. By degrees he became one of the moſt eminent ornithologiſts in this or any other country. His merit is ſo well known in this reſpect, as to render any eulogium on his performances unneceſſary: but it may be obſerved, that he never truſted to others what he could perform himſelf; and often found it ſo difficult to give ſatisfaction to his own mind, that he frequently made three or four drawings to delineate the object in its moſt lively character, attitude, and repreſentation. In 1743, the firſt volume of the Hiſtory of Birds was publiſhed in quarto. His ſubſcribers exceeding even his moſt ſanguine expectations, a ſecond volume appeared in 1747. The third volume was publiſhed in 1750. In 1751, the fourth volume came from the preſs. This volume being the laſt he intended to publiſh at that time, he ſeems to have conſidered it as the moſt perfect of his productions in natural hiſtory; and therefore devoutly offered it up to the great God of nature, in humble gratitude for all the good things he had received from him in this world. Our author, in 1758, continued his labours under a new title, viz. *Gleanings of Natural Hiſtory*. A ſecond volume of the Gleanings was publiſhed in 1760. The third part, which made the ſeventh and laſt volume of his works, appeared in 1764. Thus our author, after a long ſeries of years, the moſt ſtudious application, and the moſt extenſive correſpondence to every quarter of the world, concluded a work which contains engravings and deſcriptions of more than 600 ſubjects in natural hiſtory, not before deſcribed or delineated. He likewiſe added a general index in French and Engliſh; which was afterwards perfected, with the Linnæan names, by that great naturaliſt Linnæus himſelf, who frequently honoured him with his friendſhip and correſpondence. Some time after Mr Edwards had been appointed library keeper to the Royal College of Phyſicians, he was, on St Andrew's day, in the year 1750, preſented with an honorary compliment by the preſident and council of the Royal Society, with the gold medal, the donation of Sir Godfrey Copley, Bart. annually given on that day to the author of any new diſcovery in art or nature, in conſideration of his natural hiſtory juſt then completed. A copy of this medal he had afterwards engraved, and placed under the title in the firſt volume of his hiſtory. He was a few years afterwards elected fellow of the Royal Society, and of the Society of Antiquaries, London; and alſo a member of many of the academies of ſciences and learning in different parts of Europe. In compliment to theſe honorary diſtinctions from ſuch learned bodies, he preſented elegant coloured copies of all his works to the Royal College of Phyſicians, the Royal Society, the Society of Antiquarians, and to the Britiſh muſeum: alſo to the Royal Academy of Sciences at Paris, from whom he received the moſt polite and obliging letter of thanks by their then ſecretary Monſieur Deſouchy. His collection of drawings, which amounted to upwards of 900, were purchaſed by the earl of Bute. They contain a great number of Britiſh as well as foreign birds, and other animals hitherto not accurately delineated or deſcribed. After the publication of the laſt work, being arrived at his 70th year, he found his ſight begin to fail, and his hand loſt its wonted ſteadineſs. He retired from public employment to a little houſe which he purchaſed at Plaiſtow; previous to which, he diſpoſed of all the copies, as well as plates, of his works. The converſation of a few ſelect friends, and the peruſal of a few ſelect books, were the amuſement of the evening of his life; and now and then he made an excurſion to ſome of the principal cities in England, particularly to Briſtol, Bath, Exeter, and Norwich. Some years before his death, the alarming depredations of a cancer, which baffled all the efforts of phyſical ſkill, deprived him of the ſight of one of his eyes: he alſo ſuffered much from the ſtone, a complaint to which at different periods of his life he had been ſubject. Yet it has been remarked, that in the ſevereſt paroxyſms of miſery, he was ſcarcely known to utter a ſingle complaint. Having completed his 80th year, emaciated with age and ſickneſs, he died on the 23d of July 1773, deſervedly lamented by a numerous acquaintance.

EDYSTONE LIGHT-HOUSE, lying off Plymouth harbour, was firſt erected by the corporation of the Trinity-houſe in 1696; in conſideration of which, the maſters, &c. of Engliſh ſhipping agreed to pay one penny a ton outwards and inwards. It was demoliſhed by the ſtorm of 1703, and re-erected by act of parliament in the 4th of Queen Anne, and the ſame duty on tonage of ſhips granted for its ſupport; which law was enforced in the 8th of June. It has been ſince deſtroyed and rebuilt.

EECKHOUT (Gerbrant Vander), hiſtory and portrait painter, was born at Amſterdam in 1621, and was a diſciple of Rembrandt; whoſe manner of deſigning, colouring, and penciling, he imitated ſo nearly, that it is difficult to diſtinguiſh between ſeveral of his paintings and thoſe of his maſter. He painted after nature, and with ſuch a force as only nature can equal: his touch and the colouring are the ſame as Rembrandt's; but he rather excelled him in the extremities of his figures. His principal employment was for portraits; and in thoſe he was admirable: but he ſurpaſſed all his contemporaries in the power he had of painting the mind in the countenance. But although Eeckhout painted portraits to ſuch a degree of perfection, yet was he much more pleaſed to paint hiſtorical ſubjects, and he executed them with equal ſucceſs. In that ſtyle his compoſition is rich and full of judgment; the diſtribution of his maſſes of light and ſhadow is truly excellent; and in the opinion of many connoiſſeurs he had more tranſparence in his colouring, and better expreſſion, than his maſter. He died in 1674.

EEL, in ichthyology, a ſpecies of Muræna.

*Eel Fiſhing.* See Bobbing and Sniggling.

The ſilver eel may be catched with ſeveral ſorts of baits, as powdered beef, garden worms, minnows, hens guts, fiſh garbage, &c. The moſt proper time for taking them is in the night, faſtening your line to the bank ſides, with your laying hook in the water: or a line may be thrown with good ſtore of hooks, baited and plumbed, with a float to diſcover where the line lies, that they may be taken up in the morning.

*Microſcopic Eels.* See Animalcule, N° 8.

*Eels in vinegar*, are ſimilar to thoſe in ſour paſte. The taſte of vinegar was formerly thought to be occaſioned by the biting of theſe little animals, but that opinion has been long exploded. Mentzelius ſays, he has obſerved the actual transformation of theſe little creatures into flies: but as this hath never been obſerved by any other perſon, nor is there an inſtance of ſuch a transformation in any other animalcule, it ſeems probable that Mentzelius hath been miſtaken in his obſervations.

*Eel Spear*, a forked inſtrument with three or four jagged teeth, uſed for catching the eels: that with the four teeth is beſt, which they ſtrike into the mud at the bottom of the river, and if it ſtrike againſt any eels it never fails to bring them up.

EFFARE', or Effraye', in heraldry, a term applied to a beaſt rearing on its hind legs, as if it were frighted or provoked.

EFFECT, in a general ſenſe, is that which reſults from, or is produced by, any cauſe. See Cause.

EFFEMINATE, womaniſh, unmanly, voluptuous.

Effeminate *(effeminati)*, according to the vulgate, are mentioned in ſeveral places of ſcripture. The word is there uſed to ſignify ſuch as were conſecrated to ſome profane god, and proſtituted themſelves in honour of him. The Hebrew word *kadeſh*, tranſlated *effeminatus*, properly ſignifies *conſecrated*, and hence was attributed to thoſe of either ſex, who publicly proſtituted themſelves in honour of Baal and Aſtarte. Moſes expreſsly forbids theſe irregularities among the Iſraelites; but the hiſtory of the Jews ſhows, that they were notwithſtanding frequently practiſed. Levit. xxiii. 18.

EFFENDI, in the Turkiſh language, ſignifies *maſter*: and accordingly is a title very extenſively applied; as to the mufti and emirs, to the prieſts of moſques, to men of learning, and of the law. The grand chancellor of the empire is called *reis-effendi*.

EFFERVESCENCE, an inteſtine motion excited betwixt the parts of two bodies of different natures, when

when they reciprocally diſſolve each other. Efferveſcences are commonly attended with bubbles, vapours, ſmall jets of the liquid, and a hiſſing noiſe; and theſe phenomena are occaſioned by the air which at that time diſengages itſelf. Sometimes alſo they are accompanied with a great degree of heat, the cauſe of which is not ſo well known.

Formerly the word *fermentation* was alſo applied to efferveſcences; but now that word is confined to the motion naturally excited in animal and vegetable matters, and from which new combinations among their principles take place.

EFFIGY, the portrait, figure, or exact repreſentation of a perſon.

EFFIGY, is alſo uſed for the print or impreſſion of a coin, repreſenting the prince's head who ſtruck it.

*EFFIGY, to execute or degrade in*, denotes the execution or degradation of a condemned contumacious criminal, who cannot be apprehended or ſeized. In France, they hang a picture on a gallows or gibbet, wherein is repreſented the criminal, with the quality or manner of the puniſhment: at the bottom is written the ſentence of condemnation. Such perſons as are ſentenced to death are executed in effigy.

EFFLORESCENCE, among phyſicians, the ſame with exanthema. See EXANTHEMA.

EFFLORESCENCE, in chemiſtry, denotes the formation of a kind of mealy powder on the ſurface of certain bodies. Effloreſcence is occaſioned either by decompoſition or drying. The effloreſcence which happens to cobalt and martial pyrites is of the firſt; and that obſerved on the cryſtals of marine alkali, Glauber's ſalt, &c. of the latter kind. An effloreſcence is ſometimes alſo a ſpecies of cryſtallization, the nature of which is not well underſtood; as, the beautiful vegetations which ſhoot up from vitriolated tartar acidulated either with the vitriolic or nitrous acids, the ſaline ſpiculæ which are obſerved to ſhoot from ſalt butter, &c.

Beſides the common cryſtallization of ſalts, all of them have the property of appearing in the form of an effloreſcence, or ſmall ſaline ſpiculæ, when mixed with any thick ſubſtance, particularly lime. Whatever ſalt happens to be made uſe of, there is little or no difference in the effloreſcence. Thus, in butter very much ſalted, the ſea ſalt ſhoots in the form of long ſpiculæ, though the ſea ſalt itſelf never ſhoots but in the form of cubical cryſtals. In like manner, Glauber's ſalt will appear in the form of an effloreſcence, as well as the foſſil alkali, &c. nor will the form of the cryſtals of the effloreſcence be perceptibly different from thoſe of ſea ſalt. The effloreſcences which we ſee very commonly upon walls are in general Glauber's ſalt. In ſome caſes (but ſeldom in ſuch effloreſcences as we have examined) they are compoſed of foſſil alkali. The reaſon of theſe differences is not known. In almoſt all caſes of this kind there ſeems to be a real growth of ſalt. On one ſpot of a plaſter wall about two feet ſquare, which we obſerved particularly, this growth was very evident. The produce was a true Glauber's ſalt; and by frequently taking off the effloreſcence, eight ounces were procured; nor did the prolific virtue of the wall ſeem to be in the leaſt impaired by the waſte.

EFFLORESCENTIA, in botany, (from *effloreſco* to bloom); the preciſe time of the year and month in which every plant ſhows its firſt flowers.

Some plants flower twice a-year, as is common between the tropics; others oftener, as the monthly roſe. The former are called by botaniſts *biferæ*; the latter, *multiferæ*.

The time of flowering is determined by the degree of heat which each ſpecies requires. Mezereon and ſnowdrop produce their flowers in February; primroſe, in the beginning of March; the greater number of plants, during the month of May; corn, and other grain, in the beginning of June; the vine, in the middle of the ſame month; ſeveral compound flowers, in the months of July and Auguſt; laſtly, meadow-ſaffron flowers in the month of October, and announces the ſpeedy approach of winter.

Graſs of Parnaſſus always flowers about the time of cutting down the hay; and in Sweden, the different ſpecies of thiſtle, mountain lettuce, ſuccory, and balſam, ſeldom flower till after the ſummer ſolſtice: the country men even know, as by a kalendar, that the ſolſtice is paſt when theſe plants begin to produce their flowers.

The temperature of the ſeaſons has a mighty influence both in accelerating and retarding the flowering of plants. All plants are earlier in warm countries: hence ſuch as are cultivated out of their native ſoil, never flower till the heat of the climate, or ſituation into which they are removed, is equal to that under the influence of which they produced flowers in their own country. For this reaſon, all exotics from warm climates are later in this country than many plants which it naturally produces.

In general, we may obſerve, that the plants of the coldeſt countries, and thoſe produced on the mountains in all climates, being of equal temperature, flower about the ſame time, *viz.* during our ſpring in Europe.

Plants that grow betwixt the tropics, and thoſe of temperate climates, flower during our ſummer.

Plants of temperate climates, ſituated under the ſame parallel of latitude with certain parts of Europe, but removed much farther to the weſt, ſuch as Canada, Virginia, and Miſſiſſippi, do not produce flowers till autumn.

Plants of temperate climates in the oppoſite hemiſphere to Europe, flower during our winter, which is the ſummer of theſe regions.

Linnæus and Adanſon have given a ſketch of the different times in which plants flower at Upſal and Paris.

EFFLUVIUM, in phyſiology, a term much uſed by philoſophers and phyſicians, to expreſs the minute particles which exhale from moſt, if not all, terreſtrial bodies, in form of ſenſible vapours.

EFFRONTES, in church hiſtory, a ſect of heretics, in 1534, who ſcraped their forehead with a knife till it bled, and then poured oil into the wound. This ceremony ſerved them inſtead of baptiſm. They are likewiſe ſaid to have denied the divinity of the Holy Spirit.

EFFUSION, the pouring out of any liquid thing with ſome degree of force. In the ancient heathen ſacrifices there were divers effuſions of wine and other liquors, called *libations*.

Effusion, or Fusion, in aſtronomy, denotes that part of the ſign Aquarius, repreſented on celeſtial globes and planiſpheres, by the water iſſuing out of the urn of the water-bearer.

EFT, in zoology, the Engliſh name of the common lizard. See Lacerta.

EGERIA, or Ægeria, a nymph held in great veneration by the Romans. She was courted by Numa Pompilius; and, according to Ovid, ſhe became his wife. This prince frequently viſited her; and that he might introduce his laws and new regulations into the ſtate, he ſolemnly declared before the Roman people, that they were previouſly ſanctified and approved by the nymph Egeria. Ovid ſays, that Egeria was ſo diſconſolate at the death of Numa, that ſhe melted into tears, and was changed into a fountain by Diana. She is reckoned by many as a goddeſs who preſided over the pregnancy of women; and ſome maintain that ſhe is the ſame as Lucina.

EGG, in phyſiology a body formed in certain females, in which is contained an embryo or fœtus of the ſame ſpecies, under a cortical ſurface or ſhell. The exterior part of an egg is the ſhell; which in a hen, for inſtance, is a white, thin, and friable cortex, including all the other parts. The ſhell becomes more brittle by being expoſed to a dry heat. It is lined everywhere with a very thin but a pretty tough membrane, which dividing at, or very near, the obtuſe end of the egg, forms a ſmall bag, where only air is contained. In new laid eggs this follicle appears very little, but becomes larger when the egg is kept.

Within this are contained the albumen or white, and the vitellus or yolk; each of which have their different virtues.

The albumen is a cold, viſcous, white liquor in the egg, different in conſiſtence in its different parts. It is obſerved, that there are two diſtinct albumens, each of which is encloſed in its proper membrane. Of theſe one is very thin and liquid: the other is more denſe and viſcous, and of a ſomewhat whiter colour; but, in old and ſtale eggs, after ſome days incubation, inclining to a yellow. As this ſecond albumen covers the yolk on all ſides, ſo it is itſelf ſurrounded by the other external liquid. The albumen of a fecundated egg is as ſweet and free from corruption, during all the time of incubation, as it is in new laid eggs; as is alſo the vitellus. As the eggs of hens conſiſt of two liquors ſeparated one from another, and diſtinguiſhed by two branches of umbilical veins, one of which goes to the vitellus, and the other to the albumen; ſo it is very probable that they are of different natures, and conſequently appointed for different purpoſes.

When the vitellus grows warm with incubation, it becomes more humid, and like melting wax or fat; whence it takes up more ſpace. For as the fœtus increaſes, the albumen inſenſibly waſtes away and condenſes: the vitellus, on the contrary, ſeems to loſe little or nothing of its bulk when the fœtus is perfected, and only appears more liquid and humid when the abdomen of the fœtus begins to be formed.

The chick in the egg is firſt nouriſhed by the albumen; and when this is conſumed, by the vitellus, as with milk. If we compare the chalazæ to the extremities of an axis paſſing through the vitellus, which is of a ſpherical form, this ſphere will be compoſed of two unequal portions, its axis not paſſing through its centre; conſequently, ſince it is heavier than the white, its ſmaller portion muſt always be uppermoſt in all poſitions of the egg.

The yellowiſh white round ſpot, called *cicatricula*, is placed on the middle of the ſmaller portion of the yolk; and therefore, from what has been ſaid in the laſt paragraph, muſt always appear on the ſuperior part of the vitellus.

Not long before the excluſion of the chick, the whole yolk is taken into its abdomen; and the ſhell, at the obtuſe end of the egg, frequently appears cracked ſome time before the excluſion of the chick. The chick is ſometimes obſerved to perforate the ſhell with its beak. After excluſion, the yolk is gradually waſted, being conveyed into the ſmall guts by a ſmall duct.

Eggs differ very much according to the birds that lay them, as to their colour, form, bigneſs, age, and the different way of dreſſing them: thoſe moſt uſed in food are hens eggs; of which, ſuch as are new laid are beſt.

As to the preſervation of eggs, it is obſerved that the egg is always quite full when it is firſt laid by the hen; but from that time it gradually becomes leſs and leſs ſo, to its decay: and however compact and cloſe its ſhell may appear, it is nevertheleſs perforated with a multitude of ſmall holes, though too minute for the diſcernment of our eyes, the effect of which is a daily decreaſe of matter within the egg, from the time of its being laid; and the perſpiration is much quicker in hot weather than in cold.

To preſerve the egg freſh, there needs no more than to preſerve it full, and ſtop its tranſpiration; the method of doing which is, by ſtopping up thoſe pores with matter which is not ſoluble in watery fluids: and on this principle it is, that all kinds of varniſh, prepared with ſpirit of wine, will preſerve eggs freſh for a long time, if they are carefully rubbed all over the ſhell: tallow, or mutton fat, is alſo good for this purpoſe; for ſuch as are rubbed over with this, will keep as long as thoſe coated over with varniſh.

*Artificial Method of Hatching Eggs*. See Hatching.

EGINA. See Ægina.

EGINHART, ſecretary to the emperor Charles the Great, was a German. He is the moſt ancient hiſtorian of that nation, and wrote very eloquently for a man of the 9th century. It is ſaid, that he inſinuated himſelf ſo well into the favour of Imma, daughter to Charles the Great, that he obtained from her whatever he deſired. Charles the Great, having found out the intrigue, did not do as Auguſtus, who is thought to have baniſhed Ovid becauſe he believed him to be too much favoured by Julia; for he married the two lovers together, and gave them a fine eſtate in land.

EGLANTINE, in botany. See Rosa.

EGLON, a king of the Moabites, who oppreſſed the Iſraelites for 18 years (Judges iii. 12—14.). Calmet confounds this ſervitude of the Hebrews with that under Chuſan-riſhathaim, making it to ſubſiſt only eight years, from the year of the world 2591 to 2599; whereas

whereas this ſervitude under Eglon laſted 18 years, and commenced in the year of the world 2661, and 62 years after they had been delivered by Othniel from the ſubjection of Chuſan-riſhathaim.

EGRA, a town of Bohemia, formerly imperial, but now ſubject to the houſe of Auſtria. It contains a great number of able artificers, and is famous for its mineral waters. Wallenſtein, the emperor's general, was aſſaſſinated here in 1634. The French became maſters of this town in 1741; but afterwards being blocked up, they were forced to capitulate on September 7th, 1743. It is looked upon as a town of the greateſt conſequence in Bohemia, except Prague. It is ſeated on a river of the ſame name, in E. Long. 12. 30. N. Lat. 50. 21.

EGRET, in ornithology, a ſpecies of ardea. See Ardea.

EGYPT, an extenſive country of Africa, lying between 30° and 36° of eaſt longitude, and between 21° and 31° of north latitude. It is bounded by the Mediterranean on the north; by the Red ſea and iſthmus of Suez, which divide it from Arabia, on the eaſt; by Abyſſinia or Ethiopia, on the ſouth; and by the deſerts of Barca and Nubia, on the weſt; being 600 miles in length from north to ſouth, and from 100 to 200 in breadth from eaſt to weſt.

1 ferent nes.

As a nation, the Egyptians may with juſtice lay claim to as high antiquity as any in the world. The country was moſt probably peopled by Mizraim the ſon of Ham and grandſon of Noah.—By its ancient inhabitants it was called *Chemia*, and is ſtill called *Chemi* in the language of the *Copts* or native Egyptians; and this name it is ſuppoſed to have received from Ham the ſon of Noah. In ſcripture, we find it moſt generally named *Mizraim;* though in the Pſalms it is ſtyled the *land of Ham.*—To us it is beſt known by the name *Egypt,* the etymology of which is more uncertain.—Some derive it from *Ægyptus,* a ſuppoſed king of the country: others ſay it ſignifies no more than "the land of the *Copts;*" *Aia* in Greek ſignifying a country, and *Æcoptos* being eaſily ſoftened into *Ægyptus.*—The moſt probable opinion, however, ſeems to be, that it received its name from the blackneſs of its ſoil, and the dark colour both of its river and inhabitants: for ſuch a blackiſh colour is by the Greeks called *ægyptios* from *gyps, and ægyps* "a vulture;" and by the Latins, *ſubvulturius.* For the ſame reaſon, other names of a ſimilar import have been given to this country by the Greeks; ſuch as *Aeria,* and *Melambolus:* the river itſelf was called *Melo* or *Melas;* by the Hebrews, *Shihor;* and by the Ethiopians, *Siris;* all of which ſignify "black."

Ancient Egypt is by ſome divided into two parts, the Upper and Lower Egypt: by others into three, the Upper Egypt, properly ſo called, or *Thebais;* the Middle Egypt, or *Heptanomes;* and the Lower Egypt, the beſt part of which was the *Delta,* or that ſpace encompaſſed by the branches of the Nile. See Thebais, &c.

The Egyptians, like the Chineſe, pretend to an exceſſive antiquity, pretending to have records for ten, twenty, or even fifty thouſand years. Thus their hiſtory is ſo much involved in obſcurity and fable, that for many ages it muſt be paſſed over in ſilence.—The firſt mortal king whom the Egyptians own to have reigned in that country, was *Menes* or *Menas.* At what time he reigned, it would be to very little purpoſe to inquire. He had been preceded, however, by a ſet of immortals, who it ſeems left him the kingdom in a very bad ſituation: for the whole country, except Thebais, was a moraſs; the people alſo were entirely deſtitute of religion, and every kind of knowledge which could render their life comfortable and happy. Menes diverted the courſe of the Nile, which before that time had waſhed the foot of a ſandy mountain near the borders of Libya, built the city of Memphis, inſtructed his ſubjects, and did other things of a ſimilar kind which are uſually attributed to the founders of kingdoms.

2 Invaded by the ſhepherds.

From the time of Menes, the Egyptian chronology is filled with a liſt of 330 kings, who reigned 1400 years, but did nothing worthy of notice.—The firſt diſtinct piece of hiſtory we find concerning Egypt, is the irruption of the *Shepherds,* by whom the country was ſubdued; but whether this revolution happened during the vaſt interval of indolence above mentioned, or before or after, cannot be known. The affair is thus related by Manetho. It happened, in the reign of Timaus king of Egypt, that God being diſpleaſed with the Egyptians, they ſuffered a great revolution: for a multidude of men, ignoble in their race, took courage, and, pouring from the eaſt into Egypt, made war with the inhabitants; who ſubmitted to them without reſiſtance. The ſhepherds, however, behaved with the greateſt cruelty; burnt the cities, threw down the temples of the gods; and put to death the inhabitants, carrying the women and children into captivity. This people came from Arabia, and were called *Hycſos,* or *king-ſhepherds.* They held Egypt in ſubjection for 259 years; at the end of which period, they were obliged by a king of Upper Egypt, named *Amoſis,* or *Thethmoſis,* to leave the country. This prince's father had, it ſeems, gained great advantages over them, and ſhut them up in a place called *Abaris,* or *Avaris,* containing 10,000 acres of land. Here they were cloſely beſieged by Amoſis, with an army of 400,000 men; but at laſt the king, finding himſelf unable to reduce them by force, propoſed an agreement, which was readily accepted. In conſequence of this agreement, the ſhepherds withdrew from Egypt with their families, to the number of 240,000; and, taking the way of the deſert, entered Syria: but fearing the Aſſyrians, who were then very powerful, and maſters of Aſia, they entered the land of Judæa; and built there a city capable of holding ſo great a multitude, and called it *Jeruſalem.*

According to Mr Bruce, the ſhepherds who invaded Egypt were no other than the inhabitants of Barabra. They were, he ſays, *carriers* to the Cuſhites who lived farther to the ſouth. The latter had built the many ſtately temples in Thebes and other cities of Egypt; though, according to him, they had no dwelling places but holes or caves in the rocks. Being a commercial people, they remained at home collecting and preparing their articles, which were diſperſed by the *barabers* or ſhepherds already mentioned. Theſe, from the nature of their employment, lived in moveable habitations, as the Tartars do at this day. By the Hebrews, he tells us, they were called *phut,* but *ſhepherds* by every other people; and from the name *baraber,* the word *Barabra* is derived. By their employment, which was the diſperſing the Arabian and African goods all over the continent, they had become a great and powerful people; and from their oppoſite diſpoſitions and manners, became very frequently enemies to the Egyptians. To one Salatis our author aſcribes the deſtruction of Thebes in Upper Egypt, ſo much celebrated by Homer for its magnificence. But this certainly cannot be the caſe; for Homer wrote long after the time of Joſeph: and we find that even then the Egyptians had the ſhepherds in abhorrence, in all probability becauſe they had been grievouſly oppreſſed by them. Mr Bruce counts three invaſions of theſe people; the firſt, that of Salatis already mentioned, who overthrew the firſt dynaſty of Egyptian kings from Menes, and deſtroyed Thebes: the ſecond was that of Sabacco or *So*; for according to him this was not the name of a ſingle prince, but of a people, and ſignifies *ſhepherds*: and the third, after the building of Memphis, where 240,000 of them were beſieged as above mentioned. But accounts of this kind are evidently inconſiſtent in the higheſt degree; for how is it poſſible that the *third* invaſion, antecedent to the building of Jeruſalem, could be poſterior to the *ſecond*, if the latter happened only in the days of Hezekiah?

In theſe early ages, however, it would ſeem that the kingdom of Egypt had been very powerful and its dominion very widely extended; ſince we find it ſaid, that the *Bactrians* revolted from Oſymandyas, another Egyptian king of very high antiquity, and of whoſe wealth the moſt marvellous accounts are given.

After an unknown interval of time from this monarch, reigned Seſoſtris. He was the firſt great warrior whoſe conqueſts are recorded with any degree of diſtinctneſs. In what age of the world he lived, is uncertain. Some chronologers, among whom is Sir Iſaac Newton, are of opinion, that he is the Seſac or Shiſhak, who took Jeruſalem in the reign of Rehoboam the ſon of Solomon. Others, however, place him much earlier; and Mr Whiſton will have him to be the Pharaoh who refuſed to part with the Iſraelites, and was at laſt drowned in the Red ſea. Mr Bryant endeavours to prove that no ſuch perſon ever exiſted; but that in his hiſtory, as well as that of many ancient heroes, we have an abridgment of that of the Cuſhites or Babylonians, who ſpread themſelves over gerat part of the then known world, and everywhere brought the people in ſubjection to them. His reign is reckoned the moſt extraordinary part of the Egyptian hiſtory; and the following ſeems to be the leaſt fabulous account that can be got of it. The father of Seſoſtris was told in a dream, by the god Vulcan, that his ſon, who was then newly born, or perhaps ſtill unborn, ſhould be lord of the whole earth. His father, upon the credit of this viſion, got together all the males in the land of Egypt that were born on the ſame day with Seſoſtris; appointed nurſes and proper perſons to take care of them, and had them treated like his own child; being perſuaded that they who had been the conſtant companions of his youth would prove the moſt faithful miniſters and ſoldiers. As they grew up, they were inured to laborious exerciſes; and, in particular, were never permitted to taſte any food till they had performed a courſe of 180 furlongs, upwards of 22 of our miles. When the old king imagined they were ſufficiently educated in the martial way he deſigned them to follow, they were ſent by way of trial of their abilities againſt the Arabians. In this expedition Seſoſtris proved ſucceſsful, and in the end ſubdued that people who had never before been conquered. He was ſent to the weſtward, and conquered the greateſt part of Africa; nor could he be ſtopped in his career till he arrived at the Atlantic ocean. Whilſt he was on this expedition, his father died; and then Seſoſtris reſolved to fulfil the prediction of Vulcan, by actually conquering the whole world. As he knew that this muſt take up a long time, he prepared for his journey in the beſt manner poſſible. The kingdom he divided into 36 provinces, and endeavoured to ſecure the affections of the people by gifts both of money and land. He forgave all who had been guilty of offences, and diſcharged the debts of all his ſoldiers. He then conſtituted his brother Arais the ſupreme regent; but forbade him to uſe the diadem, and commanded him to offer no injury to the queen or her children, and to abſtain from the royal concubines. His army conſiſted of 600,000 foot, 24,000 horſe, and 27,000 chariots. Beſides theſe land forces, he had at ſea two mighty fleets; one, according to Diodorus, of 400 ſail. Of theſe fleets, one was deſigned to make conqueſts in the weſt, and the other in the eaſt; and therefore the one was built on the Mediterranean and the other on the Red ſea. The firſt of theſe conquered Cyprus, the coaſt of Phœnicia, and ſeveral of the iſlands called *Cyclades*; the other conquered all the coaſts of the Red ſea; but its progreſs was ſtopped by ſhoals and difficult places which the navigators could not paſs, ſo that he ſeems not to have made many conqueſts by ſea.

With the land forces Seſoſtris marched againſt the Ethiopians and Troglodites; whom he overcame, and obliged them to pay him a tribute of gold, ebony, and ivory. From thence he proceeded as far as the promontory of Dira, which lay near the ſtraits of Babelmandel, where he ſet up a pillar with an inſcription in ſacred characters. He then marched on to the country where cinnamon grows, or at leaſt to ſome country where cinnamon at that time was brought, probably ſome place in India; and here he in like manner ſet up pillars, which were to be ſeen for many ages after. As to his farther conqueſts, it is agreed by almoſt all authors of antiquity, that he overran and pillaged the whole continent of Aſia, and ſome part of Europe. He croſſed the Ganges, and erected pillars on its banks; and from thence he is ſaid to have marched eaſtward to the very extremity of the Aſiatic continent. Returning from thence, he invaded the Scythians and Thracians; but all authors do not agree that he conquered them. Some even affirm, that he was overthrown by them with great ſlaughter, and obliged to abandon a great part of his booty and military ſtores. But whether he had good or bad ſucceſs in theſe parts, it is a common opinion that he ſettled a colony in Colchis. Herodotus, however, who gives the moſt particular account of the conqueſts of this monarch, does not ſay whether the colony was deſignedly planted by Seſoſtris; or whether part of his army loitered behind the reſt, and took up their reſidence in that region. From his own knowledge, he aſſerts, that the inhabitants of that country were undoubtedly of Egyptian deſcent. This was evident from the perſonal reſemblance they bore to the Egyptians,

tians, who were ſwarthy complexioned and frizzle haired; but more eſpecially from the conformity of their cuſtoms, particularly circumciſion.

The utmoſt boundary of this mighty monarch's conqueſts, however, was in the country of Thrace; for beyond this country his pillars were nowhere to be ſeen. Theſe pillars he was accuſtomed to ſet up in every country which he conquered, with the following inſcription, or one to the ſame purpoſe: "Seſoſtris, king of kings, and lord of lords, ſubdued this country by the power of his arms." Beſides theſe, he left alſo ſtatues of himſelf; two of which, according to Herodotus, were to be ſeen in his time; the one on the road between Epheſus and Phocæa, and the other between Smyrna and Sardis: they were armed after the Ethiopian and Egyptian manner, holding a javelin in one hand and a bow in the other. Acroſs the breaſt they had a line drawn from one ſhoulder to the other, with the following inſcription: "This region I obtained by theſe my ſhoulders." They were miſtaken for images of Memnon.

urns to
pt.

The reaſons given by Seſoſtris for his returning into Egypt from Thrace, and thus leaving the conqueſt of the world unfiniſhed, were the want of proviſions for his army, and the difficulty of the paſſes. Moſt probably, however, his return was haſtened by the intelligence he received from the high prieſt of Egypt, concerning the rebellious proceedings of his brother; who, encouraged by his long abſence, had aſſumed the diadem, violated the queen, and alſo the royal concubines. On receiving this news, Seſoſtris haſtened from Thrace; and at the end of nine years came to Peluſium in Egypt, attended by an innumerable multitude of captives taken from many different nations, and loaded with the ſpoils of Aſia. The treacherous brother met him at this city; and it is ſaid, with very little probability, that Seſoſtris accepted of an invitation to an entertainment from him. At this he drank freely, together with the queen and the reſt of the royal family. During the continuance of the entertainment, Armais cauſed a great quantity of dried reeds to be laid round the apartment where they were to ſleep; and as ſoon as they were retired to reſt ſet fire to the reeds. Seſoſtris perceiving the danger he was in, and that his guards, overcharged with liquor, were incapable of aſſiſting him, ruſhed through the flames, and was followed by his wife and children. In thankſgiving for this wonderful deliverance, he made ſeveral donations to the gods, particularly to Vulcan the god of fire. He then took vengeance on his brother Armais, ſaid to be the Danaus of the Greeks, who, being on this occaſion driven out of Egypt, withdrew into Greece.

4
great
ks.

Seſoſtris now laid aſide all thoughts of war, and applied himſelf wholly to ſuch works as might tend to the public good, and his own future reputation. In order to prevent the incurſions of the Syrians and Arabians, he fortified the eaſt ſide of Egypt with a wall which ran from Peluſium through the deſert to Heliopolis, for 187½ miles. He raiſed alſo an incredible number of vaſt and lofty mounts of earth, to which he removed ſuch towns as had before been ſituated too low, in order to ſecure them from the inundations of the Nile. All the way from Memphis to the ſea he dug canals which branched out from the Nile; and not only made an eaſier communication between different places, but rendered the country in a great meaſure impaſſable to an enemy. He erected a temple in every city in Egypt, and dedicated it to the ſupreme deity of the place; but in the courſe of ſuch a great undertaking as this neceſſarily muſt have been, he took care not to employ any of his Egyptian ſubjects. Thus he ſecured their affection, and employed the vaſt multitude of captives he had brought along with him; and to perpetuate the memory of a tranſaction ſo remarkable, he cauſed to be inſcribed on all theſe temples, "No one native laboured hereon." In the city of Memphis, before the temple of Vulcan, he raiſed ſix gigantic ſtatues, each of one ſtone. Two of them were 30 cubits high, repreſenting himſelf and his wife; the other four were 20 cubits each, and repreſented his four ſons. Theſe he dedicated to Vulcan in memory of his above mentioned deliverance. He raiſed alſo two obeliſks of marble 120 cubits high, and charged them with inſcriptions, denoting the greatneſs of his power, his revenues, &c.

The captives taken by Seſoſtris are ſaid to have been treated with the greateſt barbarity; ſo that at laſt they reſolved at all events to deliver themſelves from a ſervitude ſo intolerable. The Babylonians particularly were concerned in this revolt, and laid waſte the country to ſome extent; but being offered a pardon and a place to dwell in, they were pacified, and built for themſelves a city, which they called *Babylon*. Towards the conquered princes who waited on him with their tribute the Egyptian monarch behaved with unparalleled inſolence. On certain occaſions he is ſaid to have unharnaſſed his horſes, and, yoking kings together, made them draw his chariot. One day, however, obſerving one of the kings who drew his chariot to look back upon the wheels with great earneſtneſs, he aſked what made him look ſo attentively at them? The unhappy prince replied, "O king, the going round of the wheel puts me in mind of the viciſſitudes of fortune: for as every part of the wheel is uppermoſt and lowermoſt by turns, ſo it is with men; who one day ſit on a throne, and on the next are reduced to the vileſt degree of ſlavery." This anſwer brought the inſulting conqueror to his ſenſes; ſo that he gave over the practice, and thenceforth treated his captives with great humanity. At length this mighty monarch loſt his ſight, and laid violent hands on himſelf.

5
His death.

After the death of Seſoſtris, we meet with another chaſm of an indeterminate length in the Egyptian hiſtory. It concludes with the reign of Amaſis or Ammoſis; who being a tyrant, his ſubjects joined Actiſanes the king of Ethiopia to drive him out.—Thus Actiſanes became maſter of the kingdom; and after his death follows another chaſm in the hiſtory, during which the empire is ſaid to have been in a ſtate of anarchy for five generations.—This period brings us down to the times of the Trojan war. The reigning prince in Egypt was at that time called *Cetes;* by the Greeks, *Proteus*. The prieſts reported that he was a magician; and that he could aſſume any ſhape he pleaſed, even that of fire. This fable, as told by the Greeks, drew its origin from a cuſtom among the Egyptians, perhaps introduced by Proteus. They were uſed to adorn and diſtinguiſh the heads of their kings with the repreſentations of animals or vegetables, or

Origin of
the fable of
Proteus.

7 Arrival of Paris and Helen in Egypt.

8 Egypt conquered by Sabbaco.

even with burning incenſe, in order to ſtrike the beholders with the greater awe. Whilſt Proteus reigned, Paris or Alexander, the ſon of Priam king of Troy, was driven by a ſtorm on the coaſt of Egypt, with Helen, whom he was carrying off from her huſband. But when the Egyptian monarch heard of the breach of hoſpitality committed by Paris, he ſeized him, his miſtreſs, and companions, with all the riches he had brought away with him from Greece. He detained Helen, with all the effects belonging to Menelaus her huſband, promiſing to reſtore them to the injured party whenever they were demanded; but commanded Paris and his companions to depart out of his dominions in three days, on pain of being treated as enemies. In what manner Paris afterwards prevailed upon Proteus to reſtore his miſtreſs, we are not told; neither do we know any thing further of the tranſactions of this prince's reign nor of his ſucceſſors, except what has entirely the air of fable, till the days of Sabbaco the Ethiopian, who again conquered this kingdom. He began his reign with an act of great cruelty, cauſing the conquered prince to be burnt alive: nevertheleſs, he no ſooner ſaw himſelf firmly eſtabliſhed on the throne of Egypt, than he became a new man; ſo that he is highly extolled for his mercy, clemency, and wiſdom. He is thought to have been the *So* mentioned in Scripture, and who entered into a league with Hoſhea king of Iſrael againſt Shalmaneſer king of Aſſyria. He is ſaid to have been excited to the invaſion of Egypt by a dream or viſion, in which he was aſſured that he ſhould hold that kingdom for 50 years. Accordingly, he conquered Egypt, as had been foretold; and at the expiration of the time above mentioned, he had another dream, in which the tutelar god of Thebes acquainted him, that he could no longer hold the kingdom of Egypt with ſafety and happineſs, unleſs he maſſacred the prieſts as he paſſed through them with his guards. Being haunted with this viſion, and at the ſame time abhorring to hold the kingdom on ſuch terms, he ſent for the prieſts, and acquainted them with what ſeemed to be the will of the gods. Upon this it was concluded, that it was the pleaſure of the Deity that Sabbaco ſhould remain no longer in Egypt; and therefore he immediately quitted that kingdom, and returned to Ethiopia.

9 Remarkable ſtory of Sethon.

Of *Anyſias*, who was Sabbaco's immediate ſucceſſor, we have no particulars worth notice. After him reigned one Sethon, who was both king and prieſt of Vulcan. He gave himſelf up to religious contemplation; and not only neglected the military claſs, but deprived them of their lands. At this they were ſo much incenſed, that they entered into an agreement not to bear arms under him; and in this ſtate of affairs Sennacherib king of Aſſyria arrived before Peluſium with a mighty army. Sethon now applied to his ſoldiers, but in vain: they unanimouſly perſiſted in refuſing to march under his banner. Being therefore deſtitute of all human aid, he applied to the god Vulcan, and requeſted him to deliver him from his enemies. Whilſt he was yet in the temple of that god, it is ſaid he fell into a deep ſleep; during which he ſaw Vulcan ſtanding at his ſide, and exhorting him to take courage. He promiſed, that if Sethon would but go out againſt the Aſſyrians, he ſhould obtain a complete victory over them. Encouraged by this aſſurance, the king aſſembled a body of artificers, ſhop-keepers, and labourers; and, with this undiſciplined rabble, marched towards Peluſium. He had no occaſion, however, to fight; for the very night after his arrival at Peluſium, an innumerable multitude of field rats entering the enemies camp, gnawed to pieces the quivers, bowſtrings, and ſhield ſtraps. Next morning, when Sethon found the enemy diſarmed, and on that account beginning to fly, he purſued them to a great diſtance, making a terrible ſlaughter. In memory of this extraordinary event, a ſtatue of Sethon was erected in the temple of Vulcan, holding in one hand a rat, and delivering theſe words: "Whoſoever beholdeth me let him be pious."

10 Reign of Pſammit chus.

Soon after the death of Sethon, the form of government in Egyt was totally changed. The kingdom was divided into twelve parts, over which as many of the chief nobility preſided. This diviſion, however, ſubſiſted but for a ſhort time. Pſammitichus, one of the twelve, dethroned all the reſt, 15 years after the diviſion had been made. The hiſtory now begins to be diveſted of fable; and from this time may be accounted equally certain with that of any other nation. The vaſt conqueſts of Seſoſtris were now no longer known; for Pſammitichus poſſeſſed no more than the country of Egypt itſelf. It appears, indeed, that none of the ſucceſſors of Seſoſtris, or even that monarch himſelf, had made uſe of any means to keep in ſubjection the countries he had once conquered. Perhaps, indeed, his deſign originally was rather to *pillage* than to conquer; and therefore, on his return, his vaſt empire vaniſhed at once. Pſammitichus, however, endeavoured to extend his dominions by making war on his neighbours; but by putting more confidence in foreign auxiliaries than in his own ſubjects, the latter were ſo much offended, that upwards of 200,000 fighting men emigrated in a body, and took up their reſidence in Ethiopia. To repair this loſs, Pſammitichus earneſtly applied himſelf to the advancement of commerce; and opened his ports to all ſtrangers, whom he greatly careſſed, contrary to the cruel maxims of his predeceſſors, who refuſed to admit them into the country. He alſo laid ſiege to the city of Azotus in Syria, which held out for 29 years againſt the whole ſtrength of the kingdom; from which we may gather, that, as a warrior, Pſammitichus was by no means remarkable. He is reported to have been the firſt king of Egypt that drank wine. He alſo ſent to diſcover the ſprings of the Nile; and is ſaid to have attempted to diſcover the moſt ancient nation in the world by the following method. Having procured two newly born children, he cauſed them to be brought up in ſuch a manner that they never heard a human voice. He imagined that theſe children would naturally ſpeak the original language of mankind: therefore, when, at two years of age, they pronounced the Phrygian word *beccos* (or ſome ſound reſembling it), which ſignifies bread, he concluded that the Phrygians were the moſt ancient people in the world.

11 Succeede by Nech

Nechus, the ſon and ſucceſſor of Pſammitichus, is the *Pharaoh-Necho* of Scripture, and was a prince of an enterpriſing and warlike genius. In the beginning of his reign, he attempted to cut through the iſthmus of Suez, between the Red ſea and the Mediterranean; but, through the invincible obſtacles which nature has thrown in the way of ſuch undertakings, he was obliged

ged to abandon the enterpriſe, after having loſt 120,000 men in the attempt. After this he ſent a ſhip, manned with ſome expert Phœnician mariners, on a voyage to explore the coaſts of Africa. Accordingly, they performed the voyage; ſailed round the continent of Africa; and after three years returned to Egypt, where their relation was deemed incredible.

12
is wars
th Joſiah
d Nebu-
adnez-
r.

The moſt remarkable wars in which this king was engaged are recorded in the ſacred writings. He went out againſt the king of Aſſyria, by the divine command, as he himſelf told Joſiah; but being oppoſed by the king of Judea, he defeated and killed him at Megiddo; after which he ſet up, in that country, King Jehoiakim, and impoſed on him an annual tribute of 100 talents of ſilver and one talent of gold. He then proceeded againſt the king of Aſſyria; and weakened him ſo much, that the empire was ſoon after diſſolved. Thus he became maſter of Syria and Phœnicia; but in a ſhort time, Nebuchadnezzar king of Babylon came againſt him with a mighty army. The Egyptian monarch, not daunted by the formidable appearance of his antagoniſt, boldly ventured a battle; but was overthrown with prodigious ſlaughter, and Nebuchadnezzar became maſter of all the country to the very gates of Peluſium.

13
ries a
rtial and
ceſsful
nce.

The reign of Apries, the *Pharaoh-Hophra* of Scripture, preſents us with a new revolution in the Egyptian affairs. He is repreſented as a martial prince, and in the beginning of his reign very ſucceſsful. He took by ſtorm the rich city of Sidon; and having overcome the Cypriots and Phœnicians in a ſea fight, returned to Egypt laden with ſpoil. This ſucceſs probably incited Zedekiah king of Judæa to enter into an alliance with him againſt Nebuchadnezzar king of Babylon. The bad ſucceſs of this alliance was foretold by the prophet Jeremiah; and accordingly it happened. For Nebuchadnezzar having ſat down with his army before Jeruſalem, Apries marched from Egypt, with a deſign to relieve the city; but no ſooner did he perceive the Babylonians approaching him, than he retreated as faſt as he could, leaving the Jews expoſed to the rage of their mercileſs enemies; who were thereupon treated as Jeremiah had foretold; and by this ſtep Apries brought upon himſelf the vengeance denounced by the ſame prophet. The manner in which theſe predictions were fulfilled is as follows: The Cyreneans, a colony of the Greeks, being greatly ſtrengthened by a numerous ſupply of their countrymen under their third king *Battus* ſtyled *the Happy*, and encouraged by the Pythian oracle, began to drive out their Libyan neighbours, and ſhared their poſſeſſions among themſelves. Hereupon Andica king of Libya ſent a ſubmiſſive embaſſy to Apries, and implored his protection againſt the Cyreneans. Apries complied with his requeſt, and ſent a powerful army to his relief. The Egyptians were defeated with great ſlaughter; and thoſe who returned complained that the army had been ſent off by Apries in order to be deſtroyed, and that he might tyrannize without controul over the remainder of his ſubjects. This thought catching the attention of the giddy multitude, an almoſt univerſal defection enſued. Apries ſent one Amaſis, a particular friend, in whom he thought he could confide, to bring back his people to a ſenſe of their duty. But by this friend he was betrayed; for Amaſis, taking the opportunity of the preſent ferment, cauſed himſelf to be proclaimed king. Apries then deſpatched one Patarbemis, with orders to take Amaſis, and bring him alive before him. This he found impoſſible, and therefore returned without his priſoner; at which the king was ſo enraged, that he commanded Patarbemis's noſe and ears to be cut off. This piece of cruelty completed his ruin; for when the reſt of the Egyptians who continued faithful to Apries beheld the inhuman mutilation of ſo worthy and noble a perſon as Patarbemis was, they to a man deſerted Apries, and went over to Amaſis.

ſubjects
olt.

Both parties now prepared for war; the uſurper having under his command the whole body of native Egyptians; and Apries only thoſe Ionians, Carians, and other mercenaries whom he could engage in his ſervice. The army of Apries amounted only to 30,000; but, though greatly inferior in number to the troops of his rival, as he well knew that the Greeks were much ſuperior in valour, he did not doubt of victory. Nay, ſo far was Apries puffed up with this notion, that he did not believe it was in the power even of any *god* to deprive him of his kingdom. The two armies ſoon met, and drew up in order of battle near Memphis. A bloody engagement enſued; in which, though the army of Apries behaved with the greateſt reſolution, they were at laſt overpowered with numbers, and utterly defeated, the king himſelf being taken priſoner. Amaſis now took poſſeſſion of the throne without oppoſition. He confined Apries in one of his palaces, but treated him with great care and reſpect. The people, however, were implacable, and could not be ſatisfied while he enjoyed his life. Amaſis, therefore, at laſt found himſelf obliged to deliver him into their hands. Thus the prediction received its final completion: Apries was delivered up to thoſe *who ſought his life*; and who no ſooner had him in their power, than they ſtrangled him, and laid his body in the ſepulchre of his anceſtors.

16
Apries defeated and taken priſoner by Amaſis.

17
Egypt invaded by Nebuchadnezzar.

During theſe inteſtine broils, which muſt have greatly weakened the kingdom, it is probable that Nebuchadnezzar invaded Egypt. He had been for 13 years before this employed in beſieging Tyre, and at laſt had nothing but an empty city for his pains. To make himſelf ſome amends, therefore, he entered Egypt, miſerably haraſſed the country, killed and carried away great numbers of the inhabitants, ſo that the country did not recover from the effects of this incurſion for a long time after. In this expedition, however, he ſeems not to have aimed at any permanent conqueſt, but to have been induced to it merely by the love of plunder, and of this he carried with him an immenſe quantity to Babylon.

18
Happy adminiſtration of Amaſis.

During the reign of Amaſis, Egypt is ſaid to have been perfectly happy, and to have contained 20,000 populous cities. That good order might be kept among ſuch vaſt numbers of people, Amaſis enacted a law, by which every Egyptian was bound once a-year to inform the governor of his province by what means he gained his livelihood; and if he failed of this, to put him to death. The ſame puniſhment he decreed to thoſe who could not give a ſatisfactory account of themſelves.

This monarch was a great favourer of the Greeks, and married a woman of Grecian extract. To many

Greek cities, as well as particular perſons, he made conſiderable preſents. Beſides theſe, he gave leave to the Greeks in general to come into Egypt, and ſettle either in the city of Naucratis, or carry on their trade upon the ſea coaſts; granting them alſo temples, and places where they might erect temples to their own deities. He received alſo a viſit from Solon the celebrated Athenian lawgiver, and reduced the iſland of Cyprus under his ſubjection.

19
Offends
Cambyſes
king of
Perſia.

This great proſperity, however, ended with the death of Amaſis, or indeed before it. The Egyptian monarch had ſome how or other incenſed Cambyſes king of Perſia. The cauſe of the quarrel is uncertain; but whatever it was, the Perſian monarch vowed the deſtruction of Amaſis. In the mean time *Phanes* of Halicarnaſſus, commander of the Grecian auxiliaries in the pay of Amaſis, took ſome private diſguſt; and leaving Egypt, embarked for Perſia. He was a wiſe and able general, perfectly well acquainted with every thing that related to Egypt; and had great credit with the Greeks in that country. Amaſis was immediately ſenſible how great the loſs of this man would he to him, and therefore ſent after him a truſty eunuch with a ſwift galley. Phanes was accordingly overtaken in Lycia, but not brought back; for making his guard drunk, he continued his journey to Perſia, and preſented himſelf before Cambyſes, as he was meditating the deſtruction of the Egyptian monarchy.

20
And Polycrates tyrant of
Samos.

At this dangerous criſis alſo, the Egyptian monarch imprudently made Polycrates the tyrant of Samos his enemy. This man had been the moſt remarkable perhaps of any recorded in hiſtory, for an uninterrupted courſe of ſucceſs, without the intervention of one ſingle unfortunate event. Amaſis, who was at this time in ſtrict alliance with Polycrates, wrote him a letter, in which, after congratulating him on his proſperity, he told him that he was afraid leſt his ſucceſſes were too many, and he might be ſuddenly thrown down into the greateſt miſery. For this reaſon he adviſed him voluntarily to take away ſomething from his own happineſs; and to caſt away that which would grieve him moſt if he was accidentally to loſe it. Polycrates followed his advice, and threw into the ſea a ſignet of ineſtimable value. This, however, did not anſwer the intended purpoſe. The ſignet happened to be ſwallowed by a fiſh, which was taken a few days afterwards, and thus was reſtored to Polycrates. Of this Amaſis was no ſooner informed, than, conſidering Polycrates as really *unhappy*, and already on the brink of deſtruction, he reſolved to put an end to the friendſhip which ſubſiſted between them. For this purpoſe he deſpatched a herald to Samos, commanding him to acquaint Polycrates, that he renounced his alliance, and all the obligations between them; that he might not mourn his misfortunes with the ſorrow of a friend. Thus Amaſis left Polycrates at liberty to act againſt him, if he choſe to do ſo; and accordingly he offered to aſſiſt Cambyſes with a fleet of ſhips in his Egyptian expedition.

21
Egypt invaded by
Cambyſes.

Amaſis had not, however, the misfortune to ſee the calamities of his country. He died about 525 years before Chriſt, after a reign of 44 years; and left the kingdom to his ſon Pſammenitus, juſt as Cambyſes was approaching the frontiers of the kingdom. The new prince was ſcarce ſeated on the throne, when the Perſians appeared. Pſammenitus drew together what forces he could, in order to prevent them from entering the kingdom. Cambyſes, however, immediately laid ſiege to Peluſium, and made himſelf maſter of it by the following ſtratagem: he placed in the front of his army a great number of cats, dogs, and other animals that were deemed ſacred by the Egyptians. He then attacked the city, and took it without oppoſition; the garriſon, which conſiſted entirely of Egyptians, not daring to throw a dart or ſhoot an arrow againſt their enemies, leſt they ſhould kill ſome of the holy animals.

22
Cruelty
defeat of
the Egy
tians.

Cambyſes had ſcarce taken poſſeſſion of the city, when Pſammenitus advanced againſt him with a numerous army. But before the engagement, the Greeks who ſerved under Pſammenitus, to ſhow their indignation againſt their treacherous countryman Phanes, brought his children into the camp, killed them in the preſence of their father and of the two armies, and then drank their blood. The Perſians enraged at ſo cruel a ſight, fell upon the Egyptians with the utmoſt fury, put them to flight, and cut the greateſt part of them in pieces. Thoſe who eſcaped fled to Memphis, where they were ſoon after guilty of a horrid outrage. Cambyſes ſent a herald to them in a ſhip from Mitylene: but no ſooner did they ſee her come into the port, than they flocked down to the ſhore, deſtroyed the ſhip, and tore to pieces the herald and all the crew; afterwards carrying their mangled limbs into the city, in a kind of barbarous triumph. Not long after, they were obliged to ſurrender: and thus Pſammenitus fell into the hands of his inveterate enemy, who was now enraged beyond meaſure at the cruelties exerciſed upon the children of Phanes, the herald, and the Mitylenean ſailors.

23
Their
dreadful
puniſhm
by Camb
ſes.

The rapid ſucceſs of the Perſians ſtruck with ſuch terror the Libyans, Cyreneans, Barcæans, and other dependents or allies of the Egyptian monarch, that they immediately ſubmitted. Nothing now remained but to diſpoſe of the captive king, and revenge on him and his ſubjects the cruelties which they had committed. This the mercileſs victor executed in the ſevereſt manner. On the 10th day after Memphis had been taken, Pſammenitus and the chief of the Egyptian nobility were ignominiouſly ſent into one of the ſuburbs of that city. The king being there ſeated in a proper place, ſaw his daughter coming along in the habit of a poor ſlave with a pitcher to fetch water from the river, and followed by the daughters of the greateſt families in Egypt, all in the ſame miſerable garb, with pitchers in their hands, drowned in tears, and loudly bemoaning their miſerable ſituation. When the fathers ſaw their daughters in this diſtreſs, they burſt into tears, all but Pſammenitus, who only caſt his eyes on the ground and kept them fixed there. After the young women, came the ſon of Pſammenitus, with 2000 of the young nobility, all of them with bits in their mouths and halters round their necks, led to execution. This was done to expiate the murder of the Perſian herald and the Mitylenean ſailors; for Cambyſes cauſed ten Egyptians of the firſt rank to be publicly executed for every one of thoſe that had been ſlain. Pſammenitus, however, obſerved the ſame conduct as before, keeping his eyes ſtedfaſtly fixed on the ground, though all the Egyptians around him made the loudeſt lamentations,

tions. A little after this he ſaw an intimate friend and companion, now advanced in years, who having been plundered of all he had, was begging his bread from door to door in the ſuburbs. As ſoon as he ſaw this man, Pſammenitus wept bitterly; and calling out to him by his name, ſtruck himſelf on the head as if he had been frantic. Of this the ſpies who had been ſet over him to obſerve his behaviour, gave immediate notice to Cambyſes, who thereupon ſent a meſſenger to inquire the cauſe of ſuch immoderate grief. Pſammenitus anſwered, That the calamities of his own family confounded him, and were too great to be lamented by any outward ſigns of grief; but the extreme diſtreſs of a boſom friend gave more room for reflection, and therefore extorted tears from him. With this anſwer Cambyſes was ſo affected, that he ſent orders to prevent the execution of the king's ſon; but theſe came too late, for the young prince had been put to death before any of the reſt. Pſammenitus himſelf was then ſent for into the city, and reſtored to his liberty: and had he not ſhowed a deſire of revenge, might perhaps have been truſted with the government of Egypt; but being diſcovered hatching ſchemes againſt the government, he was ſeized, and condemned to drink bull's blood.

4 t be- s a nce of erſian, fter- s of recian e.

The Egyptians were now reduced to the loweſt degree of ſlavery. Their country became a province of the Perſian empire: the body of Amaſis their late king was taken out of his grave; and after being mangled in a ſhocking manner was finally burnt. But what ſeemed more grievous than all the reſt, their god Apis was ſlain, and his prieſts ignominiouſly ſcourged; and this inſpired the whole nation with ſuch a hatred to the Perſians, that they could never afterwards be reconciled to them. As long as the Perſian empire ſubſiſted, the Egyptians could never ſhake off their yoke. They frequently revolted indeed, but were always overthrown with prodigious loſs. At laſt they ſubmitted, without oppoſition, to Alexander the Great: after his death, Egypt again became a powerful kingdom; though ſince the conqueſt of it by Cambyſes to the preſent time it hath never been governed but by foreign princes, agreeable to the prophecy of Ezekiel, "There ſhall be no more a prince of the land of Egypt."

ed to ny , who s the

On the death of Alexander the Great, Egypt, together with Libya, and that part of Arabia which borders on Egypt, were aſſigned to Ptolemy Lagus as governor under Alexander's ſon by Roxana, who was but newly born. Nothing was farther from the intention of this governor, than to keep the provinces in truſt for another. He did not, however, aſſume the title of *king*, till he perceived his authority ſo firmly eſtabliſhed that it could not be ſhaken; and this did not happen till 19 years after the death of Alexander, when Antigonus and Demetrius had unſucceſsfully attempted the conqueſt of Egypt.

From the time of his firſt eſtabliſhment on the throne, Ptolemy, who had aſſumed the title of *Soter*, reigned 20 years; which added to the former 19, make up the 39 years which hiſtorians commonly allow him to have reigned alone.—In the 39th year of his reign, he made one of his ſons, named *Philadelphus*, partner to the empire; declaring him his ſucceſſor, to the prejudice of his eldeſt ſon named *Ceraunus*; being excited thereto by his violent love for *Berenice* Philadelphus's mother. When the ſucceſſion was thus ſettled, Ceraunus immediately quitted the court; and fled at laſt into Syria, where he was received with open arms by Seleucus Nicator, whom he afterwards murdered.

The moſt remarkable tranſaction of this reign was the embelliſhing of the city of Alexandria, which Ptolemy made the capital of his new kingdom, and of which an account is given under the article ALEXANDRIA. About 284 years before Chriſt, died Ptolemy Soter, in the 41ſt year of his reign, and 84th of his age. He was the beſt prince of his race; and left behind him an example of prudence, juſtice, and clemency which few of his ſucceſſors choſe to follow. Beſides the provinces originally aſſigned to him, he has added to his empire thoſe of Cælo-Syria, Ethiopia, Pamphylia, Lycia, Caria, and ſome of the Cyclades. His ſucceſſor, Ptolemy Philadelphus, added nothing to the extent of the empire; nor did he perform any thing worthy of notice except embelliſhing further the city of Alexandria, and entering into an alliance with the Romans. In his time, one Magas, the governor of Libya and Cyrene, revolted: and held theſe provinces as an independent prince, notwithſtanding the utmoſt efforts of Ptolemy to reduce him. At laſt an accommodation took place; and a marriage was propoſed between Berenice, the only daughter of Magas, and Ptolemey's eldeſt ſon. The young princeſs was to receive all her father's dominions by way of dowry, and thus they would again be brought under the dominion of Ptolemy's family. But before this treaty could be put in execution, Magas died; and then Apamea, the princeſs's mother, did all ſhe could to prevent the match. This, however, ſhe was not able to do; though her efforts for that purpoſe produced a deſtructive war of four years continuance with Antiochus Theus king of Syria, and the acting of a cruel tragedy in the family of the latter. See SYRIA.

26 Succeeded by Philadelphus.

27 Ptolemy Euergetes a great conqueror.

About 246 years before Chriſt, Ptolemy Philadelphus died; and was ſucceeded by his eldeſt ſon Ptolemy, who had been married to Berenice the daughter of Magas as above related. In the beginning of his reign, he found himſelf engaged in a war with Antiochus Theus king of Syria. From this he returned victorious, and brought with him 2500 ſtatues and pictures, among which were many of the ancient Egyptian idols, which had been carried away of Cambyſes into Perſia. Theſe were reſtored by Ptolemy to their ancient temples; in memory of which favonr, the Egyptians gave him the ſurname of *Euergetes*, or the Beneficent. In this expedition he greatly enlarged his dominions, making himſelf maſter of all the countries that lie between Mount Taurus and the confines of India. An account of theſe conqueſts was given by himſelf, inſcribed on a monument, to the following effect. "Ptolemy Euergetes, having received from his father the ſovereignty of Egypt, Libya, Syria, Phœnice, Cyprus, Lycia, Caria, and the other Cyclades, aſſembled a mighty army of horſe and foot, with a great fleet, and elephants, out of Trogloditia and Ethiopia; ſome of which had been taken by his father, and the reſt by himſelf, and brought from thence, and trained up for war; with this great force he ſailed into Aſia; and having conquered all the provinces which lie on this ſide the Euphrates, Cilicia, Pamphylia, Ionia, the Helleſpont,

Helleſpont, and Thrace, he croſſed that river with all the forces of the conquered countries, and the kings of thoſe nations, and reduced Meſopotamia, Babylonia, Suſiana, Perſia, Media, and all the country as far as Bactria."

On the king's return from this expedition, he paſſed through Jeruſalem, where he offered many ſacrifices to the God of Iſrael, and ever afterwards expreſſed a great favour for the Jewiſh nation. At this time, the Jews were tributaries to the Egyptian monarchs, and paid them annually 20 talents of ſilver. This tribute, however, Onias, who was then high prieſt, being of a very covetous diſpoſition, had for a long time neglected to pay, ſo that the arrears amounted to a very large ſum. Soon after his return, therefore, Ptolemy ſent one of his courtiers named *Athenion* to demand the money, and deſired him to acquaint the Jews that he would make war upon them in caſe of a refuſal. A young man, however, named *Joſeph*, nephew to Onias, not only found means to avert the king's anger, but even got himſelf choſen his receiver general, and by his faithful diſcharge of that important truſt, continued in high favour with Ptolemy as long as he lived.

28 Cleomenes king of Sparta takes refuge in Egypt.

Ptolemy Euergetes having at laſt concluded a peace with Seleucus the ſucceſſor of Antiochus Theus king of Syria, attempted the enlargement of his dominions on the ſouth ſide. In this he was attended with ſuch ſucceſs, that he made himſelf maſter of all the coaſts of the Red ſea, both on the Arabian and Ethiopian ſides, quite down to the ſtraits of Babelmandel. On his return he was met by ambaſſadors from the Achæans, imploring his aſſiſtance againſt the Etolians and Lacedemonians. This the king readily promiſed them: but they having in the mean time engaged Antigonus king of Macedon to ſupport them, Ptolemy was ſo much offended, that he ſent powerful ſuccours to Cleomenes king of Sparta; hoping, by that means, to humble both the Achæans and their new ally Antigonus. In this, however, he was diſappointed; for Cleomenes, after having gained very conſiderable advantages over the enemy, was at laſt entirely defeated in the battle of Sellaſia, and obliged to take refuge in Ptolemy's dominions. He was received by the Egyptian monarch with the greateſt demonſtrations of kindneſs; a yearly penſion of 24 talents was aſſigned him, with a promiſe of reſtoring him to the Spartan throne; but before this could be accompliſhed, the king of Egypt died, in the 27th year of his reign, and was ſucceeded by his ſon Ptolemy Philopater.

29 Ptolemy Philopater a cruel tyrant.

Thus we have ſeen the Egyptian empire brought to a very great height of power; and had the ſucceeding monarchs been careful to preſerve that ſtrength of empire tranſmitted to them by Euergetes, it is very probable that Egypt might have been capable of holding the balance againſt Rome, and after the deſtruction of Carthage prevented that haughty city from becoming miſtreſs of the world. But after the death of Ptolemy Euergetes, the Egyptian empire, being governed only by weak or vicious monarchs, quickly declined, and from that time makes no conſpicuous figure in hiſtory. Ptolemy Philopater began his reign with the murder of his brother; after which, giving himſelf up to all manner of licentiouſneſs, the kingdom fell into a kind of anarchy. Cleomenes the Spartan king ſtill reſided at court; and being now unable to bear the diſſolute manners which prevailed there, he preſſed Philopater to give him the aſſiſtance he had promiſed for reſtoring him to the throne of Sparta. This he the rather inſiſted upon, becauſe he had received advice that Antigonus king of Macedon was dead, that the Achæans were engaged in a war with the Etolians, and that the Lacedemonians had joined the latter againſt the Achæans and Macedonians. Ptolemy, when afraid of his brother Magas, had indeed promiſed to aſſiſt the king of Sparta with a powerful fleet, hoping by this means to attach him to his own intereſt; but now when Magas was out of the way, it was determined by the king, or rather his miniſters, that Cleomenes ſhould not be aſſiſted, nor even allowed to leave the kingdom; and this extravagant reſolution produced the deſperate attempt of Cleomenes, of which an account is given in the hiſtory of SPARTA.

Of the diſorders which now enſued in the government, Antiochus king of Syria, ſurnamed *the Great*, took the advantage, and attempted to wreſt from Ptolemy the provinces of Cælo-Syria and Paleſtine. But in this he was finally diſappointed; and might eaſily have been totally driven out of Syria, had not Ptolemy been too much taken up with his debaucheries to think of carrying on the war. The diſcontent occaſioned by this piece of negligence ſoon produced a civil war in his dominions, and the whole kingdom continued in the utmoſt confuſion till his death, which happened in the 17th year of his reign and 37th of his age.

3 Extrao nary ſ concer the Je

During the reign of Philopater happened a very extraordinary event with regard to the Jews, which is mentioned in the Maccabees *. The king of Egypt, while on his Syrian expedition, had attempted to enter the temple of Jeruſalem; but being hindered by the Jews, he was filled with the utmoſt rage againſt the whole nation. On his return to Alexandria, he reſolved to make thoſe who dwelt in that city feel the firſt effects of his vengeance. He began with publiſhing a decree, which he cauſed to be engraved on a pillar erected for that purpoſe at the gate of his palace, excluding all thoſe who did not ſacrifice to the gods worſhipped by the king. By this means the Jews were debarred from ſuing to him for juſtice, or obtaining his protection when they happened to ſtand in need of it. By the favour of Alexander the Great, Ptolemy Soter, and Euergetes, the Jews enjoyed at Alexandria the ſame privileges with the Macedonians. In that metropolis the inhabitants were divided into three ranks or claſſes. In the firſt were the Macedonians, or original founders of the city, and along with them were enrolled the Jews; in the ſecond were the mercenaries who had ſerved under Alexander; and in the third the native Egyptians. Ptolemy now, to be revenged of the Jews, ordered, by another decree, that they ſhould be degraded from the firſt rank, and enrolled among the native Egyptians. By the ſame decree it was enacted, that all of that nation ſhould appear at an appointed time before the proper officers, in order to be enrolled among the common people; that at the time of their enrollment they ſhould have the mark of an ivy leaf, the badge of Bacchus, impreſſed with a hot iron on their faces; that all who were thus marked ſhould be made ſlaves; and, laſtly, that if any one ſhould ſtand out againſt this decree, he ſhould be

---

* Lib. 3, 4, 5

immediately put to death. That he might not, however, ſeem an enemy to the whole nation, he declared, that thoſe who ſacrificed to his gods ſhould enjoy their former privileges, and remain in the ſame claſs. Yet, notwithſtanding this tempting offer, 300 only out of many thouſand Jews who lived in Alexandria could be prevailed upon to abandon their religion in order to ſave themſelves from ſlavery.

The apoſtates were immediately excommunicated by their brethren: and this their enemies conſtrued as done in oppoſition to the king's order; which threw the tyrant into ſuch a rage, that he reſolved to extirpate the whole nation, beginning with the Jews who lived in Alexandria and other cities of Egypt, and proceeding from thence to Judæa and Jeruſalem itſelf. In conſequence of this cruel reſolution, he commanded all the Jews that lived in any part of Egypt to be brought in chains to Alexandria, and there to be ſhut up in the Hippodrome, which was a very ſpacious place without the city, where the people uſed to aſſemble to ſee horſe races and other public diverſions. He then ſent for Herman maſter of the elephants; and commanded him to have 500 of theſe animals ready againſt the next day, to let looſe upon the Jews in the Hippodrome. But when the elephants were prepared for the execution, and the people were aſſembled in great crowds to ſee it, they were for that day diſappointed by the king's abſence. For, having been late up the night before with ſome of his debauched companions, he did not awake till the time for the ſhow was over, and the ſpectators returned home. He therefore ordered one of his ſervants to call him early on the following day, that the people might not meet with a ſecond diſappointment. But when the perſon awaked him according to his order, the king was not yet returned to his ſenſes; having withdrawn, exceedingly drunk, only a ſhort time before. As he did not remember the order, he therefore fell into a violent paſſion, and threatened with death the ſervant who had awaked him; and this cauſed the ſhow to be put off till the third day. At laſt the king came to the Hippodrome attended with a vaſt multitude of ſpectators; but when the elephants were let looſe, inſtead of falling upon the Jews, they turned their rage againſt the ſpectators and ſoldiers, and deſtroyed great numbers of them. At the ſame time, ſome frightful appearances which were ſeen in the air ſo terrified the king, that he commanded the Jews to be immediately ſet at liberty, and reſtored them to their former privileges. No ſooner were they delivered from this danger than they demanded leave to put to death ſuch of their nation as had abandoned their religion; and this being granted, they deſpatched the apoſtates without excepting a ſingle man.

tor ri- , ius, ſ- ed

Philopater was ſucceeded by Ptolemy Epiphanes; and he, after a reign of 24 years, by Ptolemy Philometor. In the beginning of his reign, a war commenced with the king of Syria, who had ſeized on the provinces of Cælo-Syria and Paleſtine in the preceding reign. In the courſe of this war, Philometor was either voluntarily delivered up to Antiochus or taken priſoner. But however this was, the Alexandrians deſpairing of his ever being able to recover his liberty, raiſed to the throne his brother Ptolemy, who took the name of *Euergetes II.* but was afterwards called *Phyſcon* or "the great bellied," on account of the prominent belly which by his gluttony and luxury he had acquired. He was ſcarce ſeated on the throne, however, when Antiochus Epiphanes, returning into Egypt, drove out Phyſcon, and reſtored the whole kingdom except Peluſium, to Philometor. His deſign was to kindle a war betwixt the two brothers ſo that he might have an opportunity of ſeizing the kingdom for himſelf. For this reaſon he kept to himſelf the city of Peluſium; which being the key of Egypt, he might at his pleaſure re-enter the country. But Philometor, appriſed of his deſign, invited his brother Phyſcon to an accommodation; which was happily effected by their ſiſter Cleopatra. In virtue of this agreement, the brothers were to reign jointly, and to oppoſe to the utmoſt of their power Antiochus, whom they conſidered as a common enemy. On this the king of Syria invaded Egypt with a mighty army, but was prevented by the Romans from conquering it.

Egypt.

32 Philometor reſtored, and reigns jointly with his brother.

33 Difference between the two brothers decided by the Roman ſenate.

The two brothers were no ſooner freed from the apprehenſions of a foreign enemy than they began to quarrel with each other. Their differences ſoon came to ſuch a height, that the Roman ſenate interpoſed. But before the ambaſſadors employed to inquire into the merits of the cauſe could arrive in Egypt, Phyſcon had driven Philometor from the throne, and obliged him to quit the kingdom. On this the dethroned prince fled to Rome, where he appeared meanly dreſſed, and without attendants. He was very kindly received by the ſenate; who were ſo well ſatisfied of the injuſtice done him, that they immediately decreed his reſtoration. He was reconducted accordingly; and, on the arrival of the ambaſſadors in Egypt, an accommodation between the two brothers was negotiated. By this agreement, Phyſcon was put in poſſeſſion of Libya and Cyrene, and Philometor of all Egypt and the iſland of Cyprus; each of them being declared independent of the other in the dominion allotted to them. The treaty, as uſual, was confirmed with oaths and ſacrifices, and was broken almoſt as ſoon as made. Phyſcon was diſſatisfied with his ſhare of the dominions; and therefore ſent ambaſſadors to Rome, deſiring that the iſland of Cyprus might be added to his other poſſeſſions. This could not be obtained by the ambaſſadors; and therefore Phyſcon went to Rome in perſon. His demand was evidently unjuſt; but the Romans, conſidering that it was their intereſt to weaken the power of Egypt as much as poſſible, without further ceremony adjudged the iſland to him.

34 Iſland of Cyprus adjudged to Phyſcon.

Phyſcon ſet out from Rome with two ambaſſadors; and arriving in Greece on his way to Cyprus, he raiſed there a great number of mercenaries, with a deſign to ſail immediately to that iſland and conquer it. But the Roman ambaſſadors telling him, that they were commanded to put him in poſſeſſion of it by fair means and not by force, he diſmiſſed his army, and returned to Libya, while one of the ambaſſadors proceeded to Alexandria. Their deſign was to bring the two brothers to an interview on the frontiers of their dominions, and there to ſettle matters in an amicable manner. But the ambaſſador who went to Alexandria, found Philometor very averſe from compliance with the decree of the ſenate. He put off the ambaſſador ſo long, that Phyſcon ſent the other alſo to Alexandria, hoping that the joint perſuaſions of the two would induce

Egypt.

duce Philometor to comply. But the king, after entertaining them at an immenſe charge for 40 days, at laſt plainly refuſed to ſubmit, and told the ambaſſadors that he was reſolved to adhere to the firſt treaty. With this anſwer the Roman ambaſſadors departed, and were followed by others from the two brothers. The ſenate, however, not only confirmed their decree in favour of Phyſcon, but renounced their alliance with Philometor, and commanded his ambaſſador to leave the city in five days.

35 Philometor refuſes to comply.

36 Rebellion againſt Phyſcon.

In the mean time, the inhabitants of Cyrene having heard unfavourable accounts of Phyſcon's behaviour during the ſhort time he reigned in Alexandria, conceived ſo ſtrong an averſion againſt him, that they reſolved to keep him out of their country by force of arms. On receiving intelligence of this reſolution, Phyſcon dropped all thoughts of Cyprus for the preſent; and haſtened with all his forces to Cyrene, where he ſoon got the better of his rebellious ſubjects, and eſtabliſhed himſelf in the kingdom. His vicious and tyrannical conduct, however, ſoon eſtranged from him the minds of his ſubjects, in ſuch a manner, that ſome of them entering into a conſpiracy againſt him, fell upon him one night as he was returning to his palace, wounded him in ſeveral places, and left him for dead on the ſpot. This he laid to the charge of his brother Philometor; and as ſoon as he was recovered, took another voyage to Rome. Here he made his complaints to the ſenate, and ſhowed them the ſcars of his wounds, accuſing his brother of having employed the aſſaſſins from whom he received them. Though Philometor was known to be a man of a moſt humane and mild diſpoſition, and therefore very unlikely to have been concerned in ſo black an attempt; yet the ſenate, being offended at his refuſing to ſubmit to their decree concerning the iſland of Cyprus, hearkened to this falſe accuſation; and carried their prejudice ſo far, that they not only refuſed to hear what his ambaſſadors had to ſay, but ordered them immediately to depart from the city. At the ſame time, they appointed five commiſſioners to conduct Phyſcon into Cyprus, and put him in poſſeſſion of that iſland, enjoining all their allies in thoſe parts to ſupply him with forces for that purpoſe.

Phyſcon having by this means got together an army which ſeemed to him to be ſufficient for the accompliſhment of his deſign, landed in Cyprus; but being there encountered by Philometor in perſon, he was entirely defeated, and obliged to ſhelter himſelf in a city called *Lapitho*. Here he was cloſely beſieged, and at laſt obliged to ſurrender. Every one now expected that Phyſcon would have been treated as he deſerved; but his brother, inſtead of puniſhing, reſtored him to the government of Libya and Cyrene, adding ſome other territories inſtead of the iſland of Cyprus, and promiſing him his daughter in marriage. Thus an end was put to the war between the two brothers; for the Romans were aſhamed any longer to oppoſe a prince who had given ſuch a ſignal inſtance of his juſtice and clemency.

37 He is defeated and taken priſoner by Philometor

On his return to Alexandria, Philometor appointed one Archias governor of Cyprus. But he, ſoon after the king's departure, agreed with Demetrius king of Syria, to betray the iſland to him for 500 talents. The treachery was diſcovered before it took effect; and the traitor, to avoid the puniſhment due to his crime, laid violent hands on himſelf. Ptolemy being offended with Demetrius for this attempt on Cyprus, joined Attalus king of Pergamus, and Ariarathes king of Cappadocia, in ſetting up a pretender to the crown of Syria. This was Alexander Balas; to whom he even gave his daughter Cleopatra in marriage, after he had placed him on the throne of Syria. But he, notwithſtanding theſe and many other favours, being ſuſpected of having entered into a plot againſt his benefactor, Ptolemy became his greateſt enemy; and marching againſt him, routed his army in the neighbourhood of Antioch. He did not, however, long enjoy his victory; for he died in a few days after the engagement, of the wounds he had received.

Deat Philo tor.

On the death of Philometor, Cleopatra the queen deſigned to ſecure the throne for her ſon. But ſome of the principal nobility declaring for Phyſcon, a civil war was about to enſue, when matters were compromiſed on condition that Phyſcon ſhould marry Cleopatra, that he ſhould reign jointly with her during his life, and declare her ſon by Philometor heir to the crown. Theſe terms were no ſooner agreed upon than Phyſcon married Cleopatra, and, on the very day of the nuptials, murdered her ſon in her arms. This was only a prelude to the cruelties which he afterwards practiſed on his ſubjects. He was no ſooner ſeated on the throne, than he put to death all thoſe who had ſhown any concern for the murder of the young prince. He then wreaked his fury on the Jews, whom he treated more like ſlaves than ſubjects, on account of their having favoured the cauſe of Cleopatra. His own people were treated with little more ceremony. Numbers of them were every day put to death for the ſmalleſt faults, and often for no fault at all, but merely to gratify his inhuman temper. His cruelty towards the Alexandrians is particularly mentioned under the article ALEXANDRIA. In a ſhort time, being wearied of his queen, who was alſo his ſiſter, he divorced her; and married her daughter, who was alſo called *Cleopatra*, and whom he had previouſly raviſhed. In ſhort, his behaviour was ſo exceedingly wicked, that it ſoon became quite intolerable to his ſubjects; and he was obliged to fly to the iſland of Cyprus with his new queen, and *Memphitis*, a ſon he had by her mother.

Mon wicke of Ph

4 He is en ou

On the flight of the king, the divorced queen was placed on the throne by the Alexandrians; but Phyſcon, fearing leſt a ſon whom he had left behind ſhould be appointed king, ſent for him into Cyprus, and cauſed him to be aſſaſſinated as ſoon as he landed. This provoked the people againſt him to ſuch a degree, that they pulled down and daſhed to pieces all the ſtatues which had been erected to him in Alexandria. This the tyrant ſuppoſed to have been done at the inſtigation of the queen, and therefore reſolved to revenge it on her by killing his own ſon whom he had by her. He therefore, without the leaſt remorſe, cauſed the young prince's throat to be cut; and having put his mangled limbs into a box, ſent them as a preſent to his mother Cleopatra. The meſſenger with whom this box was ſent, was one of his guards. He was ordered to wait till the queen's birthday, which approached, and was to be celebrated with extraordinary pomp; and in the midſt of the general rejoicing, he was to deliver the preſent.

4 Murd his ſo

The horror and deteſtation occaſioned by this unexampled piece of cruelty cannot be expreſſed. An army pt.

army was ſoon raiſed, and the command of it given to one *Marſyas*, whom the queen had appointed general, and enjoined to take all the neceſſary ſteps for the defence of the country. On the other hand, Phyſcon, having hired a numerous body of mercenaries, ſent them, under the command of one *Hegelochus*, againſt the Egyptians. The two armies met on the frontiers of Egypt, on which a bloody battle enſued; but at laſt the Egyptians were entirely defeated, and Marſyas was taken priſoner. Every one expected that the captive general would have been put to death with the ſevereſt torments; but Phyſcon, perceiving that his cruelties only exaſperated the people, reſolved to try whether he could regain their affections by lenity; and therefore pardoned Marſyas, and ſet him at liberty.—Cleopatra, in the mean time, being greatly diſtreſſed by this overthrow, demanded aſſiſtance from Demetrius king of Syria, who had married her eldeſt daughter by Philometor, promiſing him the crown of Egypt for his reward. Demetrius accepted the propoſal without heſitation, marched with all his forces into Egypt, and there laid ſiege to Peluſium. But he being no leſs hated in Syria than Phyſcon was in Egypt, the people of Antioch, taking advantage of his abſence, revolted againſt him, and were joined by moſt of the other cities in Syria. Thus Demetrius was obliged to return; and Cleopatra, being now in no condition to oppoſe Phyſcon, fled to Ptolemais, where her daughter the queen of Syria at that time reſided. Phyſcon was then reſtored to the throne of Egypt, which he enjoyed without further moleſtation till his death; which happened at Alexandria, in the 29th year of his reign, and 67th of his age.

To Phyſcon ſucceeded Ptolemy Lathyrus, about 122 years before Chriſt; but he had not reigned long, before his mother, finding that he would not be entirely governed by her, by falſe ſurmiſes ſtirred up the Alexandrians, who drove him from the throne, and placed on it his youngeſt brother Alexander. Lathyrus after this was obliged to content himſelf with the government of Cyprus, which he was permitted to enjoy in quiet. Ptolemy Alexander, in the mean time, finding he was to have only the ſhadow of ſovereignty, and that his mother Cleopatra was to have all the power, ſtole away privately from Alexandria. The queen uſed every artifice to bring him back, as well knowing that the Alexandrians would never ſuffer her to reign alone. At laſt her ſon yielded to her entreaties; but ſoon after, underſtanding that ſhe had hired aſſaſſins to deſpatch him, he cauſed her to be murdered.

4

ed.

The death of the queen was no ſooner known to the Alexandrians, than, diſdaining to be commanded by a parricide, they drove out Alexander, and recalled Lathyrus.—The depoſed prince for ſome time led a rambling life in the iſland of Cos; but having got together ſome ſhips, he, the next year, attempted to return into Egypt. But being met by *Tyrrhus*, Lathyrus's admiral, he was defeated, and obliged to fly to Myra in Lycia. From Myra he ſteered his courſe towards Cyprus, hoping that the inhabitants would place him on the throne, inſtead of his brother. But *Chareas*, another of Lathyrus's admirals, coming up with him while he was ready to land, an engagement enſued, in which Alexander's fleet was diſperſed, and he himſelf killed.

Egypt.

45
Cyrenaica
bequeathed
to the Romans.

During theſe diſturbances, *Apion* king of Cyrenaica, the ſon of Ptolemy Phyſcon by a concubine, having maintained peace and tranquillity in his dominions during a reign of 21 years, died, and by his will left his kingdom to the Romans: and thus the Egyptian empire was conſiderably reduced and circumſcribed.

46
City of
Thebes
ruined.

Lathyrus being now delivered from all competitors, turned his arms againſt the city of Thebes, which had revolted from him. The king marched in perſon againſt the rebels; and, having defeated them in a pitched battle, laid cloſe ſiege to their city. The inhabitants defended themſelves with great reſolution for three years. At laſt, however, they were obliged to ſubmit, and the city was given up to be plundered by the ſoldiery. They left everywhere the moſt melancholy monuments of their avarice and cruelty; ſo that Thebes, which till that time had been one of the moſt wealthy cities of Egypt, was now reduced ſo low that it never afterwards made any figure.

47
Alexander
II. ſucceeds
Lathyrus.

About 76 years before Chriſt, Ptolemy Lathyrus was ſucceeded by Alexander II. He was the ſon of the Ptolemy Alexander for whom Lathyrus had been driven out; and had met with many adventures. He was firſt ſent by Cleopatra into the iſland of Cos, with a great ſum of money, and all her jewels; as thinking that was the ſafeſt place where they could be kept. When Mithridates king of Pontus made himſelf maſter of that iſland, the inhabitants delivered up to him the young Egyptian prince, together with all the treaſures. Mithridates gave him an education ſuitable to his birth; but he, not thinking himſelf ſafe with a prince who had ſhed the blood of his own children, fled to the camp of Sylla the Roman dictator, who was then making war in Aſia. From that time he lived in the family of the Roman general, till news was brought to Rome of the death of Lathyrus. Sylla then ſent him to Egypt to take poſſeſſion of the throne. But, before his arrival, the Alexandrians had choſen Cleopatra for their ſovereign. To compromiſe matters, however, it was agreed, that Ptolemy ſhould marry her, and take her for his partner in the throne. This was accordingly done; and 19 days after the marriage, the unhappy queen was murdered by her huſband, who for 15 years afterwards ſhowed himſelf ſuch a monſter of wickedneſs, that a general inſurrection at laſt enſued among his ſubjects, and he was obliged to fly to Pompey the Great, who was then carrying on the war againſt Mithridates king of Pontus. But Pompey refuſing to concern himſelf in the matter, he retired to the city of Tyre, where he died ſome months after.

48
Marries
Cleopatra,

49
Leaves his
kingdom
to the Romans.

When he was forced to ſhut himſelf up in the city of Tyre, Alexander had ſent ambaſſadors to Rome, in order to influence the ſenate in his favour. But, dying before the negotiation was finiſhed, he made over by his laſt will all his rights to the Roman people, declaring them heirs to his kingdom: not out of any affection to the republic; but with a view to raiſe diſputes between the Romans and his rival Auletes, whom the Egyptians had placed on the throne. The will was brought to Rome, where it occaſioned warm debates. Some were for taking immediate poſſeſſion of the kingdom. Others thought that no notice ſhould be taken of ſuch a will, becauſe Alexander had no right to diſpoſe of his dominions in prejudice of his ſucceſſor, and to exclude from the crown thoſe who were of of the royal family of Egypt. Cicero repreſented, that ſuch a notorious impoſition would debaſe the majeſty of the Roman people, and involve them in endleſs wars and diſputes; that the fruitful fields of Egypt would be a ſtrong temptation to the avarice of the people, who would inſiſt on their being divided among them; and laſtly, that by this means the bloody quarrels about the Agrarian laws would be revived. Theſe reaſons had ſome weight with the ſenate; but what chiefly prevented them from ſeizing on Egypt at this time was, that they had lately taken poſſeſſion of the kingdom of Bithynia in virtue of the will of Nicomedes, and of Cyrene and Libya by the will of Apion. They thought, therefore, that if they ſhould, on the like pretence, take poſſeſſion of the kingdom of Egypt, this might too much expoſe their deſign of ſetting up a kind of univerſal monarchy, and occaſion a formidable combination againſt them.

50
Character of Auletes the new king.

Auletes, who was now raiſed to the throne by the Egyptians, is ſaid to have ſurpaſſed all the kings that went before him in the effeminacy of his manners. The name *Auletes*, which ſignifies the *flute-player*, was given him becauſe he piqued himſelf on his ſkill in performing upon that inſtrument, and was not aſhamed even to contend for the prize in the public games. He took great pleaſure in imitating the manners of the Bacchanals; dancing in a female dreſs, and in the ſame meaſures that they uſed during the ſolemnity of their god Bacchus; and hence he had the ſurname of the *New Dionyſius* or *Bacchus*. As his title to the crown was diſputable (he being only the ſon of a concubine), the firſt care of Auletes was to get himſelf acknowledged by the Romans, and declared their ally. This was obtained by applying to Julius Cæſar, who was at that time conſul, and immenſely in debt, Cæſar being glad of ſuch an opportunity of raiſing money, made the king of Egypt pay pretty dear for his alliance. Six thouſand talents, a ſum equal to 1,162,500l. Sterling, were paid partly to Cæſar himſelf, and partly to Pompey, whoſe intereſt was neceſſary for obtaining the conſent of the people. Though the revenues of Egypt amounted to twice this ſum, yet Auletes found it impoſſible for him to raiſe it without ſeverely taxing his ſubjects. This occaſioned a general diſcontent; and while the people were almoſt ready to take up arms, a moſt unjuſt decree paſſed at Rome for ſeizing the iſland of Cyprus. When the Alexandrians heard of the intentions of the republic, they preſſed Auletes to demand that iſland as an ancient appendage of Egypt; and, in caſe of a refuſal, to declare war againſt that haughty and imperious people, who, they now ſaw, though too late, aimed at nothing leſs than the ſovereignty of the world. With this requeſt the king refuſed to comply; upon which his ſubjects, already provoked beyond meaſure at the taxes with which they were loaded, flew to arms, and ſurrounded the palace. The king had the good luck to eſcape their fury, and immediately leaving Alexandria, ſet ſail for Rome.

51
Is acknowledged by the Romans.

52
Is driven from the throne, and flies to Rome.

In his way to that city, he landed on the iſland of Rhodes, where the famous Cato at that time was, being on his way to Cyprus, to put the unjuſt decree of the ſenate in execution. Auletes, deſirous to confer with a man of his prudence, immediately ſent to acquaint him with his arrival. He imagined, that, upon this notice, Cato would immediately come and wait upon him; but the proud Roman told the meſſenger, that if the king of Egypt had any thing to ſay to Cato, he might, if he thought proper, come to his houſe. Accordingly the king went to pay him a viſit; but was received with very little ceremony by Cato, who did not even vouchſafe to riſe out of his ſeat when he came into his preſence. When Auletes had laid his affairs before this haughty republican, he was blamed by him for leaving Egypt, the richeſt kingdom in the world, in order to expoſe himſelf, as he ſaid, to the indignities he would meet with at Rome. There Cato told him, that nothing was in requeſt but wealth and grandeur. All the riches of Egypt, he ſaid, would not be ſufficient to ſatisfy the avarice of the leading men in Rome. He therefore adviſed him to return to Egypt; and ſtrive, by a more equitable conduct, to regain the affections of his people. He even offered to reconduct him thither, and employ his good offices in his behalf. But though Ptolemy was ſenſible of the propriety of this advice, the friends he had with him diſſuaded him from following it, and accordingly he ſet out for Rome.

Aulete

On his arrival in this metropolis, the king found, to his great concern, that Cæſar, in whom he placed his greateſt confidence, was then in Gaul. He was received, however, by Pompey with great kindneſs. He aſſigned him an apartment in his own houſe, and omitted nothing that lay in his power to ſerve him. But, notwithſtanding the protection of ſo powerful a man, Auletes was forced to go from houſe to houſe like a private perſon, ſoliciting the votes of the ſenators. After he had ſpent immenſe treaſures in procuring a ſtrong party in the city, he was at laſt permitted to lay his complaints before the ſenate; and at the ſame time there arrived an embaſſy from the Alexandrians, conſiſting of 100 citizens, to acquaint the ſenate with the reaſons of their revolt.

55
Berenic
raiſed t
throne
Egypt.

When Auletes firſt ſet out for Rome, the Alexandrians, not knowing what was become of him, placed on the throne his daughter Berenice; and ſent an embaſſy into Syria to Antiochus Aſiaticus, inviting him into Egypt to marry the queen, and reign in partnerſhip with her. Antiochus was dead before the arrival of the ambaſſadors; upon which the ſame propoſal was made to his brother Seleucus, who readily accepted it. This Seleucus is deſcribed by Strabo as monſtrouſly deformed in body, and ſtill more ſo in mind. The Egyptians nicknamed him *Cybioſactes*, or *the Scullion*; a name which ſeemed more fit for him than any other. He was ſcarce ſettled on the throne, when he gave a ſignal inſtance of his ſordid and avaricious temper. Ptolemy the firſt had cauſed the body of Alexander the Great to be depoſited in a coffin of maſſy gold. This the king ſeized upon; and by that means provoked his wife Berenice to ſuch a degree, that ſhe cauſed him to be murdered. She then married one Archelaus, high prieſt of Comana in Pontus, who pretended to be the ſon of Mithridates the Great; but was, in fact, only the ſon of that monarch's general.

Auletes was not a little alarmed on hearing of theſe tranſactions, eſpecially when the ambaſſadors arrived, who he feared would overturn all the ſchemes he had laboured ſo much to bring about. The embaſſy was headed by one Dion, a celebrated Academic philoſopher who

who had many powerful friends at Rome. But Ptolemy found means to get both him and moſt of his followers aſſaſſinated; and this intimidated the reſt to ſuch a degree, that they durſt not execute their commiſſion, or, for ſome time, even demand juſtice for the murder of their colleagues.

58
etes
ders the
ptian
aſſa-

The report of ſo many murders, however, at laſt ſpread a general alarm. Auletes, ſure of the protection of Pompey, did not ſcruple to own himſelf the perpetrator of them. Nay, though an action was commenced againſt one Aſcitius, an aſſaſſin who had ſtabbed Dion the chief of the embaſſy above mentioned, and the crime was fully proved; yet he was acquitted by the venal judges, who had all been bribed by Ptolemy. In a ſhort time, the ſenate paſſed a decree, by which it was enacted, that the king of Egypt ſhould be reſtored by force of arms. All the great men in Rome were ambitious of this commiſſion; which, they well knew, would be attended with immenſe profit. Their conteſts on this occaſion took up a conſiderable time; and at laſt a prophecy of the Sybil was found out, which forbade the aſſiſting an Egyptian monarch with an army. Ptolemy, therefore, wearied out with ſo long a delay, retired from Rome, where he had made himſelf generally odious, to the temple of Diana at Epheſus, there to wait the deciſion of his fate. Here he remained a conſiderable time: but as he ſaw that the ſenate came to no reſolution, tho' he had ſolicited them by letters ſo to do; at laſt, by Pompey's advice, he applied to Gabinius the proconſul of Syria. This Gabinius was a man of a moſt infamous character, and ready to undertake any thing for money. Therefore, though it was contrary to an expreſs law for any governor to go out of his province without poſitive orders from the ſenate and people of Rome, yet Gabinius ventured to tranſgreſs this law, upon condition of being well paid for his pains. As a recompenſe for his trouble, however, he demanded 10,000 talents; that is, 1,937,500l. ſterling. Ptolemy, glad to be reſtored on any terms, agreed to pay the above mentioned ſum; but Gabinius would not ſtir till he had received one half of it. This obliged the king to borrow it from a Roman knight named *Caius Rabirius Poſthumius;* Pompey interpoſing his credit and authority for the payment of the capital and intereſt.

Gabinius now ſet out for Egypt, attended by the famous Mark Antony, who at this time ſerved in the army under him. He was met by Archelaus, who ſince the departure of Auletes had reigned in Egypt jointly with Berenice, at the head of a numerous army. The Egyptians were utterly defeated, and Archelaus taken priſoner in the firſt engagement. Thus Gabinius might have put an end to the war at once: but his avarice prompted him to diſmiſs Archelaus on his paying a conſiderable ranſom; after which, pretending that he had made his eſcape, freſh ſums were demanded from Ptolemy for defraying the expences of the war. For theſe ſums Ptolemy was again obliged to apply to Rabirius, who lent him what money he wanted at a very high intereſt. At laſt, however, Archelaus was defeated and killed, and thus Ptolemy again became maſter of all Egypt.

61
chelaus
eated
l killed.

No ſooner was Auletes firmly ſettled on the throne, than he put to death his daughter Berenice, and oppreſſed his people with the moſt cruel exactions, in order to procure the money he had been obliged to borrow while in a ſtate of exile. Theſe oppreſſions and exactions the cowardly Egyptians bore with great patience, being intimidated by the garriſon which Gabinius had left in Alexandria. But neither the fear of the Romans, nor the authority of Ptolemy, could make them put up an affront offered to their religion. A Roman ſoldier happened to kill a cat, which was an animal held ſacred and even worſhipped by the Egyptians; and no ſooner was this ſuppoſed ſacrilege known, than the Alexandrians made a general inſurrection, and, gathering together in crowds, made their way through the Roman guards, dragged the ſoldier out of his houſe, and, in ſpite of all oppoſition, tore him in pieces.

62

[illegible] to
[illegible], and
the people
oppreſſed.

Notwithſtanding the heavy taxes, however, which Ptolemy laid on his people, it doth not appear that he had any deſign of paying his debts. Rabirius, who, as we have already obſerved, had ſent him immenſe ſums, finding that the king affected delays, took a voyage to Egypt, in order to expoſtulate with him in perſon. Ptolemy paid very little regard to his expoſtulations; but excuſed himſelf on account of the bad ſtate of his finances. For this reaſon he offered to make Rabirius collector general of his revenues, that he might in that employment pay himſelf. The unfortunate creditor accepted the employment for fear of loſing his debt. But Ptolemy, ſoon after, upon ſome frivolous pretence or other, cauſed him and all his ſervants to be cloſely confined. This baſe conduct exaſperated Pompey as much as Rabirius; for the former had been in a manner ſecurity for the debt, as the money had been lent at his requeſt, and the buſineſs tranſacted at a country houſe of his near Alba. However, as Rabirius had reaſon to fear the worſt, he took the firſt opportunity of making his eſcape, glad to get off with life from his cruel and faithleſs debtor. To complete his misfortunes, he was proſecuted at Rome as ſoon as he returned, 1. For having enabled Ptolemy to corrupt the ſenate with ſums lent him for that purpoſe. 2. For having debaſed and diſhonoured the character of a Roman knight, by farming the revenues, and becoming the ſervant of a foreign prince. 3. For having been an accomplice with Gabinius, and ſharing with him the 10,000 talents which that proconſul had received for his Egyptian expedition. By the eloquence of Cicero he was acquitted; and one of the beſt orations to be found in the writings of that author was compoſed on this occaſion. Gabinius was alſo proſecuted; and, as Cicero ſpoke againſt him, he very narrowly eſcaped death. He was, however, condemned to perpetual baniſhment, after having been ſtripped of all he was worth. He lived in exile till the time of the civil wars, when he was recalled by Cæſar, in whoſe ſervice he loſt his life.

63
Ingratitude
of Auletes

64
Leaves his
children to
the care of
the Romans.

Auletes enjoyed the throne of Egypt about four years after his re-eſtabliſhment; and at his death left his children, a ſon and two daughters, under the tuition of the Roman people. The name of the ſon was *Ptolemy*, thoſe of the daughters were *Cleopatra* and *Arſinoe*. This was the Cleopatra who afterwards became ſo famous, and had ſo great a ſhare in the civil wars of Rome. As the tranſactions of the preſent reign, however, are ſo cloſely connected with the affairs of Rome, that they cannot be well underſtood without knowing the ſituation of the Romans at that time, we refer for an account of them to the *Hiſtory of Rome*.

65
State of Egypt till its conqueſt by the caliph of Cairwan.

With Cleopatra ended the family of Ptolemy Lagus, the founder of the Grecian empire in Egypt, after it had held that country in ſubjection for the ſpace of 294 years. From this time Egypt became a province of the Roman empire, and continued ſubject to the emperors of Rome or Conſtantinople. In the year 642, it was conquered by the Arabs under Amru Ebn al As, one of the generals of the caliph Omar. In the year 889, an independent government was ſet up in this kingdom by Ahmed Ebn Tolun, who rebelled againſt Al Mokhadi caliph of Bagdad. It continued to be governed by him and his ſucceſſors for 27 years, when it was again reduced by Al Moctafi caliph of Bagdad. In about 30 years after, we find it again an independent ſtate, being joined with Syria under Mahomet Ebn Taj, who had been appointed governor of theſe provinces. This government, however, was alſo but ſhort lived; for in the year 968 it was conquered by Jawhar, one of the generals of Moez Ledinillah, the Fatemite caliph of Cairwan in Barbary. See Barbary, N° 34.

66
Moez takes poſſeſſion of his new kingdom.

No ſooner was Moez informed of the ſucceſs of his general, than he prepared with all expedition to go and take poſſeſſion of his new conqueſt. Accordingly he ordered all the vaſt quantities of gold which he and his predeceſſors had amaſſed, to be caſt into ingots of the ſize and figure of the millſtones uſed in hand mills, and conveyed on camels backs into Egypt. To ſhow that he was fully determined to abandon his dominions in Barbary, and to make Egypt the reſidence of himſelf and his ſucceſſors, he cauſed the remains of the three former princes of his race to be removed from Cairwan in Barbary, and to be depoſited in a ſtately moſque erected for that purpoſe in the city of Cairo in Egypt. This was a moſt effectual method to induce his ſucceſſors to reſide in Egypt alſo, as it was become an eſtabliſhed cuſtom and duty among thoſe princes frequently to pay their reſpectful viſits to the tombs of their anceſtors.

67
Will not ſuffer prayers to be ſaid for the caliph of Bagdad.

To eſtabliſh himſelf the more effectually in his new dominions, Moez ſuppreſſed the uſual prayers made in the moſques for the caliphs of Bagdad, and ſubſtituted his own name in their ſtead. This was complied with, not only in Egypt and Syria, but even throughout all Arabia, the city of Mecca alone excepted. The conſequence was, a ſchiſm in the Mahomedan faith, which continued upwards of 200 years, and was attended with continual anathemas, and ſometimes deſtructive wars between the caliphs of Bagdad and of Egypt.—Having fully eſtabliſhed himſelf in his kingdom, he died in the 45th year of his age, three years after he had left his dominions in Barbary; and was ſucceeded by his ſon Abu Al Manſur Barar, ſurnamed Aziz Billah.

68
Unſucceſsful expedition into Syria.

The new caliph ſucceeded to the throne at the age of 21; and committed the management of affairs entirely to the care of Jawhar, his father's long experienced general and prime miniſter. In 978, he ſent this famous warrior to drive out Al Aftekin, the emir of Damaſcus. The Egyptian general accordingly formed the ſiege of that place; but at the end of two months, was obliged to raiſe it, on the approach of an army of Karmatians under the command of Al Hakem. As Jawhar was not ſtrong enough to venture an engagement with theſe Karmatians, it was impoſſible for him to hinder them from effecting a junction with the forces of Al Aftekin. He therefore retreated, or rather fled, towards Egypt with the utmoſt expedition; but being overtaken by the two confederate armies, he was ſoon reduced to the laſt extremity. He was, however, permitted to reſume his march, on condition that he paſſed under Al Aftekin's ſword and Al Hakem's lance; and to this diſgraceful condition Jawhar found himſelf obliged to ſubmit. On his arrival in Egypt, he immediately adviſed Al Aziz to undertake an expedition in perſon into the eaſt, againſt the combined army of Turks, Karmatians, and Damaſcenes, under the command of Al Aftekin and Al Hakem. The caliph followed his advice; and advancing againſt his enemies, overthrew them with great ſlaughter. Al Aftekin himſelf eſcaped out of the battle; but was afterwards taken and brought to Al Aziz, who made him his chamberlain, and treated him with great kindneſs. Jawhar, in the mean time, was diſgraced on account of his bad ſucceſs; and in his diſgrace he continued till his death, which happened in the year of our Lord 990, and of the Hegira 381.

69
Aleppo b ſieged wit out ſucce

This year Al Aziz having received advice of the death of Saado'dawla prince of Aleppo, ſent a formidable army under the command of a general named *Manjubekin*, to reduce that place. Lulu, who had been appointed guardian to Saado'dawla's ſon, finding himſelf preſſed by the Egyptians, who carried on the ſiege with great vigour, demanded aſſiſtance from the Greek emperor. Accordingly, he ordered a body of troops to advance to Lulu's relief. Manjubekin, being informed of their approach, immediately raiſed the ſiege, and advanced to give them battle. An obſtinate engagement enſued, in which the Greeks were at laſt overthrown with great ſlaughter. After this victory, Manjubekin puſhed on the ſiege of Aleppo very briſkly; but finding the place capable of defending itſelf much longer than he at firſt imagined, and his proviſions beginning to fail, he raiſed the ſiege. The caliph upon this ſent him a very threatening letter, and commanded him to return before Aleppo. He did ſo; and continued the ſiege for 13 months; during all which time it was defended by Lulu with incredible bravery. At laſt, the Egyptians hearing that a numerous army of Greeks was on their way to relieve the city, they raiſed the ſiege, and fled with the utmoſt precipitation. The Greeks then took and plundered ſome of the cities which Al Aziz poſſeſſed in Syria; and Manjubekin made the beſt of his way to Damaſcus, where he ſet up for himſelf. Al Aziz being informed of this revolt, marched in perſon againſt him with a conſiderable army; but being taken ill by the way, he expired, in the 21ſt year of his reign and 42d of his age.

Al Aziz was ſucceeded by his ſon Abu Al Manſur, ſurnamed Al Hakem; who, being only 11 years of age, was put under the tuition of a eunuch of approved integrity.

70
Strange madneſs the caliph Al Hake

This reign is remarkable for nothing ſo much as the ſtrange madneſs with which the caliph was ſeized in the latter part of it. This manifeſted itſelf firſt by his iſſuing many prepoſterous edicts; but at length grew to ſuch a height, that he fancied himſelf a god, and found no fewer than 16,000 perſons who owned him as ſuch. Theſe were moſtly the Dararians, a new ſect ſprung up about this time, who were ſo called from their chief, Mohammed Ebn Iſhmael, ſurnamed Darari. He is ſuppoſed to have inſpired the mad caliph with this impious notion; and, as Darari ſet up for a ſecond Moſes, he did not ſcruple to aſſert that Al Hakem was the great Creator of the univerſe. For this reaſon, a zealous Turk ſtabbed him in the caliph's chariot. His death was followed by a three days uproar in the city of Cairo; during which, Darari's houſe was pulled down, and many of his followers maſſacred. The ſect, however, did not expire with its author. He left behind him a diſciple named Hamza, who, being encouraged by the mad caliph, ſpread it far and wide thro' his dominions. This was quickly followed by an abrogation of all the Mahommedan faſts, feſtivals, and pilgrimages, the grand one to Mecca in particular; ſo that the zealous Mahometans were now greatly alarmed, as juſtly ſuppoſing that Al Hakem deſigned entirely to ſuppreſs the worſhip of the true God, and introduce his own in its place. From this apprehenſion, however, they were delivered by the death of the caliph; who was aſſaſſinated, by a contrivance of his own ſiſter, in the year 1020.

Al Hakem was ſucceeded by his ſon Al Thaher, who reigned 15 years; and left the throne to a ſon under ſeven years of age, named Al Moſtanſer Billah.— In the year 1041, a revolt happened in Syria; but Al Moſtanſer having ſent a powerful army into that country, under the command of one *Anuſhtekin*, he not only reduced the rebels, but conſiderably enlarged the Egyptian dominions in Syria.

ad.

In 1054, a Turk named Al Baſſaſiri, having quarrelled with the vizir Al Kayem caliph of Bagdad, fled to Egypt, and put himſelf under the protection of Al Moſtanſer. The latter, imagining this would be a favourable opportunity for enlarging his dominions, and perhaps ſeizing on the city of Bagdad, ſupplied Baſſaſiri with money and troops. By this aſſiſtance, he was enabled to poſſeſs himſelf of Arabian Irak, and ravaged that province to the very gates of Bagdad. On this, Al Kayem wrote to Togrol Beg, or Tangrolipix, the Turkiſh ſultan, who poſſeſſed very extenſive dominions in the eaſt, to come to his aſſiſtance. The ſultan immediately complied with his requeſt, and ſoon arrived at Bagdad with a formidable army and 18 elephants. Of this Baſſaſiri gave notice to Al Moſtanſer, and entreated him to exert himſelf further for his ſupport againſt ſo powerful an enemy. This was accordingly done, but nothing worthy of notice happened till the year 1058. At this time Baſſaſiri having found means to excite Ibrahim the ſultan's brother to a revolt, Togrol Beg was obliged to employ all his force againſt him. This gave Baſſaſiri an opportunity of ſeizing on the city of Bagdad itſelf; and the unfortunate caliph, according to ſome, was taken priſoner, or, according to others, fled out of the city. Baſſaſiri, on his entry, cauſed Al Moſtanſer to be immediately proclaimed caliph in all quarters of the city. Al Kayem's vizir he cauſed to be led on a camel through the ſtreets of Bagdad, dreſſed in a woollen gown, with a high red bonnet, and a leathern collar about his neck, a man laſhing him all the way behind. Then being ſewed up in a bull's hide, with the horns placed over his head, and hung upon hooks, he was beaten without ceaſing till he died. The imperial palace was plundered, and the caliph himſelf detained a cloſe priſoner.

74
The caliph reſtored.

This ſucceſs was but ſhort lived; for, in 1059, Togrol Beg defeated his brother Ibrahim, took him priſoner, and ſtrangled him with a bow ſtring. He then marched to Bagdad, which Baſſaſiri thought proper to abandon at his approach. Here the caliph Al Kayem was delivered up by Mahras, the governor of a city called *Haditha*, who had the charge of him. The caliph was immediately reſtored to his dignity; which Baſſaſiri no ſooner underſtood, than he again advanced towards the city. Againſt him Togrol Beg ſent a part of his army under ſome of his generals, while he himſelf followed with the reſt. A battle enſued, in which the army of Baſſaſiri was defeated, and he himſelf killed. His head was brought to Togrol Beg, who cauſed it to be carried on a pike through the ſtreets of Bagdad.

75
Decline of the Egyptian empire.

Thus the hopes of Al Moſtanſer were entirely fruſtrated; and from this period we may date the declenſion of the Egyptian empire under the caliphs. They had made themſelves maſters of almoſt all Syria; but no ſooner was Baſſaſiri's bad ſucceſs known, than the younger part of the citizens of Aleppo revolted, and ſet up Mahmud Azzo'dawla, who immediately laid ſiege to the citadel. Al Moſtanſer ſent a powerful army againſt him, which Azzo'dawla entirely defeated, and took the general himſelf priſoner; and ſoon after this, he made himſelf maſter both of the city and citadel, with all their dependencies. In his new dominions he behaved with the greateſt cruelty, deſtroying every thing with fire and ſword, and making frequent incurſions into the neighbouring provinces, which he treated in the ſame manner.

76
Terrible famine and plague.

This diſaſter was ſoon followed by others ſtill more terrible. In 1066, a famine raged over all Egypt and Syria, with ſuch fury, that dogs and cats were ſold for four or five Egyptian dinars each, and other proviſions in proportion. Multitudes of people died in Cairo for want of food. Nay, ſo great was the ſcarcity, that the vizir had but one ſervant left who was able to attend him to the caliph's palace, and to whom he gave the care of his horſe when he alighted at the gate. But, at his return, he was ſurpriſed to find that the horſe had been carried off, killed and eaten by the famiſhed people. Of this he complained to the caliph; who cauſed three of them who had carried off the horſe to be hanged. Next day, however, he was ſtill more ſurpriſed to hear, that all the fleſh had been picked off the bones of the three unhappy criminals, ſo that nothing but the ſkeletons were left. And to ſuch a degree of miſery were the inhabitants, not only in Cairo but through all Egypt, reduced, that the carcaſes of thoſe who died were ſold for food at a great price, inſtead of being buried. All this time the caliph ſhowed the greateſt kindneſs and beneficence towards his unhappy ſubjects; inſomuch that of 10,000 horſes, mules, and camels, which he had in his ſtables when the famine began, he had only three left when it was removed.

77
Invaded by the Turks.

The famine was followed by a plague; and this by an invaſion of the Turks under Abu Ali Al Haſan Naſerod'dawla, the very general who had been ſent againſt

gainſt the rebel Azzo'dawla and defeated by him. He began with beſieging the caliph in his own palace; and the unhappy prince, being in no condition to make reſiſtance, was obliged to buy himſelf off at the expence of every thing valuable that was left in his exhauſted capital and treaſury. This, however, did not hinder thoſe mercileſs plunderers from ravaging all the Lower Egypt from Cairo to Alexandria, and committing the moſt horrid cruelties through that whole tract.—This happened in the years 1067 and 1068; and in 1069 and 1070, there happened two other revolts in Syria: ſo that this country was now almoſt entirely loſt.

78 Jeruſalem taken.

In 1095 died the caliph Al Moſtanſer, having reigned 60 years; and was ſucceeded by his ſon Abul Kaſem, ſurnamed Al Moſtali. The moſt remarkable tranſaction of this prince's reign, was his taking the city of Jeruſalem from the Turks in 1098; but this ſucceſs was only of ſhort duration; for it was the ſame year taken by the cruſaders.

79 A revolution in the kingdom.

From this time to the year 1164, the Egyptian hiſtory affords little elſe than an account of the inteſtine broils and conteſts between the vizirs or prime miniſters, who were now become ſo powerful, that they had in a great meaſure ſtripped the caliphs of their civil power, and left them nothing but a ſhadow of ſpiritual dignity. Theſe conteſts at laſt gave occaſion to a revolution, by which the race of Fatemite caliphs was totally extinguiſhed. This revolution was accompliſhed in the following manner. One *Shawer*, having overcome all his competitors, became vizir to Al Aded, the eleventh caliph of Egypt. He had not been long in poſſeſſion of this office, when Al Dargam, an officer of rank, endeavoured to deprive him of it. Both parties quickly had recourſe to arms; and a battle enſued, in which Shawer was defeated, and obliged to fly to Nuroddin prince of Syria, by whom he was graciouſly received, and who promiſed to reinſtate him in his office of vizir. As an inducement to Nuroddin to aſſiſt him more powerfully, Shawer told him that the cruſaders had landed in Egypt, and made a conſiderable progreſs in the conqueſt of it. He promiſed alſo, that, in caſe he was reinſtated in his office, he would pay Nuroddin annually the third part of the revenues of Egypt; and would, beſides, defray the whole expence of the expedition.

As Nuroddin bore an implacable hatred to the Chriſtians, he readily undertook an expedition againſt them, for which he was to be ſo well paid. He therefore ſent an army into Egypt under the command of Shawer and a general named *Aſadoddin*. Dargam, in the mean time, had cut off ſo many generals whom he imagined favourable to Shawer's intereſt, that he thereby weakened the military force of the kingdom, and in a great meaſure deprived himſelf of the power of reſiſtance. He was therefore eaſily overthrown by Aſadoddin, and Shawer reinſtated in the office of vizir. The faithleſs miniſter, however, no ſooner ſaw himſelf firmly eſtabliſhed in his office, than he refuſed to fulfil his engagements to Nuroddin by paying the ſtipulated ſums. Upon this, Aſadoddin ſeized Peluſium and ſome other cities. Shawer then entered into an alliance with the cruſaders, and Aſadoddin was beſieged by their combined forces in Peluſium. Nuroddin, however, having invaded the Chriſtian dominions in Syria, and taken a ſtrong fortreſs called *Harem*, Shawer and his confederates thought proper to hearken to ſome terms of accommodation, and Aſadoddin was permitted to depart for Syria.

In the mean time, Nuroddin, having ſubdued the greateſt part of Syria and Meſopotamia, reſolved to make Shawer feel the weight of his reſentment on account of his perfidious conduct. He therefore ſent back Aſadoddin into Egypt with a ſufficient force, to compel Shawer to fulfil his engagements: but this the vizir took care to do before the arrival of Aſadoddin; and thus, for the preſent, avoided the danger. It was not long, however, before he gave Nuroddin freſh occaſion to ſend this general againſt him. That prince had now driven the cruſaders almoſt entirely out of Syria, but was greatly alarmed at their progreſs in Egypt; and conſequently offended at the alliance which Shawer had concluded with them, and which he ſtill perſiſted in obſerving. This treaty was alſo thought to be contrived on purpoſe to prevent Shawer from being able to fulfil his promiſe to Nuroddin, of ſending him annually a third of the revenues of Egypt. Nuroddin therefore again deſpatched Aſadoddin into Egypt, in the year 1166, with a ſufficient force, and attended by the famous Salahaddin, or Saladin, his own nephew. They entered the kingdom without oppoſition, and totally defeated Shawer and the cruſaders. They next made themſelves maſters of Alexandria; and, after that, overran all the Upper Egypt. Saladin was left with a conſiderable garriſon in Alexandria; but Aſadoddin was no ſooner gone, than the cruſaders laid ſiege to that city. This at laſt obliged Aſadoddin to return to its relief. The great loſſes he had ſuſtained in this expedition probably occaſioned his agreeing to a treaty with Shawer, by which he engaged to retire out of Egypt, upon being paid a ſum of money.

Aſadoddin was no ſooner gone, than Shawer entered into a freſh treaty with the Franks. By this new alliance he was to attack Nuroddin in his own dominions, as he was at that time engaged in quelling ſome revolters, which would effectually prevent his ſending any more forces into Egypt. This treaty ſo provoked the Syrian prince, that he reſolved to ſuſpend his other conqueſts for ſome time, and exert his whole ſtrength in the conqueſt of Egypt.

80 Conqueſt of the cr ſaders.

By this time the cruſaders had reduced Peluſium, and made a conſiderable progreſs in the kingdom, as well as in ſome other countries, through the diviſions which reigned among the Mahometan princes. In ſuch places as they conquered, they put almoſt every body to the ſword, Chriſtians as well as Mahometans; ſelling their priſoners for ſlaves, and giving up the towns to be plundered by the ſoldiers. From Peluſium they marched to Cairo; which was then in no poſture of defence, and in the utmoſt confuſion, by reaſon of the diviſions which reigned in it. Shawer, therefore, as ſoon as he heard of their approach, cauſed the ancient quarter called *Meſr* to be ſet on fire, and the inhabitants to retire into the other parts. He alſo prevailed upon the caliph to ſolicit the aſſiſtance of Nuroddin; which the latter was indeed pretty much inclined of himſelf to grant, as it gave him the faireſt opportunity he could have wiſhed for, both of driving the cruſaders out of Egypt, and of ſeizing the kingdom

Egypt. dom to himſelf. For this purpoſe he had already raiſed an army of 60,000 horſe under his general Aſadoddin; and, on the receipt of Al Aded's meſſage, gave them orders to ſet out immediately. The cruſaders were now arrived at Cairo; and had ſo cloſely beſieged that place, that neither Shawer nor the caliph knew any thing of the approach of the Moſlem army which was haſtening to their relief. The vizir, therefore, finding it impoſſible to hold out long againſt the enemy, had recourſe to his old ſubterfuge of treaties and high promiſes. He ſent the enemy 100,000 dinars, and promiſed them 900,000 more, if they would raiſe the ſiege; which they, dreading the approach of Aſadoddin, very readily accepted.

81 ey are ulſed by army of roddin nce of maſcus. The army of Nuroddin now approached the capital by haſty marches, and were everywhere received with the greateſt demonſtrations of joy. Aſadoddin, on his arrival at Cairo, was invited by Al Aden to the royal palace, where he was entertained in the moſt magnificent manner, and received ſeveral preſents; nor were Saladin and the other principal officers leſs magnificently treated. Shawer alſo, conſcious of his perfidious conduct, was no leſs aſſiduous in attending punctually upon him. But having invited the general and ſome others to an entertainment, he had formed a ſcheme of having them ſeized and murdered. The plot, however, being diſcovered, Shawer himſelf had his head cut off, and Aſadoddin was made vizir in his ſtead. He did not, however, long enjoy his new dignity; for he died two months and five days after his inſtalment, being ſucceeded in his office of vizir by his nephew Saladin. 82 din becomes vizir Egypt.

The new vizir was the youngeſt of all the grandees who aſpired to that office, but had already given ſome ſignal proofs of his valour and conduct. What determined the caliph to prefer him to all the reſt is not known; but it is certain that ſome of them were highly diſpleaſed with his promotion, and even publicly declared that they would not obey him. In order to gain theſe to his intereſt, therefore, Saladin found it neceſſary to diſtribute among them part of the vaſt treaſures left by his uncle; by which means he ſoon governed Egypt without controul, as had been cuſtomary with the vizirs for ſome time before. Soon after his being inſtalled into the office of vizir, he gave a total defeat to the negroes who guarded the royal palace, and had oppoſed his election; by which means, and a ſtrong garriſon he had placed in the caſtle of Cairo, his power became firmly eſtabliſhed. Though he had not the leaſt intention of continuing in his allegiance to Nuroddin, he did not think it prudent at firſt to declare himſelf. He ſent for his father, however, and the reſt of his family, who were in Nuroddin's dominions, in order, as he ſaid, to make them partakers of his grandeur and happineſs. Nuroddin did not think proper to deny this requeſt; though, being already jealous of the great power of Saladin, he inſiſted that his family ſhould conſider him only as one of his generals in Egypt.

A good underſtanding ſubſiſted between Nuroddin and Saladin for ſome time, which did not a little contribute to raiſe the credit of the latter with the Egyptians. In 1169, Nuroddin ſent him orders to omit the name of Al Aded, the caliph of Egypt, in the public prayers, and ſubſtitute that of the caliph of Bagdad in its place. This was at any rate a dangerous attempt [illegible] vour [illegible] Al A[illegible], or if it did not, it gave Sa[illegible] opportunity of engroſſing even that ſmall remnant of power which was left to the caliph. Al Aded, however, was not ſenſible of his diſgrace; for he was on his deathbed, and paſt recovery, when Nuroddin's orders were executed. After his death, Saladin ſeized on all his wealth and valuable effects; which conſiſted of jewels of prodigious ſize, ſumptuous furniture, a library containing 100,000 volumes, &c. His family he cauſed to be cloſely confined in the moſt private and retired part of the palace; and either manumitted his ſlaves, or kept them for himſelf, or diſpoſed of them to others. 83 Seizes the effects of the caliph.

Saladin was now arrived at the higheſt pitch of wealth, power, and grandeur. He was, however, obliged to behave with great circumſpection with regard to Nuroddin; who ſtill continued to treat him as his vaſſal, and would not ſuffer him to diſpute the leaſt of his commands. He relied for advice chiefly on his father Ayub; who was a conſummate politician, and very ambitious of ſeeing his ſon raiſed to the throne of Egypt. He therefore adviſed Saladin to continue ſtedfaſt in his reſolutions; and, whilſt he amuſed Nuroddin with feigned ſubmiſſions, to take every method in his power to ſecure himſelf in the poſſeſſion of ſo valuable a kingdom. Nuroddin himſelf, however, was too great a maſter in the art of diſſimulation to be eaſily impoſed on by others; and therefore, though he pretended to be well pleaſed with Saladin's conduct, he was all this time raiſing a powerful army, with which he was fully determined to invade Egypt the following year. But while he meditated this expedition, he was ſeized with a quinſy at the caſtle of Damaſcus, which put an end to his life, in the year 1173. 84 Aſpires to the crown.

Saladin, though now freed from the apprehenſions of ſuch a formidable enemy, dared not venture to aſſume the title of *Sovereign*, while he ſaw the ſucceſſor of Nuroddin at the head of a very powerful army, and no leſs deſirous than able to diſpoſſeſs him. For this reaſon his firſt care was to ſecure to himſelf an aſylum, in caſe he ſhould be obliged to leave Egypt altogether. For this purpoſe he choſe the kingdom of Nubia; but having deſpatched his brother Malek Turanſhah thither, at the head of a conſiderable army, the latter was ſo much ſtruck with the ſterility and deſolate appearance of the country, that he returned without attempting any thing. Saladin then ſent his brother into Arabia Felix, in order to ſubdue that country, which had been for ſome time held by Abdalnabi an Arabian prince. Malek entered the country without oppoſition; and having brought Abdalnabi to a general action, entirely defeated him, took him priſoner, and threw him into irons. He then overran and reduced under ſubjection to Saladin great part of the country, taking no fewer than 80 caſtles or fortreſſes of conſiderable ſtrength. 85 Subdues Arabia Felix.

After this good fortune, Saladin, now ſure of a convenient place of refuge in caſe of any misfortune, aſſumed the title of *Sultan* or ſovereign of Egypt; and was acknowledged as ſuch by the greater part of the ſtates. The zeal of the Egyptians for the Fatemite caliphs, however, ſoon produced a rebellion. One *Al Kanz*, or *Kanzanaddowla*, governor of a city in Upper Egypt, aſſembled a great army of blacks, or rather ſwarthy 86 Aſſumes the title of ſultan.

ſwarthy natives; and marching directly into the lower country, was there joined by great numbers of other Egyptians. Againſt them Saladin deſpatched his brother Malek, who ſoon defeated and entirely diſperſed them. This, however, did not prevent another inſurrection under an impoſtor, who pretended to be David the ſon of Al Aden the laſt Fatemite caliph, and had collected a body of 100,000 men. But before theſe had time to do any great damage, they were ſurpriſed by the ſultan's forces, and entirely defeated. Above 300 were publicly hanged, and a vaſt number periſhed in the field, inſomuch that it was thought ſcarce a fourth part of the whole body eſcaped.

About this time Saladin gained a conſiderable advantage over the cruſaders, commanded by William II. king of Sicily. That prince had invaded Egypt with a numerous fleet and army, with which he laid cloſe ſiege to Alexandria both by ſea and land. Saladin, however, marched to the relief of the city with ſuch ſurpriſing expedition, that the cruſaders were ſeized with a ſudden panic, and fled with the utmoſt precipitation, leaving all their military engines, ſtores, and baggage behind.

87
Saladin made ſovereign of Damaſcus.

In the year 1175, the inhabitants of Damaſcus begged of Saladin to accept the ſovereignty of that city and its dependencies; being jealous of the miniſter, who had the tuition of the reigning prince, and who governed all with an abſolute ſway. The application was no ſooner made, than the ſultan ſet out with the utmoſt celerity to Damaſcus, at the head of a choſen detachment of 700 horſe. Having ſettled his affairs in that city, he appointed his brother Saif Al Iſlam governor of it; and ſet out for Hems, to which he immediately laid ſiege. Having made himſelf maſter of this place, he then proceeded to Hamah. The city very ſoon ſurrendered, but the citadel held out for ſome time. Saladin pretended that he accepted the ſovereignty of Damaſcus and the other places he had conquered, only as deputy to Al Malek Al Saleh, the ſucceſſor of Nuroddin, and who was then under age; and that he was deſirous of ſending Azzoddin, who commanded in the citadel, with a letter to Aleppo, where the young prince reſided. This ſo pleaſed Azzoddin, that he took the oath of fidelity to Saladin, and immediately ſet out with the ſultan's letter. He had not, however, been long at Aleppo before he was by the miniſter's orders thrown into priſon; upon which his brother, who had been appointed governor of the citadel Hamah in his abſence, delivered it up to Saladin without further ceremony. The ſultan then marched to Aleppo, with a deſign to reduce it; but, being vigorouſly repulſed in ſeveral attacks, he was at laſt obliged to abandon the enterpriſe. At the ſame time, Kamſchlegin, Al Malek's miniſter or vizir, hired the chief of the Bataniſts, or Aſſaſſins*, to murder him. Several attempts were made in conſequence of this application; but all of them, happily for Saladin, miſcarried.

After raiſing the ſiege of Aleppo, Saladin returned to Hems, which place the cruſaders had inveſted. On his approach, however, they thought proper to retire; after which, the ſultan made himſelf maſter of the ſtrong caſtle belonging to that place, which before he had not been able to reduce. This was ſoon followed by the reduction of Baalbec: and theſe rapid conqueſts ſo alarmed the miniſters of Al Malek, that, entering into a combination with ſome of the neighbouring princes, they raiſed a formidable army, with which they deſigned to cruſh the ſultan at once. Saladin, fearing the event of a war, offered to cede Hems and Hamah to Al Malek, and govern Damaſcus only as his lieutenant: but theſe terms being rejected, a battle enſued; in which the allied army was utterly defeated, and the ſhattered remains of it ſhut up in the city of Aleppo. This produced a treaty, by which Saladin was left maſter of all Syria, excepting only the city of Aleppo and the territory belonging to it.

83
Defeats hi enemies.

89
Receives a terrible overthrow from the cruſaders.

In 1176 Saladin returned from the conqueſt of Syria, and made his triumphal entry into Cairo. Here, having reſted himſelf and his troops for ſome time, he began to encompaſs the city with a wall 29,000 cubits in length, but which he did not live to finiſh. Next year he led a very numerous army into Paleſtine againſt the cruſaders. But here his uſual good fortune failed him. His army was entirely defeated. Forty thouſand of his men were left dead on the field; and the reſt fled with ſo much precipitation, that, having no towns in the neighbourhood where they could ſhelter themſelves, they traverſed the vaſt deſert between Paleſtine and Egypt, and ſcarce ſtopped till they reached the capital itſelf. The greateſt part of the army by this means periſhed; and as no water was to be had in the deſert above mentioned, almoſt all the beaſts died of thirſt before the fugitives arrived on the confines of Egypt. Saladin himſelf ſeemed to have been greatly intimidated; for in a letter to his brother Al Malek, he told him, that "he was more than once in the moſt imminent danger; and that God, as he apprehended, had delivered him from thence, in order to reſerve him for the execution of ſome grand and important deſign."

In the year 1182, the ſultan ſet out on an expedition to Syria with a formidable army, amidſt the acclamations and good wiſhes of the people. He was, however, repulſed with loſs both before Aleppo and Al Mawſel, after having ſpent much time and labour in beſieging theſe two important places.

90
The Chriſtians receive a great defe at ſea.

In the mean time, a moſt powerful fleet of European ſhips appeared on the Red ſea, which threatened the cities of Mecca and Medina with the utmoſt danger. The news of this armament no ſooner reached Cairo, than Abu Becr, Saladin's brother, who had been left viceroy in the ſultan's abſence, cauſed another to be fitted out with all ſpeed under the command of Lulu, a brave and experienced officer, who quickly came up with them, and a dreadful engagement enſued. The Chriſtians were defeated after an obſtinate reſiſtance, and all the priſoners butchered in cold blood. This proved ſuch a terrible blow to the Europeans, that they never more ventured on a like attempt.

91
Saladin's rapid conqueſts.

In 1183, Saladin continued to extend his conqueſts. The city of Amida in Meſopotamia ſurrendered to him in eight days; after which, being provoked by ſome violences committed by the prince of Aleppo, he reſolved at all events to make himſelf maſter of that place. He was now attended with better ſucceſs than formerly; for as his army was very numerous, and he puſhed on the ſiege with the utmoſt vigour. Amadoddin the prince capitulated, upon condition of being allowed to poſſeſs certain cities in Meſopotamia which had

---

* See *Aſſaſſin.*

had formerly belonged to him, and being ready to attend the ſultan on whatever expedition he pleaſed. After the conqueſt of Aleppo, Saladin took three other cities, and then marched againſt his old enemies the cruſaders. Having ſent out a party to reconnoitre the enemy, they fell in with a conſiderable detachment of Chriſtians; whom they eaſily defeated, taking about 100 priſoners, with the loſs of only a ſingle man on their ſide. The ſultan, animated by this firſt inſtance of ſucceſs, drew up his forces in order of battle, and advanced againſt the cruſaders, who had aſſembled their whole army at Sepphoris in Galilee. On viewing the ſultan's troops, however, and perceiving them to be greatly ſuperior in ſtrength to what they had at firſt apprehended, they thought proper to decline an engagement, nor could Saladin with all his ſkill force them to it. But though it was found impoſſible to bring the cruſaders to a deciſive engagement, Saladin found means to haraſs them greatly, and deſtroyed great numbers of their men. He carried off alſo many priſoners, diſmantled three of their ſtrongeſt cities, laid waſte their territories, and concluded the campaign with taking another ſtrong town.

2
ians
de-

For three years Saladin continued to gain ground on the cruſaders, yet without any deciſive advantage; but in 1187, the fortune of war was remarkably unfavourable to them. The Chriſtians now found themſelves obliged to venture a battle, by reaſon of the cruel ravages committed in their territories by Saladin, and by reaſon of the encroachments he daily made on them. Both armies therefore being reſolved to exert their utmoſt efforts, a moſt fierce and bloody battle enſued. Night prevented victory from declaring on either ſide, and the fight was renewed with equal obſtinacy next day. The victory was ſtill left undecided; but the third day the ſultan's men finding themſelves ſurrounded by the enemy on all ſides but one, and there alſo hemmed in by the river Jordan, ſo that there was no room to fly, fought like men in deſpair, and at laſt gained a moſt complete victory. Vaſt numbers of the Chriſtians periſhed on the field. A large body found means to retire in ſafety to the top of a neighbouring hill covered with wood; but being ſurrounded by Saladin's troops, who ſet fire to the wood, they were all obliged to ſurrender at diſcretion. Some of them were butchered by their enemies as ſoon as they delivered themſelves into their hands, and others thrown into irons. Among the latter were the king of Jeruſalem himſelf, Arnold prince of Al Shawbec and Al Carac, the maſters of the Templars and Hoſpitalers, with almoſt the whole body of the latter. So great was the conſternation of the Chriſtians on this occaſion, that one of Saladin's men is ſaid to have taken 30 of them priſoners, and tied them together with the cord of his tent, to prevent them from making their eſcape. The maſters of the Templars and Hoſpitalers, with the knights acting under them, were no ſooner brought into Saladin's preſence, than he ordered them all to be cut in pieces. He called them *Aſſaſſins* or *Bataniſts*; and had been wont to pay 50 dinars for the head of every Templar or Hoſpitaler that was brought him. After the engagement, Saladin ſeated himſelf in a magnificent tent, placing the king of Jeruſalem on his right hand, and Arnold prince of Al Shawbec and Al Carac on his left. Then he drank to the former, who was at that time ready to expire with thirſt, and at the ſame time offered him a cup of ſnow water. This was thankfully received; and the king immediately drank to the prince of Al Carac, who ſat near him. But here Saladin interrupted him with ſome warmth: "I will not (ſays he) ſuffer this curſed rogue to drink; as that, according to the laudable and generous cuſtom of the Arabs, would ſecure to him his life." Then, turning towards the prince, he reproached him with having undertaken the expedition while in alliance with himſelf, with having intercepted an Egyptian caravan in the time of profound peace, and maſſacring the people of which it was compoſed, &c. Notwithſtanding all this, he told him, he would grant him his life, if he would embrace Mahometaniſm. This condition, however, was refuſed; and the ſultan, with one ſtroke of his ſcimitar, cut off the prince's head. This greatly terrified the king of Jeruſalem; but Saladin aſſured him he had nothing to fear, and that Arnold had brought on himſelf a violent death by his want of common honeſty.

93
His further conqueſts.

The cruſaders being thus totally defeated and diſperſed, Saladin next laid ſiege to Tiberias, which capitulated in a ſhort time. From thence he marched towards Acca or Ptolemais, which likewiſe ſurrendered after a ſhort ſiege. Here he found 4000 Mahometan priſoners in chains, whom he immediately releaſed. As the inhabitants enjoyed at preſent a very extenſive trade, the place being full of merchants, he found there not only vaſt ſums of money, but likewiſe a great variety of wares exceedingly valuable, all which he ſeized and applied to his own uſe. About the ſame time his brother Al Malec attacked and took a very ſtrong fortreſs in the neighbourhood; after which the ſultan divided his army into three bodies, that he might with the greater facility overrun the territories of the Chriſtians. Thus, in a very ſhort time, he made himſelf maſter of Neapolis, Cæſarea, Sepphoris, and other cities in the neighbourhood of Ptolemais, where his ſoldiers found only women and children, the men having been all killed or taken priſoners. His next conqueſt was Joppa, which was taken by ſtorm after a vigorous reſiſtance. Every thing being then ſettled, and a diſtribution made of the ſpoils and captives, Saladin marched in perſon againſt Tebrien, a ſtrong fortreſs in the neighbourhood of Sidon; which was taken by aſſault, after it had ſuſtained a ſiege of ſix days. No ſooner was he maſter of this place, than he ordered the fortreſs to be razed, and the garriſon put to the ſword. From Tebrien the victorious ſultan proceeded to Sidon itſelf; which, being deſerted by its prince. ſurrendered almoſt on the firſt ſummons. Berytus was next inveſted, and ſurrendered in ſeven days. Among the priſoners Saladin found in this place the prince of a territory called *Hobeil*, who by way of ranſomed delivered up his dominions to him, and was of conſequence releaſed. About the ſame time, a Chriſtian ſhip, in which was a nobleman of great courage and experience in war, arrived at the harbour of Ptolemais, not knowing that it was in the hands of Saladin. The governor might eaſily have ſecured the veſſel; but neglecting the opportunity, ſhe eſcaped to Tyre, where the above mentioned nobleman, together with the prince of Hobeil, contributed not a little to retrieve the affairs of the Chriſtians, and enable them to make a ſtand for four years after.

94 Jeruſalem taken. Saladin in the mean time went on with his conqueſts. Having made himſelf maſter of Aſcalon after a ſiege of 14 days, he next inveſted Jeruſalem. The garriſon was numerous, and made an obſtinate defence; but Saladin having at laſt made a breach in the walls by ſapping, the beſieged deſired to capitulate. This was at firſt refuſed: upon which the Chriſtian ambaſſador made the following ſpeech: "If that be the caſe, know, O ſultan, that we who are extremely numerous, and have been reſtrained from fighting like men in deſpair only by the hopes of an honourable capitulation, will kill all our wives and children, commit all our wealth and valuable effects to the flames, maſſacre 5000 priſoners now in our hands, leave not a ſingle beaſt of burden or animal of any kind belonging to us alive, and level with the ground the rock you eſteem ſacred, together with the temple Al Akſa. After this we will ſally out upon you in a body; and doubt not but we ſhall either cut to pieces a much greater number of you than we are, or force you to abandon the ſiege." This deſperate ſpeech had ſuch an effect upon Saladin, that he immediately called a council of war, at which all the general officers declared, that it would be moſt proper to allow the Chriſtians to depart unmoleſted. The ſultan therefore allowed them to march out freely and ſecurely with their wives, children, and effects; after which he received ten dinars from every man capable of paying that ſum, five from every woman, and two from every young perſon under age. For the poor who were not able to pay any thing, the reſt of the inhabitants raiſed the ſum of 30,000 dinars.

Moſt of the inhabitants of Jeruſalem were eſcorted by a detachment of Saladin's troops to Tyre; and ſoon after, he advanced with his army againſt that place. As the port was blocked up by a ſquadron of five men of war, Saladin imagined that he ſhould eaſily become maſter of it. But in this he found himſelf miſtaken. For, one morning by break of day, a Chriſtian fleet fell upon his ſquadron, and entirely defeated it; nor did a ſingle veſſel eſcape their purſuit. A conſiderable number of the Mahometans threw themſelves into the ſea during the engagement; moſt of whom were drowned, though ſome few eſcaped. About the ſame time Saladin himſelf was vigorouſly repulſed by land; ſo that, after calling a council of war, it was thought proper to raiſe the ſiege.

In 1188, Saladin, though his conqueſts were not ſo rapid and conſiderable as hitherto, continued ſtill ſuperior to his enemies. He reduced the city of Laodicea and ſome others, together with many ſtrong caſtles; but met alſo with ſeveral repulſes. At laſt he took the road to Antioch; and having reduced all the fortreſſes that lay in his way, many of which had been deemed impregnable, Bohemond prince of Antioch was ſo much intimidated, that he deſired a truce for ſeven or eight months. This Saladin found himſelf obliged to comply with, on account of the prodigious fatigues his men had ſuſtained, and becauſe his auxiliaries now demanded leave to return home.

95 Cruſaders retrieve their affairs. All theſe heavy loſſes of the Chriſtians, however, proved in ſome reſpects an advantage, as they were thus obliged to lay aſide their animoſities, which had originally proved the ruin of their affairs. Thoſe who had defended Jeruſalem, and moſt of the other fortreſſes taken by Saladin, having retreated to Tyre, formed there a very numerous body. This proved the means of preſerving that city, and alſo of re-eſtabliſhing their affairs for the preſent. For, having received powerful ſuccours from Europe, they were enabled in 1189 to take the field with 30,000 foot and 2000 horſe. Their firſt attempt was upon Alexandretta; from whence they diſlodged a ſtrong party of Mahometans, and made themſelves maſters of the place with very little loſs. They next laid ſiege to Ptolemais; of which Saladin had no ſooner received intelligence, than he marched to the relief of the place. After ſeveral ſkirmiſhes with various ſucceſs, a general engagement enſued, in which Saladin was defeated with the loſs of 10,000 men. This enabled the Chriſtians to carry on the ſiege of Ptolemais with greater vigour; which place, however, they were not able to reduce for the ſpace of two years.

This year the ſultan was greatly alarmed by an account that the emperor of Germany was advancing to Conſtantinople with an army of 260,000 men, in order to aſſiſt the other cruſaders. This prodigious armament, however, came to nothing. The multitude was ſo reduced with ſickneſs, famine, and fatigue, that ſcarce 1000 of them reached the camp before Ptolemais. The ſiege of that city was continued, though with bad ſucceſs on the part of the Chriſtians. They were repulſed in all their attacks, their engines were burnt with naphtha, and the beſieged always received ſupplies of proviſions in ſpite of the utmoſt efforts of the beſiegers; at the ſame time that a dreadful famine and peſtilence raged in the Chriſtian camp, which ſometimes carried off 200 people a-day.

96 Richar of Eng arrives Aſia. In 1191, the Chriſtians received powerful ſuccours from Europe. Philip II. of France, and Richard I. of England (from his great courage ſurnamed *Cœur de Lion*) arrived at the camp before Ptolemais. The latter was eſteemed the braveſt and moſt enterpriſing of all the generals the cruſaders had; and the ſpirits of his ſoldiers were greatly elated by the thoughts of acting under ſuch an experienced commander. Soon after his arrival, the Engliſh ſunk a Mahometan ſhip of vaſt ſize, having on board 650 ſoldiers, a great quantity of arms and proviſions, going from Berytus to Ptolemais. Of the ſoldiers and ſailors who navigated this veſſel, only a ſingle perſon eſcaped; who being taken priſoner by the Engliſh, was deſpatched to the ſultan with the news of the diſaſter. The beſieged ſtill defended themſelves with the greateſt reſolution; and the king of England happening to fall ſick, the operations of the beſiegers were conſiderably delayed. On his recovery, however, the attacks were renewed with ſuch fury, that the place was every moment in danger of being taken by aſſault. This induced them to ſend a letter to Saladin, informing him, that if they did not receive ſuccours the very next day, they would be obliged to ſubmit. As this town was the ſultan's principal magazine of arms, he was greatly affected with the account of their diſtreſs, eſpecially as he found it impoſſible to relieve them. The inhabitants, therefore, found themſelves under a neceſſity of ſurrendering the place. One of the terms of the capitulation was, that the cruſaders ſhould receive a very conſiderable ſum of money from Saladin, in conſe-

quence of their delivering up the Mahometan priſoners they had in their hands. This article Saladin refuſed to comply with; and, in conſequence of his refuſal, Richard cauſed 3000 of thoſe unfortunate men to be ſlaughtered at once.

17
ts Sa-

After the reduction of Ptolemais, the king of England, now made generaliſſimo of the cruſaders, took the road to Aſcalon, in order to beſiege that place; after which, he intended to make an attempt upon Jeruſalem itſelf. Saladin propoſed to intercept his paſſage, and placed himſelf in the way with an army of 300,000 men. On this occaſion was fought one of the greateſt battles of that age. Saladin was totally defeated, with the loſs of 40,000 men; and Aſcalon ſoon fell into the hands of the cruſaders. Other ſieges were afterwards carried on with ſucceſs, and Richard even approached within ſight of Jeruſalem, when he found, that, by reaſon of the weakened ſtate of his army, and the diviſions which prevailed among the officers who commanded it, he ſhould be under the neceſſity of concluding a truce with the ſultan. This was accordingly done in the year 1192; the term was, three years, three months, three weeks, three days, and three hours; ſoon after which the king of England ſet out on his return to his own dominions.

9
nt of

In 1193 Saladin died, to the inexpreſſible grief of all true Mahometans, who held him in the utmoſt veneration. His dominions in Syria and Paleſtine were ſhared out among his children and relations into many petty principalities. His ſon Othman ſucceeded to the crown of Egypt: but as none of his ſucceſſors poſſeſſed the enterpriſing genius of Saladin, the hiſtory from that time till the year 1250 affords nothing remarkable. At this time the reigning ſultan Malek Al Salek was dethroned and ſlain by the *Mamelucs* or *Mamlouks*, as they are called, a kind of mercenary ſoldiers who ſerved under him. In conſequence of this revolution, the Mamelucs became maſters of Egypt, and choſe a ſultan from among themſelves.—Theſe Mamlouks are thought to have been young Turks or Tartars, ſold to private perſons by the merchants, from whom they were bought by the ſultan, educated at his expence, and employed to defend the maritime places of the kingdom. The reaſon of this inſtitution originally was, that the native Egyptians were become ſo cowardly, treacherous, and effeminate, from a long courſe of ſlavery, that they were unfit for arms. The Mamlouks, on the contrary, made moſt excellent ſoldiers; for having no friends but among their own corps, they turned all their thoughts to their own profeſſion. According to M. Volney, they came originally from Mount Caucaſus, and are diſtinguiſhed by the flaxen colour of their hair. Here they were found by the cruſaders, and were by them called *Mamelucs*, or more correctly *Mamlouks*. The expedition of the Tartars in in 1227 proved indirectly the means of introducing them into Egypt. Theſe horrible conquerors, having ſlaughtered and maſſacred till they were weary, brought along with them an immenſe number of ſlaves of both ſexes, with whom they filled all the markets in Aſia. The Turks, taking advantage of the opportunity, purchaſed about 12,000 young men, whom they bred up in the profeſſion of arms, in which they ſoon attained to great perfection; but becoming mutinous, like the Roman pretorian bands, they turned their arms againſt their maſters, and in 1250 depoſed and murdered the caliph, as has been already related.

100
Driven out by the Borgites.

The Mamlouks having got poſſeſſion of the government, and neither underſtanding nor putting a value upon any thing beſides the art of war, every ſpecies of learning decayed in Egypt, and a great degree of barbariſm was introduced. Neither was their empire of long duration notwithſtanding all their martial abilities. The reaſon of this was, that they were originally only a ſmall part of the ſultan of Egypt's ſtanding forces. As a numerous ſtanding army was neceſſary in a country where the fundamental maxim of government was, that every native muſt be a ſlave, they were at firſt at a loſs how to act; being juſtly ſuſpicious of all the reſt of the army. At laſt they reſolved to buy Chriſtian ſlaves, and educate them in the ſame way that they themſelves had formerly been. Theſe were commonly brought from Circaſſia, where the people, though they profeſſed Chriſtianity, made no ſcruple of ſelling their children. When they were completed in their military education, theſe ſoldiers were diſpoſed of through all the fortreſſes erected in the country to bridle the inhabitants; and becauſe in their language ſuch a fort was called *Borge*, the new militia obtained the name of *Borgites*. By this expedient the Mamlouks imagined they would be able to ſecure themſelves in the ſovereignty. But in this they were miſtaken. In proceſs of time, the old Mamlouks grew proud, inſolent, and lazy: and the Borgites, taking advantage of this, roſe upon their maſters, deprived them of the government, and transferred it to themſelves about the year 1382.

101
Egypt conquered by Selim.

The Borgites, as well as the former, aſſumed the name of *Mamlouks*; and were famous for their valour and ferocity of conduct. They were almoſt perpetually engaged in wars either foreign or domeſtic; and their dominion laſted till the year 1517, when they were invaded by Selim the Turkiſh ſultan. The Mamlouks defended themſelves with incredible valour; notwithſtanding which, being overpowered by numbers, they were defeated in every engagement. The ſame year, their capital, the city of Cairo, was taken, with a terrible ſlaughter of thoſe who defended it. The ſultan was forced to fly; and, having collected all his force, ventured a deciſive battle. The moſt romantic efforts of valour, however, were inſufficient to cope with the innumerable multitude which compoſed the Turkiſh army. Moſt of his men were cut in pieces, and the unhappy prince himſelf was at laſt obliged to take ſhelter in a marſh. He was dragged from his hiding-place, where he had ſtood up to the ſhoulders in water, and ſoon after put to death. With him ended the glory, and almoſt the exiſtence, of the Mamlouks, who were now everywhere ſearched for and cut in pieces.

This was the laſt great revolution in the Egyptian affairs: a revolution very little to the advantage of the natives, who may well doubt whether their ancient or modern conquerors have behaved with the greater degree of barbarity. Selim gave a ſpecimen of his government, the very day after his being put in full poſſeſſion of it, by the death of Tuman Bey the unfortunate ſultan above mentioned. Having ordered a theatre to be erected with a throne upon it on the banks of the

Nile, he cauſed all the priſoners, upwards of 30,000 in number, to be beheaded in his preſence, and their bodies thrown into the river.

102 His horrid cruelty.

Notwithſtanding this horrid cruelty of Selim, he did not attempt the total extermination of the race of Mamlouks, though this would have been quite agreeable to the maxims of Turkiſh policy; but in the preſent caſe he ſeems to have recollected, that if he eſtabliſhed a pacha in Egypt with the ſame powers with which he inveſted thoſe of other parts, he would be under ſtrong temptations to revolt by reaſon of the diſtance from the capital.

103 New form of government introduced by Selim.

He therefore propoſed a new form of government, by which the power being diſtributed among the different members of the ſtate, ſhould preſerve an equilibrium, ſo that the dependence of the whole ſhould be upon himſelf. With this view, he choſe from among the Mamlouks who had eſcaped the general maſſacre, a divan, or council of regency, conſiſting of the pacha and chiefs of the ſeven military corps. The former was to notify to this council the orders of the Porte, to ſend the tribute to Conſtantinople, and provide for the ſafety of government both external and internal; while, on the other hand, the members of the council had a right to reject the orders of the pacha, or even of depoſing him, provided they could aſſign ſufficient reaſons. All civil and political ordinances muſt alſo be ratified by them. Beſides this, he formed the whole body into a

104 His edict for a republic.

republic; for which purpoſe he iſſued an edict to the following purpoſe: "Though, by the help of the Almighty, we have conquered the whole kingdom of Egypt with our invincible armies; nevertheleſs our benevolence is willing to grant to the 24 ſangiacs (A) of Egypt a republican government, with the following conditions.

"I. That our ſovereignty ſhall be acknowledged by the republic; and in token of their obedience, our lieutenant ſhall be received as our repreſentative: but to do nothing againſt our will or the republic; but, on the contrary, ſhall co-operate with it for its welfare on all occaſions. Or if he ſhall attempt to infringe any of its privileges, the republic is at liberty to ſuſpend him from his authority, and to ſend to our Sublime Porte a complaint againſt him, &c.

"II. In time of war, the republic ſhall provide 12,000 troops at its own expence, to be commanded by a ſangiac or ſangiacs.

"III. The republic ſhall raiſe annually and ſend to our Sublime Porte the ſum of 560,000 aſlany (B), accompanied by a ſangiac, who ſhall have a ſatisfactory receipt, &c.

"IV. The ſame ſum to be raiſed for the uſe of Medina, and Kiabe or Mecca.

"V. No more troops of Janizaries ſhall be kept by the republic in time of peace than 14,000; but in time of war they may be increaſed to oppoſe our and the republic's enemies.

"VI. The republic ſhall ſend annually to our granary, out of the produce of the country, one million of caſiz (C) or meaſures of corn, viz, 600,000 of wheat and 400,000 of barley.

"VII. The republic, fulfilling theſe articles, ſhall have a free government over all the inhabitants of Egypt, independent of our lieutenant; but ſhall execute the laws of the country with the advice of the mollah or high prieſt under our authority and that of our ſucceſſors.

"VIII. The republic ſhall be in poſſeſſion of the mint as heretofore; but with this condition, that it ſhall be under the inſpection of our lieutenant, that the coin may not be adulterated.

"IX. That the republic ſhall elect a *ſheik bellet* out of the number of beys, to be confirmed by our lieutenant; and that the ſaid ſheik bellet ſhall be our repreſentative, and ſhall be eſteemed by all our lieutenants, and all our officers both of high and low rank, as the head of the republic; and if our lieutenant is guilty of oppreſſion, or exceeds the bounds of his authority, the ſaid ſheik bellet ſhall repreſent the grievances of the republic to our Sublime Porte: but in caſe any foreign enemy or enemies diſturb the peace of the republic, we and our ſucceſſors engage to protect it with our utmoſt power until peace is re-eſtabliſhed, without any coſt or expence to the republic.

"Given and ſigned by our *clemency* to the republic of Egypt."

105 The Tur iſh power now alm entirely loſt.

Thus the power of the Mamlouks ſtill continued in a very conſiderable degree, and by degrees increaſed ſo much as to threaten a total loſs of dominion to the Turks. During the laſt 50 years, the Porte having relaxed from its vigilance, ſuch a revolution has taken place, that the Turkiſh power is now almoſt reduced to nothing. But in order to underſtand this, we muſt conſider the way in which the race of Mamlouks is continued or multiplied in Egypt. This is not in the ordinary way, by marriage: on the contrary, M. Volney aſſures us, that "during 350 years in which there

106 Why the children the Mam louks and Turks all die in Egypt.

have been Mamlouks in Egypt, not one of them has left ſubſiſting iſſue; all their children periſh in the firſt or ſecond deſcent. Almoſt the ſame thing holds good with regard to the Turks; and it is obſerved, that they can only ſecure the continuance of their families by marrying women who are natives, which the Mamlouks have always diſdained. The means by which they are perpetuated and multiplied are the ſame by which they were firſt eſtabliſhed, viz. by ſlaves brought from their original country. From the time of the Moguls this commerce has been continued on the banks of the Cuban and Phaſis in the ſame manner as it is carried on in Africa, by the wars among the hoſtile tribes, and the miſery or avarice of the inhabitants, who ſell their children to ſtrangers. The ſlaves thus procured are firſt brought to Conſtantinople, and afterwards diſperſed through the empire, where they are purchaſed by the wealthy. When the Turks ſubdued Egypt (ſays M. Volney), they ſhould undoubtedly have prohibited this dangerous traffic; their omitting

ting which ſeems about to diſpoſſeſs them of their conqueſt, and which ſeveral political errors have long been preparing.

“ For a conſiderable time the Porte had neglected the affairs of this province; and in order to reſtrain the pachas, had ſuffered the divan to extend its power till the chiefs of the janizaries and azabs were left without controul. The ſoldiers themſelves, become citizens by the marriages they had contracted, were no longer the creatures of Conſtantinople; and a change introduced into their diſcipline ſtill more increaſed theſe diſorders. At firſt the ſeven military corps had one common treaſury; and though the ſociety was rich, individuals, not having any thing at their own diſpoſal, could effect nothing. The chiefs, finding their power diminiſhed by this regulation, had intereſt enough to get it aboliſhed, and obtained permiſſion to poſſeſs diſtinct property, lands, and villages. And as theſe lands and villages depended on the Mamlouk governors, it was neceſſary to conciliate them to prevent their oppreſſions. From that moment the beys acquired an aſcendancy over the ſoldiers, who till then had treated them with diſdain; and this could not but continually increaſe, ſince their governments procured them conſiderable riches. Theſe they employed in creating themſelves friends and creatures. They multiplied their ſlaves; and after emancipating them, employed all their intereſt to promote them to various employments, and advance them in the army. Theſe upſtarts, retaining for their patrons the ſame ſuperſtitious veneration common in the Eaſt, formed factions implicitly devoted to their pleaſure.”

him
ya.

Thus, about the year 1746, Ibrahim, one of the kiayas (D) of the janizaries, rendered himſelf in reality maſter of Egypt; having managed matters ſo well, that of the 24 beys or ſangiacs eight were of his houſehold. His influence too was augmented by always leaving vacancies in order to enjoy the emoluments himſelf; while the officers and ſoldiers of his corps were attached to his intereſt: and his power was completed by gaining over Rodoan, the moſt powerful of all the colonels, to his intereſt. Thus the pacha became altogether unable to oppoſe him, and the orders of the ſultan were leſs reſpected than thoſe of Ibrahim. On his death in 1757, his family, i. e. his enfranchiſed ſlaves, continued to rule in a deſpotic manner. Waging war, however, among each other, Rodoan, and ſeveral other chiefs were killed; until, in 1766, Ali Bey, who had been a principal actor in the diſturbances, overcame his enemies, and for ſome time rendered himſelf abſolute maſter of Egypt.

108
ory of
Bey.

Of this man there are various accounts. The following is that given by M. Volney. He begins with obſerving, that the private hiſtory of the Mamlouks in general muſt be ſubject to great uncertainty, by reaſon of their being generally carried off from their parents at a time of life when they can remember but little or nothing of their parents; and he remarks, that they are likewiſe unwilling to communicate the little they may happen to remember. It is moſt commonly ſuppoſed, however, that Ali Bey was born among the Abazans, a people of Mount Caucaſus; from whom, next to the Circaſſians, the ſlaves moſt valued by the Turks, and other nations who deal in that commodity are to be obtained.

109
He is bought and educated by Ibrahim Kiaya.

Having been brought to a public ſale at Cairo, Ali Bey was bought by two Jew brothers named Iſaac and Youſef, who made a preſent of him to Ibrahim Kiaya. At this time he is ſuppoſed to have been about 13 or 14 years old, and was employed by his patron in offices ſimilar to thoſe of the pages belonging to European princes. The uſual education was alſo given him; viz. that of learning to manage a horſe well; fire a carabine and piſtol; throw the djerid, a kind of dart uſed in the diverſions of that country, and which ſhall be afterwards deſcribed. He was alſo taught the exerciſe of the ſabre, and a little reading and writing. In all the feats of activity juſt mentioned, he diſcovered ſuch impetuoſity, that he obtained the ſurname of *Djendali*, or “madman;” and as he grew up, diſcovered an ambition proportionable to the activity diſplayed in his youth. About the age of 18 or 20, his patron gave him his freedom; the badge of which among the Turks is the letting the beard grow, for among that people it is thought proper only for women and ſlaves to want a beard. By his kind patron alſo he was promoted to the rank of kachef or governor of a diſtrict, and at laſt elected one of the 24 beys. By the death of Ibrahim in 1757, he had an oportunity of ſatisfying his ambition; and now engaged in every ſcheme for the promotion or diſgrace of the chiefs, and had a principal ſhare in the ruin of Rodoan Kiaya above mentioned. Rodoan's place was quickly filled by another, who did not long enjoy it; and in 1762 Ali Bey, then ſtyled *Sheik-el-Beled*, having got Abdelrahman, the poſſeſſor at that time, exiled, procured himſelf to be elected in his room.

110
He is baniſhed, but returns, and throws off the Turkiſh yoke,

However, he ſoon ſhared the fate of the reſt, being condemned to retire to Gaza. This place, being under the dominion of a Turkiſh pacha, was by no means agreeable; for which reaſon Ali having turned off to another place, kept himſelf concealed for ſome time, until in 1766 his friends at Cairo procured his recal. On this he appeared ſuddenly in that city; and in one night killed four of the beys who were inimical to his deſigns, baniſhed the reſt, and aſſumed the whole power to himſelf. Still, however, his ambition was not ſatisfied; and he determined on nothing leſs then to throw off his dependence on the Porte altogether, and become ſultan of Egypt. With this view he expelled the pacha, refuſed to pay the accuſtomed tribute, and in the year 1768 proceeded to coin money in his own name. The Porte being at that time on the eve of a dangerous war with Ruſſia, had not leiſure to attend to the proceedings of Ali Bey; ſo that the latter had an opportunity of going forward with his enterpriſes very vigorouſly.

111
Overcomes an Arabian prince,

His firſt expedition was againſt an Arabian prince named *Hammam*; againſt whom he ſent his favourite Mohammed Bey, under pretence that the former had concealed a treaſure intruſted with him by Ibrahim Kiaya, and that he afforded protection to rebels. Having deſtroyed this unfortunate prince, he next began to put in execution a plan propoſed to him

(D) Theſe were the commanding officers of the janizaries, azabs, &c. who after the firſt year laid down their employments, and became veterans, with a voice in the divan.

112
Propoſes to make Mecca the emporium of Eaſt Indian commerce.

by a young Venetian merchant, of rendering Jedda, the port of Mecca, an emporium for all the commerce of India ; and even imagined he ſhould be able to make the Europeans abandon the paſſage to the Indies by the Cape of Good Hope. With this view, he fitted out ſome veſſels at Suez ; and manning them with Mamlouks, commanded the bey Haſſan to ſail with them to Jedda, and ſeize upon it, while a body of cavalry under Mohammed Bey advanced againſt the town. Both theſe commiſſions were executed according to his wiſh, and Ali became quite intoxicated with his ſucceſs. Nothing but ideas of conqueſt now occupied his mind, without conſidering the immenſe diſproportion between his own force and that of the grand ſignior. Circumſtances, it muſt be owned, were at that time very favourable to his ſchemes. The ſheik Daher was in rebellion againſt the Porte in Syria ; and the pacha of Damaſcus had ſo exaſperated the people by his extortions, that they were ready for a revolt.

113
His expedition into Syria.

Having therefore made the neceſſary preparations, Ali Bey deſpatched in 1770 about 500 Mamlouks to take poſſeſſion of Gaza, and thus ſecure an entrance into Paleſtine. Oſman, the pacha of Damaſcus, however, no ſooner heard of the invaſion than he prepared for war with the utmoſt diligence, while the troops of Ali Bey held themſelves in readineſs to fly on the firſt attack. They were relieved from their embarraſſment by Sheik Daher, who haſtened to their aſſiſtance, while Oſman fled without even offering to make the leaſt reſiſtance ; thus leaving the enemy maſters of all Paleſtine without ſtriking a ſtroke. About the end of February 1771, the grand army of Ali Bey arrived ; which, by the repreſentations made of it in Europe, was ſuppoſed to conſiſt of 60,000 men.

114
Volney's account of his army.

M. Volney, however, informs us, that this army was far from containing 60,000 ſoldiers ; though he allows that there might be two-thirds of that number, who were claſſed as follows : 1. Five thouſand Mamlouks, conſtituting the whole effective part of the army. 2. Fifteen hundred Arabs from Barbary on foot, conſtituting the whole infantry of the army. Beſides theſe, the ſervants of the Mamlouks, each of whom had two, would conſtitute a body of 10,000 men. A number of other ſervants would conſtitute a body of 2000 ; and the reſt of the number would be made up by ſutlers and other uſual attendants on armies. It was commanded by Mohammed Bey the friend of Ali. " But (ſays our author) as to order and diſcipline, theſe muſt not be mentioned. The armies of the Turks and Mamlouks are nothing but a confuſed multitude of horſemen, without uniforms, on horſes of all colours and ſizes, without either keeping their ranks or obſerving any regular order." This rabble took the road to Acre, leaving wherever they paſſed ſufficient marks of their rapacity and want of diſcipline. At Acre a junction was formed with the troops of Sheik Daher, conſiſting of 1500 Safadians (the name of Sheik Daher's ſubjects, from *Safad*, a village of Galilee, originally under his juriſdiction). Theſe were on horſeback, and accompanied by 1200 Motualis cavalry under the command of Sheik Naſif, and about 1000 Mogrebian infantry. Thus they proceeded towards Damaſcus, while Oſman prepared to oppoſe them by another army equally numerous and ill regulated : and M. Volney gives the following deſcription of their operations : " The reader muſt not here figure to himſelf a number of complicated and artificial movements : ſuch as thoſe which, within the laſt century, have reduced war with us to a ſcience of ſyſtem and calculation.

115
Their a
ſurd me
thod of
carrying
war.

The Aſiatics are unacquainted with the firſt elements of this conduct. Their armies are mere mobs, their marches ravages, their campaigns inroads, and their battles bloody frays. The ſtrongeſt or the moſt adventurous party goes in queſt of the other, which frequently flies without making any reſiſtance. If they ſtand their ground, they engage pell-mell, diſcharge their carabines, break their ſpears, and hack each other with their ſabres; for they have ſeldom any cannon, and when they have, they are but of little ſervice. A panic frequently diffuſes itſelf without cauſe ; one party flies, the other ſhouts victory ; the vanquiſhed ſubmit to the will of the conqueror, and the campaign often terminates without a battle.

" Such, in a great meaſure, were the military operations in Syria in the year 1771. The combined army of Ali Bey and Sheik Daher marched to Damaſcus. The pachas waited for them ; they approached, and, on the 6th of June, a deciſive action took place : the Mamlouks and Safadians ruſhed on the Turks with ſuch fury, that, terrified at their courage, they immediately took to flight, and the pachas were not the laſt in endeavouring to make their eſcape. The allies became maſters of the country, and took poſſeſſion of the city without oppoſition, there being neither walls nor ſoldiers to defend it. The caſtle alone reſiſted. Its ruined fortifications had not a ſingle cannon, much leſs gunners ; but it was ſurrounded by a muddy ditch, and behind the ruins were poſted a few muſketeers : and theſe alone were ſufficient to check this army of cavalry. As the beſieged, however, were already conquered by their fears, they capitulated the third day, and the place was to be ſurrendered next morning, when, at day-break, a moſt extraordinary revolution took place."

116
Defecti
of Ali E
general

This was no leſs than the defection of Mohammed Bey himſelf, whom Oſman had gained over in a conference during the night. At the moment, therefore, that the ſignal of ſurrender was expected, this treacherous general ſounded a retreat, and turned towards Egypt with all his cavalry, flying with as great precipitation as if he had been purſued by a ſuperior army. Mohammed continued his march with ſuch celerity, that the report of his arrival in Egypt reached Cairo only ſix hours before him. Thus Ali Bey found himſelf at once deprived of all his expectations of conqueſt ; and what was worſe, found a traitor whom he durſt not puniſh at the head of his forces. A ſudden reverſe of fortune now took place. Several veſſels laden with corn for Sheik Daher were taken by a Ruſſian privateer ; and Mohammed Bey, whom he deſigned to have put to death, not only made his eſcape, but was ſo well attended that he could not be attacked. His followers continuing daily to increaſe in number, Mohammed ſoon became ſufficiently ſtrong to march towards Cairo ; and, in the month of April 1772, having defeated the troops of Ali in a rencounter, entered the city ſword in hand, while the latter had ſcarce time to make his eſcape with 800 Mamlouks. With difficulty he was enabled to get to Syria by the aſſiſtance of Sheik Daher, whom he immediately joined with the troops

troops he had with him. The Turks under Oſman were at that time beſieging Sidon, but raiſed the ſiege on the approach of the allied army, conſiſting of about 7000 cavalry. Though the Turkiſh army was at leaſt three times their number, the allies did not heſitate to attack them, and gained a complete victory. Their affairs now began to wear a more favourable aſpect; but the military operations were retarded by the ſiege of Yafa, a place which had revolted; and which, though defended only by a garden wall, without any ditch, held out for eight months. In the beginning of 1773 it capitulated, and Ali Bey began to think of returning to Cairo. For this purpoſe Sheik Daher had promiſed to furniſh him with ſuccours; and the Ruſſians, with whom he had now contracted an alliance, made him a promiſe of the like kind. Ali, however, ruined every thing by his own impatience. Deceived by an aſtrologer, who pretended that the auſpicious moment when he was highly favoured by the ſtars was juſt arrived, he would needs ſet out without waiting for the arrival of his allies. He was alſo farther deceived by a ſtratagem of Mohammed, who had by force extorted from the friends of Ali Bey letters preſſing his return to Cairo, where the people were weary of his ungrateful ſlave, and wanted only his preſence in order to expel him. Confiding in theſe promiſes, Ali Bey imprudently ſet out with his Mamlouks and 1500 Safadians given him by Daher; but had no ſooner entered the deſert which ſeparates Gaza from Egypt, than he was attacked by a body of 1000 choſen Mamlouks who were lying in wait for his arrival. They were commanded by a young bey, named *Mourad;* who being enamoured of the wife of Ali Bey, had obtained a promiſe of her from Mohammed, in caſe he could bring him her huſband's head. As ſoon as Mourad perceived the duſt by which the approach of Ali Bey's army was announced, he ruſhed upon him, attacked and took priſoner Ali Bey himſelf, after wounding him in the forehead with a ſabre. Being conducted to Mohammed Bey, the latter pretended to treat him with extraordinary reſpect, and ordered a magnificent tent to be erected for him; but in three days he was found dead of his wounds, as was given out; though ſome affirm, perhaps with equal reaſon, that he was poiſoned.

120
ucceeded
Moham-
Bey.

After the death of Ali Bey, Mohammed Bey took upon him the ſupreme dignity; but this change of maſters proved of very little ſervice to the Egyptians. At firſt he pretended to be only the defender of the rights of the ſultan, remitted the uſual tribute to Conſtantinople, and took the cuſtomary oath of unlimited obedience; after which he ſolicited permiſſion to make war upon Sheik Daher, the ally of Ali Bey. The reaſon of this requeſt was a mere perſonal pique; and as ſoon as it was granted, he made the moſt diligent preparations for war. Having procured an extraordinary train of artillery, he provided foreign gunners, and gave the command of them to an Engliſhman named *Robinſon.* He brought from Suez a cannon 16 feet long, which had for a conſiderable time remained uſeleſs; and at length, in the month of February 1776, he appeared in Syria with an army equal in number to that which he had formerly commanded when in the ſervice of Ali Bey. Daher's forces, deſpairing of being able to cope with ſuch a formidable armament, abandoned Gaza, which Mohammed immediately took poſſeſſion of, and then marched towards a fortified town named Yafa. The hiſtory of this ſiege M. Volney gives as a ſpecimen of the Aſiatic manner of conducting operations of that kind. "Yafa (ſays he), the ancient Joppa, is ſituated on a part of the coaſt, the general level of which is very little above the ſea. The city is built on an eminence, in the form of a ſugar loaf, in height about 130 feet perpendicular. The houſes, diſtributed on the declivity, appear riſing above each other, like the ſteps of an amphitheatre. On the ſummit is a ſmall citadel, which commands the town; the bottom of the hill is ſurrounded by a wall without a rampart, of 12 or 14 feet high, and two or three in thickneſs. The battlements on the top are the only tokens by which it is diſtinguiſhed from a common garden wall. This wall, which has no ditch, is environed by gardens, where lemons, oranges, and citrons, grow in this light ſoil to a moſt prodigious ſize. The city was defended by five or ſix hundred Safadians and as many inhabitants, who, at the ſight of the enemy, armed themſelves with their ſabres and muſkets; they had likewiſe a few braſs canon, 24 pounders, without carriages; theſe they mounted as well as they could, on timbers prepared in a hurry; and ſupplying the place of experience by hatred and courage, they replied to the ſummons of the enemy with menaces and cannon ſhot.

122
Account of
the ſiege of
Yafa: a
ſpecimen of
the Aſiatic
method of
beſieging
towns.

"Mohammed, finding he muſt have recourſe to force, formed his camp before the town; but was ſo little acquainted with the buſineſs in which he was engaged, that he advanced within half cannon ſhot. The bullets, which ſhowered upon the tents, apprizing him of his error, he retreated; and, by making a freſh experiment, was convinced he was ſtill too near. At length he diſcovered the proper diſtance, and ſet up his tent, in which the moſt extravagant luxury was diſplayed: around it, without any order, were pitched thoſe of the Mamlouks, while the Barbary Arabs formed huts with the trunks and branches of the orange and lemon trees, and the followers of the army arranged themſelves as they could: a few guards were diſtributed here and there; and, without making a ſingle entrenchment, they called themſelves encamped.

"Batteries were now to be erected, and a ſpot of riſing ground was made choice of to the ſouth-eaſtward of the town, where, behind ſome garden walls, eight pieces of canon were pointed, at 200 paces from the town; and the firing began, notwithſtanding the muſquetry of the enemy, who, from the tops of the terraces, killed ſeveral of the gunners.

"It is evident that a wall only three feet thick, and without a rampart, muſt ſoon have a large breach in it; and the queſtion was not how to mount, but how to get through it? The Mamlouks were for doing it on horſeback; but they were made to comprehend that this was impoſſible; and they conſented, for the firſt time, to march on foot. It muſt have been a curious ſight to ſee them, with their huge breeches of thick Venetian cloth, embarraſſed with their tucked-up *beniches*, their crooked ſabres in hand, and piſtols hanging to their ſides, advancing and tumbling among the ruins of the wall. They imagined that they had conquered every difficulty when this obſtacle was ſurmounted; but the beſieged, who formed a better judgment, waited till they arrived at the empty ſpace between the city and wall; where they aſſailed them from the terraces and windows of the houſes with ſuch a ſhower of bullets, that the Mamlouks did not ſo much as think of ſetting them on fire, but retired under a perſuaſion that the breach was utterly impracticable, ſince it was impoſſible to enter it on horſeback. Morad Bey brought them ſeveral times back to the charge, but in vain.

123
The town taken and the inhabitants maſſacred.

" Six weeks paſſed in this manner; and Mohammed was diſtracted with rage, anxiety, and deſpair. The beſieged however, whoſe numbers were diminiſhed by the repeated attacks, became weary of defending alone the cauſe of Daher. Some perſons began to treat with the enemy; and it was propoſed to abandon the place, on the Egyptians giving hoſtages. Conditions were agreed upon, and the treaty might be conſidered as concluded, when, in the midſt of the ſecurity occaſioned by this belief, ſome Mamlouks entered the town; numbers of others followed their example, and attempted to plunder. The inhabitants defended themſelves, and the attack recommenced: the whole army then ruſhed into the town, which ſuffered all the horrors of war; women and children, young and old men, were all cut to pieces, and Mohammed, equally mean and barbarous, cauſed a pyramid formed of the heads of theſe unfortunate ſufferers to be raiſed as a monument of his victory."

124
Death of Mohammed Bey.

By this diſaſter the greateſt terror and conſternation were everywhere diffuſed. Sheik Daher himſelf fled, and Mohammed ſoon became maſter of Acre alſo. Here he behaved with his uſual cruelty, and abandoned the city to be plundered by his ſoldiers. The French merchants claimed an exemption, and it was procured with the utmoſt difficulty: nor was even this likely to be of any conſequence; for Mohammed, informed that the treaſures of Ibrahim kiaya of Daher had been depoſited in that place, made an immediate demand of them, threatening every one of the merchants with death if the treaſures were not inſtantly produced. A day was appointed for making the ſearch; but before this came, the tyrant himſelf died of a malignant fever after two days illneſs. His death was no ſooner known than the army made a precipitate retreat, ſuch as has been already mentioned from Damaſcus. Sheik Daher continued his rebellion for ſome time, but was at laſt entirely defeated, and his head ſent to Conſtantinople by Haſſan Pacha the Turkiſh high-admiral.

125
Hiſtory of Egypt from that time to the year 1786.

The death of Mohammed was no ſooner known in Egypt, than Morad Bey haſtened to Cairo in order to diſpute the ſovereignty with Ibrahim Bey, who had been intruſted with the government on his departure from that place for Syria. Preparations for war were made on both ſides; but at laſt, both parties finding that the conteſt muſt be attended with great difficulty, as well as very uncertain in the event, thought proper to come to an accommodation, by which it was agreed that Ibrahim ſhould retain the title of Sheik El Beled, and the power was to be divided between them. But now the beys and others who had been promoted by Ali Bey, perceiving their own importance totally annihilated by this new faction, reſolved to ſhake off the yoke, and therefore united in a league under the title *of the Houſe of Ali Bey*. They conducted their matters with ſo much ſilence and dexterity, that both Morad and Ibrahim were obliged to abandon Cairo. In a ſhort time, however, they returned and defeated their enemies though three times their number; but notwithſtanding this ſucceſs, it was not in their power totally to ſuppreſs the party. This indeed was owing entirely to their unſkilfulneſs in the art of war, and their operations for ſome time were very trifling. At laſt, a new combination having been formed among the beys, five of them were ſentenced to baniſhment in the Delta. They pretended to comply with this order, but took the road of the deſert of the Pyramids, through which they were purſued for three days to no purpoſe. At laſt they arrived ſafe at *Miniah*, a village ſituated on the Nile, 40 leagues above Cairo. Here they took up their reſidence, and being maſters of the river, ſoon reduced Cairo to diſtreſs by intercepting its proviſions. Thus a new expedition became neceſſary, and Ibrahim took the command of it upon himſelf. In the month of October 1783 he ſet out with an army of 3000 cavalry; the two armies ſoon came in ſight of each other, but Ibrahim thought proper to terminate the affair by negotiation. This gave ſuch offence to Morad, who ſuſpected ſome plot againſt himſelf, that he left Cairo. A war betwixt the two rivals was now daily expected, and the armies continued for 25 days in ſight of each other, only ſeparated by the river. Negotiations took place; and the five exiled beys, finding themſelves abandoned by Morad, took to flight, but were purſued and brought back to Cairo. Peace ſeemed now to be re-eſtabliſhed; but the jealouſy of the two rivals producing new intrigues, Morad was once more obliged to quit Cairo in 1784. Forming his camp, however, directly at the gates of the city, he appeared ſo terrible to Ibrahim, that the latter thought proper in his turn to retire to the deſert, where he remained till March 1785. A new treaty then took place; by which the rivals agreed to ſhare the power between them, though there was certainly very little probability that ſuch a treaty would be long obſerved. Since that time we have no accounts of any remarkable tranſaction in Egypt; nor indeed can we reaſonably expect any thing of conſequence in a country where matters are managed, as M. Volney expreſſes himſelf, by a ſeries of " cabals, intrigues, treachery, and murders."

Of late Egypt has been viſited by ſeveral travellers, all of whom have publiſhed deſcriptions of the country, its productions, inhabitants, &c. The lateſt are M. Savary, M. Volney, the baron de Tott, and Mr Bruce; and from the accounts publiſhed by thoſe gentlemen the following geographical deſcription is principally compiled.

126
Account of the country.

This country is ſtill divided into two principal parts, called the *Upper* and *Lower Egypt*. According to M. Savary, the former is only a long narrow valley beginning at Sienna and terminating at Cairo. It is bounded by two chains of mountains running from north to ſouth, and taking their riſe from the laſt cataract of the Nile. On reaching the latitude of Cairo they ſeparate to the right and left; the one taking the direction of Mount Colzoum, the other terminating in ſome ſand banks near Alexandria; the former being compoſed of high and ſteep rocks, the latter of ſandy hillocks over a bed of calcareous ſtone. Beyond theſe mountains are deſerts bounded by the Red ſea on the eaſt, and on the weſt by other parts of Africa; having in the middle that long plain which, even where wideſt, is not more than nine leagues over. Here the Nile is confined in its courſe betwixt theſe inſuperable barriers, and during the time of its inundation overflows the country all the way to the foot of the mountains; and Mr Bruce obſerves that there is a gradual ſlope from the bed of the river to thoſe mountains on both ſides. The baron de Tott ſays, that the mountains four leagues from the Nile, and facing Cairo, "are only a ridge of rocks of about 40 or 50 feet high, which divide Egypt from the plains of Libya; which ridge accompanies the courſe of the river, at a greater or leſſer diſtance, and ſeems as if only intended to ſerve as a bank to the general inundation."

Lower Egypt, according to M. Savary, comprehends all the country between Cairo, the Mediterranean, the iſthmus of Suez and Libya. "This immenſe plain (ſays he) preſents on the borders of its parching ſands a ſtrip of lands cultivated along the canals of the river, and in the middle a triangular iſland to which the Greeks gave the name of *Delta*;" at the top of the angle of which the baron de Tott informs us the rocks of Libya and the coaſts of Arabia open and recede from each other towards the eaſt and weſt, parallel to the Mediterranean. This great extent of country, from the kingdom of Barca to Gaza, is either overflowed by the river, or capable of being ſo; which thus fertilizes in a high degree a tract of country ſeemingly devoted to perpetual barrenneſs on account of the want of rain and the heat of the climate.

27 According to the teſtimonies of both Mr Bruce and M. Volney, the coaſt of Egypt is ſo extremely low, that it cannot be diſcovered at ſea till the mariners come within a few leagues of it. In ancient times the ſailors pretended to know when they approached this country, by a kind of black mud brought up by their ſounding line from the bottom of the ſea; but this notion, though as old as the days of Herodotus, has been diſcovered to be a miſtake by Mr Bruce; who found the mud in queſtion to ariſe while the veſſel was oppoſite to the deſerts of Barca. All along the coaſt of Egypt a ſtrong current ſets to the eaſtward.

28 In former times Egypt was much celebrated for its fertility; and there is great reaſon to believe, that were the ſame pains beſtowed upon the cultivation of the ground, and the diſtribution of the waters of the Nile in a proper manner, the ſame fertility would ſtill be found to remain. The cauſe of decreaſe in the produce of Egypt we ſhall deſcribe in the words of M. Savary. "The canals," ſays he, ſpeaking of the Delta, "which uſed to convey fertility with their waters, are now filled. The earth no longer watered, and continually expoſed to the burning ardour of the ſun, is converted into a barren ſand. In thoſe places where formerly were ſeen rich fields and flouriſhing towns, on the Peluſiac, the Tarictic, and the Mendeſian branches, which all ſtrike out from the canal of Damietta, nothing is to be found at this day but a few miſerable hamlets, ſurrounded by date trees and by deſerts. Theſe once navigable canals are now no more than a vain reſemblance of what they were: they have no communication with the lake Menzall, but what is merely temporary, on the ſwelling of the Nile; they are dry the remainder of the year. By deepening them by removing the mud depoſited by the river ſince the Turks have made themſelves maſters of Egypt, the country they paſs through would be again fertilized, and the Delta recover a third of its greatneſs."

129 Savary's account of the formation of the Delta.

Concerning this iſland it has been the opinion of a great many, even from very ancient times, that it was produced by the mud brought down by the inundations of the Nile: and this opinion we find adopted in the ſtrongeſt manner by M. Savary. His account of the ſuppoſed riſe of the Delta, and indeed of the greateſt part of Egypt, is to the following purpoſe. In thoſe early ages where hiſtory has not fixed any epoch, a certain people deſcended from the mountains near the cataracts into the valley overflowed by the Nile, and which was then an uninhabitable moraſs overgrown with reeds and canes. In what manner, or from what motive, theſe people were induced to deſcend from their ancient habitations to ſuch a place, or how they found means to penetrate into a moraſs which he expreſsly tells us was *impenetrable*, we are not informed, neither is it to our preſent purpoſe to inquire. At that time, however, the ſea bathed the feet of thoſe mountains where the pyramids are built, and advanced far into Libya. It covered alſo part of the iſthmus of Suez, and every part of what we now call the Delta formed a great gulf. After many ages the Egyptians, by what means is unknown, at leaſt not ſpecified by our author (though they ought to have been ſo, as the country it ſeems was then overflowed not only by the river but by the ocean), formed canals to carry off the ſtagnant waters of the Nile; oppoſed ſtrong dykes to its ravages; and, tired of dwelling in the caverns of rocks, built towns and cities upon ſpots elevated either by nature or art. Already the river was kept within its bounds, the habitations of men were out of the reach of its inundations, and experience had taught the people to foreſee and announce them. One of the kings of Egypt undertook to change the courſe of the river. After running 150 leagues between the barriers already mentioned, meeting with an unſurmountable obſtacle to the right, it turned ſuddenly to the left; and taking its courſe to the ſouthward of Memphis, it ſpreads its waters through the ſands of Libya. The prince we ſpeak of cauſed a new bed to be dug for it to the eaſt of Memphis; and by means of a large dyke obliged it to return between the mountains, and diſcharge itſelf into the gulf that bathes the rock on which the caſtle of Cairo is built. The ancient bed of the river was ſtill to be ſeen in the time of Herodotus, and may even be traced at this day acroſs the deſerts, paſſing to the weſtward of the lakes of Natrum. The Arabs ſtill beſtow upon it the name of *Bahr Belama*, "or ſea without water," and it is now almoſt choked up. To the labours of this monarch Egypt is indebted for the Delta. A reflux of the ſea was occaſioned by the enormous weight of the waters of the Nile, which precipitated themſelves into the bottom of the gulf. Thus the ſands and mud carried along with them were collected into heaps; and thus the Delta, at firſt very inconſiderable, roſe out of the ſea of which it repelled the limits. It was a gift of the river, and it has ſince been defended from the attacks of the ocean by raiſing dykes around it. Five hundred years before the Trojan war, according to Herodotus,

rodotus, the Delta was in its infancy; eight cubits of water being then ſufficient to overflow it. Strabo tells us, that boats paſſed over it from one extremity to the other; and that its towns, built upon artificial eminences, reſembled the iſlands of the Egean ſea. At the time that Herodotus viſited this country 15 cubits were neceſſary to cover all the Lower Egypt; but the Nile then overflowed the country for the ſpace of two days journey to the right and left of the iſland. Under the Roman empire 16 cubits performed the ſame effect. When the Arabs came to have the dominion, 17 cubits were requiſite; and at this day 18 are neceſſary to produce a plentiful crop; but the inundation ſtops at Cairo and the neighbouring country, without being extended over the Lower Egypt. Sometimes, however, the Nile riſes to 22 cubits; and the cauſe of this phenomenon is the mud for ſo many years accumulated on the iſland. Here, in the ſpace of 3284 years, we ſee the Delta elevated 14 cubits. Our author wrote in 1777, and informs us that he twice made the tour of the iſland during the time of the inundation. "The river (ſays he) flowed in full ſtreams in the great branches of Roſetta and Damietta, as well as in thoſe which paſs through the interior part of the country; but it did not overflow the lands, except in the lower parts, where the dykes were pierced for the purpoſe of watering the plantations of rice. We muſt not, however, imagine, as ſeveral travellers pretend, that this iſland will continue to riſe, and that it will become unfruitful. As it owes its increaſe to the annual ſettling of the mud conveyed thither by the Nile, when it ceaſes to be overflowed it will no longer increaſe in height, for it is demonſtrated that culture is not ſufficient to raiſe land.

"It is natural to imagine that the Delta has increaſed in length as well as in height; and of this we may look upon the following fact to be a remarkable proof. Under the reign of Pſammiticus, the Mileſians, with 30 veſſels, landed at the mouth of the Bolbitine branch of the Nile, now called that of *Roſetta*, where they fortified themſelves. There they built a town called *Metelis*, the ſame as *Facüe*, which, in the Coptic vocabularies, has preſerved the name of *Meſſil*. This town, formerly a ſeaport, is now nine leagues diſtant from the ſea; all which ſpace the Delta has increaſed in length from the time of Pſammiticus to the preſent. Homer, in his Odyſſey, puts the following words in the mouth of Menelaus. 'In the ſtormy ſea which waſhes Egypt there is an iſland called *Pharos*. Its diſtance from the ſhore is ſuch, that a veſſel with a fair wind may make the paſſage in a day.' From the way in which he ſpeaks of this iſland in other places, alſo, we may ſuppoſe that the iſland of Pharos, in his time, was not leſs than 20 leagues diſtant from the Egyptian coaſt, though now it forms the port of Alexandria; and this ſentiment is confirmed by the moſt ancient writers.

"What prodigious changes great rivers occaſion on the ſurface of the globe! How they elevate, at their mouths, iſlands which become at length large portions of the continent! It is thus that the Nile has formed almoſt all the Lower Egypt, and created out of the waters the Delta, which is 90 leagues in circumference. It is thus that the Meander, conſtantly repelling the waves of the Mediterranean, and gradually filling up the gulf into which it falls, has placed in the middle of the land the town of Miletus, formerly a celebrated harbour. It is thus that the Tigris and the Euphrates, let looſe from the Armenian hills, and ſweeping with them in their courſe the ſands of Meſopotamia, are imperceptibly filling up the Perſian gulf."

130 Mr Bru reaſons the contrary op nion.

Theſe are the reaſons aſſigned by M. Sayary for thinking that the Delta, as well as the greateſt part of the Lower Egypt, had been produced by the Nile; but this opinion is violently conteſted by other late travellers, particularly Mr Bruce, who has given a pretty long diſſertation upon it, as well as many occaſional remarks through the courſe of his work. He begins with obſerving, 1. That the country of Egypt is entirely a valley bounded by rugged mountains; whence it might ſeem natural to imagine that the Nile, overflowing a country of this kind, would be more ready to waſh away the ſoil than to add to it. 2. It is obſerved by Dr Shaw, and the ſame is confirmed by our author, that there is a gentle ſlope from the middle of the valley to the foot of the mountains on each ſide; ſo that the middle, in which is the channel of the Nile, is really higher than any other part of the valley. Large trenches are cut acroſs the country from the channel of the river, and at right angles with it, to the foot of the mountains. 3. As the river ſwells, the canals become filled with water, which naturally deſcending to the foot of the mountains, runs out at the farther end, and overflows the adjacent level country. 4. When the water, having attained the loweſt ground, begins to ſtagnate, it does not acquire any motion by reaſon of the canal's being at right angles with the channel of the Nile, unleſs in the caſe of exceſſive rains in Ethiopia, when the water by its regurgitation again joins the ſtream. In this caſe, the motion of the current is communicated to the whole maſs of waters, and every thing is ſwept away by them into the ſea. 5. It has been the opinion of ſeveral authors, that there was a neceſſity for meaſuring the height of the inundation on account of the quantity of mud brought down annually by the waters, by which the landmarks were ſo covered, that the proprietors could not know their own grounds after the river ſubſided. But whatever might be the reaſon of this covering of the landmarks in ancient times, it is certain that the mud left by the Nile could not be ſo in the time of Herodotus, or during any period of time aſſigned by that hiſtorian; for he aſſigns only one foot of increaſe of ſoil throughout Egypt in an hundred years from the mud left by the river; the increaſe during one year, therefore, being only the hundredth part of a foot, could not cover any landmark whatever. Beſides, the Egyptian lands are at this day parted by huge blocks of granite, which frequently have gigantic heads at the ends of them; and theſe could not, at the rate mentioned by Herodotus, be covered in ſeveral thouſand years. 6. The Nile does not now bring down any great quantity of mud; and it is abſurd to ſuppoſe that it can at preſent bring down as much as it did ſoon after the creation, or the ages immediately ſucceeding the deluge. Throughout Abyſſinia, according to the teſtimony of our author, the channel of every torrent is now worn to the bare rock, and almoſt every rivulet runs in a hard ſtony bed, all the looſe earth being long ago waſhed away; ſo that an annual and equable increaſe of the earth from the ſediment of the waters is impoſſible. 7. Our author made a great number of trials of the water of the Nile during the time of its inundation in different places. At Baſboch, when juſt coming down from the cultivated parts of Abyſſinia, and before it enters Sennaar, the ſediment is compoſed of fat earth and ſand, and its quantity is exceedingly ſmall. At the junction of the Nile and Aſtaboras the quantity of ſediment is very little augmented; conſiſting ſtill of the ſame materials, but now moſtly ſand. At Syene the quantity of ſediment was almoſt nine times greater than before; but was now compoſed almoſt entirely of ſand, with a very ſmall quantity of black earth. The concluſion of our author's experiments, however, is different from what we ſhould have been led to expect from thoſe juſt mentioned. "The experiment at Roſetta (ſays he) was not ſo often repeated as the others: but the reſult was, that in the ſtrength of the inundation the ſediment conſiſted moſtly of ſand; and, towards the end, was much the greater part earth. I think theſe experiments concluſive, as neither the Nile coming freſh from Abyſſinia, nor the Atbara, though joined by the Mareb, likewiſe from the ſame country, brought any great quantity of ſoil from thence."

8. Our author goes on to obſerve, that had the Nile brought down the quantities of mud which it has been ſaid to do, it ought to have been moſt charged with it at Syene; as there it contained the whole that was to be conveyed by it into Egypt. Inſtead of this, however, the principal part of the ſediment at this place was ſand; and this is very naturally accounted for from the vaſt quantities of ſand taken up by the winds in the deſerts between Gooze and Syene. Here our traveller frequently ſaw vaſt pillars of this kind of ſand, which is ſo fine and light as to form an impalpable powder, traverſing the deſert in various directions. Many of theſe were driven upon the river; and when it became calm in the evening, fell down into it entirely; thus affording materials for the many ſandy iſlands to be met with in the Nile.

9. Mr Bruce adopts the opinion of thoſe who ſuppoſe that there has been a continual decreaſe of water ſince the creation of the world. In this caſe, therefore, if the land of Egypt had been continually increaſing in height while the water that was to cover it decreaſed; there muſt have been frequent famines on account of the want of a ſufficient inundation. But ſo far is this from being the caſe, that, according to the teſtimony of ſeveral Arabian MSS. there had not, when Mr Bruce was in Egypt, been one ſcarce ſeaſon from the lowneſs of the inundation for 34 years; though during the ſame ſpace they had three times experienced a famine by too great an abundance of water, which carried away the millet.

10. If there had been ſuch an increaſe of land as Herodotus and others ſuppoſe, it muſt now have been very perceptible in ſome of the moſt ancient public monuments. This, however, is by no means the caſe. The baſe of every obeliſk in Upper Egypt is to this day quite bare and viſible. Near Thebes there are ſtill extant two coloſſal ſtatues, plainly deſigned for nilometers, and which ought by this time to have been almoſt covered with earth; but notwithſtanding the length of time theſe have remained there, they are ſtill bare to the very baſe.

121
Opinions of various authors concerning the riſe of the Nile in ancient times.

The ſtrongeſt argument which the advocates for the increaſe of land of Egypt can make uſe of is, that the meaſures by which the quantity of inundation is determined are ſmaller now than in former times; and theſe ſmall meaſures are ſaid to have been introduced by the Saracens. On this Mr Bruce very juſtly obſerves, that ſuch an expedient could not have anſwered any good purpoſe; as no decreaſe of the meaſure could have augmented the quantity of corn produced by the ground. M. Savary obſerves, that, to render his calculation concerning the growth of land in Egypt abſolutely exact, it would be neceſſary to determine the preciſe length of the Greek, Roman, and Arabian cubit; and even to know the different alterations which that meaſure had undergone among theſe people: But this nicety he thinks needleſs; looking upon the general fact to be fully eſtabliſhed by what he had ſaid before. Mr Bruce, however, has treated the ſubject with much greater accuracy. He obſerves, that from the ſituation of Canopus, the diſtance betwixt Egypt and Cyprus, and the extenſion of the land to the northward, it appears that no addition of any conſequence has been made to it for 3000 years paſt. The only argument left for the increaſe of land therefore muſt be taken from the nilometer. The uſe of this inſtrument was to determine the quantity of inundation, that ſo it might be known whether the crop would be ſufficient to enable the people to pay the taxes exacted of them by the ſovereign or not. The firſt ſtep was to know what ſpace of ground was overflowed in a given number of years; and this being determined by menſuration, the next thing was to aſcertain the produce of the ground upon an average. Thus becoming acquainted with the greateſt and leaſt crops produced, together with the exact extent of ground overflowed, they were furniſhed with all the neceſſary principles for conſtructing a nilometer; and nothing now remained but to erect a pillar in a proper place, and divide it exactly into cubits. This was accordingly done; the pillar was firſt divided into cubits, and theſe again were ſubdivided into digits. The firſt diviſion of this kind was undoubtedly that mentioned in Scripture, and called the *cubit of a man;* being the length of the arm from the middle of the round bone in the elbow to the point of the middle finger; a meaſure ſtill in uſe among all rude nations. As no ſtandard could be found by which this meaſure might be exactly determined, authors have differed very much concerning the true length of the cubit when reduced to our feet and inches. Dr Arbuthnot reckons two cubits mentioned in Scripture; one of them containing one foot nine inches and $\frac{888}{1000}$ of an inch; the other one foot and $\frac{824}{1000}$ of a foot; but Mr Bruce is of opinion that both of theſe are too large. He found, by menſuration, the Egyptian cubit to be exactly one foot five inches and three-fifths of an inch; and Herodotus mentions, that in his time the cubit uſed for determining the increaſe of the Nile was the Samian cubit, about 18 of our inches. The latter alſo informs us, that in the time of Moeris, the minimum of increaſe was 8 cubits, at which time all Egypt below the city of Memphis was overflowed; but that in his time 16 or at leaſt 15 cubits were neceſſary to produce the ſame effect. But to this account Mr Bruce objects, that Herodotus could have no certain information concerning the nilometer, becauſe he himſelf ſays that the prieſts, who alone had acceſs to it, would tell him nothing of the matter. Herodotus alſo informs us, that in the time of Moeris, great lakes were dug to carry off the waters of the inundation; and this ſuperfluous quantity Mr Bruce ſuppoſes to have been conveyed into the deſert for the uſe of the Arabs, and that by ſuch a vaſt drain the riſe of the water on the nilometer would undoubtedly be diminiſhed. But even granting that there was ſuch a difference between the riſe of the water in the time of Moeris and in that of Herodotus, it does not appear that any thing like it has appeared ever ſince. Strabo, who travelled into Egypt 400 years after the time of Herodotus, found that eight cubits were then the minimum, as well as in the time of Moeris. From ſome paſſages in Strabo, however, it appears that it required a particular exertion of induſtry to cauſe this quantity of water produce a plentiful crop; but there is not the leaſt reaſon to ſuppoſe, that the very ſame induſtry was not neceſſary in the time of Moeris; ſo that ſtill there is not any increaſe of land indicated by the nilometer. About 100 years afterwards, when the emperor Adrian viſited Egypt, we are informed from unqueſtionable authority, that 16 cubits were the minimum when the people were able to pay their tribute; and in the fourth century, under the emperor Julian, 15 cubits were the ſtandard; both which accounts correſpond with that of Herodotus. Laſtly, Procopius, who lived in the time of Juſtinian, informs us, that 18 cubits were then requiſite for a minimum.

132 No increaſe of land in theſe ages can reaſonably be ſuppoſed;

From theſe accounts, ſo various and diſcordant, it is obvious that no certain concluſion can be drawn. It is not indeed eaſy to determine the reaſon of this difference in point of fact. The only conjecture we can offer is, that as it appears that by proper care a ſmaller quantity of water will anſwer the purpoſe of producing a plentiful crop, ſo it is not unreaſonable to ſuppoſe that at different periods the induſtry of the people has varied ſo much as to occaſion the diſagreement in queſtion. This would undoubtedly depend very much upon their governor; and indeed Strabo informs us that it was by the care of the governor Petronius, that ſuch a ſmall quantity of water was made to anſwer the purpoſe. The concluſion drawn by Mr Bruce from the whole of the accounts above related, is, that from them it is moſt probable that no increaſe of land has been indicated by the nilometer from the time of Moeris to that of Juſtinian.

133 nor in more modern times.

On the conqueſt of Egypt by the Saracens, their barbarous and ſtupid caliph deſtroyed the nilometer, cauſing another to be built in its ſtead, and afterwards fixed the ſtandard of paying tribute conſiderably below what it had uſually been. The Egyptians were thus kept in continual terror, and conſtantly watched the new nilometer to obſerve the gradual increaſe or decreaſe of the water. On this he ordered the new nilometer to be deſtroyed, and another to be conſtructed, and all acceſs to it to be denied to the people. Which prohibition is ſtill continued to Chriſtians; though our author found means to get over this obſtacle, and has given a figure of the inſtrument itſelf. That the people might not, however, be ſuppoſed to remain in total ignorance of their ſituation, he commanded a proclamation to be daily made concerning the height of the water, but in ſuch an unintelligible manner that nobody was made any wiſer; nor, according to our author, is the proclamation underſtood at this day. From his own obſervations, however, Mr Bruce concludes, that 15 cubits are now the minimum of inundation, and as this coincides with the accounts of it in the times of Herodotus and Adrian, he ſuppoſes with great probability, that the ſame quantity of water has been neceſſary to overflow this country from the earlieſt accounts to the preſent time.

134 M. Savary's opinio concerning the iſle of Pharos refuted by M Volney.

It now remains only to take notice of what is ſaid by M. Savary concerning the former diſtance of the iſland of Pharos from the land to which it is now joined. With regard to his other aſſertions concerning the city of Metelis having been once a ſea port, M. Volney proves that he has quoted Strabo unfairly, and conſequently no ſtreſs is to be laid upon them. The principal, indeed the only, evidence which therefore remains, is the paſſage already quoted from Homer, viz. that "the iſland of Pharos is as far diſtant from one of the mouths of the Nile as a veſſel can ſail in one day before the wind." "But (ſays M. Volney) when Homer ſpeaks of the diſtance of this iſland, he does not mean its diſtance from the ſhore oppoſite, as that traveller (M. Savary) has tranſlated him, but from the land of Egypt and the river Nile. In the ſecond place, by a day's ſail we muſt not underſtand that indefinite ſpace which the veſſels, or rather the boats, of the ancient Greeks, could paſs through in a day; but an accurate and determined meaſure of 540 ſtadia. This meaſure is aſcertained by Herodotus, and is the preciſe diſtance between Pharos and the Nile, allowing, with M. d'Anville, 27,000 toiſes to 540 ſtadia. It is therefore far from being proved, that the increaſe of the Delta or of the continent was ſo rapid as has been repreſented; and, if we were diſpoſed to maintain it, we ſhould ſtill have to explain how this ſhore, which has not gained half a league from the days of Alexander, ſhould have gained eleven in the far ſhorter period from the time of Menelaus to that conqueror. The utmoſt extent of the encroachment of this land upon the ſea, however, may be learned from the words of Herodotus; who informs us, that "the breadth of Egypt, along the ſea coaſt, from the gulf of Plinthine to the lake Serbonis near Mount Caſius, is 3600 ſtadia; and its length from the ſea to Heliopolis 1500 ſtadia." Allowing therefore the ſtadium of Herodotus to be between 50 and 51 French toiſes, the 1500 ſtadia juſt mentioned are equal to 76,000 toiſes; which, at the rate of 57,000 to a degree, gives one degree and near 20 minutes and a half. But from the aſtronomical obſervations of M. Niebuhr, who travelled for the king of Denmark in 1761, the difference of latitude between Heliopolis, now called *Matarea*, and the ſea, being one degree 29 minutes at Damietta, and one degree 24 minutes at Roſetta, there is a difference on one ſide of three minutes and a half, or a league and a half, encroachment; and eight minutes and a half, or three leagues and a half on the other."

Thus the diſpute concerning the augmentation of the land of Egypt by the Nile ſeems to be abſolutely decided; and the encroachments of it on the ſea ſo trifling, that we may juſtly doubt whether they exiſt, or whether we are not entirely to attribute the apparent differences to thoſe which certainly take place betwixt the ancient and modern menſuration. M. Volney gives a very particular deſcription of the face of the country; but takes notice of the inconveniences under which travellers labour in this country, by which it is rendered extremely difficult to to ſay any thing certain with regard to the nature of the ſoil or mineral productions. Theſe ariſe from the barbarity and ſuperſtition of the people, who imagine all the Europeans to be magicians and ſorcerers, who come by their magic art to diſcover the treaſures which the genii have concealed under the ruins. So deep rooted is this opinion, that no perſon dares walk alone in the fields, nor can he find any one willing to accompany him; by which means he is confined to the banks of the river, and it is only by comparing the accounts of various travellers that any ſatisfactory knowledge can be acquired.

35 ey's nt of ace of oun-

According to this author, the entrance into Egypt at Roſetta preſents a moſt delightful proſpect, by the perpetual verdure of the palm trees on each ſide, the orchards watered by the river, with orange, lemon, and other fruit trees, which grow there in vaſt abundance; and the ſame beautiful appearance is continued all the way to Cairo. As we proceed farther up the river, he ſays, that nothing can more reſemble the appearance of the country than the marſhes of the Lower Loire, or the plains of Flanders: inſtead, however, of the numerous trees and country houſes of the latter, we muſt imagine ſome thin woods of palms and ſcyamores, with a few villages of mud-walled cottages built on artificial mounds. All this part of Egypt is very low and flat, the declivity of the river being ſo gentle, that its waters do not flow at a greater rate than one league in an hour. Throughout the country nothing is to be ſeen but palm trees, ſingle or in clumps, which become more rare in proportion as you advance; with wretched villages compoſed of huts with mud walls, and a boundleſs plain, which at different ſeaſons is an ocean of freſh water, a miry moraſs, a verdant field, or a duſty deſert; and on every ſide an extenſive and foggy horizon, where the eye is wearied and diſguſted. At length, towards the junction of the two branches of the river, the mountains of Cairo are diſcovered on the eaſt; and to the ſouth-weſt three detached maſſes appear, which from their triangular form are known to be the pyramids. We now enter a valley which turns to the ſouthward, between two chains of parallel eminences. That to the eaſt, which extends to the Red ſea, merits the name of a mountain from its ſteepneſs and height, as well as that of a deſert from its naked and ſavage appearance. Its name in the Arabic language is *Mokattam*, or the *hewn mountain*. The weſtern is nothing but a ridge of rock covered with ſand, which has been very properly termed a *natural mound* or *cauſeway*. In ſhort, that the reader may at once form an idea of this country, let him imagine on one ſide a narrow ſea and rocks; on the other, immenſe plains of ſand; and in the middle, a river, flowing through a valley of 150 leagues in length and from three to ſeven wide, which at the diſtance of 30 leagues from the ſea ſeparates into two arms; the branches of which wander over a ſoil almoſt free from obſtacles, and void of declivity.

From comparing his own obſervations with thoſe of other travellers, our author concludes, that the baſis of all Egypt from *Aſcuan* (the ancient Syene) to the Mediterranean, is a continued bed of calcareous ſtone of whitiſh hue, and ſomewhat ſoft, containing the ſame kind of ſhells met with in the adjacent ſeas, and which forms the immenſe quarries extending from Sacuadi to Manſalout for the ſpace of more than 25 leagues, according to the teſtimony of Father Sicard.

136 Mr Bruce's account of the deſerts, marble mountains, &c.

Mr Bruce, however, gives us a much more particular account of the ſources from whence were derived the vaſt quantities of marble met with in the remains of ancient buildings in this country. Theſe he diſcovered during his journey from Kenne to Coſſeir on the Red ſea, before he took his expedition to Abyſſinia. He gives a moſt diſmal idea of the deſerts through which he paſſed. What houſes he met with were conſtructed, like thoſe M. Volney mentions, of clay, being no more than ſix feet in diameter, and about ten in height. The mountains were the moſt dreary and barren that can be imagined; and the heat of the ſun ſo great, that two ſticks rubbed together only for half a minute would take fire and flame. In theſe burning regions no living creature was to be met with, even the poiſonous ſerpents and ſcorpions not being able to find ſubſiſtence. The firſt animal he ſaw was a ſpecies of ants in a plain called *Hamra* from the purple colour of its ſand; and it was remarkable that theſe inſects were of the ſame colour with the ſand itſelf. No water was anywhere to be met with on the ſurface; though at a place called *Legeta* there were ſome draw-wells, the water of which was more bitter than ſoot itſelf. At Hamra the porphyry mountains and quarries begin, the ſtone of which is at firſt ſoft and brittle; but the quantity is immenſe, as a whole day was taken up in paſſing by them. Theſe porphyry mountains begin in the latitude of nearly 24 degrees, and continue along the coaſt of the Red ſea to about 22° 30′, when they are ſucceeded by the marble mountains; theſe again by others of alabaſter, and theſe laſt by baſaltic mountains. From the marble mountains our author ſelected twelve kinds, of different colours, which he brought along with him. Some of the mountains appeared to be compoſed entirely of red and others of green marble, and by their different colours afforded an extraordinary ſpectacle. Not far from the porphyry mountains the cold was ſo great, that his camels died on his return from Abyſſinia, though the thermometer ſtood no lower than 42°.

Near to Coſſeir he diſcovered the quarries whence the ancients obtained thoſe immenſe quantities of marble with which they conſtructed ſo many wonderful works. The firſt place where the marks of their operations were very perceptible, was a mountain much higher than any they had yet paſſed, and where the ſtone was ſo hard that it did not even yield to the blows of a hammer. In this quarry he obſerved that ſome ducts or channels for conveying water terminated; which, according to him, ſhows that water was one of the means by which theſe hard ſtones were cut. In four days, during which our author travelled among theſe mountains, he ſays, that he had "paſſed more granite, porphyry, marble, and jaſper, than would build Rome, Athens, Corinth, Syracuſe, Memphis, Alexandria, and half a dozen ſuch cities." It appeared to him that the paſſages between the mountains and which he calls *defiles*, were not natural but artificial openings; where even whole mountains had been cut out, in order to preſerve a gentle ſlope towards the river. This deſcent our author ſuppoſes not to be above one foot in 50; ſo that the carriages muſt have gone very eaſily, and rather required ſomething to retard

tard their velocity than any force to pull them forward. Concerning the mountains in general, he obſerves, that the porphyry is very beautiful to the eye, and is diſcovered by a fine purple ſand without any gloſs. An unvariegated marble of a green colour is generally met with in the ſame mountain; and where the two meet, the marble becomes ſoft for a few inches, but the porphyry retains its hardneſs. The granite has a dirty brown appearance, being covered with ſand; but on removing this, it appears of a gray colour with black ſpots, with a reddiſh caſt all over it. The granite mountains lie nearer to the Red ſea, and ſeem to have afforded the materials for Pompey's pillar. The redneſs above mentioned ſeems to go off on expoſure to the air; but re-appears on working or poliſhing the ſtone farther. The red marble is next to the granite, though not met with in the ſame mountain. There is alſo a red kind with white veins, and vaſt quantities of the common green ſerpentine. Some ſamples of that beautiful marble named *Iſabella* were likewiſe obſerved; one of them of that yellowiſh caſt called *quaker colour*, the other of the bluiſh kind named *dove colour*. The moſt valuable kind is that named *verde antico*, which is found next to the Nile in the mountains of ſerpentine. It is covered by a kind of blue flaky ſtone, ſomewhat lighter than a ſlate, more beautiful than moſt kinds of marble, and when poliſhed having the appearance of a volcanic lava. In theſe quarries the verde antico had been uncovered in patches of about 20 feet ſquare. There were ſmall pieces of African marble ſcattered about in ſeveral places, but no rocks or mountains of it; ſo that our author conjectures it to lie in the heart of ſome other kind. The whole is ſituated on a ridge with a deſcent to the eaſt and weſt; by which means it might eaſily be conveyed either to the Nile, or Red ſea, while the hard gravel and level ground would readily allow the heavieſt carriages to be moved with very little force.

137
Of a ſuppoſed emerald mine.

Travellers have talked of an emerald mine in theſe deſerts; but from the reſearches of Mr Bruce, it does not appear to have any exiſtence. In the Red ſea indeed, in the latitude of 25° 3′, at a ſmall diſtance from the ſouth-weſtern coaſt, there is an iſland called the *Mountain of Emeralds*; but none of theſe precious ſtones are to be met with there. Here, as well as on the continent, there were found many pieces of a green pellucid ſubſtance; but veined, and much ſofter than rock cryſtal, though ſomewhat harder than glaſs. A few yards up the mountain he found three pits, which are ſuppoſed to have been the mines whence the ancients obtained the emeralds; but though many pieces of the green ſubſtance above mentioned were met with about theſe pits, no ſigns of the true emerald could be perceived. This ſubſtance, however, he conjectures to have been the *ſmaragdus* of the Romans. In the mountains of Coſſeir, as well as in ſome places of the deſerts of Nubia, our author found ſome rocks exactly reſembling petrified wood.

138
Stones of a curious appearance.

The only metal ſaid by the ancients to be produced in Egypt is copper. On the road to Suez are found great numbers of thoſe ſtones called *Egyptian flints* and *pebbles*, though the bottom is a hard, calcareous, and ſonorous ſtone. Here alſo M. Volney tells us, that the ſtones above mentioned, and which reſemble petrified wood, are to be met with. Theſe, he ſays, are in the form of ſmall logs cut ſlanting at the ends, and might eaſily be taken for petrifactions, though he is convinced that they are real minerals.

13
Salt la

F. Sicard mentions two lakes, from the water of which is produced annually a great quantity of ſalt containing much mineral alkali; and M. Volney informs us, that the whole ſoil of this country is impregnated with ſalt; ſo that, upon digging to ſome depth in the ground, we always meet with brackiſh water impregnated in ſome degree with the mineral alkali as well as with common ſalt. The two lakes mentioned by Sicard are ſituated in the deſert to the weſt of the Delta; and are three or four leagues in length, and about a quarter of a league in breadth, with a ſolid and ſtony bottom. For nine months in the year they are without water; but in the winter time there oozes out of the earth a reddiſh violet coloured water, which fills the lakes to the height of five or ſix feet. This being evaporated by the return of the heat, there remains a bed of ſalt two feet thick and very hard, which is broken in pieces with iron bars; and no leſs than 30,000 quintals are procured every year from theſe lakes. So great is the propenſity of the Egyptian ſoil to produce ſalt, that even when the gardens are overflowed for the ſake of watering them, the ſurface of the ground, after the evaporation and abſorption of the water, appears glazed over with ſalt. The water found in the wells contains mineral alkali, marine ſalt, and a little nitre.

14
Vegeta
mould
Egypt
origina
derive
from
Ethiop

M. Volney is of opinion, that the fertile mould of Egypt, which is of a blackiſh colour, differs eſſentially from that of the other parts; and is derived from the internal parts of Ethiopia along with the waters of the Nile. This ſeems to contradict what he had before advanced againſt M. Savary concerning the increaſe of the land of Egypt by means of the waters of this river: but there is no reaſon at all to ſuppoſe this kind of earth to be of a foreign origin; it being always the reſult of vegetation and cultivation. Even the moſt barren and ſandy ſpots in the world, if properly watered, and ſuch vegetables planted in them as would grow there, in time would be covered with this black earth as well as others: and of this kind of artificial formation of ſoil, travellers give us a remarkable inſtance in the garden of the monks at Mount Sinai, where the country is naturally as barren as in any place of the world. "The monks of Sinai (ſays Dr Shaw), in a long proceſs of time, have covered over with dung and the ſweepings of their convent near four acres of naked rocks; which produce as good cabbage, roots, ſalad, and all kinds of pot herbs, as any ſoil and climate whatſoever. They have likewiſe raiſed olive, plum, almond, apple, and pear trees, not only in great numbers, but of excellent kinds. The pears particularly are of ſuch eſteem at Cairo, that there is a preſent of them ſent every year to the baſhaw and perſons of the firſt quality. Neither are their grapes inferior in ſize and flavour to any whatſoever: it being fully demonſtrated, by what this little garden produces, how far an indefatigable induſtry can prevail over nature; and that ſeveral places are capable of culture and improvement which were intended by nature to be barren, and which the lazy and ſlothful have always ſuffered to be ſo."

From this general account of the country, we may reaſonably conclude, that the natural fertility of Egypt.

41 ral ity of t not iſhed.

gypt is not diminiſhed in modern times, provided the ſame pains were taken in the cultivation of it as formerly; but this is not to be expected from the preſent degenerate race of inhabitants. "The Delta (ſays M. Savary) is at preſent in the moſt favourable ſtate for agriculture. Waſhed on the eaſt and weſt by two rivers formed by the diviſion of the Nile, each of which is as large and more deep than the Loire, interſected by innumerable rivulets; it preſents to the eye an immenſe garden, all the different compartments of which may be eaſily watered. During the three months that the Thebais is under water, the Delta poſſeſſes fields covered with rice, barley, vegetables, and winter fruits. It is alſo the only part of Egypt where the ſame field produces two crops of grain within the year, the one of rice, the other of barley."

42 od of ying ooling rater gypt.

The only cauſe of all this fertility is the Nile, without which the whole country would ſoon become an uninhabitable deſert, as rain falls very ſeldom in this part of the world. It flows with a very gentle ſtream through the flat country, and its waters are very muddy, ſo that they muſt have time to ſettle, or even require filtration before they can be drunk. For purifying the water, the Egyptians, according to M. Volney, uſe bitter almonds, with which they rub the veſſel containing it, and then the water becomes light and good; but on what principle this ingredient acts we cannot pretend to determine. Unglazed earthen veſſels filled with water are kept in every apartment; which by a continual evaporation through their porous ſubſtance, render the contained fluid very cool even in the greateſt heats *. The river continues muddy for ſix months: and during the three which immediately precede the inundation, the ſtream being reduced to an inconſiderable depth, becomes heated, green, fetid, and full of worms. The Egyptians in former times paid divine honours to the Nile, and ſtill hold it in great veneration. They believe its waters to be very nouriſhing, and that they are ſuperior to any in the world; an opinion very excuſable in them, as they have no other, and large draughts of cold water are among their higheſt luxuries.

43 e in- tion of Nile.

This river, ſwelled by the rains which fall in Abyſſinia, begins to riſe in Egypt about the month of May; but the increaſe is inconſiderable till towards the end of June, when it is proclaimed by a public crier through the ſtreets of Cairo. About this time it has uſually riſen five or ſix cubits; and when it has riſen to 16, great rejoicings are made, and the people cry out *Waſſah Allah*, that is, that God has given them abundance. This commonly takes place about the latter end of July, or at fartheſt before the 20th of Auguſt; and the ſooner it takes place, ſo much the greater are the hopes of a good crop. Sometimes, though rarely, the neceſſary increaſe does not take place till later. In the year 1705, it did not ſwell to 16 cubits till the 19th of September; the conſequence of which was that the country was depopulated by famine and peſtilence.

We may eaſily imagine that the Nile cannot overflow the whole country of itſelf in ſuch a manner as to render it fertile; for which reaſon there are innumerable canals cut from it acroſs the country, it has already been obſerved, by which the water is conveyed to diſtant places, and almoſt every town or village has one of theſe canals. In theſe parts of the country where the inundation does not reach, and where more water is required than it can furniſh, as for watering of gardens, they muſt have recourſe to artificial means for raiſing it from the river. In former times they made uſe of Archimedes's ſcrew *; but that is now diſuſed, and in place of it they have choſen the Perſian wheel. This is a large wheel turned by oxen, having a rope hung with ſeveral buckets which fill as it goes round, and empty themſelves into a ciſtern at the top. Where the banks of the river are high, they frequently make a baſon in the ſide of them, near which they fix an upright pole, and another with an axle acroſs the top of that, at one end of which they hang a great ſtone, and at the other a leathern bucket; this bucket being drawn down into the river by two men, is raiſed by the deſcent of the ſtone, and emptied into a ciſtern placed at a proper height. This kind of machine is uſed chiefly in the upper parts of the country, where the raiſing of water is more difficult than in places near the ſea. When any of their gardens or plantations want water, it is conveyed from the ciſterns into little trenches, and from thence conducted all round the beds in various rills, which the gardener eaſily ſtops by raiſing the mould againſt them with his foot, and diverts the current another way as he ſees occaſion.

144 Nilometer deſcribed.

The riſe of the inundation is meaſured, as has already been obſerved, by an inſtrument adapted for the purpoſe, and called *mikeas*, which we tranſlate *nilometer*. Mr Bruce informs us, that this is placed between Geeza and Cairo, on the point of an iſland named *Rhoda*, about the middle of the river, but ſomewhat nearer to Geeza. It is a round tower with an apartment, in the middle of which is a ciſtern neatly lined with marble. The bottom of this ciſtern reaches to that of the river, and there is a large opening by which the water has free acceſs to the inſide. The riſe of the water is indicated by an octagonal column of blue and white marble, on which are marked 20 peeks or cubits of 22 inches each. The two lowermoſt of theſe have no ſubdiviſions; but each of the reſt is divided into 24 parts called *digits*; the whole height of the pillar being 36 feet 8 inches.

145 Of the canals by which the water is conveyed &c.

When the river has attained its proper height, all the canals are opened, and the whole country laid under water. During the time of the inundation a certain vortical motion of the waters takes place: but notwithſtanding this, the Nile is ſo eaſily managed, that many fields lower than the ſurface of its waters are preſerved from injury merely by a dam of moiſtened earth not more than eight or ten inches in thickneſs. This method is made uſe of particularly in the Delta when it is threatened with a flood.

As the Nile does not always riſe to a height ſufficient for the purpoſes of agriculture, the former ſovereigns of Egypt were at vaſt pains to cut proper canals in order to ſupply the deficiency. Some of theſe are ſtill preſerved, but great numbers are rendered uſeleſs through the indolence or barbarity of their ſucceſſors. Thoſe which convey the water to Cairo, into the province of Fayoom, and to Alexandria, are beſt taken care of by government. The laſt is watched by an officer appointed for that purpoſe, whoſe office it is to hinder the Arabs of Bachria, who receive this ſuperfluous water, from turning it off before Alexandria be

provided

---

* *Eva-* r.

* See *Hydroſtatics*.

provided for, or opening it before the proper time, which would hinder the increaſe of the river. In like manner, that which conveys the water to Fayoom is watched, and cannot be opened before that of Cairo, which is called the *Canal of Trajan*. A number of other canals, only taken care of by thoſe who derive advantage from them, proceed from that arm of the Nile which runs to Damietta, and fertilize the province of Sharkia; which, making part of the iſthmus of Suez, is the moſt conſiderable of Egypt, and the moſt capable of a great increaſe of cultivation. The plains of Gaza which lie beyond, and are poſſeſſed by the Arabs, would be no leſs fertile, were it not for the exceſſive inclination theſe people have to deſtroy, ſo that they make war even with the ſpontaneous productions of the earth. A number of other canals run through the Delta; and the veſtiges of thoſe which watered the provinces to the eaſtward and weſtward, ſhow that in former times theſe were the beſt cultivated parts of Egypt. "We may alſo preſume (ſays the baron de Tott), from the extent of the ruins of Alexandria, the conſtruction of the canal, and the natural level of the lands which encompaſs the lake Mareotis, and extend themſelves weſtward to the kingdom of Barca, that this country, at preſent given up to the Arabs, and almoſt deſert, was once ſufficiently rich in productions of every kind to furniſh the city of Alexandria with its whole ſubſiſtence."

146
Air and climate of Egypt.

The air and climate of Egypt are extremely hot, not only from the height of the ſun, which in ſummer approaches to the zenith, but from the want of rain and from the vicinity of thoſe burning and ſandy deſerts which lie to the ſouthward. In the months of July and Auguſt, according to M. Volney, Reaumur's thermometer ſtands, even in the moſt temperate apartments, at the height of 24 or 25 degrees above the freezing point; and in the ſouthern parts it is ſaid to riſe ſtill higher. Hence, he ſays, only two ſeaſons ſhould be diſtinguiſhed in Egypt, the cool and the hot, or ſpring and ſummer. The latter continues for the greateſt part of the year, viz. from March to November or even longer; for by the end of February the ſun is intolerable to a European at nine o'clock in the morning. During the whole of this ſeaſon, the air ſeems to be inflamed, the ſky ſparkles, and every one ſweats profuſely, even without the leaſt exerciſe, and when covered with the lighteſt dreſs. This heat is tempered by the inundation of the Nile, the fall of the night dews, and the ſubſequent evaporation; ſo that ſome of the European merchants, as well as the natives, complain of the cold in winter. The dew we ſpeak of does not fall regularly throughout the ſummer, as with us; the parched ſtate of the country not affording a ſufficient quantity of vapour for this purpoſe. It is firſt obſerved about St John's day (June 24th), when the river has begun to ſwell, and conſequently a great quantity of water is raiſed from it by the heat of the ſun, which being ſoon condenſed by the cold of the night air, falls down in copious dews.

It might naturally be imagined, that as for three months in the year Egypt is in a wet and marſhy ſituation, the exceſſive evaporation and putrefaction of the ſtagnating waters would render it very unhealthy. But this is by no means the caſe. The great dryneſs of the air makes it abſorb vapours of all kinds with the utmoſt avidity; and theſe riſing to a great height, are carried off by the winds either to the ſouthward or northward, without having time to communicate any of their pernicious effects. This dryneſs is ſo remarkable in the internal parts of the country, that fleſh meat expoſed to the open air does not putrefy even in ſummer, but ſoon becomes hard and dry like wood. In the deſerts there are frequently dead carcaſes thus dried in ſuch a manner, and become ſo light, that one may eaſily lift that of a camel with one hand. In the maritime parts, however, this dryneſs of the air is not to be expected. They diſcover the ſame degree of moiſture which uſually attends ſuch ſituations. At Roſetta and Alexandria, iron cannot be expoſed to the air for 24 hours without ruſting. According to M. Volney, the air of Egypt is alſo ſtrongly impregnated with ſalts: for which opinion he gives the following reaſon: "The ſtones are corroded by natrum (mineral alkali), and in moiſt places long cryſtallizations of it are to be found, which might be taken for ſaltpetre. The wall of the Jeſuits garden at Cairo, built with earth and bricks, is everywhere covered with a cruſt of this natrum as thick as a crown piece: and when this garden has been overflowed by the waters of the kalidj (canal), the ground, after they have drained off, appears ſparkling on every ſide with cryſtals, which certainly were not brought thither by the water, as it ſhows no ſign of ſalt either to the taſte or by diſtillation."—But whatever may be the quantity of ſalt contained in the earth, it is certain that M. Volney's opinion of its coming thither from the air cannot be juſt. The ſalt in queſtion is exceſſively fixed, and cannot be diſſipated into the air without the violent heat of a glaſshouſe furnace; and even after this has been done, it will not remain diffuſed through the atmoſphere, but quickly falls back again. No experiments have ever ſhown that any ſalt was or could be diffuſed in the air, except volatile alkali, and this is now known to be formed by the union of two permanently elaſtic fluids; and it is certain that a ſaline air would quickly prove fatal to the animals who breathed it. The abundance of this kind of ſalt in Egypt therefore only ſhows, that by ſome unknown operation the heat of the ſun forms it from the two ingredients of earth and water, though we do not yet underſtand the manner, nor are able to imitate this natural operation.

147
Why ex
plants w
not thri
in Egyp

To this ſaline property of the earth M. Volney aſcribes the exceſſive quickneſs of vegetation in Egypt, which is ſo great, that a ſpecies of gourd called *kara* will, in 24 hours, ſend forth ſhoots of four inches in length; but for the ſame reaſon, in all probability, it is that no exotic plant will thrive in Egypt. The merchants are obliged annually to ſend to Malta for their garden ſeeds; for though the plants thrive very well at firſt, yet if the ſeed of them is preſerved, and ſown a ſecond year, they always come up too tall and ſlender.

By reaſon of the great dryneſs of the air, Egypt is exempted from the phenomena of rain, hail, ſnow, thunder, and lightning. Eartquakes are alſo ſeldom heard of in this country; though ſometimes they have been very fatal and deſtructive, particularly one in the year 1112. In the Delta, it never rains in ſummer, 148 ſe of dews in pt.

ſummer, and very ſeldom at any other time. In 1761, however, ſuch a quantity of rain unexpectedly fell, that a great number of houſes, built with mud-walls, tumbled entirely down by being ſoaked with the water, to which they were unaccuſtomed. In the Higher Egypt the rain is ſtill leſs frequent; but the people, ſenſible of the advantages which accrue from it, always rejoice when any falls, however inſufficient to anſwer the purpoſe. This deficiency of rain is ſupplied by the inundation and dews already mentioned. The latter proceed, as has already been ſaid, partly from the waters of the inundation and partly from the ſea. At Alexandria, after ſunſet, in the month of April, the clothes expoſed to the air and the terraces are ſoaked with them as if it had rained. Theſe dews are more or leſs copious according to the direction of the wind. They are produced in the greateſt quantity by the weſterly and northerly winds, which blow from the ſea; but the ſouth and ſouth-eaſt winds, blowing over the deſerts of Africa and Arabia, produce none.

149 nark regu- ty of the ds.

The periodical return of winds from a certain quarter is a very remarkable phenomenon in this country. When the ſun approaches the tropic of Cancer, they ſhift from the eaſt to the north; and, during the month of June, they always blow from the north or north-weſt. They continue northerly all the month of July, varying only ſometimes towards the eaſt, and ſometimes the contrary way. About the end of this month, and during the whole of Auguſt and September, they blow directly from the north, and are but of a moderate ſtrength, though ſomewhat weaker in the night than in the day. Towards the end of September they return to the eaſt, though they do not abſolutely fix on that point, but blow more regularly from it than any other except the north. As the ſun approaches the ſouthern tropic, they become more variable and tempeſtuous, blowing moſt commonly from the north, north-eaſt, and weſt, which they continue to do throughout the months of December, January, and February; and, during that ſeaſon, the vapours raiſed from the Mediterranean condenſe into miſt, or even ſometimes into rain. Towards the end of February, and in the ſucceeding month, they more frequently blow from the ſouth than from any other quarter. During ſome part of the month of March and in that of April, they blow from the ſouth, ſouth-eaſt, and ſouth-weſt; ſometimes from the north and eaſt, the latter becoming moſt prevalent about the end of that month, and continuing during the whole of May.

150 ns in yſſinia in Ar- ia oc- oned by oppo- currents ir.

It is to the long continuance of the north winds, formerly called the *Eteſians winds*, that Egypt probably owes its extreme dryneſs, as well as part of the inundation by which it is fertilized. From the month of April to July, there appear to be two immenſe currents in the atmoſphere, the under one blowing from the north, and the upper from the ſouth. By the former the vapours are raiſed from the Mediterranean and ſouthern parts of Europe, where they are carried over Abyſſinia, diſſolving there in immenſe deluges of rain; while by the latter the ſuperfluous vapours, or thoſe raiſed from the country of Abyſſinia itſelf, are carried northward toward the ſources of the Euphrates. Here the clouds coming from the ſouth, deſcending into the lower part of the atmoſphere, diſſolve in like manner into rain, and produce an inundation of the Euphrates ſimilar to that of the Nile, and immediately ſucceeding it. Mr Bruce had an opportunity of aſcertaining this fact in the month of June 1768; for at that time, while on a voyage from Sidon to Alexandria, he obſerved great numbers of thin white clouds moving rapidly from the ſouth, and in direct oppoſition to the Eteſian winds.

151 Of the hot winds.

Beſides the ordinary winds here ſpoken of, Egypt is infeſted with the deſtructive blaſts common to all warm countries which have deſerts in their neighbourhood. Theſe have been diſtinguiſhed by various names, ſuch as *poiſonous winds*, *hot winds of the deſert*, *Samiel*, *the wind of Damaſcus*, *Kamſin*, and *Simoom*. In Egypt they are denominated "winds of 50 days," becauſe they moſt commonly prevail during the 50 days preceding and following the equinox; though, ſhould they blow conſtantly during one half of that time, an univerſal deſtruction would be the conſequence. Of theſe travellers have given various deſcriptions. M. Volney ſays, that the violence of their heat may be compared to that of a large oven at the moment of drawing out the bread. They always blow from the ſouth; and are undoubtedly owing to the motion of the atmoſphere over ſuch vaſt tracts of hot ſand, where it cannot be ſupplied by a ſufficient quantity of moiſture. When they begin to blow, the ſky loſes its uſual ſerenity, and aſſumes a dark, heavy, and alarming aſpect, the ſun himſelf laying aſide his uſual ſplendor, and becoming of a violet colour. This terrific appearance ſeems not to be occaſioned by any real haze or cloud in the atmoſphere at that time, but ſolely to the vaſt quantity of fine ſand carried along by thoſe winds, and which is ſo exceſſively ſubtile that it penetrates every where. The motion of this wind is always rapid, but its heat is not intolerable till after it has continued for ſome time. Its pernicious qualities are evidently occaſioned by its exceſſive avidity of moiſture. Thus it dries and ſhrivels up the ſkin; and by doing the ſame to the lungs, will in a ſhort time produce ſuffocation and death. The danger is greateſt to thoſe of a plethoric habit of body, or who have been exhauſted by fatigue; and putrefaction ſoon takes place in the bodies of ſuch as are deſtroyed by it. Its extreme dryneſs is ſuch, that water ſprinkled on the floor evaporates in a few minutes; all the plants are withered and ſtripped of their leaves; and a fever is inſtantly produced in the human ſpecies by the ſuppreſſion of perſpiration. It uſually laſts three days, but is altogether inſupportable if it continue beyond that time. The danger is greateſt when the wind blows in ſqualls, and to travellers who happen to be expoſed to its fury without any ſhelter. The beſt method in this caſe is to ſtop the noſe and mouth with an handkerchief. Camels, by a natural inſtinct, bury their noſes in the ſand, and keep them there till the ſquall is over. The inhabitants, who have an opportunity of retiring to their houſes, inſtantly ſhut themſelves up in them, or go into pits made in the earth, till the deſtructive blaſt be over.

The deſcription of a blaſt of this kind which overtook Mr Bruce in the deſert of Nubia is ſtill more terrible than that juſt given from M. Volney. We have already mentioned ſomething of the pillars of moving ſand raiſed by the winds in the deſert. Theſe were obſerved by our traveller on this occaſion in all their terrific majeſty. Sometimes they appeared to move ſlowly; at other times with incredible ſwiftneſs, ſo that they could not have been avoided by the fleeteſt horſe. Sometimes they came ſo near, that they threatened deſtruction to the whole company Frequently the tops, when arrived at an immenſe height, ſo that they were loſt in the clouds, ſuddenly ſeparated from the bodies, and diſperſed themſelves in the air; and ſometimes the whole column broke off near the middle, as if it had received a cannon ſhot; and their ſize was ſuch, that, at the diſtance of about three miles, they appeared ten feet in diameter. Next day they appeared of a ſmaller ſize, but more numerous, and ſometimes approached within two miles of the company. The ſun was now obſcured by them, and the tranſmiſſion of his rays gave them a dreadful appearance, reſembling pillars of fire. This was pronounced by the guide to be a ſign of the approaching *Simoom* or hot wind; and he directed, that, when it came, the people ſhould fall upon their faces and keep their mouths on the ſand, to avoid the drawing in this pernicious blaſt with their breath. On his calling out that the Simoom was coming, Mr Bruce turned for a moment to the quarter from whence it came, which was the ſouth-eaſt. It appeared like a haze or fog of a purple colour, but leſs bright than the purple part of the rainbow; ſeemingly about 20 yards in breadth, and about 12 feet high from the ground. It moved with ſuch rapidity, that before he could turn about and fall upon his face, he felt the vehement heat of its current upon his face; and even after it paſſed over, which was very quickly, the air which followed was of ſuch an heat as to threaten ſuffocation. Mr Bruce had unfortunately inſpired ſome part of the pernicious blaſt; by which means he almoſt entirely loſt his voice, and became ſubject to an aſthmatic complaint, from which he did not get free for two years. The ſame phenomenon occurred twice more on their journey thro' this deſert. The ſecond time, it came from the ſouth a little to the eaſt: but it now ſeemed to have a ſhade of blue along with the purple, and its edges were leſs perfectly defined; reſembling rather a thin ſmoke, and having about a yard in the middle tinged with blue and purple. The third time, it was preceded by an appearance of ſandy pillars more magnificent than any they had yet obſerved; the ſun ſhining through them in ſuch a manner as to give thoſe which were neareſt a reſemblance of being ſpangled with ſtars of gold. The ſimoom which followed had the ſame blue and purple appearance as before, and was followed by a moſt ſuffocating wind for two hours, which reduced our travellers to the loweſt degree of weakneſs and deſpondency. It was remarkable that this wind always came from the ſouth-eaſt, while the ſandy pillars, which prognoſticated its approach, affected to keep to the weſtward, and to occupy the vaſt circular ſpace incloſed by the Nile to the weſt of their route, going round by Chaigie towards Dongola. The heaps of ſand left by them when they fell, or raiſed by the whirlwinds which carried them up, were 12 or 13 feet high, exactly conical, tapering to a fine point, and their baſes well proportioned.

152
Of the inhabitants of Egypt.

The inhabitants of Egypt may now be diſtinguiſhed into four diſtinct races of people.

I. The *Arabs*, who may be ſubdivided into three claſſes. 1. The poſterity of thoſe who ſettled here immediately after the conqueſt of the country by Amrou Ebn Al As the khalif Omar's general. 2. The *Magrebians*, or Weſtern Arabs, who at different times have migrated from the countries to the weſtward of Egypt, and are deſcended from the Saracen conquerors of Mauritania. 3. The *Bedouins*, or Arabs of the deſert, known to the ancients by the name of *Scenites*, or dwellers in tents. The firſt of theſe claſſes are now found among the huſbandmen and artizans; and are diſtinguiſhed from the others by being of a more robuſt habit of body, as well as of a larger ſtature than the others. They are in general five feet four inches high; and many of them attain two or three inches more, and are muſcular without being fleſhy. Their countenances are almoſt black, but their features are not diſagreeable; and as thoſe of the country do not ally themſelves in marriage but with the people of their own tribe, their faces have all a ſtrong reſemblance to each other. This is not the caſe with ſuch as live in towns, by reaſon of their promiſcuous marriages. The ſecond claſs are more numerous in the Said, where they have villages and even diſtinct ſovereigns of their own. Like the former, they apply themſelves to agriculture and mechanical occupations. The Bedouins paſs their lives among the rocks, ruins, and ſequeſtrated places where they can find water; ſometimes uniting in tribes and living in low ſmoky tents, and ſhifting their habitations from the deſert to the banks of the river and back again, as beſt ſuits their conveniency. Their time of inhabiting the deſert is the ſpring; but after the inundation they take up their reſidence in Egypt, in order to profit by the fertility of the country. Some farm lands in the country which they cultivate, but change annually. In general, all theſe Bedouins are robbers, and are a great terror to travellers as well as to the huſbandmen; but though their number is eſtimated at not leſs than 30,000, they are diſperſed in ſuch a manner that they cannot attempt any thing of conſequence.

II. The *Copts* are deſcendants of thoſe inhabitants of Egypt whom the Arabs ſubdued, and who were compoſed of original Egyptians, Perſians, and Greeks. M. Volney is of opinion that their name of Copts is only an abbreviation of the Greek word *Aigouptios*, an Egyptian. They are principally to be met with in the Said, though ſome alſo inhabit the Delta. They have all a yellowiſh duſky complexion, puffed up viſage, ſwoln eyes, flat noſes, and thick lips; and in fact the exact countenance of a mulatto. M. Volney, from a view of the ſphynx, and finding its features to be ſuch as is juſt now deſcribed, concludes, that the ancient Egyptians were real negroes; which he thinks is likewiſe confirmed by a paſſage in Herodotus, where he concludes, that the inhabitants of Colchis were deſcended from the Egyptians, "on account of the blackneſs of their ſkins and frizzled hair." M. Volney alſo remarks, that the countenance of the negroes is ſuch as exactly repreſents that ſtate of contraction aſſumed by our faces when ſtrongly affected by heat. The eye-brows are knit, the cheeks riſe, the eye-lids are contracted, and the mouth diſtorted; and this ſtate of contraction to which the features of the negroes are perpetually expoſed in the hot climates they inhabit, is become particularly characteriſtic. Exceſſive cold and ſnow produces the ſame effect; and hence this

this kind of countenance is alſo common among the Tartars; while, in the temperate climates, the features are proportionably lengthened, and the whole countenance expanded.

The Copts profeſs the Chriſtian religion, but follow the hereſy of the Eutychians, whence they have been perſecuted by the Greeks; but having at laſt got the better of their adverſaries, they are become the depoſitaries of the regiſters of the lands and tribes. At Cairo they are called *writers;* and are the intendants, ſecretaries, and collectors for government. The head of their claſs is writer to the principal chief; but they are all hated by the Turks to whom they are ſlaves, as well as by the peaſants whom they oppreſs. Their language bears a great reſemblance to the Greek; but they have five letters in their alphabet, as well as a number of words in their language, which may be conſidered as the remains of the ancient Egyptian. Theſe are found to bear a near reſemblance to the dialects of ſome of the neighbouring nations, as the Arabic, Ethiopian, Syriac, &c. and even of thoſe who lived on the banks of the Euphrates. The language of the Copts, however, has fallen into diſuſe for upwards of 300 years. On the conqueſt of the country by the Saracens, the latter obliged the people to learn their language; and about the year 722 the uſe of the Greek tongue was prohibited throughout the whole of their empire: the Arabic language then of courſe became univerſal; while the others, being only met with in books, ſoon became totally neglected. The true Coptic, therefore, though there is a tranſlation of the ſcriptures and many books of devotion written in it, is underſtood by nobody, not even the monks and prieſts.

III. The *Turks*, who have the title of being maſters of Egypt, but are chiefly to be met with at Cairo, where they poſſeſs the religious and military employments. Formerly they poſſeſſed alſo the poſts under government; but theſe are now occupied by the fourth race of inhabitants, viz.

IV. The *Mamlouks*. Of the origin of theſe we have already given ſome account: we have only, therefore, to relate ſome of the moſt remarkable particulars concerning their conſtitution and government, manners, &c.

Theſe people, as has already been mentioned, are the real maſters of Egypt; and in order to ſecure themſelves in the poſſeſſion of the country, they have taken ſeveral precautions. One of the principal of theſe is the degradation of the two military corps of azabs and janizaries, both of which were formerly very formidable. They have been able to effect this only in conſequence of the corrupt and wretched government of the Turks; for before the revolt of Ibrahim Kiaya, the Turkiſh troops, which ought to have conſiſted of 40,000, were reduced to leſs than half that number through the avarice and malverſation of their officers. Their degradation was completed by Ali Bey; who having firſt diſplaced all the officers who gave him any umbrage, left their places vacant, and ſo reduced the conſequence of the whole, that the azabs and janizaries are now only a rabble of vagabonds, who dread the Mamlouks as much as the meaneſt of the populace. The principal body of the Mamlouks reſide at Cairo; but many of them are diſperſed through the country, in order to keep up their authority, collect the tribute, and oppreſs the people: yet it ſhould ſeem very eaſy for the Porte to diſpoſſeſs them of this uſurped authority, as their number is ſuppoſed not to exceed 8500, including among theſe a great many youth under 20 years of age.

153
Abſurd dreſs and accoutrements of the Mamlouks.

The Mamlouks are all horſemen; and as war is accounted the only honourable employment among them, it is reckoned diſgraceful to walk on foot, none but cavalry being accounted ſoldiers. The other inhabitants are allowed only the uſe of mules and aſſes; and the ſame mark of indignity is impoſed upon Europeans; though, by proper management and liberal preſents, this may be got over. In the year 1776 lord Algernoun Percy afterwards lord Louvaine, and the earl of Charlemont, obtained permiſſion to ride upon horſeback. The Mamlouks, however, are not incited to this continual appearance on horſeback merely by their ſuppoſed ſuperiority to the reſt of the inhabitants; it is rendered neceſſary by their dreſs, which is extremely unwieldy and cumberſome. It conſiſts of a wide ſhirt of thin yellowiſh-coloured cotton; over which is a gown of Indian linen, or ſome of the light ſtuffs of Damaſcus or Aleppo. Over this is a ſecond covering of the ſame form and wideneſs, with ſleeves reaching down to the ends of the fingers. The former covering is called *antari*, and the latter *caftan*. The caftan is uſually made of ſilk or ſome finer ſtuff than the under garments; and both of them are faſtened by a long belt, which divides the whole dreſs into two bundles. Over all theſe they have a third, named *djouba*, conſiſting of cloth without lining, and made nearly ſimilar to the others, but that the ſleeves are cut in the elbow. This coat is lined, ſometimes even in ſummer, with fur; and as if all this was not ſufficient, they have an outer covering called the *beniche*, which is the cloak or robe of ceremony; and ſo completely covers the body, that even the ends of the fingers are not to be ſeen. Thus, when the beniche and other accoutrements are on, the whole body appears like a long ſack, with a bare neck and bald head covered with a turban thruſt out of it. This turban is called a *kaouk;* and is of a cylindrical form, yellow, and turned up on the outſide with a roll of muſlin artificially folded up. On their feet they have a ſock of yellow leather reaching up to the heels, ſlippers without any quarters, which conſequently are always ready to be left behind in walking. Laſtly, to complete this extraordinary dreſs, they have a kind of pantaloon or trowſers, long enough to reach up to the chin, and ſo large that each of the legs is big enough to contain the whole body; but that they may walk more at their eaſe under ſuch a number of impediments, they tie all the looſe parts of their dreſs with a running ſaſh. "Thus ſwaddled (ſays M. Volney), we may imagine the Mamlouks are not very active walkers; and thoſe who are not acquainted by experience with the prejudices of different countries, will find it ſcarcely poſſible to believe that they look on this dreſs as exceedingly commodious. In vain we may object that it hinders them from walking, and encumbers them unneceſſarily on horſeback; and that in battle a horſeman once diſmounted is a loſt man. They reply, *It is the cuſtom*, and every objection is anſwered."

In the accoutrements of their horſes, the Mamlouks are almoſt equally abſurd. The ſaddle is a clumſy piece of furniture, weighing with the ſaddle-cloths not leſs than 25 pounds; while the weight of the ſtirrups is never leſs than 9 or 10 pounds, nay, frequently exceeds 13. On the back-part of the ſaddle riſes a truſſequin about eight inches in height. while a pummel before projects four or five inches. in ſuch a manner as to endanger the breaſt of the horſeman if he ſhould happen to ſtoop. Inſtead of a ſtuffed frame, they have three thick woollen coverings below the ſaddle; the whole being faſtened by a ſurcingle, which, inſtead of a buckle, is tied with leather thongs in very complicated knots, and liable to ſlip. Inſtead of a crupper they have a large martingale which throws them upon the horſes ſhoulders. The ſtirrups are made of copper, longer and wider than the foot, having circular edges an inch high in the middle, and gradually declining toward each end. The edges are ſharp, and uſed inſtead of ſpurs, by which means the poor animal's ſides are much wounded. The weight of the furniture has already been mentioned; and is the more ridiculous as the Egyptian horſes are very ſmall. The bridle is equally ill contrived, and greatly injures the horſe's mouth, eſpecially by reaſon of the violent method they have of managing the animal. Their uſual way is to put the horſe to a full gallop, and ſuddenly ſtop him when at full ſpeed. Thus checked by the bit, he bends in his hind legs, ſtiffens the fore ones, and moves along as if he ſcarce had joints in his body: yet, notwithſtanding all thoſe diſadvantages, our author acknowledges that they are vigorous horſemen, having a martial appearance which pleaſes even ſtrangers.

154
Their arms, education, &c.

In the choice of their arms they have ſhown themſelves more judicious. Their principal weapon is an Engliſh carbine about 30 inches long; but ſo large in the bore, that it can diſcharge 10 or 12 balls at a time, which can ſcarce fail of doing great execution even from the moſt unſkilful hand. Beſides two large piſtols carried in the belt, they have ſometimes a heavy mace at the bow of the ſaddle for knocking down their enemy; and by the ſhoulder-belt they ſuſpend a crooked ſabre meaſuring 24 inches in a ſtraight line from the hilt to the point, but 30 at leaſt in the curve. The reaſon of the preference given to the crooked blade is, that the effect of a ſtraight one depends merely on the force with which it falls, and is confined to a ſmall ſpace, but that of a crooked one is continued longer by the action of the arm in retiring. The Mamlouks commonly procure their ſabres from Conſtantinople, or other parts of Europe; but the beys rival each other in thoſe of Perſia and ſuch as are fabricated of the ancient ſteel of Damaſcus. For theſe they frequently pay as high as 40l. or 50l. ſterling; but though it muſt be allowed that the edge of theſe weapons is exquiſitely keen, yet they have the defect of being almoſt as brittle as glaſs. The whole education and employment of the Mamlouks conſiſts in the exerciſe of theſe weapons, or what is conducive to it; ſo that we ſhould imagine they might at laſt become altogether irreſiſtible. Every morning the greater part of them exerciſe themſelves in a plain near Cairo, by firing their carbines and piſtols in the moſt expeditious manner, having an earthen veſſel for a mark to ſhoot at; and the perſon who breaks it is highly applauded by the beys who attend in order to encourage them. Here alſo they exerciſe themſelves in the uſe of the ſabre, as well as of the bow and arrows; though they do not any longer make uſe of theſe laſt in their engagements. Their favourite diverſion is throwing the *djerid*; a word properly ſignifying a reed, but which is generally made uſe of to ſignify any ſtaff thrown by the hand after the manner of the Roman pilum. In this exerciſe they make uſe of the branches of the palm-tree freſh ſtripped. Theſe branches, which have the form of the ſtalk of an artichoke, are about four feet long, and weigh five or ſix pounds. With theſe the cavaliers enter the liſts, riding full ſpeed, and throwing them afterwards at each other from a conſiderable diſtance. As ſoon as the aſſailant has thrown his weapon, he turns his horſe, and his antagoniſt purſues in his turn. The diverſion, however, frequently turns out very ſerious, as ſome are capable of throwing theſe weapons with force ſufficient to wound their antagoniſts mortally. Ali Bey was particularly dexterous at this kind of ſport, and frequently killed thoſe who oppoſed him. All theſe military exerciſes, however, are by no means ſufficient to render the Mamlouks formidable in the field. In their engagements they have neither order, diſcipline, nor even ſubordination; ſo that their wars are only ſcenes of robbery, plunder, and tumultuary encounters, which begin very often ſuddenly in the ſtreets of Cairo without the leaſt warning. If the contention happens to be transferred to the country, it is ſtill carried on in the ſame manner. The ſtrongeſt or moſt daring party purſues the other. If they are equal in courage, they will perhaps appoint a field of battle, and that without the leaſt regard to advantages of ſituation, but fighting in platoons, with the boldeſt champions at the head of each. After mutual defiances the attack begins, and every one chooſes out his man. After diſcharging their fire-arms, if they have an opportunity they attack with their ſabres; and ſuch as happen to be diſmounted are helped up again by their ſervants; but if nobody happens to be near, the ſervants will frequently kill them for the ſake of the money they carry about them. Of late, however, the ordinary Mamlouks, who are all ſlaves to the reſt, ſeem convinced that their patrons are the perſons principally intereſted; for which reaſon they reaſonably enough conclude that they ought to encounter the greateſt dangers. Hence they generally leave them to carry on the diſpute by themſelves; and being always ſure of finding a maſter who will employ them, they generally return quietly to Cairo until ſome new revolution takes place.

155
Are not formidable in war.

156
Their expenſive way of living.

The mode of living among the Mamlouks is exceedingly expenſive, as may eaſily be conceived from what has already been related. There is not one of them who does not coſt above 100l. Sterling annually, and many of them upwards of 200l. At every return of the faſt of Ramadan, their maſters muſt give them a new ſuit of French and Venetian cloths, with ſtuffs from India and Damaſcus. Frequently they require new horſes and harneſs: they muſt likewiſe have piſtols and ſabres from Damaſcus, with gilt ſtirrups, and ſaddles and bridles plated with ſilver. The chiefs are diſtinguiſhed from the vulgar by the trinkets and precious ſtones they wear; by riding Arabian horſes of 200l. or 300l. value, wearing ſhawls of Caſhmire in value from 25l. to 50l. each, with a variety of peliſſes, the cheapeſt of which coſts above 20l. Even the European merchants have given into this kind of extravagance;

vagance ; ſo that not one of them looks upon his wardrobe to be decently furniſhed unleſs it be in value 500 l. or 600 l.

157 ir bad acter.

Anciently it was cuſtomary for the women to adorn their heads with ſequins ; but this is now rejected as not ſufficiently expenſive. Inſtead of theſe, diamonds, emeralds, and rubies, are now ſubſtituted ; and to theſe they add French ſtuffs and laces. In other reſpects the character of the Mamlouks is almoſt the worſt that can be imagined Without affection, tie, or connection with each other or with the reſt of mankind, they give themſelves up without control to the moſt enormous vices ; and, according to M Volney, they are at once ferocious, perfidious, ſeditious, baſe, deceitful, and corrupted by every ſpecies of debauchery, not excepting even the unnatural vice ; of which he tells us not one is free, this being the very firſt leſſon each of them receives from his maſter, all being originally ſlaves, as has already been mentioned.

158 erable of the ptians.

As theſe are the preſent governors of Egypt, we may eaſily judge that the condition of the common people cannot be very agreeable. The greater part of the lands indeed are in the hands of the Mamlouks, beys, and profeſſors of the law, the property of all others being very precarious. Contributions are to be paid, or damages repaired, every moment ; and there is neither right of ſucceſſion nor inheritance for real property, but every thing muſt be purchaſed from government. The peaſants are allowed nothing but what is barely ſufficient to ſuſtain life. They cultivate rice and corn indeed, but are not at liberty to uſe either. The only food allowed them is dora or Indian millet, from which they make a kind of taſteleſs bread ; and of this, with water and raw onions, conſiſts all their fare throughout the year. They eſteem themſelves happy, therefore, if along with theſe they can ſometimes procure a little honey, cheeſe, ſour milk, or a few dates. They are very fond of fleſh meat and fat ; neither of which, however, they have an opportunity of taſting except at extraordinary feſtivals. Their ordinary dreſs conſiſts of a ſhirt of coarſe blue linen, and a clumſy black cloak ; with a ſort of black bonnet over their heads ; and over all they wear a long red woollen handkerchief. Their arms, legs, and breaſts, are naked, and moſt of them do not even wear drawers. They live in mud-walled huts of the moſt miſerable conſtruction, where they are expoſed to the inconveniences of ſmoke, heat, and unwholeſome air ; to all which are to be added the continual fears they live in of being robbed by the Arabs, oppreſſed by the Mamlouks, or ſome other grievous calamity. The only converſation is concerning the inteſtine troubles and miſery of the country, murders, baſtinadoes, and executions. Here ſentence of death is executed without the leaſt delay or form of trial. The officers who go the rounds in the ſtreets either by night or day, are attended by executioners, who carry along with them leathern bags for receiving the heads they cut off in theſe expeditions. Even the appearance of guilt is not neceſſary to infer a capital puniſhment ; for frequently nothing more is requiſite than the poſſeſſion of wealth, or being ſuppoſed to poſſeſs it. In this caſe the unfortunate perſon is ſummoned before ſome bey ; and when he makes his appearance, a ſum of money is demanded of him. If he denies that he poſſeſſes it, he is thrown on his back, and receives two or three hundred blows on the ſoles of his feet, nay perhaps is put to death without any ceremony. The only ſecurity of thoſe who poſſeſs any wealth in this country therefore is, to preſerve as great an appearance of poverty as poſſible.

159 Diſeaſes prevalent in this country.

Though the climate of Egypt is far from being unhealthy ; yet there are not a few diſeaſes which ſeem to be peculiar to it, and to have their origin either from the conſtitution of the atmoſphere, or the manner of living of the inhabitants. One of theſe till lately has been ſuppoſed to be the plague ; which opinion we find ſupported by Dr Mead, who has endeavoured to aſſign a natural reaſon why it ſhould take its origin in this country. But it is now univerſally agreed, that the plague never originates in the interior parts of Egypt, but always begins at Alexandria, paſſing ſucceſſively from thence to Roſetta, Cairo, Damietta, and the reſt of the Delta. It is likewiſe obſerved, that its appearance is always preceded by the arrival of ſome veſſel from Smyrna or Conſtantinople ; and that, if the plague has been very violent in either of theſe cities, the danger to Egypt is the greater. On proper inquiry, it is found to be really a native of Conſtantinople ; from whence it is exported by the abſurd negligence of the Turks, who refuſe to take any care to prevent the ſpreading of the infection. As they ſell even the clothes of the dead without the leaſt ceremony, and ſhips laden with this pernicious commodity are ſent to Alexandria, it is no wonder that it ſhould ſoon make its appearance there. As ſoon as it has reached Cairo, the European merchants ſhut themſelves up with their families in their *khans* or lodgings, taking care to have no further communication with the city. Their proviſions are now depoſited at the gate of the khan, and are taken up by the porter with iron tongs ; who plunges them into a barrel of water provided for the purpoſe. If they have occaſion to ſpeak to any perſon, they take care to keep at ſuch a diſtance as to avoid touching or even breathing upon each other. By theſe precautions they certainly eſcape the general calamity, except by accident ; and it not long ago happened that the diſeaſe was conveyed by a cat into the dwellings of the French merchants in Cairo ; by which two were infected, and one died. In this manner they are impriſoned for three or four months, without any other amuſement than walking on their terraces in the evenings, cards, or converſation with one another. There is a remarkable difference betwixt the plague at Conſtantinople and in Egypt. In the former, it is moſt violent in ſummer ; and in the latter in winter, ending there always in the month of June. It is alſo remarkable, that the water-carriers of Egypt, whoſe backs are conſtantly wet from the nature of their occupation, never have the plague. It appears in Egypt every fourth or fifth year, when it makes ſuch ravages as would depopulate the country, were it not for the vaſt concourſe of ſtrangers which arrive here every year from all parts of the Turkiſh empire.

A malady which ſeems in reality to be peculiar to Egypt is blindneſs. This is ſo common at Cairo, as M. Volney informs us, that out of 100 people whom he has met on the ſtreet, he might reckon 20 quite blind ; 10 without the ſight of one eye ; and 20 others with their eyes red, purulent, or blemiſhed. Almoſt every one, ſays he, wears a fillet, a token of an approaching or convaleſcent ophthalmy. In conſidering the cauſes of this diſorder, he reckons the ſleeping upon terraces to be a principal one. The ſouth wind, he ſays, cannot be the cauſe; otherwiſe the Bedouins would be equally ſubject to it with the Egyptians themſelves: but what is with the greateſt probability to be aſſigned as the cauſe, according to our author, is the very poor and little nutritive food which the natives are obliged to uſe. "The cheeſe, ſour-milk, honey, confection of grapes, green fruits, and raw vegetables (ſays he), which are the ordinary food of the people, produce in the ſtomach a diſorder which phyſicians have obſerved to affect the ſight; the raw onions, eſpecially, which they devour in great quantities, have a peculiar heating quality, as the monks of Syria made me remark on myſelf. Bodies thus nouriſhed, abound in corrupted humours, which are conſtantly endeavouring a diſcharge. Diverted from the ordinary channels, by habitual perſpiration, theſe humours fly to the exterior parts, and fix themſelves where they find the leaſt reſiſtance. They therefore naturally attack the head, becauſe the Egyptians, by ſhaving it once a-week, and covering it with a prodigiouſly hot head-dreſs, principally attract to it the perſpiration; and if the head receives ever ſo ſlight an impreſſion of cold on being uncovered, this perſpiration is ſuppreſſed, and falls upon the teeth, or ſtill more readily on the eyes as being the tendereſt part. It will appear the more probable that the exceſſive perſpiration of the head is a principal cauſe, when we reflect that the ancient Egyptians, who went bare-headed, are not mentioned by phyſicians as being ſo much afflicted with ophthalmies; though we are informed by hiſtorians that ſome of the Pharaohs died blind. The Arabs of the deſert alſo, who cover the head but little, eſpecially when young, are alſo very little ſubject to them." In this country blindneſs is often the conſequence of the ſmall-pox, a diſorder very frequent and very fatal among the Egyptians; and no doubt the more dangerous on account of their abſurd method of treating it, of which it is needleſs to enter into any diſcuſſion in this place. They are not unacquainted with inoculation; but ſeem not to be ſenſible of its advantages, as they very ſeldom practiſe it.

To the ſame cauſe, *viz.* unwholeſome food, M. Volney aſcribes the general deformity of the beggars, and the miſerable appearance of the children; which he ſays are no where ſo wretched. "Their hollow eyes, pale and puffed faces, ſwollen bellies, meagre extremities, and yellow ſkins, make them always ſeem as if they had not long to live. Their ignorant mothers pretend that this is the effect of the *evil eye* of ſome envious perſon, who has bewitched them; and this ancient prejudice is ſtill general in Turkey: but the real cauſe is the badneſs of their food. In ſpite of the taliſmans, therefore, an incredible number of them periſh; nor is any city more fatal to the population of the neighbouring country than Grand Cairo."

The venereal diſeaſe, which, for reaſons beſt known to themſelves, the inhabitants call the *bleſſed evil*, is ſo general at Cairo, that one half of the inhabitants are infected. It is extremely difficult to cure, though the ſymptoms are comparatively very mild, inſomuch that people who are infected with it will frequently live to the age of 80; but it is fatal to children born with the infection, and exceedingly dangerous to ſuch as emigrate to a colder climate.

Beſides theſe, there are two uncommon diſeaſes met with in Egypt, *viz.* a cutaneous eruption which returns annually; and a ſwelling of the teſticles, which often degenerates into an enormous hydrocele. The former comes on towards the end of June or beginning of July, making its appearance in red ſpots and pimples all over the body, occaſioning a very troubleſome itching. The cauſe of this diſtemper, in M. Volney's opinion, is the corruption of the waters of the Nile, which towards the end of April become very putrid, as has already been obſerved. After this has been drunk for ſome time, the waters of the inundation, which are freſh and wholeſome, tend to introduce ſome change in the blood and humours; whence a cutaneous eruption is the natural conſequence.

The hydrocele moſt commonly attacks the Greeks and Copts; and is attributed to the quantity of oil they make uſe of, as well as to their frequent hot-bathing. Our author remarks, that "in Syria as well as in Egypt, conſtant experience has ſhown, that brandy diſtilled from common figs, or from the fruit of the ſycamore tree, as well as from dates and the fruit of the nopal, has a moſt immediate effect on the teſticles, which it renders hard and painful the third or fourth day after it has been drunk; and if the uſe of it be not diſcontinued, the diſorder degenerates into a confirmed hydrocele. Brandy diſtilled from dried raiſins has not the ſame effect: this is always mixed with aniſeeds; and is very ſtrong, being diſtilled three times. The Chriſtians of Syria and the Copts of Egypt make great uſe of it; the latter eſpecially drink whole bottles of it at their ſupper. I imagined this an exaggeration; but I have myſelf had ocular proofs of its truth, though nothing could equal my aſtoniſhment that ſuch exceſſes do not produce inſtant death, or at leaſt every ſymptom of the moſt inſenſible drunkenneſs."

In the ſpring ſeaſon malignant fevers prevail in this country; concerning which our author mentions no remarkable particular, but that eggs are a kind of poiſon, and that bleeding is very prejudicial. He recommends a vegetable diet, and the bark in very large quantity.

160
Commer
of Cairo
conſiderable.

Notwithſtanding the oppreſſion which the Egyptians labour under, a very conſiderable trade is carried on from Cairo. This flouriſhing ſtate of commerce in the midſt of the moſt deſperate barbarity and deſpotiſm is owing to three cauſes. 1. That all the commodities conſumed in Egypt are collected within the walls of that city. 2. That the Mamlouks and all the people of property reſide in that place, and there ſpend their whole revenues. 3. By the ſituation of this city it is a centre of circulation; correſponding with Arabia and India, by the Red Sea; with Abyſſinia and the interior parts of Africa, by the Nile; and with Europe and the Turkiſh empire, by means of the Mediterranean. A caravan comes here annually from Abyſſinia, bringing from 1000 to 1200 ſlaves, with gum, ivory, gold-duſt, oſtrich-feathers, parrots, and monkeys.—Another, which ſets out from the extreme parts of Morocco, takes in pilgrims for Mecca from all that country as far ſouth as the mouth of the river Senegal. It conſiſts of not fewer than three or four thouſand camels;

mels; and, paſſing along the coaſts of the Mediterranean, collects likewiſe the pilgrims from Algiers, Tripoli, and Tunis, arriving at laſt at Alexandria by the way of the deſert. Proceeding thence to Cairo, it joins the Egyptian caravan; and then ſetting out both together, they take their journey to Mecca, from whence they return in one hundred days; but the Morocco pilgrims, who have ſtill 600 leagues to go, are upwards of a year in returning. The commodities they bring along with them are, India ſtuffs, ſhawls, gums, perfumes, pearls, and principally coffee. Beſides the profits of this merchandize, conſiderable ſums ariſe from the duties paid by pilgrims, and the ſums expended by them.

The caravans above mentioned are not the only means by which theſe commodities are brought to Cairo. They arrive alſo at Suez, to which port the ſoutherly winds bring in the month of May ſix or eight and twenty ſail of veſſels from Jedda. Small caravans likewiſe arrive from time to time from Damaſcus with ſilk and cotton ſtuffs, oils, and dried fruits. During the proper ſeaſon there are alſo a number of veſſels in the road of Damietta, unloading hogſheads of tobacco from Latakia, vaſt quantities of which are conſumed in this country. For this commodity rice is taken in exchange; while other veſſels bring clothing, arms, furs, paſſengers, and wrought ſilk from Conſtantinople. There are other veſſels which come from Marſeilles, Leghorn, and Venice, with cloths, cochineal, Lyons ſtuffs and laces, grocery ware, paper, iron, lead, Venetian ſequins, and German dahlers. Theſe are conveyed to Roſetta in barks called by M. Volney *djerm*, but which ſeem to be the ſame mentioned by Mr Bruce under the name of *canja*, and which are particularly deſcribed by him. He informs us, that there is a peculiarity in the form of this veſſel which makes it uſeful for navigating the river Nile; and that is, that the keel is not ſtraight, but a portion of a parabola, whoſe curve is almoſt inſenſible to the eye. Hence, as ſand-banks are very common in the Nile, and veſſels are apt to ſtrike them when the water becomes low, the middle of the canja will be aground while the extremities are afloat, and thus by means of oars and other aſſiſtance, it is always poſſible to get clear; but were the keel ſtraight, this would be altogether impoſſible, by reaſon of the vaſt ſails thoſe veſſels carry, which would urge them on with too much force to be recovered. The accommodation on board thoſe veſſels is much better than what could be expected: but they are liable to the depredations of robbers, who either ſwim under water in the day time, or upon goats ſkins during the night; though theſe ſeldom attack any boats where there are Europeans, whom they dread on account of their ſkill in fire-arms.

51 ls na- the de- l.

From ſo many ſources we need not wonder that the commerce of Cairo ſhould be in a very flouriſhing ſtate. In 1783, according to the report of the commiſſioner-general of the cuſtoms, it amounted to no leſs than 6,250,000 l. but notwithſtanding this ſhow of wealth, the trade carried on at Cairo contributes very little to the enriching of the people. This will readily appear, when we conſider, that great part of the coffee and other merchandiſe brought from India is exported to foreign countries, the value being paid in goods from Turkey and other European countries; while the country conſumption conſiſts entirely, or moſtly, in articles of luxury already finiſhed, and the produce given in return is moſtly in raw materials.

162
Of cutting through the Iſthmus of Suez.

Schemes have frequently been projected of enlarging the commerce of Egypt by cutting through the Iſthmus of Suez, and thus joining the Mediterranean and Red Seas by a canal. This is looked upon by M. Volney as impracticable. He owns, indeed, that no objection can ariſe from the diſtance, which is not more than 18 or 19 leagues; neither does any obſtacle ariſe from mountains, or the inequality of levels, the whole being a ſandy barren plain. The difficulty, which he conſiders as inſuperable, proceeds from the nature of the correſponding coaſts of the Mediterranean and Red Seas; both of which are low and ſandy, where the water forms lakes, ſhoals, and moraſſes, ſo that ſhips cannot come within a conſiderable diſtance of either; and it would be ſcarce poſſible to cut a permanent canal amidſt theſe ſhifting ſands: not to mention, that the ſhore is deſtitute of harbours, which muſt be entirely the work of art. The country, beſides, has not a drop of freſh water; which it would therefore be neceſſary to bring as far as from the Nile. The beſt method of effecting this junction therefore is by means of the river itſelf; and for this the ground is perfectly well calculated. This has been already done by ſeveral Egyptian princes, particularly Seſoſtris; and the canal is ſaid to have been 170 feet wide, and deep enough for large veſſels. After the Grecian conqueſt it was renewed by the Ptolemies, then by Trajan, and laſtly by the Arabs. Part of it ſtill remains, running from Cairo to the north-eaſt of the *Berket-el-Hadj*, or Lake of the Pilgrims, where it loſes itſelf. At preſent the commerce with Suez is only carried on by means of caravans, which ſet out towards the end of April or beginning of May, or in the months of July and Auguſt; waiting the arrival of the veſſels, and ſetting out on their departure. The caravans are very numerous; that with which M. Volney travelled conſiſting of 5000 or 6000 men and 3000 camels. The country is as deſert and barren as poſſible, without a ſingle tree or the ſmalleſt ſpot of verdure; ſo that every neceſſary for thoſe who accompany the caravan muſt be carried on the backs of the camels, wood and water not excepted.

The cuſtom-houſes of Egypt are in the hands of the Chriſtians of Syria. Formerly they were managed by Jews; but theſe were completely ruined by the extortions of Ali Bey in 1769. The Syrian Chriſtians came from Damaſcus ſomewhat more than 50 years ago; and having by their economy and induſtry gained poſſeſſion of the moſt important branches of commerce, they were at length enabled to farm the cuſtom-houſes, which is an office of great conſequence. There were at firſt only three or four families of them; but their number has ſince increaſed to more than 500, and they are reckoned very opulent.

163
Low ſtate of the arts and learning.

From what has already been ſaid concerning the ſtate of the Egyptians, we may naturally conclude, that the arts and all kinds of learning are at a very low ebb among them. Even the moſt ſimple of the mechanical profeſſions are ſtill in a ſtate of infancy. The work of their cabinet-makers, gunſmiths, and lockſmiths, is extremely clumſy. There are manufactures of gunpowder and ſugar; but the quality of both are very indifferent. The only thing in which they can be ſaid to arrive at any degree of perfection is the manufacture of ſilk ſtuffs; though even theſe are far leſs highly finiſhed than thoſe of Europe, and likewiſe bear a much higher price. One very extraordinary art indeed is ſtill extant among the Egyptians, and appears to have exiſted in that country from the moſt remote antiquity; and that is a power of enchanting the moſt deadly ſerpents in ſuch a manner, that they ſhall allow themſelves to be handled, nay even hurt in the ſevereſt manner, without offering to bite the perſon who injures them. Thoſe who have this art are named PSYLLI; to which article we refer for an account of what has been ſaid on the ſubject by ancient and modern travellers.

For a deſcription of thoſe ſtupendous and almoſt indeſtructible monuments of human grandeur, the pyramids, ſo often taken notice of and deſcribed by travellers; ſee the article PYRAMIDS.

EGYPTIANS, or GYPSIES. See GYPSIES.

EHRETIA, in botany: A genus of the monogynia order, belonging to the pentandria claſs of plants; and in the natural method ranking under the 41ſt order, *Aſperifoliæ*. The fruit is a bilocular berry; the ſeeds ſolitary and bilocular; the ſtigma emarginated.

EHRHARTA, in botany: A genus of the monogynia order, belonging to the hexandria claſs of plants. The calyx is a two-valved, abbreviated, and one-flowered glume; the corolla is a double glume, each two-valved: the exterior one compreſſed, and ſcymeter-ſhaped, tranſverſely wrinkled, and gaſhed at the baſe. There are ſix ſtamina, three on each ſide the piſtil in a parallel line. The ſtigma is ſimple, compreſſed, four-tufted, and torn at the top.

EHUD, the ſon of Gera, a Benjamite, a man left-handed, who delivered Iſrael from the oppreſſion of Eglon king of Moab, under whom they ſerved for 18 years. See EGLON. It being cuſtomary for the Iſraelites to ſend a preſent or tribute to the king of Moab; in the year of the world 2579, being the laſt year of their ſervitude, Ehud was appointed to carry it, who having a deſign either to free his country from this oppreſſion, or periſh in the attempt, had for this purpoſe provided himſelf with a dagger which had two edges, and which he had concealed on his right ſide, (Judges iii. 15, &c.). After he had delivered the preſent, pretending he had ſomething of great importance to communicate to the king, he obtained a private audience of him; when taking his opportunity, he ſtabbed him with the poniard to the heart, and ſo ſhutting the door after him, had time to make his eſcape; for as the king was a very corpulent man, his attendants ſuppoſed that he was either repoſing or eaſing himſelf, and therefore forbore to enter his apartment until Ehud was quite gone. As ſoon as he came to mount Ephraim, he gathered together the Iſraelites that lay neareſt him, acquainted them with what he had done; and then ſecuring the fords of Jordan that none of them might eſcape, he fell upon the Moabites, and ſubdued them.

EIA, or EY, in our old writers, are uſed for an iſland. Hence the names of places ending in *ey*, denotes them to be iſlands. Thus, Ramſey, the iſle of rams; Shepey, the iſle of ſheep, &c.

EIA is alſo ſometimes uſed for water; and hence the names of places near waters or lakes terminate in *ey*.

EJACULATOR, in anatomy, a name applied to two muſcles of the penis from their office in the ejection of the ſeed. See ANATOMY, *Table of the Muſcles*.

EICETÆ, called alſo HEICETÆ and HICETÆ, heretics of the ſeventh century, who made profeſſion of the monaſtic life.— From that paſſage in Exodus, where Moſes and the children of Iſrael are ſaid to have ſung a ſong in praiſe of the Lord, after they had paſſed the Red Sea, wherein their enemies had periſhed; the eicetæ concluded, that they muſt ſing and dance to praiſe God aright; and as Mary the propheteſs, ſiſter of Moſes and Aaron, took a drum in her hand, on the ſame occaſion, and all the women did the like, to teſtify their joy, by playing, beating, and dancing; the eicetæ, the better to imitate their conduct herein, endeavoured to draw women to them to make profeſſion of the monaſtic life, and aſſiſt in their mirth.

EICK. See BRUGES.

EIDER-DUCK. See ANAS.

*EIDER-Down.* See DOWN.

EJECTA, a term uſed by lawyers for a woman deflowered or caſt from the virtuous.

EJECTION, in the animal economy, evacuation, or the diſcharging any thing through ſome of the emunctories, as by ſtool, vomit, &c

EJECTION, in Scots law, is the turning out the poſſeſſor of any heritable ſubject by force; and is either *legal* or *illegal*. Legal ejection is where a perſon having no title to poſſeſs, is turned out by the authority of law. Illegal ejection is one perſon's violently turning another out of poſſeſſion without lawful authority.

EJECTMENT, in Engliſh law, a writ or action which lies for the leſſee for years, on his being ejected or put out of his land, before the expiration of his term, either by the leſſor or a ſtranger. It may alſo be brought by the leſſor againſt the leſſee, for rent in arrears, or holding over his term, &c. Ejectment of late years is become an action in the place of many real actions, as writs of right, formedons, &c. which are very difficult, as well as tedious and expenſive; and this is now the common action for trial of titles, and recovering of lands, &c. illegally held from the right owner; yet where entry is taken away by diſcents, fines, recoveries, diſſeiſins, &. an ejectment ſhall not be brought; whereby we find that all titles cannot be tried by this action.

The method of proceeding in the action of ejectment is to draw up a declaration, and feign therein a leaſe for three, five, or ſeven years, to him that would try the title; and alſo feign a caſual ejector or defendant; and then deliver the declaration to the ejector, who ſerves a copy of it on the tenant in poſſeſſion, and gives notice at the bottom for him to appear and defend his title; or that he the feigned defendant will ſuffer judgment by default, whereby the true tenant will be turned out of poſſeſſion; to this declaration the tenant is to appear at the beginning of next term by his attorney, and conſent to a rule to be made defendant, inſtead of the caſual ejector, and take upon him the defence, in which he muſt confeſs leaſe, judgment, entry, and auſter, and at the trial ſtand upon the title only: but in caſe the tenant in poſſeſſion does not appear, and enter into the ſaid rule in time, after the declaration ſerved, then, on affidavit being made of the ſervice of the declaration, with the notice to appear as aforeſaid,

ſaid, the court will order judgment to be entered againſt the caſual ejector by default; and thereupon the tenant in poſſeſſion, by writ *habere facias poſſeſſionem*, is turned out of his poſſeſſion. On the trial in ejectment, the plaintiff's title is to be ſet forth from the perſon laſt ſeiſed in fee of the lands in queſtion, under whom the leſſor claims down to the plaintiff, proving the deeds, &c. and the plaintiff ſhall recover only according to the right which he has at the time of bringing his action. And here, another who hath title to the land, upon a motion made for that purpoſe, may be defendant in the action with the tenant in poſſeſſion, to defend his title; for the poſſeſſion of the lands is primarily in queſtion, and to be recovered, which concerns the tenant, and the title thereto is tried collaterally, which may concern ſome other.

EKRON, a city and government of the Philiſtines. It fell by lot to the tribe of Judah, in the firſt diviſion made by Joſhua (xv. 45.), but afterwards it was given to the tribe of Dan (*id.* xix. 43.) It was ſituated very near the Mediterranean, between Aſhdod and Jamnia. Ekron was a powerful city, and it does not appear by hiſtory that the Jews were ever ſole peaceable poſſeſſors of it: the Ekronites were the firſt who ſaid that it was neceſſary to ſend back the ark of the God of Iſrael, in order to be delivered from thoſe calamities which the preſence of it brought upon their country, (1 Sam. v. 10.) The idol Baalzebub was principally adored at Ekron (2 Kings i. 2, &c.)

ELÆAGNUS, OLEASTER, or *Wild Olive:* A genus of the monogynia order, belonging to the tetrandria claſs of plants; and in the natural method ranking under the 16th order, *Calyciſloræ*. There is no corolla; the calyx is campanulated, quadrifid, ſuperior; the fruit is a plum below the campanulated calyx. There are three ſpecies: 1. The ſpinoſa, or eaſtern broad-leaved olive with a large fruit, is a native of the Levant and ſome parts of Germany. The leaves are about two inches long, and one and a half broad in the middle. They are placed alternate, and of a ſilver colour: at the footſtalk of every leaf there comes out a pretty long ſharp thorn, which are alternately longer: the flowers are ſmall, the inſide of the empalement is yellow, and they have a ſtrong ſcent when fully open. 2. The inermis, without thorns, is that kind commonly preſerved in the gardens of this country. The leaves are more than three inches long, and half an inch broad, and have a ſhining appearance like ſattin. The flowers come out at the footſtalks of the leaves, ſometimes ſingly, at other times two, and ſometimes three, at the ſame place. The outſide of the empalement is ſilvery and ſtudded; the inſide of a pale yellow, and having a very ſtrong ſcent. The flowers appear in July, and are ſometimes ſucceeded by fruit. 3. The latifolia, with oval leaves, is a native of Ceylon, and ſome other parts of India. In this country it riſes with a woody ſtem to the height of eight or nine feet, dividing into many crooked branches, garniſhed with oval and ſilvery leaves, which have ſeveral irregular ſpots of a dark colour on the ſurface. They are placed alternately on the branches, and continue all the year.

*Culture*, &c. The two firſt may be propagated by laying down the young ſhoots in autumn. They will take root in one year; when they may be cut off from the old trees, and either tranſplanted into a nurſery for two or three years to be trained up, or into places where they are to remain. The proper time for this is in the beginning of March or early in the autumn. They ſhould be placed where they may be ſcreened from high winds; for they grow very freely, and are apt to be ſplit by the wind if they are too much expoſed. The third ſort is too tender to endure the open air of this country; and therefore muſt be kept in a warm ſtove, except during a ſhort time in the warmeſt part of ſummer.

From the flowers of theſe plants an aromatic and cordial water has been drawn, which is ſaid to have been ſucceſsfully uſed in putrid and peſtilential fevers. The genus elæagnus is not to be confounded with the oleaſter or wild olive of Gerard, Parkinſon, and Ray. The laſt is only a particular ſpecies of olive, called by Tourneſort and Caſpar Bauhine, *olea ſylveſtris*. See OLEA.

ELÆOCARPUS, in botany: A genus of the monogynia order, belonging to the polyandria claſs of plants; and in the natural method ranking with thoſe of which the order is doubtful. The corolla is pentapetalous and lacerated; the calyx is pentaphyllous; and the fruit is a plum, with a wrinkled kernel.

ELÆOTHESIUM, in antiquity, the anointing room, or place where thoſe who were to wreſtle or had bathed anointed themſelves. See GYMNASIUM.

ELAIS, in botany; a genus belonging to the natural order of *Palmæ*. The male calyx is hexaphyllous; the corolla ſexfid; the ſtamina ſix: The female calyx is hexaphyllous; the corolla hexapetalous; the ſtigmata three; the fruit a fibrous plum, with a three-valved nut or kernel.

ELAM (anc. geog.), a country frequently mentioned in Scripture, and lying to the ſouth-eaſt of Shinar. In the time of Daniel (viii. 2.), Suſiana ſeems to have been part of it; and before the captivity, it does not appear that the Jews called Perſia by any other name. Elymæ and Elymais are often mentioned by the ancients. Ptolemy, though he makes Elymais a province of Media, yet he places the Elymæ in Suſiana, near the ſea-coaſt. Stephanus takes it to be a part of Aſſyria; but Pliny and Joſephus more properly of Perſia, whoſe inhabitants this latter tells us ſprang from the Elamites. The beſt commentators agree, that the Elamites, who were the anceſtors of the Perſians, were deſcended from Elam the ſon of Shem. It is likewiſe allowed, that the moſt ancient among the inſpired writers conſtantly intend Perſia, when they ſpeak of Elam and the kingdom of Elam. Thus, not to detain the reader with unneceſſary quotations, when the prophet Jeremiah (xlix. 39.), after denouncing many judgments againſt this country, adds theſe words, "But it ſhall come to paſs in the latter days, that I will bring again the captivity of Elam, ſaith the Lord," he is always underſtood to mean the reſtoration of the kingdom of the Perſians by Cyrus, who ſubdued the Babylonians, as they before had ſubdued the Perſians.

ELAPHEBOLIA, in Grecian antiquity, a feſtival in honour of Diana the huntreſs. In the celebration a cake was made in the form of a deer (ἐλαφος), and offered to the goddeſs. It owed its inſtitution to the following circumſtance: When the Phocians had been ſeverely

ſeverely beaten by the Theſſalians, they reſolved, by the perſuaſion of one Deiphantus, to raiſe a pile of combuſtible materials, and burn their wives, children, and effects, rather than ſubmit to the enemy. This reſolution was unanimouſly approved by the women, who decreed Deiphantus a crown for his magnanimity. When every thing was prepared, before they fired the pile, they engaged their enemies, and fought with ſuch deſperate fury, that they totally routed them, and obtained a complete victory. In commemoration of this unexpected ſucceſs, this feſtival was inſtituted to Diana, and obſerved with the greateſt ſolemnity.

ELAPHEBOLIUM, in Grecian antiquity, the ninth month of the Athenian year, anſwering to the latter part of February and beginning of March. It conſiſted of 30 days; and took its name from the feſtival elaphebolia, kept in this month, in honour of Diana the huntreſs, as mentioned in the preceding article.

ELASMIS, in natural hiſtory, a genus of talcs, compoſed of ſmall plates in form of ſpangles; and either ſingle, and not farther fiſſile; or, if complex, only fiſſile to a certain degree, and that in ſomewhat thick laminæ.—Of theſe talcs there are ſeveral varieties, ſome with large and others with ſmall ſpangles, which differ alſo in colour and other peculiarities.

ELASTIC, in natural philoſophy, an appellation given to all bodies endowed with the property of elaſticity. See ELASTICITY.

*Elastic Fluids.* See AIR, ELECTRICITY, GAS, and *Elastic Vapours* below.

*Elastic Reſin.* See CAOUTCHOUC.

*Elastic Vapours* are ſuch as may, by any external mechanical force, be compreſſed into a ſmaller ſpace than what they originally occupied; reſtoring themſelves, when the preſſure is taken off, to their former ſtate with a force exactly proportioned to that with which they were at firſt compreſſed. Of this kind are all the aerial fluids without exception, and all kinds of fumes raiſed by means of heat whether from ſolid or fluid bodies.

Of theſe, ſome retain their elaſticity only when a conſiderable degree of heat is applied to them or the ſubſtance which produces them; while others remain elaſtic in every degree of cold, either natural or artificial, that has yet been obſerved. Of the former kind are the vapours of water, ſpirit of wine, mercury, ſal ammoniac, and all kinds of ſublimable ſalts; of the latter, thoſe of ſpirit of ſalt, mixtures of vitriolic acid and iron, nitrous acid, and various other metals, and in ſhort the different ſpecies of aerial fluids indiſcriminately.

The elaſtic force with which any one of theſe fluids is endowed has not yet been calculated, as being ultimately greater than any obſtacle we can put in its way. Thus, if we compreſs the atmoſpherical air, we ſhall find that for ſome little time it will eaſily yield to the force we apply; but every ſucceeding moment the reſiſtance will become ſtronger, and a greater and greater force muſt be applied in order to compreſs it farther. As the compreſſion goes on, the veſſel containing the air becomes hot; but no power whatever has yet been able to deſtroy the elaſticity of the contained fluid in any degree; for upon removing the preſſure, it is always found to occupy the very ſame ſpace that it did before. The caſe is the ſame with aqueous ſteam, to which a ſufficient heat is applied to keep it from condenſing into water. This will yield to a certain degree; but every moment the reſiſtance becomes greater, until at laſt it will overcome any obſtacles whatever. An example of the power of this kind of ſteam we have every day in the ſteam engine; and the vapours of other matters, both ſolid and fluid, have frequently manifeſted themſelves to be endowed with an equal force. Thus the force of the vapours of ſpirit of wine has occaſioned terrible accidents when the worm has been ſtopped, and the head of the ſtill abſurdly tied down to prevent an exploſion; the vapours of mercury have burſt an iron box; and thoſe of ſal ammoniac, volatile ſalts, nitrous acid, marine acid, phoſphorus, &c. have all been known to burſt the chemical veſſels which confined them with great force, in ſuch a manner as to endanger thoſe who ſtood near them. In ſhort, from innumerable obſervations, it may be laid down as an undoubted fact, that there is no ſubſtance whatever capable of being reduced into a ſtate of vapour, but what in that ſtate is endowed with an elaſtic force ultimately ſuperior to any obſtacle we can throw in its way.

It hath been a kind of deſideratum among philoſophers to give a ſatisfactory reaſon for this aſtoniſhing power of elaſticity in vapour, ſeemingly ſo little capable of accompliſhing any great purpoſe when in an unconfined ſtate. As air is that fluid in which, from the many experiments made upon it by the air-pump and otherwiſe, the elaſtic property has moſt frequently been obſerved, the reſearches of philoſophers were at firſt principally directed towards it. The cauſes they aſſigned, however, were very inadequate; being founded upon an hypotheſis concerning the form of the particles of the atmoſphere itſelf, which they ſuppoſed to be either rolled up like the ſprings of watches, or that they conſiſted of a kind of elaſtic flakes. This was followed by another hypotheſis concerning their ſubſtance, which was imagined to be perfectly elaſtic, and ſo ſtrong that they could not be broken by any mechanical power whatever; and thus they thought the phenomenon of the elaſticity of the air might be explained. But an inſuperable difficulty ſtill attended their ſcheme, notwithſtanding both theſe ſuppoſitions; for it was obſerved, that the elaſtic power of the air was augmented not only in proportion to the quantity of preſſure it was made to endure, but in proportion to the degree of heat applied to it at the time. Sir Iſaac Newton was aware of this difficulty; and juſtly concluded, that the phenomena of the air's elaſticity could not be ſolved on any other ſuppoſition but that of a repulſive power diffuſed all around each of its particles, which became ſtronger as they approached, and weaker as they removed from each other. Hence the common phenomena of the air-pump and condenſing-engine received a ſatisfactory explanation; but ſtill it remained to account for the power ſhown in the preſent caſe by heat, as it could not be denied that this element had a very great ſhare in augmenting the elaſticity of the atmoſphere, and ſeemed to be the only cauſe of elaſticity in other vapours. It does not appear that Sir Iſaac entered into this queſtion, but contented himſelf with attributing to heat the property of in-

increaſing repulſion, and aſcribing this to another unexplored property called *rarefaction*. Thus matters ſtood till the great diſcovery made by Dr Black, that ſome bodies have the power of abſorbing in an unknown manner the element in queſtion, and parting with it afterwards, ſo that it flows out of the body which had abſorbed it with the very ſame properties that it had before abſorption. Hence many phenomena of heat, vapour, and evaporation, were explained in a manner much more ſatisfactory than had ever been attempted or even expected before. One of theſe was that remarkable property of metals becoming hot by hammering; during which operation, in the Doctor's opinion, the element of heat is ſqueezed out from between the particles of the metal as water is from the pores of a ſponge by preſſing it between the fingers. Of the ſame nature is the phenomenon above mentioned, that air when violently compreſſed becomes hot, by reaſon of the quantity of more ſubtle element ſqueezed out from among the particles. In this manner it appears that heat and the repulſive power of Sir Iſaac Newton are the very ſame; that by diminiſhing the heat of any quantity of air, its elaſticity is effectually diminiſhed, and it will of itſelf ſhrink into a ſmaller ſpace as effectually as by mechanical preſſure. In one caſe we have what may be called ocular demonſtration of the truth of this doctrine, viz. that by throwing the focus of a ſtrong burning lens upon a ſmall quantity of charcoal *in vacuo*, the whole will be converted into inflammable air, having even a greater power of elaſticity than common air in an equal degree of heat. Here there is nothing elſe but heat or light to produce the elaſtic power, or cauſe the particles of charcoal which before *attracted* now to repel each other. In another caſe we have evidence equally ſtrong, that the element of heat by itſelf, without the preſence of that of light, is capable of producing the ſame effect. Thus when a phial of ether is put into the receiver of an air-pump, and ſurrounded by a ſmall veſſel of water, the ether boils violently, and is diſſipated in vapour, while the water freezes, and is cooled to a great degree. The diſſipation of this vapour ſhows that it has an elaſtic force; and the abſorption of the heat from the water ſhows, that this element not only *produces* the elaſticity, but actually enters into the ſubſtance of the vapour itſelf; ſo that we have not the leaſt reaſon to conclude that there is any other repulſive power by which the particles are kept at a diſtance from one another than the ſubſtance of the heat itſelf. In what manner it acts, we cannot pretend exactly to explain, without making hypotheſes concerning the form of the minute particles of matter, which muſt always be very uncertain. All known phenomena, however, concur in rendering the theory juſt now laid down extremely probable. The elaſticity of the ſteam of water is exactly proportioned to the degree of heat which flows into it from without; and if this be kept up to a ſufficient degree, there is no mechanical preſſure which can reduce it into the ſtate of water. This, however, may very eaſily be done by abſtracting a certain portion of the latent heat it contains; when the elaſtic vapour will become a denſe and heavy fluid. The ſame thing may be done in various ways with the permanently elaſtic fluids. Thus the pureſt dephlogiſticated air, when made to part with its latent heat by burning with iron, is converted into a gravitating ſubſtance of an unknown nature, which adheres ſtrongly to the metal. If the decompoſition is performed by means of inflammable air, both together unite into an heavy, aqueous, or acid fluid; if by mixture with nitrous air, ſtill the heat is diſcernible, though leſs violent than in the two former caſes. The decompoſition indeed is ſlower, but equally complete, and the dephlogiſticated air becomes part of the nitrous acid, from which it may be again expelled by proper means: but of theſe means heat muſt always be one; for thus only the elaſticity can be reſtored, and the air be recovered in its proper ſtate. The ſame thing takes place in fixed air, and all other permanently elaſtic fluids capable of being abſorbed by others. The concluſion therefore which we can only draw from what data we have concerning the compoſition of elaſtic vapours is, that all of them are formed of a terreſtrial ſubſtance, united with the element of heat in ſuch a manner that part of the latter may be ſqueezed out from among the terreſtrial particles; but in ſuch a manner, that as ſoon as the preſſure is taken off, the ſurrounding fluid ruſhes in, and expands them to their original bulk: and this expanſion or tendency to it will be increaſed in proportion to the degree of heat, juſt as the expanſion of a ſponge would be exceedingly augmented, if we could contrive to convey a ſtream of water into the heart of it, and make the liquid flow out with violence through every pore in the circumference. In this caſe, it is evident that the water would act as a *power of repulſion* among the particles of the ſponge, as well as the fire does among the particles of the water, charcoal, or whatever other ſubſtance is employed. Thus far we may reaſon from analogy; but in all probability the internal and eſſential texture of theſe vapours will for ever remain unknown. Their obvious properties, as well as ſome of their more latent operations in many caſes, are treated of under a variety of articles in this work, as AEROLOGY, EVAPORATION, VOLCANO, &c.

It has been imagined by ſome, that the artificial elaſtic fluids have not the ſame mechanical property with common air, viz. that of occupying a ſpace inverſely proportional to the weights with which they are preſſed: but this is found to be a miſtake. All of them likewiſe have been found to be non-conductors of electricity, though probably not all in the ſame degree. Even aqueous vapour, when intimately mingled with any permanently elaſtic fluid, refuſes to conduct this fluid, as is evident from the highly electrical ſtate of the atmoſphere in very dry weather, when we are certain that aqueous vapour muſt abound very much, and be intimately mixed with it. The colour of the electric ſpark, though it may be made viſible in all kinds of permanently elaſtic vapours, is very different in different fluids. Thus in inflammable and alkaline air it is red or purple, but in fixed air it appears white.

**ELASTICITY**, or ELASTIC *Force*, that property of bodies wherewith they reſtore themſelves to their former figure, after any external preſſure.

The cauſe or principle of this important property elaſticity, or ſpringineſs, is variouſly aſſigned. The Carteſians account for it from the materia ſubtilis making an effort to paſs through pores that are too narrow for it. Thus, ſay they, in bending, or compreſſing, a hard elaſtic body, *e. gr.* a bow, its parts recede from each other on the convex ſide, and approach on the concave: conſequently the pores are contracted or ſtraitened on the concave ſide; and if they were before round, are now, for inſtance, oval: ſo that the materia ſubtilis, or matter of the ſecond element, endeavouring to paſs out of thoſe pores thus ſtraitened, muſt make an effort, at the ſame time, to reſtore the body to the ſtate it was in when the pores were more patent and round, *i. e.* before the bow was bent: and in this conſiſts its elaſticity.

Other later and more wary philoſophers account for elaſticity much after the ſame manner as the Carteſians; with this only difference, that in lieu of the ſubtile matter of the Carteſians, theſe ſubſtitute Ether, or a fine etherial medium that pervades all bodies.

Others, ſetting aſide the precarious notion of a materia ſubtilis, account for elaſticity from the great law of nature ATTRACTION, or the cauſe of the COHESION of the parts of ſolid and firm bodies. Thus, ſay they, when a hard body is ſtruck or bent, ſo that the component parts are moved a little from each other, but not quite disjointed or broke off, or ſeparated ſo far as to be out of the power of that attracting force whereby they cohere; they muſt certainly, on the ceſſation of the external violence, ſpring back to their former natural ſtate.

Others reſolve elaſticity into the preſſure of the atmoſphere: for a violent tenſion, or compreſſion, tho' not ſo great as to ſeparate the conſtituent particles of bodies far enough to let in any foreign matter, muſt yet occaſion many little vacuola between the ſeparated ſurfaces; ſo that upon the removal of the force they will cloſe again by the preſſure of the aerial fluid upon the external parts. See ATMOSPHERE.

Laſtly, others attribute the elaſticity of all hard bodies to the power of reſilition in the air included within them: and ſo make the elaſtic force of the air the principle of elaſticity in all other bodies.

*The ELASTICITY of Fluids* is accounted for from their particles being all endowed with a centrifugal force; when Sir Iſaac Newton, prop. 23. lib 2. demonſtrates, that particles, which naturally avoid or fly off from one another by ſuch forces as are reciprocally proportioned to the diſtances of their centre, will compoſe an elaſtic fluid, whoſe denſity ſhall be proportional to its compreſſion; and *vice verſa*, if any fluid be compoſed of particles that fly off and avoid one another, and hath its denſity proportional to its compreſſion, then the centrifugal forces of thoſe particles will be reciprocally as the diſtances of their centres.

*ELASTICITY of the Air*, is the force wherewith that element dilates itſelf, upon removing the force whereby it was before compreſſed. See AIR, and ATMOSPHERE.

The elaſticity or ſpring of the air was firſt diſcovered by Galileo. Its exiſtence is proved by this experiment of that philoſopher: An extraordinary quantity of air being intruded by means of a ſyringe into a glaſs or metal ball, till ſuch time as the ball, with this acceſſion of air, weigh conſiderably more in the balance than it did before; upon opening the mouth thereof, the air ruſhes out, till the ball ſink to its former weight. From hence we argue, that there is juſt as much air gone out, as compreſſed air had been crowded in. Air, therefore, returns to its former degree of expanſion, upon removing the force that compreſſed or reſiſted its expanſion; conſequently it is endowed with an elaſtic force. It muſt be added, that as the air is found to ruſh out in every ſituation or direction of the orifice, the elaſtic force acts every way, or in every direction.

The elaſticity of the air makes a conſiderable article in PNEUMATICS.

The cauſe of the elaſticity of the atmoſphere hath been commonly aſcribed to a repulſion between its particles; but this can give us only a very ſlight idea of the nature of its elaſticity. The term *repulſion*, like that of *attraction*, requires to be defined; and in all probability will be found in moſt caſes to be the effect of the action of ſome other fluid. Thus, we find, that the elaſticity of the atmoſphere is very conſiderably affected by heat. Suppoſing a quantity of air heated to ſuch a degree as is ſufficient to raiſe Fahrenheit's thermometer to 212, it will then occupy a conſiderable ſpace. If it is cooled to ſuch a degree as to ſink the thermometer to 0, it will ſhrink up into leſs than half the former bulk. The quantity of repulſive power therefore acquired by the air, while paſſing from one of theſe ſtates to the other, is evidently owing to the heat added to or taken away from it. Nor have we any reaſon to ſuppoſe, that the quantity of elaſticity or repulſive power it ſtill poſſeſſes is owing to any other thing than the fire contained in it. The ſuppoſing repulſion to be a primary cauſe independent of all others, hath given riſe to many erroneous theories, and been one very great mean of embarraſſing philoſophers in their accounting for the phenomena of ELECTRICITY.

ELATE, in botany, a genus belonging to the natural order of *Palmæ*. There is no male calyx; the corolla is tripetalous, with three ſtamina. There is no female calyx; the corolla is tripetalous, with one piſtil; the fruit is an oval acuminated plum.

Plate CLXX

ELATER, in zoology; a genus of inſects, belonging to the order of coleoptera. The antennæ are ſetaceous; and an elaſtic ſpring or ſpine projects from the hinder extremity of the breaſt or under ſide of the thorax. By means of this kind of ſpring, the animal, when turned upon his back, contrives to leap up into the air, and ſo turn itſelf. It varies in ſize; and when the inſect is young and newly metamorphoſed, its elytra are of a beautiful deep red; but in a few days they change to a much darker hue, and are nearly of a cheſnut colour. In the ſtate of larvæ it inhabits the trunks of decayed trees, and is there transformed. With the help of its wings it iſſues from its priſon, flutters upon flowers, wanders over the fields, and conceals itſelf in thickets or under the bark of trees.

ELATERIUM, in botany: A genus of the monandria order, belonging to the monœcia claſs of plants; and in the natural method ranking under the 34th order, *Cucurbitaceæ*. There is no male calyx; the corolla is ſalver-ſhaped; there is no female calyx; the corolla ſalver-ſhaped; the capſule inferior, unilocular, and bivalved.

ELATERIUM, Ελατηριον, in pharmacy, a violently purgative

gative medicine, prepared from the wild cucumber.

ELATH, or Eloth, a part of Idumæa, ſituated upon the Red Sea, which David in his conqueſt of Edom took (2 Sam. viii. 14.), and there eſtabliſhed a trade to all parts of the world. His ſon, we ſee, built ſhips in Elath, and ſent them from thence to Ophir for gold, 2 Chr. viii. 17, 18. It continued in the poſſeſſion of the Iſraelites about 150 years, till in the time of Joram, the Edomites recovered it (2 Kings viii. 20.); but it was again taken from them by Azariah, and by him left to his ſon, 2 Kings xiv. 22. His grandſon Ahaz, however, loſt it again to the king of Syria (*ib.* xvi. 6.); and the Syrians had it in their hands a long while, till after many changes under the Ptolemies, it came at length into the poſſeſſion of the Romans.

ELATINE, in botany: A genus of the tetragynia order, belonging to the octandria claſs of plants; and in the natural method ranking under the 15th order, *Inundatæ*. The calyx is tetraphyllous; the petals four; the capſule quadrilocular, quadrivalved, and depreſſed.

ELATOSTEMA, in botany: A genus of the pentandria order, belonging to the monœcia claſs of plants. The male flowers have no calyx; the corolla is quinquepartite; the ſtamina are five filaments. There are female flowers on the ſame plant; theſe have no calyx nor corolla; the pericarpium is a very ſmall oblong, bivalve, monoſpermous capſule; the ſeeds ſingle and egg-ſhaped.

ELBE, a large river in Germany, which, riſing on the confines of Sileſia, runs through Bohemia, Saxony, and Brandenburg; and afterwards dividing the duchy of Luxenburg from that of Mecklenburg, as alſo the duchy of Bremen from Holſtein, it falls into the German ocean, about 70 miles below Hamburg. It is navigable for great ſhips higher than any river in Europe.

ELBING, a city of Poliſh Pruſſia, in the palatinate of Marienburg, ſituated in E. Long. 20. 0. N. Lat. 54 15, on a bay of the Baltic ſea, called the *Friſchaff*, near the mouth of the Viſtula. The town is large, populous, and very well built. It is divided into two parts, called the old and new town, which are both of them very well fortified. The old town has a handſome tower, with a good college. The ſtadthouſe and the academy are good buildings, with pleaſant gardens, which are worth ſeeing. The place has a conſiderable trade, eſpecially in ſturgeon, mead, cheeſe, butter, and corn. It is ſeated in a champaign level like Holland, very fruitful and populous. The inhabitants are partly Lutherans and partly Roman Catholics. The Boors in the neighbourhood have as good houſes and apparel almoſt as the nobility of Courland.

ELBOW, the outer angle made by the flexure or bend of the arm. That eminence whereon the arm reſts, called by us *elbow*, is by the Latins called *cubitus*, and the Greeks αγκων, and by others ολεκρανον.

Elbow is alſo uſed by architects, maſons, &c. for an obtuſe angle of a wall, building, or road, which diverts it from its right line.

ELCESAITES, in church-hiſtory, ancient heretics, who made their appearance in the reign of the emperor Trajan, and took their name from their leader Elceſai. The Elceſaites kept a mean between the Jews, Chriſtians, and Pagans; they worſhipped but one God, obſerved the Jewiſh ſabbath, circumciſion, and the other ceremonies of the law. They rejected the Pentateuch, and the prophets; nor had they any more reſpect for the writings of the apoſtles, particularly thoſe of St Paul.

ELDERS, or Seniors, in Jewiſh hiſtory, were perſons the moſt conſiderable for age, experience, and wiſdom. Of this ſort were the 70 men whom Moſes aſſociated to himſelf in the government of his people; ſuch, likewiſe, afterwards were thoſe who held the firſt mark in the ſynagogue, as preſidents.

In the firſt aſſemblies of the primitive Chriſtians, thoſe who held the firſt place were called *elders*. The word *preſbyter*, often uſed in the New Teſtament, is of the ſame ſignification: hence the firſt councils of Chriſtians were called *preſbyteria*, or *councils of elders*.

Elders is alſo a denomination ſtill retained in the Preſbyterian diſcipline. The elders are officers, who, in conjunction with the paſtors, or miniſters, and deacons, compoſe the conſiſtories or kirk-ſeſſions, meeting to conſider, inſpect, and regulate, matters of religion and diſcipline. They are choſen from among the people, and are received publicly with ſome degree of ceremony. In Scotland, there is an indefinite number of elders in each pariſh; generally about 12. See *Kirk-Seſſions*, and Presbytery.

Elder, in botany. See Sambucus.

ELEA, or Elis, (anc. geog.), a diſtrict of Peloponneſus, ſituated between Achaia and Meſſenia, reaching from Arcadia quite to the weſt or Ionian ſea: ſo called from Elis, a cognominal town. See Elis.

ELEATIC philosophy, among the ancients; a name given to that of the stoics, becauſe taught at 'Ελεα. in Latin *Velia*, a town of the Lucani.

The founder of this philoſophy, or of the Eleatic ſect, is ſuppoſed to have been Xenophanes, who lived about the 56th Olympiad, or between 500 or 600 years before Chriſt. This ſect was divided into two parties, which may be denominated *metaphyſical* and *phyſical*; the one rejecting, and the other approving, the appeal to fact and experiment. Of the former kind were Xenophanes, Parmenides, Meliſſus, and Zeno, of Elea. They are ſuppoſed to have maintained principles not very unlike thoſe of Spinoza; they held the eternity and immutability of the world; that whatever exiſted was only one being; that there was neither any generation nor corruption; that this one being was immoveable and immutable, and was the true God; and whatever changes ſeemed to happen in the univerſe, they conſidered as mere appearances and illuſions of ſenſe. However, ſome learned men have ſuppoſed, that Xenophanes and his followers, ſpeaking metaphyſically, underſtood by the univerſe, or the one being, not the material world, but the originating principle of all things, or the true God, whom they expreſsly affirm to be incorporeal. Thus Simplicius repreſents them as merely metaphyſical writers, who diſtinguiſhed between things natural and ſupernatural; and who made the former to be compounded of different principles. Accordingly, Xenophanes maintained, that the earth conſiſted of air and fire, that all things were produced out of the earth, and the ſun and ſtars out of clouds, and that there were four elements. Parmenides

menides alſo diſtinguiſhed between the doctrine concerning metaphyſical objects, called *truth*, and that concerning phyſical or corporeal things, called *opinion*; with reſpect to the former there was one immoveable principle, but in the latter two that were moveable, viz. fire and earth, or heat and cold; in which particulars Zeno agreed with him. The other branch of the Eleatic ſect were the atomic philoſophers, who formed their ſyſtem from an attention to the phenomena of nature; of theſe the moſt conſiderable were Leucippus, Democritus, and Protagoras.

ELECAMPANE, in botany. See INULA.

ELECT, (from *eligo*, "I chooſe") CHOSEN, in the Scriptures, is applied to the primitive Chriſtians; in which ſenſe, the elect are thoſe choſen and admitted to the favour and bleſſing of Chriſtianity.

ELECT, in ſome ſyſtems of theology, is a term appropriated to the ſaints, or the predeſtinated: in which ſenſe the elect are thoſe perſons who are ſaid to be predeſtinated to glory as the end, and to ſanctification as the means.

ELECT is likewiſe applied to archbiſhops, biſhops, and other officers, who are choſen, but not yet conſecrated, or actually inveſted with their office or juriſdiction.

The emperor is ſaid to be elect before he is inaugurated and crowned; a lord-mayor is elect, before his predeceſſor's mayoralty is expired, or the ſword is put in his hands.

ELECTION, the choice that is made of any thing or perſon, whereby it is preferred to ſome other. There ſeems this difference, however, between choice and election, that election has uſually a regard to a company or community, which makes the choice; whereas choice is ſeldom uſed but when a ſingle perſon makes it.

ELECTION, in Britiſh polity, is the people's choice of their repreſentatives in parliament. (See PARLIAMENT.) In this conſiſts the exerciſe of the democratical part of our conſtitution: for in a democracy there can be no exerciſe of ſovereignty but by ſuffrage, which is the declaration of the people's will. In all democracies, therefore, it is of the utmoſt importance to regulate by whom, and in what manner, the ſuffrages are to be given. And the Athenians were ſo juſtly jealous of this prerogative, that a ſtranger, who interfered in the aſſemblies of the people, was puniſhed by their laws with death; becauſe ſuch a man was eſteemed guilty of high treaſon, by uſurping thoſe rights of ſovereignty to which he had no title. In Britain, where the people do not debate in a collective body, but by repreſentation, the exerciſe of this ſovereignty conſiſts in the choice of repreſentatives. The laws have therefore very ſtrictly guarded againſt uſurpation or abuſe of this power, by many ſalutary proviſions; which may be reduced to theſe three points, 1. The qualifications of the electors. 2. The qualifications of the elected. 3. The proceedings at elections.

*Blackſt. Comment.*

(1.) As to the qualifications of the electors. The true reaſon of requiring any qualification, with regard to property, in voters, is to exclude ſuch perſons as are in ſo mean a ſituation, that they are eſteemed to have no will of their own. If theſe perſons had votes, they would be tempted to diſpoſe of them under ſome undue influence or other. This would give a great, an artful, or a wealthy man, a larger ſhare in elections than is conſiſtent with general liberty. If it were probable that every man would give his vote freely, and without influence of any kind: then, upon the true theory and genuine principles of liberty, every member of the community, however poor, ſhould have a vote in electing thoſe delegates to whoſe charge is committed the diſpoſal of his property, his liberty, and his life. But ſince that can hardly be expected in perſons of indigent fortunes, or ſuch as are under the immediate dominion of others, all popular ſtates have been obliged to eſtabliſh certain qualifications; whereby ſome, who are ſuſpected to have no will of their own, are excluded from voting, in order to ſet other individuals, whoſe will may be ſuppoſed independent, more thoroughly upon a level with each other.

And this conſtitution of ſuffrages is framed upon a wiſer principle, with us, than either of the methods of voting, by centuries or by tribes, among the Romans. In the method by centuries, inſtituted by Servius Tullius, it was principally property, and not numbers, that turned the ſcale: in the method by tribes, gradually introduced by the tribunes of the people, numbers only were regarded, and property entirely overlooked. Hence the laws paſſed by the former method had uſually too great a tendency to aggrandize the patricians or rich nobles: and thoſe by the latter had too much of a levelling principle. Our conſtitution ſteers between the two extremes. Only ſuch are entirely excluded as can have no will of their own: there is hardly a free agent to be found, but what is intitled to a vote in ſome place or other in the kingdom. Nor is comparative wealth, or property, entirely diſregarded in elections; for though the richeſt man has only one vote at one place, yet, if his property be at all diffuſed, he has probably a right to vote at more places than one, and therefore has many repreſentatives. This is the ſpirit of our conſtitution: not that we aſſert it is in fact quite ſo perfect as we have endeavoured to deſcribe it; for if any alteration might be wiſhed or ſuggeſted in the preſent form of parliaments, it ſhould be in favour of a more complete repreſentation of the people.

But to return to the qualifications; and firſt thoſe of electors for knights of the ſhire. 1. By ſtatute 8 Hen. VI. c. 7. and 10 Hen. VI. c. 2. (amended by 14 Geo. III. c. 58.) the knights of the ſhire ſhall be choſen of people, whereof every man ſhall have freehold to the value of forty ſhillings by the year within the county; which (by ſubſequent ſtatutes) is to be clear of all charges and deductions, except parliamentary and parochial taxes. The knights of ſhires are the repreſentatives of the landholders, or landed intereſt of the kingdom: their electors muſt therefore have eſtates in lands or tenements within the county repreſented. Theſe eſtates muſt be freehold, that is, for term of life at leaſt; becauſe beneficial leaſes for long terms of years were not in uſe at the making of theſe ſtatutes, and copyholders were then little better than villeins, abſolutely dependent upon their lords. This freehold muſt be of 40 ſhillings annual value; becauſe that ſum would then, with proper induſtry, furniſh all the neceſſaries of life, and render the freeholder, if he pleaſed, an independent man: For biſhop Fleetwood, in his *chronicon precioſum*, written at the beginning of the preſent century, has fully proved 40 ſhillings in the reign of Henry VI. to have been equal to 12 pounds *per annum* in the reign of Queen Anne; and, as the value of money is very conſiderably lowered ſince the biſhop wrote, we may fairly conclude, from this and other circumſtances, that what was equivalent to 12 pounds in his days, is equivalent to 20 at preſent. The other leſs important qualifications of the electors for counties in England and Wales may be collected from the ſtatutes cited below (A); which direct, 2. That no perſon under 21 years of age ſhall be capable of voting for any member. This extends to all ſorts of members as well for boroughs as counties; as does alſo the next, *viz.* 3. That no perſon convicted of perjury, or ſubornation of perjury, ſhall be capable of voting in any election. 4. That no perſon ſhall vote in right of any freehold, granted to him fraudulently to qualify him to vote. Fraudulent grants are ſuch as contain an agreement to reconvey, or to defeat the eſtate granted; which agreements are made void, and the eſtate is abſolutely veſted in the perſon to whom it is ſo granted. And, to guard the better againſt ſuch frauds, it is farther provided, 5. That every voter ſhall have been in the actual poſſeſſion, or receipt of the profits, of his freehold to his own uſe for 12 kalendar months before; except it came to him by deſcent, marriage, marriage-ſettlement, will, or promotion to a benefice or office. 6. That no perſon ſhall vote in reſpect of an annuity or rent-charge, unleſs regiſtered with the clerk of the peace 12 kalendar months before. 7. That in mortgaged or truſt-eſtates, the perſon in poſſeſſion, under the abovementioned reſtrictions, ſhall have the vote. 8. That only one perſon ſhall be admitted to vote for any one houſe or tenement, to prevent the ſplitting of freeholds. 9. That no eſtate ſhall qualify a voter, unleſs the eſtate has been aſſeſſed to ſome land-tax aid, at leaſt 12 months before the election. 10. That no tenant by copy of court-roll ſhall be permitted to vote as a freeholder. Thus much for the electors in counties.

As for the electors of citizens and burgeſſes, theſe are ſuppoſed to be the mercantile part or trading intereſt of this kingdom. But as trade is of a fluctuating nature, and ſeldom long fixed in a place, it was formerly left to the crown to ſummon, *pro re nata*, the moſt flouriſhing towns to ſend repreſentatives to parliament. So that as towns increaſed in trade, and grew populous, they were admitted to a ſhare in the legiſlature. But the misfortune is, that the deſerted boroughs continued to be ſummoned, as well as thoſe to whom their trade and inhabitants were transferred; except a few which petitioned to be eaſed of the expence, then uſual, of maintaining their members: four ſhillings a-day being allowed for a knight of the ſhire, and two ſhillings for a citizen or burgeſs; which was the rate of wages eſtabliſhed in the reign of Edward III. Hence the members for boroughs now bear above a quadruple proportion to thoſe for counties; and the number of parliament men is increaſed ſince Forteſcue's time, in the reign of Henry VI. from 300 to upwards of 500, excluſive of thoſe for Scotland. The univerſities were, in general, not empowered to ſend burgeſſes to parliament; though once, in 28 Edw. I. when a parliament was ſummoned to conſider of the king's right to Scotland, there were iſſued writs, which required the univerſity of Oxford to ſend up four or five, and that of Cambridge two or three, of their moſt diſcreet and learned lawyers for that purpoſe. But it was king James I. who indulged them with the permanent privilege to ſend conſtantly two of their own body; to ſerve for thoſe ſtudents who, though uſeful members of the community, were neither concerned in the landed nor the trading intereſt; and to protect in the legiſlature the rights of the republic of letters. The right of election in boroughs is various, depending entirely on the ſeveral charters, cuſtoms, and conſtitutions of the reſpective places; which has occaſioned infinite diſputes: tho' now, by ſtatute 2 Geo. II. c. 24. the right of voting for the future ſhall be allowed according to the laſt determination of the houſe of commons concerning it; and, by ſtatute 3 Geo. III. c. 15. no freeman of any city or borough (other than ſuch as claim by birth, marriage, or ſervitude) ſhall be intitled to vote therein, unleſs he hath been admitted to his freedom 12 kalendar months before.

(2) Next, as to the qualifications of perſons to be *elected* members of the houſe of commons. Some of theſe depend upon the law and cuſtom of parliaments, declared by the houſe of commons; others upon certain ſtatutes. And from theſe it appears, 1. That they muſt not be aliens born or minors. 2. That they muſt not be any of the 12 judges, becauſe they ſit in the lords' houſe; nor of the clergy, for they ſit in the convocation; nor perſons attainted of treaſon, or felony, for they are unfit to ſit any where. 3. That ſheriffs of counties, and mayors and bailiffs of boroughs, are not eligible in their reſpective juriſdictions, as being returning officers; but that ſheriffs of one county are eligible to be knights of another. 4. That, in ſtrictneſs, all members ought to have been inhabitants of the places for which they are choſen; but this, having been long diſregarded, was at length entirely repealed by ſtatute 14 Geo. III. c. 58. 5. That no perſons concerned in the management of any duties or taxes created ſince 1692, except the commiſſioners of the treaſury, nor any of the officers following (viz. commiſſioners of prizes, tranſports, ſick and wounded, wine-licences, navy, and victualling; ſecretaries or receivers of prizes; comptrollers of the army-accounts; agents for regiments; governors of plantations, and their deputies; officers of Minorca or Gibraltar; officers of the exciſe and cuſtoms; clerks or deputies in the ſeveral offices of the treaſury, exchequer, navy, victualling, admiralty, pay of the army or navy, ſecretaries of ſtate, ſalt, ſtamps, appeals, wine-licences, hackney-coaches, hawkers, and pedlars), nor any perſons that hold any new office under the crown created ſince 1705, are capable of being elected or ſitting as members. 6. That no perſon having a penſion under the crown during pleaſure, or for any term of years, is capable of being elected or ſitting. 7. That if any mem-

---

(A) 7 and 8 Will. III. c. 25. 10 Ann. c. 23. 2 Geo. II. c. 21. 18 Geo. II. c. 18. 31 Geo. II. c. 14. 3 Geo. III. c. 24.

member accepts an office under the crown, except an officer in the army or navy accepting a new commiſſion, his ſeat is void; but ſuch member is capable of being re-elected. 8. That all knights of the ſhire ſhall be actual knights, or ſuch notable eſquires and gentlemen as have eſtates ſufficient to be knights, and by no means of the degree of yeomen. This is reduced to a ſtill greater certainty, by ordaining, 9. That every knight of a ſhire ſhall have a clear eſtate of freehold or copyhold to the value of 600 l. *per annum*, and every citizen and burgeſs to the value of 300 l.: except the eldeſt ſons of peers and of perſons qualified to be knights of ſhires, and except the members for the two univerſities: which ſomewhat balances the aſcendant which the boroughs have gained over the counties, by obliging the trading intereſt to make choice of landed men: and of this qualification the member muſt make oath, and give in the particulars in writing, at the time of his taking his ſeat. But, ſubject to theſe ſtanding reſtrictions and diſqualifications, every ſubject of the realm is eligible of common right: though there are inſtances, wherein perſons in particular circumſtances have forfeited that common right, and have been declared ineligible *for that parliament*, by a vote of the houſe of commons; or *for ever*, by an act of the legiſlature. But it was an unconſtitutional prohibition, which was grounded on an ordinance of the houſe of *lords*, and inſerted in the *king's* writs, for the parliament holden at Coventry, 6 Hen. IV. that no apprentice or other man of the law ſhould be elected a knight for the ſhire therein: in return for which, our law-books and hiſtorians have branded this parliament with the name of *parliamentum indoctum*, or the lack-learning parliament; and Sir Edward Coke obſerves with ſome ſpleen, that there was never a good law made thereat.

(3.) The third point, regarding elections, is the method of proceeding therein. This is alſo regulated by the law of parliament, and the ſeveral ſtatutes referred to in the margin below, (B); all which we ſhall blend together, and extract out of them a ſummary account of the method of proceeding to elections.

As ſoon as the parliament is ſummoned, the lord chancellor (or if a vacancy happens during the ſitting of parliament, the ſpeaker, by order of the houſe, and without ſuch order if a vacancy happens by death in the time of a receſs for upwards of 20 days) ſends his warrant to the clerk of the crown in chancery; who thereupon iſſues out writs to the ſheriff of every county, for the election of all the members to ſerve for that county, and every city and borough therein. Within three days after the receipt of this writ, the ſheriff is to ſend his precept, under his ſeal, to the proper returning officers of the cities and boroughs, commanding them to elect their members: and the ſaid returning officers are to proceed to election within eight days from the receipt of the precept, giving four days notice of the ſame; and to return the perſons choſen, together with the precept, to the ſheriff.

But elections of knights of the ſhire muſt be proceeded to by the ſheriffs themſelves in perſon, at the next county-court that ſhall happen after the delivery of the writ. The county-court is a court held every month or oftener by the ſheriff, intended to try little cauſes not exceeding the value of 40 s. in what part of the county he pleaſes to appoint for that purpoſe: but for the election of knights of the ſhire, it muſt be held at the moſt uſual place. If the county-court falls upon the day of delivering the writ, or within ſix days after, the ſheriff may adjourn the court and election to ſome other convenient time, not longer than 16 days, nor ſhorter than 10; but he cannot alter the place, without the conſent of all the candidates: and, in all ſuch caſes, 10 days public notice muſt be given of the time and place of the election.

And, as it is eſſential to the very being of parliament that elections ſhould be abſolutely free, therefore all undue influences upon the electors are illegal, and ſtrongly prohibited. For Mr Locke ranks it among thoſe breaches of truſt in the executive magiſtrate, which, according to his notions, amount to a diſſolution of the government, "if he employs the force, treaſure, and offices of the ſociety to corrupt the repreſentatives, or openly to pre-engage the electors, and preſcribe what manner of perſons ſhall be choſen: For thus to regulate candidates and electors, and new-model the ways of election, what is it (ſays he) but to cut up the government by the roots and poiſon the very fountain of public ſecurity?" As ſoon, therefore, as the time and place of election, either in counties or boroughs, are fixed, all ſoldiers quartered in the place are to remove, at leaſt one day before the election, to the diſtance of two miles or more; and not to return till one day after the poll is ended. Riots likewiſe have been frequently determined to make an election void. By vote alſo of the houſe of commons, to whom alone belongs the power of determining conteſted elections, no lord of parliament, or lord lieutenant of a county, hath any right to interfere in the election of commoners; and, by ſtatute, the lord warden of the cinque-ports ſhall not recommend any members there. If any officer of the exciſe, cuſtoms, ſtamps, or certain other branches of the revenue, preſumes to intermeddle in elections, by perſuading any voter or diſſuading him, he forfeits L. 100, and is diſabled to hold any office.

Thus are the electors of one branch of the legiſlature ſecured from any undue influence from either of the other two, and from all external violence and compulſion. But the greateſt danger is that in which themſelves co-operate, by the infamous practice of bribery and corruption. To prevent which it is enacted, that no candidate ſhall, after the date (uſually called the *teſte*) of the writs, or after the vacancy, give any money or entertainment to his electors, or promiſe to give any, either to particular perſons, or to the place in general, in order to his being elected;

---

(B) 7 Hen. IV. c. 15. 8 Hen. 6. c. 7. 23 Hen. VI. c. 14. 1 W. & M. ſt. 1. c. 2. 2 W. & M. ſt. 1. c. 7. 5 & 6 W. & M. c. 20. 7 W. III. c. 4. 7 & 8 W. III. c. 7. and c. 25. 10 & 11 W. III. c. 7. 12 & 13 W. III. c. 10. 6 Ann. c. 23. 9 Ann. c. 5. 10 Ann. c. 19. and c. 33. 2 Geo. II. c. 24. 8 Geo. II. c. 30. 18 Geo. II. c. 18. 19 Geo. II. c. 28. 10 Geo. III. c. 16. 11 Geo. III. c. 42. 14 Geo. III. c. 15.

on pain of being incapable to ſerve for that place in parliament. And if any money, gift, office, employment, or reward be given, or promiſed to be given, to any voter, at any time, in order to influence him to give or with-hold his vote, as well he that takes as he that offers ſuch bribe forfeits L. 500, and is for ever diſabled from voting and holding any office in any corporation; unleſs, before conviction, he will diſcover ſome other offender of the ſame kind, and then he is indemnified for his own offence. The firſt inſtance that occurs of election bribery, was ſo early as 13 Eliz. when one Thomas Longe (being a ſimple man, and of ſmall capacity to ſerve in parliament) acknowledged that he had given the returning officer and others of the borough for which he was choſen four pounds to be returned member, and was for that premium elected. But for this offence the borough was amerced, the member was removed, and the officer fined and impriſoned. But as this practice hath ſince taken much deeper and more univerſal root, it hath occaſioned the making of theſe wholeſome ſtatutes; to complete the efficacy of which, there is nothing wanting but reſolution and integrity to put them in ſtrict execution.

Undue influence being thus guarded againſt, the election is to be proceeded to on the day appointed; the ſheriff or other returning officer firſt taking an oath againſt bribery, and for the due execution of his office. The candidates likewiſe, if required, muſt ſwear to their qualification, and the electors in counties to theirs; and the electors both in counties and boroughs are alſo compellable to take the oath of abjuration, and that againſt bribery and corruption. And it might not be amiſs, if the members elected were bound to take the latter oath as well as the former; which, in all probability, would be much more effectual than adminiſtering it only to the electors.

The election being cloſed, the returning officer in boroughs returns his precept to the ſheriff, with the perſons elected by the majority: and the ſheriff returns the whole, together with the writ for the county and the knights elected thereupon, to the clerk of the crown in chancery; before the day of meeting, if it be a new parliament, or within 14 days after the election, if it be an occaſional vacancy; and this under penalty of L. 500. If the ſheriff does not return ſuch knights only as are duly elected, he forfeits, by the old ſtatutes of Henry VI. L. 100; and the returning officer in boroughs, for a like falſe return, L. 40; and they are beſides liable to an action, in which double damages ſhall be recovered, by the later ſtatutes of king William: and any perſon bribing the returning officer ſhall alſo forfeit L. 300. But the members returned by him are the ſitting members, until the houſe of commons, upon petition, ſhall adjudge the return to be falſe and illegal. The form and manner of proceeding upon ſuch petition are now regulated by ſtatute 10 Geo. III. c. 16. (amended by 11 Geo. III. c. 42. and made perpetual by 14 Geo. III. c. 15.), which directs the method of chooſing by lot a ſelect committee of 15 members, who are ſworn well and truly to try the ſame, and a true judgment to give, according to the evidence.

*Election of Scots Peers.* See Lords.

*Election of Eccleſiaſtical Perſons.* Elections for the dignities of the church ought to be free, according to the ſtat. 9 Ed. II. cap. 14. If any perſons, that have a voice in elections, take any reward for an election in any church, college, ſchool, &c. the election ſhall be void. And if any perſons of ſuch ſocieties reſign their places to others for reward, they incur a forfeiture of double the ſum; and both the parties are rendered incapable of the place. Stat. 31 Eliz. cap. 6.

*Election of a Verderor of the Foreſt (electione viridariorum foreſtæ)*, in law, a writ that lies for the choice of a verderor, where any of the verderors of the foreſt are dead, or removed from their offices. This writ is directed to the ſheriff, and the verderor is to be elected by the freeholders of the county, in the ſame manner as coroners. New. Nat. Brev. 366.

Election is alſo the ſtate of a perſon who is left to his own free will, to take or do either one thing or another, which he pleaſes. See Liberty.

Election, in theology, ſignifies the choice which God, of his good pleaſure, makes of angels or men, for the objects of mercy and grace.

The election of the Jews was the choice God made of that people to be more immediately attached to his worſhip and ſervice, and for the Meſſiah to be born of them. And thus particular nations were elected to the participation of the outward bleſſings of Chriſtianity.

Election alſo, in the language of ſome divines, ſignifies a predeſtination to grace and glory, and ſometimes to glory only. And it has been enjoined as an article of faith, that predeſtination to grace is gratuitous, merely and ſimply ſo; *gratia, quia gratis data.* But the divines are much divided as to the point, whether election to glory be gratuitous, or whether it ſuppoſes obedience and good works, *i. e.* whether it be before or after the proviſion of our obedience. See Grace, and Reprobation.

ELECTIVE, ſomething that is done, or paſſes, by election. See Elector.

Some benefices are elective, others collative. Municipal offices in England are generally elective; in Spain, venal. Poland is an elective kingdom.

*Elective Attraction.* See *Chemistry-Index.*

ELECTOR, a perſon who has a right to elect or chooſe another to an office, honour, &c. See Election.

Elector is particularly, and by way of eminence, applied to thoſe princes of Germany in whom lies the right of electing the emperor; being all ſovereign princes, and the principal members of the empire.

The electoral college, conſiſting of all the electors of the empire, is the moſt illuſtrious and auguſt body in Europe. Bellarmine and Baronius attribute the inſtitution of it to pope Gregory V. and the emperor Otho III. in the tenth century; of which opinion are the generality of hiſtorians, and particularly the canoniſts: however, the number of electors was unſettled, at leaſt, till the 13th century. In 1356 Charles IV. by the golden bull, fixed the number of electors to ſeven; three eccleſiaſtics, *viz.* the archbiſhops of Mentz, Treves, and Cologne; and four ſeculars, viz. the king of Bohemia, count Palatine of the Rhine, duke of Saxony, and marquis of Brandenburg. In 1648 this order was changed, the duke of Bavaria being put in the place of the count Palatine, who having accepted the crown of Bohemia was outlawed by the emperor;

but being at length reſtored, an eight electorate was erected for the duke of Bavaria. In 1692, a ninth electorate was created, by the emperor Leopold, in favour of the duke of Hanover, of the houſe of Brunſwic Lunenburg.

There is this difference between the ſecular and eccleſiaſtical electors, that the firſt have an active and paſſive voice, that is, may chooſe and be choſen; the laſt, an active only. The three archbiſhops are to be 30 years old, before they can be advanced to the dignity; the ſeculars, 18, before they can perform the office themſelves. Theſe laſt have each their vicars, who officiate in their abſence.

Beſides the power of chooſing an emperor, the electors have alſo that of capitulating with and depoſing him; ſo that, if there be one ſuffrage wanting, a proteſt may be entered againſt the proceedings. By the right of capitulation, they attribute to themſelves great privileges, as making of war, coining, and taking care of the public intereſt and ſecurity of the ſtates; and the emperor promiſes, upon oath, to receive the empire upon theſe conditions.

The electors have precedence of all other princes of the empire, even of cardinals and kings; and are addreſſed under the title of *electoral highneſs*.

Their ſeveral functions are as follow. The elector of Mentz is chancellor of Germany, convokes the ſtates, and gives his vote before any of the reſt. The elector of Cologne is grand chancellor of Italy, and conſecrates the emperor. The elector of Treves is chancellor of the Gauls, and confers impoſition of hands upon the emperor. The count Palatine of the Rhine is great treaſurer of the empire, and preſents the emperor with a globe at his coronation. The elector of Bavaria is great maſter of the imperial palace, and carries the golden apple. The marquis of Brandenburgh is grand chamberlain, and puts the ring on the emperor's finger. The elector of Saxony is grand marſhal, and gives the ſword to the emperor. The king of Bohemia is grand butler, and puts Charlemagne's crown on the emperor's head. Laſtly, the elector of Hanover, now king of Great Britain, is arch-treaſurer, tho' firſt erected under the title of *ſtandard-bearer* of the empire.

ELECTORATE, a term uſed as well to ſignify the dignity of, as the territories belonging to, any of the electors of Germany; ſuch are Bavaria, Saxony, &c. See ELECTOR.

ELECTRIC, derived from ηλεκτρον, "amber," in phyſics, is a term applied to thoſe ſubſtances, in which the electric fluid is capable of being excited, and accumulated without tranſmitting it, and therefore called *non-conductors*. See ELECTRICITY.

# ELECTRICITY,

IN general, ſignifies the operations of a very ſubtile fluid, in moſt caſes inviſible, but which ſometimes becomes the object of our ſight and other ſenſes, diſcovering itſelf to be one of the chief agents employed in producing the phenomena of nature.

## SECT. I. *Definitions of Terms uſed in the Science.*

BEFORE we can enter upon this ſcience with propriety, even ſo far as to give an hiſtory of its riſe and progreſs, it ſeems neceſſary to give ſome explanation of the terms made uſe of by writers on electricity, that the reader may not be embarraſſed with words whoſe meaning he cannot perhaps eaſily comprehend.

1. The foundation of all that is known upon this ſubject, is the difference between electric bodies and ſuch as are not. The former may generally be diſtinguiſhed by their attracting and repelling light ſubſtances, which the latter cannot be made to do. The principal electric bodies are glaſs, amber, ſealing-wax, gum-lac, ſulphur, roſin, &c. They are often called *non-conductors*, or *electrics per ſe*.

2. The uſual way in which the electric power of any body can be diſcovered, is by rubbing it with ſome ſoft ſubſtance, generally woollen, ſilk, or fur; and, according to the ſtrength of the electric virtue, the former body will attract and repel light ſubſtances preſented to it at a greater or leſs diſtance. If the virtue is very ſtrong, the electric body will emit ſparks, or even ſtrong flaſhes of fire, to a conſiderable diſtance. In ſome caſes electricity diſcovers itſelf by heating the body, or blowing air upon it; but in both theſe ways it is much weaker than that produced by rubbing. In whatever way this power is made to ſhow itſelf, the ſubſtance poſſeſſed of it is ſaid to be *excited*.

3. *Conductors*, called alſo *non-electrics*, are ſuch ſubſtances as, though incapable of being excited, can yet in certain circumſtances convey the electric power from one body to another, and that to any imaginable diſtance. The beſt conductors are metals of all kinds, charcoal, and water.

4. Electrics, we have already obſerved, are alſo called *non-conductors*; and this name they have from their power of ſtopping the communication of the electric virtue from one body to another. Thus, though any conductor be placed properly for receiving the virtue from an excited electric, none will paſs to it if any electric ſubſtance be interpoſed; or, if the conductor be terminated by an electric, none will paſs beyond the place where the electric ſubſtance begins.

5. Inſulation is when a conducting ſubſtance is placed upon an electric, ſo that any power communicated to it cannot paſs off. It muſt be remembered, however, that all this is to be underſtood with ſome degree of limitation; for there is no ſubſtance either a perfect electric, or a perfect conductor; the beſt conductors making a ſenſible reſiſtance to the paſſage of the fluid through them when they are very long; and the moſt perfect electrics tranſmitting ſome of the fluid over, or through them. Indeed, though theſe two different kinds of ſubſtances ſeem to be ſo far removed from one another, they in reality approach to a ſurpriſing degree, inſomuch that there are many ſubſtances which can be excited as electrics, and yet have a very conſiderable conducting power.

6. The effects of the electric fluid diſcovering them-

ſelves either by attraction and repulſion, or by emitting ſtreams, or pencils as they are called, of blue light, are all claſſed under the general word *electricity;* and any body to which that power of attraction and repulſion, &c. is communicated, is ſaid to be *electrified*. If its virtue is inherent in itſelf, it is ſaid to be *excited*.

7. Electricity is found to be of two kinds; the one called *negative*, and the other *poſitive*. It is uncertain in what the difference betwixt theſe two conſiſts. Dr Franklin is of opinion that the former conſiſts in a ſuperabundance of the fluid, or when more is thrown upon any ſubſtance than it can conveniently contain; the other, when a part of it is abſtracted, and the body contains leſs than it naturally ought to do. Other theoriſts ſuppoſe, that when the fluid is directed outwards from any ſubſtance, that ſubſtance will in all caſes be electrified poſitively; and that when the fluid is either entering or has a tendency to enter into any ſubſtance, it will then be electrified negatively. This queſtion will be diſcuſſed in the courſe of the treatiſe.—The moſt remarkable differences we can perceive between the poſitive and negative electricities are that they attract each other, though ſtrongly repulſive of themſelves; that is, two bodies poſitively electrified, or negatively electrified, repel each other; but one body poſitively electrified will attract another negatively ſo; and if the electricities are very ſtrong, a ſpark will be obſerved between them at meeting. Theſe electricities are produced naturally by exciting different ſubſtances, or by uſing a different rubber to the ſame ſubſtance. Thus, glaſs uſually produces the poſitive electricity; but by uſing a certain kind of rubber, or altering the ſmoothneſs of its ſurface, it may be made to produce the negative kind. The two electricities are ſometimes called the *vitreous* and *reſinous*, as well as poſitive and negative.

## SECT. II. *Hiſtory of Electricity.*

1
ricity
firſt
ioned.

THOUGH it is certain that, ever ſince the creation of the world, the fluid we ſpeak of hath had the ſame ſhare in all the natural operations that it hath juſt now; yet the diſcovery of its action, and even of its exiſtence, is, comparatively ſpeaking, of a very late date. Thales the Mileſian, who lived about 600 years before Chriſt, was the firſt that obſerved the electrical properties of amber. Of theſe, indeed, he knew no more than that this ſubſtance would attract light bodies when it was rubbed. For 300 years after his time, we hear nothing farther concerning this ſubject. Theophraſtus then tells us, that the *lyncurium* (the ſame ſubſtance now called the *tourmalin)*, has the property of attracting light bodies, as well as amber. From this time, there is a chaſm in the hiſtory of electricity for no leſs than 1900 years. Indeed, it is ſcarce to be ſuppoſed that during this long interval any perſon applied himſelf to the inveſtigation of the ſubject; as, for the greateſt part of it, ſcience of every kind was almoſt totally extinguiſhed. The electrical properties of jet, however, and, according to Mr Boſe, of the agate, were ſome way or other diſcovered during the abovementioned period. But it was not till the beginning of the 17th century, that the ſubject of electricity became properly a diſtinct ſcience, and the foundation was laid of thoſe diſcoveries which have ſince taken place.

2
Diſcoveries of Dr Gilbert.

The firſt who can properly be called an *electrician*, was Dr William Gilbert, who, in the year 1600, wrote a book *de Magnete*, which contains a variety of electrical experiments. All theſe, however, conſidered only the attractive property of certain ſubſtances, which, from their agreement in this reſpect with amber (in Latin *electrum*), were called *electric*. Dr Gilbert's merit conſiſts in his having been at great pains to find out a number of ſuch ſubſtances, and thus conſiderably enlarging the number of electrics.

Till the year 1670, it doth not appear that any farther diſcoveries were made; except ſome trifling additions to the catalogue of electrics. About this time, Mr Boyle applied himſelf to the ſtudy of electricity. He enlarged the catalogue of electrics; and found that their electric properties were increaſed by wiping and warming them before they were rubbed. He obſerved alſo, that all kinds of bodies were attracted promiſcuouſly; and imagined that they were attracted *in vacuo* as well as in air. This laſt poſition, however, is denied by Mr Beccaria; and we ſhall afterwards ſhow that Mr Boyle muſt neceſſarily have been miſtaken. He alſo obſerved the electric light, though only in the inſtance of ſome diamonds.

3
Diſcoveries of Otto Guericke and Sir Iſaac Newton.

Otto Guericke, however, who was cotemporary with Mr Boyle, improved the ſcience much farther. He made uſe of a ſulphur globe, whirled on an axis much in the ſame way with our preſent glaſs globes. Thus he could excite a vaſtly greater power of electricity than any of his predeceſſors, and try all their experiments to much more advantage. He diſcovered electric repulſion; and not only ſaw the electric light more clearly than Mr Boyle, but heard the hiſſing ſound with which it is emitted. He alſo made another remarkable diſcovery, but which has ſince been very generally overlooked; namely, that a feather, when repelled by an excited electric, always keeps the ſame face towards the body which repels it, as the moon does to the earth.

The next diſcovery of any moment was made by Sir Iſaac Newton; who obſerved, that the electric attraction and repulſion penetrated through glaſs; and it is much to be regretted that this accurate philoſopher did not apply himſelf to the ſtudy of electricity with greater aſſiduity.

4
Remarkable diſcovery by Mr Haukſbee.

In 1709, a treatiſe was written on electricity by Mr Haukſbee; who not only far excelled all his predeceſſors and cotemporaries, but alſo made ſome diſcoveries which well deſerve the attention of the moſt expert electricians at this day. Beſides a variety of new experiments made upon electric attraction and repulſion, as well as the light emitted by electric bodies; he found a method of rendering opaque bodies tranſparent by means of electricity. He lined more than half the inſide of a glaſs globe with ſealing-wax; and having exhauſted the globe, he put it in motion; when applying his hand to excite it, he ſaw the ſhape and figure of all the parts of his hand diſtinctly and perfectly, on the concave ſuperficies of the wax within, juſt as if only pure glaſs without any wax at all had been interpoſed between his eye and his hand. The lining of wax, where it was ſpread the thinneſt, would but juſt allow the ſight of a candle through it in the dark; but in ſome places the wax was at leaſt an eighth part of an inch thick. Yet, even in theſe places, the light and figure of his hand were as diſtinguiſhable through it as any where elſe. The ſealing-wax did not adhere to the glaſs in all places; but this made no difference with regard to the tranſparency. Pitch anſwered the purpoſe equally well with ſealing-wax.

M. Haukſbee alſo made a farther improvement, by uſing a glaſs globe, which acts much more powerfully than a ſulphur one. After his death, however, not only the uſe of glaſs globes, but even the ſtudy of electricity itſelf, ſeems to have been pretty generally laid aſide for ſome time. The reaſon of this was, that the recent diſcoveries of Sir Iſaac Newton engroſſed the attention of philoſophers to ſuch a degree, that they had no leiſure for any thing elſe. After the death of that great man, however, the ſcience of electricity began to revive; and, in 1729, a capital diſcovery was made by Mr Stephen Grey. This was the diſtinction between conductors and non-conductors of electricity. As the diſcovery was entirely accidental, and attended with ſeveral curious circumſtances, we ſhall here give ſome account of it. In the month of February 1729, Mr Grey, after ſome fruitleſs attempts to excite an electric power in metals, recollected a ſuſpicion he had for ſome time entertained, that as a glaſs tube, when excited in the dark, communicated its light to various bodies, it might at the ſame time poſſibly communicate to them an electricity; that is, a power of attracting light bodies; which, as yet, was all that was underſtood by the word *electricity*. For this purpoſe he provided himſelf with a glaſs tube, three feet five inches long, and near one inch and two-tenths in diameter. To each end was fitted a cork; to keep the duſt out when the tube was not in uſe. His firſt experiments were made with a view to determine whether the tube would attract equally well with the ends ſhut as with them open. In this reſpect there was no difference; but he found that the corks attracted and repelled light ſubſtances as well, and rather better, than the tube itſelf. He then fixed an ivory ball upon a ſtalk of fir about four inches long, and thruſting the end of the ſtalk into one of the corks, he found the ball endowed with a ſtrong attractive and repulſive virtue. This experiment he repeated in many different ways; fixing the ball upon long ſticks, and upon pieces of braſs and iron wire, always with the ſame ſucceſs; but he conſtantly obſerved, that the ball at the end attracted more vigorouſly than that part of the wire neareſt the tube.

5
Difference
between e-
lectrics and
conductors
diſcovered
by Mr
Grey.

The inconvenience of uſing long wires in this manner, put Mr Grey upon trying whether the ball might be ſuſpended by a pack-thread with a loop on the tube, with equal ſucceſs; and the event fully anſwered his expectation. Having thus ſuſpended bodies of the greateſt length he conveniently could, to his tube, he aſcended a balcony 26 feet high, and faſtening a ſtring to his tube, found that the ball would attract light bodies on the ground below. This experiment ſucceeded in the greateſt heights to which he could aſcend; after which, he attempted to carry the electricity horizontally. His firſt attempt miſcarried, becauſe he ſuſpended his line, which was intended to carry the electricity horizontally, by a pack-thread; and thus the fluid got off from it: but though Mr Grey knew this was the caſe, he could not at any time think of any method to prevent it.

On the 30th of June 1729, Mr Grey paid a viſit to Mr Wheeler, in order to give him a ſpecimen of his experiments; but told him of the unſucceſsful attempt he had made to carry the electric fluid horizontally. Mr Wheeler propoſed to ſuſpend the conducting line by *ſilk* inſtead of *pack-thread*. For this advice he could give no reaſon, but that the ſilk thread was *ſmaller* than the other: however, with it they ſucceeded perfectly well. Their firſt experiment was in a matted gallery at Mr Wheeler's houſe, on the 2d of July 1729. About four feet from the end of the gallery they faſtened a line acroſs the place. The middle of this line was ſilk, the reſt pack-thread. Over the ſilken part they laid one end of the conducting line, to which was faſtened the ivory ball, and which hung down about nine feet below the line ſtretched acroſs the gallery. The conducting line was 80½ feet in length, and the other end of it was faſtened by a loop to the electric tube. Upon rubbing the tube, the ivory ball attracted and repelled light ſubſtances as the tube itſelf would have done. They next contrived to return the line, ſo that the whole length of it amounted to 147 feet; which alſo anſwered pretty well. But, ſuſpecting that the attraction would be ſtronger without doubling or returning the line, they made uſe of one carried ſtraight forward for 124 feet; and, as they expected, found the attraction in this manner ſtronger than when the line had been doubled. Thus they proceeded with their experiments; ſtill adding more conducting line, till at laſt their ſilk-ſtring broke with the weight. This they endeavoured to ſupply, firſt with a ſmall iron-wire, and then with a braſs one. The reſult of theſe experiments, however, ſoon convinced them that the ſilk refuſed to conduct the electric fluid, not on account of its *ſmallneſs*, as they had ſuppoſed, but on account of ſome difference in the matter. The wires were ſmaller than the ſilk-thread, yet the electricity was effectually carried off by them. They had recourſe, therefore, to thicker lines of ſilk; and thus conveyed the electric matter to the diſtance of 765 feet; nor did they perceive the virtue to be at all diminiſhed by the diſtance to which it was carried.

This diſcovery of the non-conducting power of ſilk was quickly followed by a diſcovery of the ſame power in many other ſubſtances: and thus, in fact, the foundation of almoſt all the ſubſequent improvements in electricity was laid; though in the ſciences, as well as in moſt others, few diſcoveries have been made by reaſoning, but many by accident. Mr Grey continued to ſtudy electricity as long as he lived; and has given a ſet of experiments, of which Dr Prieſtley ſays, "It is not eaſy to know what to make of them." He imagined that he had diſcovered in all electric ſubſtances a *perpetual attractive power*, which required no kind of excitation either by heating, rubbing, or any kind of attrition. He took 19 different ſubſtances, which were either roſin, gum-lac, ſhell-lac, bees-wax, ſulphur, pitch, or two or three of theſe differently compounded. Theſe he melted in a ſpherical iron ladle; except the ſulphur, which was beſt done in a glaſs veſſel. When theſe were taken out of the ladle, and their ſpherical ſurface hardened, he ſays they would

6
He dif
vers a
petual
tractiv
power
electri

would not attract till the heat was abated, or till they came to a certain degree of warmth; that there was then a ſmall attraction, which increaſed till the ſubſtance was cold, when it was very conſiderable. The manner in which he kept theſe ſubſtances in a ſtate of attraction was, by wrapping them in any thing which would preſerve them from the external air. At firſt, for the ſmaller bodies he uſed white paper, and for the larger ones white flannel; but afterwards, he found that black worſted ſtockings would do as well. When thus wrapped up, they were put into a large firm box, where they remained till he had occaſion to uſe them. Thus prepared, they retained their attractive virtue for four months. Theſe experiments are ſimilar to ſome others lately made and publiſhed as new diſcoveries.

7
igines can imi- the netary tions.

Some other experiments were made by Mr Grey, with regard to the attraction of electric bodies *in vacuo;* and in this he determined with Mr Boyle againſt the opinion of Mr Beccaria above mentioned. But the moſt remarkable experiments mentioned by Mr Grey, are his imitations of the planetary motions. "I have lately made (ſays he) ſeveral new experiments upon the projectile and pendulous motions of ſmall bodies by electricity; by which ſmall bodies may be made to move about large ones, either in circles or ellipſes; and thoſe either concentric or eccentric to the centre of the large body about which they move, ſo as to make many revolutions about them. And this motion will conſtantly be the ſame way that the planets move about the ſun, viz. from the right hand to the left, or from weſt to eaſt. But theſe little planets, if I may ſo call them, move much faſter in their apogeon than in the perigeon parts of their orbits; which is directly contrary to the motion of the planets about the ſun." The manner in which theſe experiments were made, as delivered by him on his death-bed to Dr Mortimer, was as follows: "Place a ſmall iron globe (ſaid he), of an inch or an inch and an half in diameter, on the middle of a circular cake of roſin, ſeven or eight inches in diameter, gently excited; and then a light body ſuſpended by a very fine thread, five or ſix inches long, held in the hand over the centre of the cake, will, of itſelf, begin to move in a circle round the iron globe, and conſtantly from weſt to eaſt. If the globe is placed at any diſtance from the centre of the circular cake, it will deſcribe an ellipſe, which will have the ſame eccentricity as the diſtance of the globe from the centre of the cake. If the cake of roſin be of an elliptical form, and the iron globe be placed in the centre of it, the light body will deſcribe an elliptical orbit of the ſame eccentricity with the form of the cake. If the globe be placed in or near one of the foci of the elliptical cake, the light body will move much ſwifter in the apogee than in the perigee of its orbit. If the iron globe is fixed on a pedeſtal an inch from the table, and a glaſs hoop, or a portion of a hollow glaſs cylinder excited, be placed round it, the light body will move as in the circumſtances mentioned above, and with the ſame varieties." He ſaid, moreover, that the light body would make the ſame revolutions, only ſmaller, round the iron globe placed on the bare table, without any electrical body to ſupport it: but he acknowledged that he had not found the experiment ſucceed if the thread was ſupported by any thing but a human hand, though he imagined any other animal ſubſtance would have anſwered the purpoſe.

Theſe experiments occaſioned a great deal of ſpeculation. Dr Mortimer was the only perſon who was able to repeat them with ſucceſs, and he only when nobody but himſelf was preſent. It was therefore generally ſuppoſed that both he and Mr Grey had been deceived: but from ſome experiments to be related hereafter, it ſeems probable that the ſucceſs of Mr Grey and Dr Mortimer was owing to their having performed their experiments with candle-light; and the failure of the others, to their having attempted them by day-light. Notwithſtanding which, it is more than probable that Mr Grey has been deceived in a number of particulars; for no motion can be performed by an artificial excitation of the electric fluid, but what is attended with much irregularity.

8
Vitreous and reſinous electricity diſcovered by Mr Du Fay.

Soon after Mr Grey's diſcovery of the difference between conductors and non-conductors of electricity, Mr Du Fay diſcovered the difference between poſitive and negative, or, as they were for ſome time called, the *vitreous* and *reſinous* electricities. This diſcovery was quite accidental. It was made in conſequence of his caſually obſerving, that a piece of leaf-gold, repelled by an excited glaſs tube, and which he meant to chaſe about the room with a piece of excited gum copal, inſtead of being repelled by it as it was by the glaſs tube, it was eagerly attracted. The ſame was the caſe with ſealing-wax, ſulphur, roſin, and a number of other ſubſtances. He diſcovered alſo, that it was impoſſible to excite a tube in which the air was condenſed.

In the year 1742, the uſe of glaſs globes was again introduced by Mr Boſe, profeſſor of philoſophy at Wittemburgh; though ſome attribute this to Chriſtian Auguſtus Hanſen, profeſſor of mathematics at Leipſic. He added alſo a prime conductor, which conſiſted of a tube of iron or tin. It was at firſt ſupported by a man ſtanding upon cakes of roſin; but afterwards ſuſpended by ſilk lines horizontally before the globe. A bundle of thread was put into the end next to the globe, which not only prevented any injury to the glaſs, put rendered the electricity ſtronger.

9
Electrical ſhock diſcovered.

The moſt remarkable diſcovery that hath yet been made in the ſcience of electricity, was in the end of the year 1745, and beginning of 1746. This was the method of giving the electric ſhock, or the accumulation of the power of electricity in a vial. This had its name of the *Leyden vial*, from Mr Cunæus, a native of Lyden, who exhibited it as he was repeating ſome experiments made by Meſſrs Muſchenbroek and Allamand, profeſſors in the univerſity of that city. He was not, however, the inventor. The merit of this diſcovery (if any merit can ariſe from a diſcovery made by accident) belongs to Mr Van Kleiſt, dean of the cathedral at Camin. On the 4th of November 1745, he ſent the following account of it to Dr Leiberkuhn at Berlin: "When a nail, or a piece of thick braſs wire, &c. is put into a ſmall apothecary's vial, and electrified, remarkable effects follow: but the vial muſt be very dry, or warm. I commonly rub it over before-hand with a finger, on which I put ſome pounded chalk. If a little mercury or a few drops of ſpirit of wine are put into it, the experiment ſucceeds the better. As ſoon as this phial and nail are removed from the electrifying glaſs, or the prime conductor to which it hath been expoſed is taken away, it throws out a pencil of flame ſo long, that with this burning machine in my hand, I have taken above 60 ſteps in walking about my room. When it is electrified ſtrongly, I can take it into another room, and there fire ſpirits of wine with it. If while it is electrifying, I put my finger, or a piece of gold which I hold in my hand, to the nail, I receive a ſhock which ſtuns my arms and ſhoulders.

"A tin tube, or a man placed upon electrics, is electrified much ſtronger by this means than in the common way. When I preſent this vial and nail to a tin tube, which I have 15 feet long, nothing but experience can make a perſon believe how ſtrongly it is electrified. Two thin glaſſes have been broken by the ſhock of it."

Soon after this, a method of giving the ſhock was diſcovered in Holland by Mr Cunæus, in the following manner: M. Muſchenbroek and his friends, obſerving that electrified bodies expoſed to the common atmoſphere, which is always replete with conducting particles of various kinds, ſoon loſt their electricity, and were capable of retaining but a ſmall quantity of it; imagined, that, were the electrified bodies terminated on all ſides by original electrics, they might be capable of receiving a ſtronger power and retaining it for a longer time. Glaſs being the moſt convenient electric for this purpoſe, and water the moſt convenient non-electric, they firſt made theſe experiments with water in glaſs bottles: but no conſiderable diſcovery was made, till Mr Cunæus, happening to hold his glaſs veſſel in one hand, and endeavouring to diſengage it from the conductor with the other (when he imagined the water had received as much electricity as the machine could give it), was ſurpriſed with a ſudden ſhock in his arms and breaſt, which he had not in the leaſt expected.

10
Behaviour of different philoſophers on this occaſion.

The diſcovery of ſuch a terrible effect of the electric power immediately raiſed the attention of all the philoſophers in Europe. Many of them greatly exaggerated their accounts; either from a natural timidity, or their love of the marvellous. Mr Muſchenbrock, who tried the experiment with a very thin glaſs bowl, told Mr Reaumur in a letter wrote ſoon after the experiment, That he felt himſelf ſtruck in his arms, ſhoulder, and breaſt, ſo that he loſt his breath; and was two days before he recovered from the effects of the blow and the terror. He added, that he would not take a ſecond ſhock for the whole kingdom of France. Mr Allamand, who made the experiment, with a common beer-glaſs, ſaid, that he loſt his breath for ſome moments; and then felt ſuch an intenſe pain all along his right arm, that he was apprehenſive of bad conſequences, but it ſoon after went off without any inconvenience, &c. Other philoſophers, on the contrary, ſhowed their heroiſm and magnanimity, by receiving a number of electric ſhocks as ſtrong as they could poſſibly make them. Mr Boſe above mentioned, wiſhed that he might die by the electric ſhock, in order to furniſh, by his death, an article for the memoirs of the academy of ſciences at Paris. "But (adds Dr Prieſtley, from whom this account is taken), *it is not given* to every electrician to die in ſo glorious a manner as the juſtly envied Richman."

11
Incredibl powers at-
tributed t
electricity

From the time of this diſcovery, electricity became the general ſubject of converſation. A great number of people all over Europe got their livelihood by going about and ſhowing the phenomena of it; and, at the ſame time, the paſſion for the marvellous ſtrongly diſcovered itſelf in ſome effects of electricity, pretended to be found out in Italy and Germany. It was aſſerted by Signior Pivati at Venice, and after him by Verati at Bologna, Mr Bianchi at Turin, and Mr Winckler at Leipſic, that if odoriferous ſubſtances were confined in glaſs veſſels, and the veſſels excited, the odours and other medicinal virtues would tranſpire through the glaſs, infect the atmoſphere of the conductor, and communicate the virtue to all perſons in contact with it; alſo, that thoſe ſubſtances, held in the hands of perſons electrified, would communicate their virtues to them; ſo that the medicines might be made to operate without being taken into the ſtomach. They even pretended to have wrought many cures by the help of electricity applied in this way. To ſee the wonderful effects of theſe *medicated tubes*, as they were called, Mr Nollet travelled into Italy, where he viſited all the gentlemen who had publiſhed any account of theſe experiments. But tho' he engaged them to repeat their experiments in his preſence, and upon himſelf; and though he made it his buſineſs to get all the information he could concerning them; he returned fully convinced, that in no inſtance had odours been found to tranſpire through the pores of excited glaſs, and that no drugs had ever communicated their virtues to people who had only held them in their hands while they were electrified. He was convinced, however, that by continued electrification without drugs, ſeveral perſons had found conſiderable relief in various diſorders; particularly, that a paralytic perſon had been cured at Geneva, and that one who was deaf of an ear, another who had a violent pain in his head, and a woman with a diſorder in her eyes, had been cured at Bologna; ſo that from this time we may date the introduction of electricity into the medicinal art. See MEDICINE-*Index*.

Another wonderful experiment was the *beatification* of Mr Boze; which other electricians, for a long time, endeavoured to repeat after him, but to no purpoſe. His deſcription of this remarkable experiment was, that if, in electrifying, large globes were employed, and the electrified perſon ſtood upon large cakes of pitch, a lambent flame would by degrees ariſe from the pitch, and ſpread itſelf around his feet; that from thence it would be propagated to his knees and body, till at laſt it aſcended to his head; that then, by continuing the electrification, the perſon's head would be ſurrounded by a glory ſuch as is in ſome meaſure repreſented by painters in their ornamenting the heads of ſaints. Dr Watſon took the utmoſt pains to repeat this experiment. He underwent the operation ſeveral times, and was ſupported during the time of it by ſolid electrics three feet high. Being electrified very ſtrongly, he felt a kind of tingling on the ſkin of his head and in many other parts of his body. The ſenſation reſembled what would ariſe from a vaſt number of inſects crawling over him at the ſame time. He conſtantly obſerved the ſenſation to be the greateſt in thoſe parts of his body which were neareſt to any non-electric; but no light appeared upon his head, though the experiment was ſeveral times made in the dark, and with ſome continuance. At laſt the Doc-

tor

tor wrote to Mr Boze himſelf, and his anſwer ſhowed that the whole had been a trick. Mr Boze acknowledged that he had made uſe of a ſuit of armour, which was decked with many bullions of ſteel, ſome pointed like nails, others like wedges, and ſome pyramidal; and that when the electriſation was very vigorous, the edges of the helmet would dart forth rays ſomething like thoſe which are painted on the heads of ſaints.

The identity of the electrical matter with lightning is a diſcovery that hath been of more practical uſe to mankind than any other. From almoſt the firſt diſcovery of the electric light, and the crackling with which it is emitted, a ſimilarity between it and the phenomena of thunder and lightning had been obſerved. This is taken notice of by Dr Wall, one of the firſt who viewed the electric light in any perfect manner. The Abbé Nollet, Mr Winckler, and others, alſo enumerated many reſemblances between the phenomena of electricity and thoſe of thunder; but they did not think of any method by which their ſuſpicions could be brought to the teſt of experience. This was firſt propoſed by Dr Franklin in 1750. He had before diſcovered the effects of pointed bodies in drawing off the electric matter more powerfully than others. This was ſuggeſted to him by one Mr Thomas Hopkinſon, who electrified an iron ball of three or four inches diameter with a needle faſtened to it, expecting to draw a ſtronger ſpark from the point of it; but was ſurpriſed to find little or none. Dr Franklin, improving on this hint, ſuppoſed that pointed rods of iron, fixed in the air when the atmoſphere was loaded with lightning, might draw from it the matter of the thunder-bolt, without noiſe or danger, into the body of the earth. His account of this ſuppoſition is given by himſelf in the following words. "The electric fluid is attracted by points. We do not know whether this property be in lightning; but ſince they agree in all the particulars in which we can already compare them, it is not improbable, that they agree likewiſe in this; let the experiment be made."

13
is ſuſpi-
on veri-
ed.

This ſuſpicion of Dr Franklin's was verified in 1752, and the diſcovery is perhaps the only one in the whole ſcience that hath not been the reſult of accident. The moſt active perſons were two French gentlemen, Meſſrs Dalibard and Delor. The former prepared his apparatus at Marly la Ville, ſituated five or ſix leagues from Paris; the other at his own houſe, on ſome of the higheſt ground in that capital. Mr Dalibard's machine conſiſted of an iron rod 40 feet long, the lower extremity of which was brought into a centry-box, where the rain could not come; while on the outſide it was faſtened to three wooden poſts by long ſilken ſtrings defended from the rain. This machine happened to be the firſt that was favoured with a viſit of the etherial fire. Mr Dalibard himſelf was not at home; but, in his abſence, he had entruſted the care of his apparatus to one Coiffier a joiner, who had ſerved 14 years among the dragoons, and on whoſe courage and underſtanding he could depend. This artiſan had all the neceſſary inſtructions given him; and was deſired to call ſome of his neighbours, particularly the curate of the pariſh, whenever there ſhould be any appearance of a thunder ſtorm. At length the long expected event arrived. On Wedneſday the 10th of May 1752, between two and three in the afternoon, Coiffier heard a pretty loud clap of thunder. Immediately he ran to the machine, taking with him a phial furniſhed with a braſs wire; and preſenting the wire to the end of the rod, a ſmall ſpark iſſued from it with a ſnap like that which attends a ſpark from an electrified conductor. Stronger ſparks were afterwards drawn in the preſence of the curate and a number of other people. The curate's account of them was, that they were of a blue colour, an inch and an half in length, and ſmelled ſtrongly of ſulphur. In making them, he received a ſtroke on his arm a little below the elbow; but he could not tell whether it came from the braſs wire inſerted into the phial, or from the bar. He did not attend to it at the time; but the pain continuing, he uncovered his arm when he went home in the preſence of Coiffier. A mark was perceived round it, ſuch as might have been made by a blow with the wire on his naked ſkin.

About a month after this, Dr Franklin himſelf had an opportunity of verifying his own hypotheſis. He was waiting for the erection of a ſpire in the city of Philadelphia, not imagining that a pointed rod of a moderate height could anſwer the purpoſe. At laſt it occurred to him, that by means of a common kite he could have a readier acceſs to the higher regions of the atmoſphere than any other way whatever. Preparing, therefore, a large ſilk handkerchief and two croſs ſticks of a proper length on which to extend it, he took the opportunity of the firſt approaching thunder-ſtorm to take a walk into a field where there was a ſhed convenient for his purpoſe. But dreading the ridicule which too commonly attends unſucceſsful attempts in ſcience, he communicated his intention to nobody but his ſon, who aſſiſted him in raiſing the kite. A conſiderable time elapſed before there was any appearence of ſucceſs. One very promiſing cloud had paſſed over the kite without any effect; when, juſt as he was beginning to deſpair, he obſerved ſome looſe threads of the hempen ſtring to ſtand erect and avoid one another, juſt as if they had been ſuſpended by the conductor of a common electrical machine. On this he preſented his knuckle to a key which was faſtened to the ſtring, and thus obtained a very evident electric ſpark. Others ſucceeded even before the ſtring was wet; but when the rain had begun to deſcend, he collected electric fire pretty copiouſly. He had afterwards an inſulated iron rod to draw the lightning into his houſe; and performed almoſt every experiment with real lightning that had before been done with the artificial repreſentations of it by electrical machines.

14
Danger of
making experiments
with lightning.

Thus a new field was opened for philoſophers; but it was ſoon found, that experiments of this kind were not always to be made without danger. This very year, 1752, the Abbe Nollet publiſhed ſome cautions to thoſe who tried experiments on lightning. He had been informed by letters from Florence and Bologna, that ſome people there had received violent ſhocks while they drew ſparks from an iron bar electrified by thunder. One of his correſpondents informed him, that once, as he was endeavouring to faſten a ſmall chain with a copper ball at one of its extremities to a great chain which communicated with the bar at the top of the building, there came a flaſh of lightning which he did not ſee, but which affected the chain with a noiſe like that of wild-fire. The obſerver in-

ſtantly

ſtantly received ſuch a ſhock, that the ball fell out of his hands, and he was ſtruck backwards four or five paces.

15 Profeſſor Richman killed by lightning.

The greateſt inſtance of the danger of theſe experiments, however, was the death of Mr Richman profeſſor at Peterſburgh above-mentioned. This happened on the 6th of Auguſt 1753, as he was making experiments on lightning drawn into his own room. He had provided himſelf with an inſtrument for meaſuring the quantity of electricity communicated to his apparatus; and as he ſtood with his head inclined to it, Mr Solokow an engraver, who was near him, obſerved a globe of blue fire, as big as his fiſt, jump from the inſtrument, which was about a foot diſtant, to Mr Richman's head. The profeſſor was inſtantly dead, and Mr Solokow was alſo much hurt. The latter, however, could give no particular account of the way in which he was affected; for, at the time the profeſſor was ſtruck, there aroſe a ſort of ſteam or vapour, which entirely benumbed him, and made him ſink down to the ground, ſo that he could not even remember to have heard the clap of thunder, which was a very loud one. The globe of fire was attended with an exploſion like that of a piſtol; the inſtrument for meaſuring the electricity (called by the profeſſor an *electrical gnomon*), was broken to pieces, and the fragments thrown about the room. Upon examining the effects of the lightning in the profeſſor's chamber, they found the door-caſe half ſplit through, and the door torn off and thrown into the room. They opened a vein in the body twice, but no blood followed; after which, they endeavoured to recover life by violent friction, but in vain: upon turning the corpſe with the face downwards during the rubbing, an inconſiderable quantity of blood ran out of the mouth. There appeared a red ſpot on the forehead, from which ſpirted ſome drops of blood through the pores, without wounding the ſkin. The ſhoe belonging to the left foot was burſt open, and uncovering the foot at that part, they found a blue mark; from whence it was concluded, that the electric matter having entered at the head, made its way out again at that foot. Upon the body, particularly on the left ſide, were ſeveral red and blue ſpots reſembling leather ſhrunk by being burnt. Many more alſo became viſible over the whole body, and particularly over the back. That upon the forehead changed to a browniſh red, but the hair of the head was not ſinged. In the place where the ſhoe was unripped, the ſtocking was entire; as was the coat every where, the waiſtcoat only being ſinged on the foreflap where it joined the hinder: but there appeared on the back of Mr Solokow's coat long narrow ſtreaks, as if red-hot wires had burned off the nap, and which could not well be accounted for.

When the profeſſor's body was opened next day, the cranium was very entire, having neither fiſſure nor contra-fiſſure: the brain was ſound; but the tranſparent pellicles of the wind-pipe were exceſſively tender, and eaſily rent. There was ſome extravaſated blood in it, as alſo in the cavities below the lungs. Thoſe of the breaſt were quite ſound; but thoſe towards the back of a browniſh black colour, and filled with more of the blood above mentioned. The throat, the glands, and the ſmall inteſtines, were all inflamed. The ſinged leather-coloured ſpots penetrated the ſkin only. In 48 hours the body was ſo much corrupted that they could ſcarce get it into a coffin.

16 Conduc uſed for preſervi houſes.

Since the diſcovery of the identity of lightning and the electric matter, long rods of iron or other metal have been made uſe of with a view to protect buildings from the danger of ſtrokes of lightning. A conſiderable diſpute has been carried on whether theſe rods ought to be pointed or not; but a committee of the royal ſociety have very lately determined it in favour of the former.

For ſome time, the ſcience of electricity ſeems to have been at a ſtand. Numberleſs improvements indeed have been made upon what was before diſcovered, but ſcarce any thing new hath been added. The only thing which can properly be reckoned a new diſcovery is that of the *electrophorus* by Signior Volta an Italian; which on many accounts may be reckoned the moſt ſurpriſing machine hitherto invented.

## SECT. III. *Of the Apparatus neceſſary for exciting Electricity, and communicating it to other Bodies*, &c.

THE inſtruments moſt in uſe for this purpoſe are thoſe called *electrical machines*, of which there have been ſo many different forms, that it would be tedious and difficult to give only a very ſhort deſcription of them all. We ſhall therefore firſt lay down the moſt neceſſary rules for conſtructing electrical machines in general; and then give a particular deſcription of thoſe machines which are moſt generally uſeful, and contain all the improvements hitherto made.

### § 1. *Of the Conſtruction of Electrical Machines.*

*Cavallo Electric*

THE principal parts of the machine are the electric, the moving engine, and the prime conductor, *i. e.* an inſulated conductor, which immediately receives the electricity from the excited electric.

17 What ſ ſtances moſt p per.

Formerly, different kinds of electrics were uſed, as glaſs, roſin, ſulphur, ſealing-wax, &c. Their forms were alſo various, as globes, cylinders, ſpheroids, &c. The reaſon of this variety was, in the firſt place, that it was not then aſcertained what ſubſtance acted moſt powerfully; and ſecondly, in order to produce a poſitive or negative electricity at pleaſure. At preſent ſmooth glaſs only is uſed; for when the machine has an inſulated rubber, the operator may produce poſitive or negative electricity at his pleaſure, without changing the electric. In regard to the form of the glaſs, thoſe commonly uſed at preſent are globes and cylinders. The moſt convenient ſize for a globe, is from nine to twelve inches diameter. They are made with one neck, which is cemented to a ſtrong braſs cap in order to adapt them to a proper frame. The beſt cement for electrical purpoſes is made with two parts of roſin, two of bees-wax, and one of the powder of red ochre. Theſe ingredients are melted, and mixed together in any veſſel over the fire; and afterwards kept for uſe. This kind of cement ſticks very faſt; and is much preferable to roſin only, as it is not ſo brittle, and at the ſame time inſulates equally well. The cylinders are made with two necks; they are uſed to the greateſt advantage without any axis; and their common ſize is from four inches diameter and eight inches long, to

twelve

twelve inches diameter and two feet long, which are perhaps as large as the workmen can conveniently make them. The glaſs generally uſed is the beſt flint; though it is not abſolutely determined which kind of metal is the beſt for electrical globes or cylinders. The thickneſs of the glaſs ſeems immaterial, but perhaps the thinneſt is preferable. It has often happened, that glaſs globes and cylinders, in the act of whirling, have burſt in innumerable pieces with great violence, and with ſome danger to the by-ſtanders. Thoſe accidents are ſuppoſed to happen when the globes or cylinders, after being blown, are ſuddenly cooled. It will therefore be neceſſary to enjoin the workmen to let them paſs gradually from the heat of the glaſs-houſe to the atmoſpherical temperature.

It has been long queſtioned, whether a coating of ſome electric ſubſtance, as roſin, turpentine, &c. on the inſide ſurface of the glaſs, has any effect to increaſe its electrical power; but now it ſeems pretty well determined, that if it does not increaſe the power of a good glaſs globe or cylinder, at leaſt it does conſiderably improve a bad one.

18
Compoſition for coating globes.

The moſt approved compoſition for lining glaſs globes or cylinders, is made with four parts of Venice turpentine, one part of roſin, and one part of bees-wax. This compoſition muſt be boiled for about two hours over a gentle fire, and ſtirred very often: afterwards it is left to cool, and reſerved for uſe. When a globe or cylinder is to be lined with this mixture, a ſufficient quantity of it is to be broken into ſmall pieces, and introduced into the glaſs; then, by holding the glaſs near the fire, the mixture is melted, and equally ſpread over all its internal ſurface to about the thickneſs of a ſixpence. In this operation, care muſt be taken that the glaſs be made hot gradually, and be continually turned, ſo that it may be heated equally in all parts, otherwiſe it is apt to break in the operation.

19
How the machine is to be ſet in motion.

In reſpect to the engine which is to give motion to the electric, multiplying wheels have been generally uſed, which, properly adapted, might give the electric a quick motion, while they are conveniently turned by a winch. The uſual method is, to fix a wheel on one ſide of the frame of the machine, which is turned by a winch, and has a groove round its circumference. Upon the braſs cap of the neck of the glaſs globe, or one of the necks of the cylinder, a pulley is fixed, whoſe diameter is about the third or fourth part of the diameter of the wheel: then a ſtring or ſtrap is put over the wheel and the pulley; and, by theſe means, when the winch is turned, the globe or cylinder makes three or four revolutions for one revolution of the wheel. There is an inconvenience generally attending this conſtruction, which is, that the ſtring is ſometimes ſo very ſlack, that the machine cannot work. To remedy this inconvenience, the wheel ſhould be made moveable with reſpect to the electric, ſo that by means of a ſcrew it might be fixed at the proper diſtance; or elſe the pulley ſhould have ſeveral grooves of different radiuſes on its circumference.

It has been cuſtomary with ſome, to turn the cylinder ſimply with a winch, without any accelerated motion; but that ſeems not ſufficient to produce the greateſt electric power the glaſs is capable of giving; for the globe or cylinder ſhould properly make about ſix revolutions in a ſecond, which is more than can be conveniently done with the winch only. This method, however, on account of its ſimplicity and eaſy conſtruction, ſhould not be diſregarded, and it may be conveniently uſed when no very great power is required.

Inſtead of the pulley and the ſtring as above deſcribed, a wheel and pinion, or a wheel and an endleſs ſcrew, has been alſo uſed. This conſtruction may anſwer tolerably well for ſmall table machines; but it muſt be conſtructed with great nicety; otherwiſe it is apt to make a diſagreeable rattling, and, without frequent oiling, ſoon wears away by the great friction of its parts.

20
Conſtruction of the rubber.

The next thing belonging to the electrical machine neceſſary to be deſcribed, is the rubber which is to excite the electric. The rubber, as it is now made, conſiſts of a cuſhion of red Baſil ſkin ſtuffed with hair or flannel, and faſtened to a piece of wood well rounded at the edges. To this is glued a flap of Perſian black ſilk, which nearly goes over one half of the cylinder. The method of uſing the amalgam is by ſpreading it on a ſeparate piece of leather, and applying it occaſionally to the under part of the cylinder while turning. Thus only a very ſmall part of the amalgam is conſumed, at the ſame time that the glaſs is very ſtrongly excited. The moſt powerful compoſition for exciting an electrical cylinder is found to be an amalgam of mercury and zinc, in the proportion of one part of the former to five of the latter. The mercury ought to be previouſly triturated with ſome melted greaſe or bees-wax, by which means the amalgam will be the finer. The compoſition called *Aurum Moſaicum*, *Aurum muſivum*, or *Moſaic gold* *, will anſwer very near as well, though ſomewhat leſs cleanly and agreeable. The rubber itſelf ſhould be ſupported by a ſpring; by which means it will eaſily ſuit any inequalities that may be on the ſurface of the glaſs; and by a ſcrew, it may be made to preſs more or leſs as occaſion requires. It ſhould likewiſe be inſulated in the moſt perfect manner; as, when inſulation is not required, it may be eaſily taken off by a chain or wire hung upon it, and thus communicate with the earth or with any unelectrified body; but where there is no contrivance for inſulating the rubber, it is impoſſible to perform many of the moſt curious electric experiments. In ſhort, to conſtruct the rubber properly, it muſt be made in ſuch a manner, that the ſide it touches in whirling may be as perfect a conductor as it can be made, in order to ſupply electricity as quick as poſſible; and the oppoſite part ſhould be as perfect a non-conductor as poſſible, in order that none of the fluid accumulated upon the glaſs may return back to the rubber; which has been found to be the caſe when the rubber was not made in a proper manner.

21
Beſt kind of amalgam.

22
How to ſupport and inſulate the rubber.

23
Mr Jones's improvement on the ſpring of the rubber.

Mr William Jones of Holborn, London, inſtrument-maker, has made a conſiderable improvement on this part of electrical machines by a very ſimple contrivance. It conſiſts in a ſpring placed within the rubber itſelf; the action of which is found to be better ſuited for adapting the rubber to the inequalities of the glaſs, than that placed entirely without the rubber. It conſiſts of a piece of flexible iron or braſs, repreſented edgeways by *A* fig. 1.; and it is evident that it acts in a much more parallel and uniform manner than the former,

Plate CLXXIII.

---

* See *Chemiſtry*, nº 1224.

Apparatus

former, which is conſtantly changing the preſſure of the line of contact betwixt the rubber and cylinder while it paſſes from the under to the upper ſide, and thus rendering the effect inconſtant and uncertain.

24
Prime conductor, &c

We come now to conſider the prime conductor, or firſt conductor; which is nothing more than an inſulated conducting ſubſtance, furniſhed with one or more points at one end, in order to collect the electricity immediately from the electric. When the conductor is of a moderate ſize, it is uſual to make it of hollow braſs; but when it is very large, then, on account of the price of the materials, it is made of paſteboard covered with tin-foil or gilt paper. The conductor is generally made cylindrical; but let the form be what it will, it ſhould always be made perfectly free from points or ſharp edges: and if holes are to be made in it, which on many accounts are very convenient, they ſhould be well rounded, and made perfectly ſmooth. Further, that end of the prime conductor which is at the greateſt diſtance from the electric ought to be made larger than the reſt, as the ſtrongeſt exertion of the electric fluid in eſcaping from the conductor is always at that end.

It has been conſtantly obſerved, that the larger the prime conductor is, the longer and denſer ſpark can be drawn from it; and the reaſon of this is, that the quantity of electricity diſcharged in a ſpark, is nearly proportional to the ſize of the conductor: on this account, the prime conductor is now made much larger than what was formerly uſed. Its ſize, however, may be ſo large, that the diſſipation of the electricity from its ſurface, may be greater than what the electric can ſupply; in which caſe, ſo large a conductor would be nothing more than an unwieldy and diſagreeable incumbrance.

Before we quit the electrical machine, it ſhould be obſerved, that, beſides the above-mentioned parts, it is neceſſary to have a ſtrong frame to ſupport the electric, the rubber, and the wheel. The prime conductor ſhould be ſupported by ſtands, with pillars of glaſs or baked wood, and not by ſilk ſtrings, which admit of continual motion. In ſhort, the machine, the prime conductor, and any other apparatus actually uſed, ſhould be made to ſtand as ſteady as poſſible, otherwiſe many inconveniences will ariſe.

Beſides the electrical machine, the electrician ſhould be provided with glaſs tubes of different ſizes, a pretty large ſtick of ſealing-wax, or a glaſs tube covered with ſealing-wax, for the negative electricity. He ſhould, at leaſt, not be without a glaſs tube about three feet long and one inch and a half in diameter. This tube ſhould be cloſed at one end, and at the other end ſhould have fixed a braſs cap with a ſtop-cock; which is uſeful in caſe it ſhould be required to condenſe or rarify the air within the tube.

The beſt rubber for a tube of ſmooth glaſs is the rough ſide of black oiled ſilk, eſpecially when it has ſome amalgam rubbed upon it; but the beſt rubber for a rough glaſs tube, a ſtick of baked wood, ſealing-wax, or ſulphur, is ſoft new flannel.

25
Directions for coating jars, &c.

The inſtruments neceſſary for the accumulation of electricity are coated electrics; among which, glaſs coated with conductors obtains the principal place: on account of its ſtrength, it may be formed into any ſhape, and it will receive a very great charge. The form of the glaſs is immaterial with reſpect to the charge it will contain; its thickneſs only is to be conſidered: for the thinner it is, the more eaſily will it receive the utmoſt charge it can bear; but it is at the ſame time more ſubject to be broken: for this reaſon, therefore, a thin coated jar or plate may be uſed very well by itſelf, and it is very convenient for many experiments; but when large batteries are to be conſtructed, then it is neceſſary to uſe glaſs a little thicker, and care ſhould be taken to have them perfectly well annealed. If a battery is required of no very great power, as containing about eight or nine ſquare feet of coated glaſs, common pint or half-pint phials may be made uſe of. They may be eaſily coated with tin-foil, ſheet-lead, or gilt-paper, on the outſide, and braſs-filings on the inſide: they occupy a ſmall ſpace, and, on account of their thinneſs, hold a very good charge. But when a large battery is required, then theſe phials cannot be uſed, for they break very eaſily; and for that purpoſe, cylindrical glaſs jars of about 15 inches high, and four or five inches in diameter, are the moſt convenient.

Appara

When glaſs plates or jars, having a ſufficiently large opening, are to be coated, the beſt method is to coat them with tin-foil on both ſides, which may be fixed upon the glaſs with varniſh, gum-water, bees-wax, &c. but in caſe the jars have not an aperture large enough to admit the tin-foil, and an inſtrument to adapt it to the ſurface of the glaſs, then braſs-filings, ſuch as are ſold by the pin-makers, may be advantageouſly uſed; and they may be ſtuck on with gum-water, bees-wax, &c. but not with varniſh, for this is apt to be ſet on fire by the diſcharge. Care muſt be taken that the coatings do not come very near the mouth of the jar, for that will cauſe the jar to diſcharge itſelf. If the coating is about two inches below the top, it will in general do very well: but there are ſome kinds of glaſs, eſpecially tinged glaſs, that when coated and charged, have the property of diſcharging themſelves more eaſily than others, even when the coating is five or ſix inches below the edge. There is another ſort of glaſs, like that of which Florence flaſks are made, which, on account of ſome unvitrified particles in its ſubſtance, is not capable of holding the leaſt charge. On theſe accounts, therefore, whenever a great number of jars are to be choſen for a large battery, it is adviſable to try ſome of them firſt, ſo that their quality and power may be aſcertained.

26
Anoth
ſubſtan
capable
anſwer
the pur
of glaſs

Electricians have often endeavoured to find ſome other electric, which might anſwer better than glaſs for this purpoſe, at leaſt be cheaper; but, except Father Beccaria's method, which may be uſed very well, no remarkable diſcovery has been made relating to this point. He took equal quantities of very pure colophonium, and powder of marble ſifted exceedingly fine, and kept them in a hot place a conſiderable time, where they became perfectly free from moiſture: he then mixed them, and melted the compoſition in a proper veſſel over the fire; and, when melted, poured it upon a table, upon which he had previouſly ſtuck a piece of tin-foil, reaching within two or three inches of the edge of the table. This done, he endeavoured with a hot iron to ſpread the mixture all over the table as equally as poſſible, and to the thickneſs of one-tenth of an inch: he afterwards coated it with another piece of tin-foil reaching within about two inches of the edge of the mixture; in ſhort, he coated a plate of this mixture like a plate of glaſs. This coated plate, from what he ſays, ſeems to have had a greater power than a glaſs plate of the ſame dimenſions, even when the weather was not very dry: and if it is not ſubject to break very eaſily by a ſpontaneous diſcharge, it may be very conveniently uſed; for it doth not very readily attract moiſture, and conſequently may hold a charge of electricity better, and longer, than glaſs: beſides, if broken, it may be repaired by a hot iron; but glaſs, when broken, cannot ſo eaſily be repaired.

27
iſchar-ing rod lect- me-rs, &c.

When a jar, a battery, or in general a coated electric, is to be diſcharged, the operator ſhould be provided with an inſtrument called the *diſcharging rod*, which conſiſts of a metal rod ſometimes ſtraight, but more commonly bended in the form of a C: they are made alſo of two joints, ſo as to open like a kind of compaſſes. This rod is furniſhed with metal knobs at its extremities, and has a non-conducting handle, generally of glaſs or baked wood, faſtened to its middle. When the operator is to uſe this inſtrument, he holds it by the handle; and touching one of the coated ſides of the charged electric with one knob, and approaching the other knob to the other coated ſide, or ſome conducting ſubſtance communicating with it, he completes the communication between the two ſides, and diſcharges the electric.

The inſtruments to meaſure the quantity, and aſcertain the quality, of electricity, are commonly called *electrometers*, and they are of four ſorts: 1. The ſingle thread; 2. the cork or pith balls; 3. the quadrant; and, 4. the diſcharging electrometer. The ſecond ſort of electrometer, *i. e.* the cork-ball electrometer, was invented by Mr Canton; the diſcharging electrometer was invented by Mr Lane, and hath been improved by Mr Henley; another on a different principle by Mr Kinnerſley; and the quadrant electrometer, which is of lateſt invention, is a contrivance of Mr Henley.

Beſides the apparatus above deſcribed, there are ſeveral other inſtruments uſeful for various experiments; but theſe will be deſcribed occaſionally. The electrician, however, ought to have by him, not only a ſingle coated jar, a ſingle diſcharging rod, or, in ſhort, only what is neceſſary to perform the common experiments; but he ſhould provide himſelf with ſeveral plates of glaſs, with jars of different ſizes, with a variety of different inſtruments of every kind, and even tools for conſtructing them; in order that he may readily make ſuch new experiments as his curioſity may induce him to try, or that may be publiſhed by other ingenious perſons who are purſuing their reſearches in this branch of philoſophy.

### § 2. *Deſcription of the moſt uſeful Electrical Machines.*

28
ſcription Doctor eſtley's chine.

2.

The firſt which may be mentioned is that deſcribed by Dr Prieſtley in his hiſtory of electricity; which, on account of its extenſive uſe, may be deſervedly called a *univerſal electrical machine*.—The baſis conſiſts of two oblong boards *a a*, which are placed in a ſituation parallel to one another, about four inches aſunder, and kept in that poſition by two pieces of wood adapted for the purpoſe. Theſe boards, when ſet horizontally on a table, and the lowermoſt of them fixed with iron cramps, form the ſupport of two perpendicular pillars of baked wood, and of the rubber of the machine. One of the pillars, together with the ſpring ſupporting the rubber, ſlides in a groove *a*, which reaches almoſt the whole length of the upper board; and, by means of a ſcrew, may be placed at any required diſtance from the pillar *b*, which is fixed, being put through a mortice in the upper board, and faſtened to the lower. In theſe two pillars are ſeveral holes for the admittance of the ſpindles of different globes; and as they may be ſituated at any diſtance from one another, they may be adapted to receive not only globes, but cylinders and ſpheroids of different ſizes. "In this machine (ſays Dr Prieſtley), more than one globe or cylinder may be uſed at once, by fixing one above the other in the different holes of the pillars; and by adapting to each a proper pulley, they may be whirled all at once, to increaſe the electricity." But this conſtruction has one capital defect, that rubbers cannot be conveniently applied; ſo that the power of ſeveral globes put together in this manner, though greater than one, is by no means equal to what it would be if the power of them all taken ſingly were united. Fig. 3. ſhows a machine of this kind contrived by Dr Watſon.

29
Several globes may be made to unite their power in this machine.

The rubber ought to be made as above directed. It is ſupported by a ſocket which receives the cylindrical axis of a round and flat piece of glaſs or baked wood *g*, the oppoſite part of which is inſerted into the ſocket of a bent ſteel ſpring *h*. Theſe parts are eaſily ſeparated, ſo that the rubber, or the piece of wood that ſerves to inſulate it, may be changed at pleaſure. The ſpring admits of a twofold alteration of poſition; being capable of either ſlipping along the groove, or moving in the contrary direction, the groove being wider than the ſcrew that faſtens the ſpring, ſo as to give it every deſirable poſition with regard to the globe or cylinder; and it is beſides furniſhed with a ſcrew which makes it preſs harder or lighter as the operator chooſes. The wheel of this machine is fixed to the table at *e*, and has ſeveral grooves for admitting more ſtrings than one, in caſe that two or three globes or cylinders are uſed at a time; and as it is diſengaged from the frame of the machine, the latter may be ſcrewed at different diſtances from the former, and ſo would be ſuited to the variable length of the ſtring. The chain connected with the rubber at *n* is for making a communication with the table, when inſulation is not wanted. The prime conductor is made of copper, hollow, and in the form of a pear; having its neck placed upwards, and its bottom, or rounded part *k*, placed on a ſtand of glaſs or baked wood. An arched wire *l* proceeds from its neck, having an open ring at its end, in which ſome ſmall pointed wires *m* are hung, that by playing lightly on the globe or cylinder collect the electric fluid from it.

30
Of Dr Ingenhouſz's

Next to Dr Prieſtley's machine is one invented by Dr Ingenhouſz, and which for its ſimplicity and conciſeneſs makes a fine contraſt with the former.—This machine conſiſts of a circular glaſs-plate about one foot diameter, which is turned vertically by a winch fixed to the iron axis that paſſes through its middle; and it is rubbed by four cuſhions, each about two inches long, ſituated at the oppoſite ends of the vertical diameter. The frame conſiſts of a bottom board, about a foot ſquare, or a foot long and ſix inches broad, which, when the machine is to be uſed, may be faſtened by an iron crank to the table. Upon this board two other ſlender and ſmaller ones are raiſed, which lie parallel to one another, and are faſtened together at their top by a ſmall piece of wood. Theſe upright boards ſupport in their middle the axis of the plate, and to them the rubbers are faſtened. The conductor is of hollow braſs; and from its extremities branches are extended, which, coming very near the extremity of the glaſs, collect the electricity from it.

The power of this machine is perhaps more than a perſon would imagine by looking at it. It may be objected, that this conſtruction will not eaſily admit of the rubbers being inſulated, nor conſequently be adapted to a great variety of experiments: but at the ſame time it muſt be allowed, that it is very portable, that it is not very liable to be out of order, and that it has a power ſufficiently ſtrong for phyſical purpoſes; on which account it may be conveniently uſed.

31
Mr Reid's portable machine.

Fig. 4. repreſents a very portable electrical machine invented by Mr Read, and improved by Mr Lane. *A* is the glaſs cylinder, moved vertically by means of the pulley at the lower end of the axis. This pulley is turned by a large wheel *B* which lies parallel to the table. There are three pulleys of different dimenſions marked in the figure; one of which revolves four times for every revolution of the large wheel *B*. The conductor *C* is furniſhed with points to collect the fluid, and is ſcrewed to the wire of a coated jar *D*, which ſtands in a ſocket between the cylinder and the wheel. The figure alſo repreſents the manner of applying Mr Lane's electrometer to this machine; of which an account ſhall be given afterwards.

Electrical machines have of late years undergone ſome very eſſential alterations and improvements; both from the ſuggeſtions of private electricians and the inventions of Meſſrs Adams, Nairne, and Jones, inſtrument makers of London. We ſhall ſubjoin a deſcription of the moſt approved ones.

32
A machine proper for philoſophical purpoſes.

Fig. 5. repreſents a moſt convenient machine for philoſophical purpoſes, and whoſe power is equal to that of much larger ones of the old conſtruction. The frame of this machine conſiſts of the bottom board *A B C D*; which, when the machine is to be uſed, muſt be faſtened to the table by two braſs or iron cramps made for that purpoſe. Upon the bottom board there are two round pillars *E F* perpendicularly raiſed; which will beſt anſwer the purpoſe if made of baked wood. Theſe ſerve to ſupport the cylinder *G* by the axles of the braſs or wood caps *H*. From one of theſe proceeds the long axle *H*, going through an hole in the pillar *F*; having a ſimple winch *I* fixed on its ſquare end; or ſometimes, as in fig. 6. below a pulley *I*. On the circumference of this pulley are ſeveral grooves in order to ſuit the variable length of the ſtring *a*, which goes round one of them, as well as round the large multiplying wheel *A*. The other cap of the cylinder has a ſmall cavity which fits the conical extremity of a ſtrong ſcrew proceeding from the pillar. The wheel *A*, which is moved by the handle, turns round a ſtrong axle proceeding from about the middle of the ſame pillar. In ſmall machines the ſimple winch may be adopted with great advantage, as is repreſented fig. 5. as not being liable to diſorder; but in large ones the multiplying wheel is indiſpenſibly neceſſary.

Fig. 6.

In all theſe machines the rubber is compoſed of a cuſhion ſtuffed with horſe-hair or flannel, faſtened to a board behind. It is covered with red Baſil leather; and from its under edge a piece of black Perſian ſilk is glued, which goes over the cylinder as at *a*, fig. 5. to near the points of the collector fixed in the conductor. Thus a greater power of electricity is excited than what could have been done by the former machines. In them a piece of leather was faſtened to the lower edge of the cuſhion, bearing againſt the cuſhion itſelf. To this piece of leather another of oiled ſilk was ſewed, covering the cylinder as above deſcribed. In this way ſome of the amalgam above deſcribed was to be laid upon the piece of leather, and worked into its ſubſtance as much as poſſible; but in the preſent method nothing more is neceſſary than to hold an amalgamated piece of leather once or twice to the cylinder while turning. The rubber is fixed to a glaſs pillar *K* (fig. 5.) which is faſtened into a wooden baſis *L* at the bottom. This turns on an hinge; and by means of a ſcrew at *M*, going through the baſis to a fixed block on the frame, the preſſure of the cuſhion may be augmented or diminiſhed at pleaſure; at the ſame time that it is rendered much more ſteady and uniform than by a flat ſliding board and tightening ſcrew as formerly uſed.

The glaſs pillar *K*, as well as all other glaſs pillars, the glaſs feet of inſulating ſtools, &c. ſhould be covered with varniſh or rather ſealing-wax; otherwiſe they will inſulate very imperfectly on account of the moiſture they attract from the air in damp weather. It was uſual to ſupport the rubber upon two ſprings ſcrewed to its back, and which proceeded from the wooden cap of the pillar, in order to give way to and ſuit the inequalities of the glaſs; but by this contrivance the line of contact with the cylinder was not always the ſame, nor its preſſure uniform, as already obſerved: but Mr William Jones has removed this difficulty by the bent ſpring repreſented fig. 1. It is fixed by a ſcrew at *B*, and gives way by ſliding notches at *a a*: its length and breadth are equal to that of the cuſhion, and its thickneſs proportional to the diameter and action of the cylinder upon it. In the machine above deſcribed, the rubber is well inſulated, which is a great advantage when it is neceſſary to connect with the cuſhion a conductor, called the *negative conductor*; and when this happens not to be the caſe, which it uſually is in making the common experiments, a chain with a ſmall hook and ring may be hung to one end of the conductor, the other falling upon the table as in fig. 5.

The prime conductor belonging to this machine is repreſented by *N* in the ſame figure. It receives the electric fluid from the cylinder, and is uſually made of braſs or tin japanned. It is inſulated by the glaſs pillar that ſupports it, and which is ſcrewed into a wooden baſis or foot. It is found more convenient to place the conductor parallel to the cylinder than with one of its ends towards it as was formerly done.

The handle of the wheel *A*, fig. 6. or the ſimple winch *I*, fig. 5. ſhould be ſo turned, that the excited part of the cylinder may revolve from the rubber to the collecting points on the conductor; the prime conductor, ſtanding then as in the figures, will be electrified poſitively, or overcharged with the electric fluid: for by the action of rubbing, the cylinder pumps, as it were, the fluid from the rubber, and every other body properly connected with it, and gives it to the

prime conductor. But if negative electricity be required, the chain muſt be removed from the rubber, and hung to the prime productor: for in this caſe, the electricity of the prime conductor will be communicated to the ground, and the rubber remaining inſulated will appear ſtrongly negative. If another conductor, equal in ſize to *N*, be connected with the rubber, as ſtrong negative electricity may be obtained from the one as poſitive electricity from the other.

33
Medical apparatus.

Fig. 6. repreſents an electrical machine with a conductor in the ſhape of a *T*; and an improved medical apparatus, where it is neceſſary to give the ſhock in the arms, will be more particularly explained afterwards, under the article *Medical Electricity*.

34
Mr Nairne's patent machine.

Fig. 7. ſhows Mr Nairne's patent electrical machine for medical purpoſes. Its principal parts are the glaſs cylinder, generally about 7 inches in diameter and 12 in length, with the two conductors parallel to it. It is furniſhed with wooden caps, and turns in two wooden pieces cemented on the top of two ſtrong glaſs pillars *EB*. Theſe pillars are made faſt into the bottom board of the machine, which is faſtened to the table by means of a crank. There are grooves made in the under part of the bottom of the crank, through which the pieces *FF* ſlide. On theſe pieces the pillars ſtand by which the two conductors are ſupported; and in order to place theſe conductors nearer to the cylinder, or remove them farther from it, the pieces on which they ſtand are moveable outwards or inwards, and may be fixed by the two ſcrew-nuts *LL*. The rubber is faſtened to the conductor *R*; and conſiſts of a cuſhion of leather ſtuffed, having a piece of ſilk glued to its under part. This laſt being turned over the ſurface of the cuſhion, and thus interpoſed between it and the glaſs, goes over the cylinder, and almoſt touches the pointed wires which are fixed on the other conductors for the purpoſe of collecting the electric fluid from the cylinder. The conductors are of tin covered with black lacker, each of them containing a large coated glaſs jar, and likewiſe a ſmaller one, or a coated tube, which are viſible when the caps *NN* are removed. To each conductor is fixed a knob *O*, for the occaſional ſuſpenſion of a chain to produce poſitive or negative electricity. That part of the winch *C* which acts as a lever in turning the cylinder, is of glaſs. Thus every part of the machine is inſulated, the cylinder itſelf and its braſs caps not excepted; by which means the leaſt quantity poſſible of electric fluid is diſſipated, and hence of courſe the effects are likely to be the more powerful. And to this the inventor has adapted ſome flexible conducting joints, a diſcharging electrometer, and other utenſils neceſſary for the practice of medical electricity.

35
Great machine at Teyler's muſeum.

To theſe deſcriptions of electrical machines, we ſhall add that of a very large and powerful one in Teyler's Muſeum at Haarlem, and which was conſtructed by one Mr John Cuthbertſon, an Engliſh mathematical inſtrument-maker. It conſiſts of two circular plates of glaſs, each 65 inches in diameter, and made to turn upon the ſame horizontal axis, at the diſtance of 7½ inches from one another. Theſe plates are excited by eight rubbers, each 15½ inches long. Both ſides of the plates are covered with a reſinous ſubſtance to the diſtance of 16½ inches from the centre, both to render the plates ſtronger, and likewiſe to prevent any of the electricity from being carried off by the axis. The prime conductor conſiſts of ſeveral pieces, and is ſupported by three glaſs pillars 57 inches in length. The plates are made of French glaſs, as this is found to produce the greateſt quantity of the electricity next to Engliſh flint, which could not be produced of ſufficient ſize. The conductor is divided into branches which enter between the plates, but collect the fluid by means of points only from one ſide of the plate. The force of two men is required to work this machine; but when it is required to be put in action for any length of time, four are neceſſary. At its firſt conſtruction nine batteries were applied to it, each having 15 jars, every one of which contained about a foot ſquare of coated glaſs; ſo that the grand battery formed by the combination of all theſe contained 135 ſquare feet. The effects of this machine were aſtoniſhing, as ſhall be mentioned in its proper place: but Dr Van Marum, who principally made experiments with it, imagining that it was ſtill capable of charging an additional quantity of coated glaſs, afterwards added to it 90 jars of the ſame ſize with the former; ſo that it now contains a coated ſurface of 225 feet, and the effects are found to be proportionable.

We come now to deſcribe ſome of the other parts of an electrical apparatus, and which, though not eſſentially neceſſary for exciting the property called *electricity*, are abſolutely ſo for communicating it from one body to another, and performing many experiments which the machines themſelves, however powerful, could not accompliſh. Of theſe, the firſt we ſhall deſcribe is that called the *diſcharger*; by which the electricity, whether poſitive or negative, collected upon one body, may be ſuddenly transferred from it to another; which is called *diſcharging* the electricity of the former, if only one body be perceptibly electrified; or of both, if the one contain poſitive and the other negative electricity.

36
Diſcharger of electricity deſcribed.

Plate CLXXIV.

Fig. 8. repreſents Mr Henley's univerſal diſcharger; an inſtrument of very extenſive uſe in forming communications between jars or directing the ſhock through any particular ſubſtance. *AB* is a flat board 15 inches long, 4 broad, and 1 thick, and forming the baſis of the inſtrument. *DC* are two glaſs pillars cemented in two holes upon the board *AB*, and furniſhed at their tops with braſs caps; each of which has a turning joint, and ſupports a ſpring tube, through which the wires *EF* and *ET* ſlide. Each of theſe caps is compoſed of three pieces of braſs, connected with each other in ſuch a manner, that the wire *EF*, beſides its ſliding through the ſocket, has two other motions, viz. an horizontal one and a vertical one. Each of the wires is furniſhed with an open ring at one end, and at the other has a braſs ball; which, by a ſhort ſpring ſocket, is ſlipped upon its pointed extremity, and may be removed from it at pleaſure. *HG* is a ſtrong circular piece of wood five inches diameter, having a ſlip of ivory inlaid on its ſurface, and furniſhed with a ſtrong cylindric foot, which fits the cavity of the ſocket *I*. This ſocket is fixed in the middle of the bottom board, and has a ſcrew at *K*; by which the foot of the circular board is made faſt at any required height.

Fig. 9. is a ſmall preſs belonging to this inſtrument. It conſiſts of two oblong pieces of wood,

which are forced together by the two ſcrews *aa*. The lower end has a cylindrical foot equal to that of the circular table *H*. When this preſs is to be uſed, it muſt be fixed into the ſocket *I*, in place of the circular board *HG*; which in that caſe is to be removed.

37 Electrical jar or Leyden phial

Fig. 10. ſhows an electrical jar or Leyden vial, for the purpoſes chiefly of giving a ſhock, or of accumulating a quantity of electricity in ſuch a manner as could not be done in any other way, without uſing an immenſe extent of electrified ſurface. It is coated on the inſide with tin-foil to the height of about three inches below the top of the cylindrical part of the glaſs; and having a wire with a round braſs knob at its extremity, which paſſes through the middle of a piece of wood *D*, is uſed as a ſtopper for the bottle. Its lower end is uſually connected with the inſide coating by means of a piece of chain or ſlender wire.

38 Electrical battery

Fig. 11 ſhows the moſt approved conſtruction of an *electrical battery;* a part of the apparatus which takes its name from its conſtruction and formidable effects. It conſiſts of a number of coated jars, placed in ſuch a manner that they may all be charged at the ſame time, and diſcharged in an inſtant; ſo that the whole power of electricity accumulated in them may be at once exerted upon the ſubſtance expoſed to the ſhock. The battery repreſented in the figure conſiſts of nine jars connected together by the wires *a, b, c, d, e, f, g, h, i;* all of which are faſtened into the wood-ſtoppers of the bottles, and meet at top in the braſs ball. Thus a communication is made between all the inſide coatings of the jars, while their outſide coatings are connected by the bottom of the box on which they ſtand; and which, that it may conduct the better, is covered with tin foil. In one ſide of the box near the bottom is an hole through which a braſs hook paſſes, and which communicates with the metallic lining of the box, and conſequently with the outſide coating of the jars. To this hook a wire or chain is occaſionally connected when a diſcharge is made; and for the more convenient making of this diſcharge, a ball and wire *B* proceed to a convenient length from the centre ball *A*. When the whole force of the battery is not required, one, two, or three jars may be removed only by preſſing down the wires belonging to them, until their extremities can ſlip out of their reſpective holes in the braſs ball, and then turning them into ſuch a poſture that they cannot have any communication with the battery. The number of jars repreſented in this figure is rather ſmall for ſome purpoſes; but it is better to join two or three ſmall batteries together rather than have a ſingle large one, which is inconvenient on account of its weight and unwieldineſs.

The conſtruction of jars and batteries is part of the buſineſs of an electrician; and he ought to be expert in coating the vials himſelf, not only becauſe of the expence attending the employment of others, but becauſe he may ſometimes be at too great a diſtance from workmen who are accuſtomed to operations of this kind. A conſiderable difficulty ariſes with reſpect to the ſize of the jars and the kind of glaſs they are to be made of. Fine flint or cryſtal glaſs may probably be made uſe of with greater advantage than any other; but the expence here becomes a very conſiderable object, eſpecially as the jars of a battery are very apt to break by reaſon of the inequality of their ſtrength; for it would ſeem that the force of the fluid in a battery is equally diſtributed among all the bottles, without any regard to their capacities of receiving a charge ſingly conſidered. Thus, if we expreſs the quantity of charge which one jar can eaſily receive by the number 10, we ought not to combine ſuch a jar in a battery with another whoſe capacity is only 8; becauſe the whole force of electricity expreſſed by 10 will be directed alſo againſt that whoſe capacity is only 8; ſo that the latter will be in danger of being broken. It will be proper, therefore, to compare the bottles with one another in this reſpect before putting them together in a battery. Beſides the conſideration of the abſolute capacity which each bottle has of receiving a charge, the time which is taken up in charging it muſt alſo be attended to; and the jars of a battery ought to be as equal as poſſible in this reſpect as well as in the former. The thinner a glaſs is, the more readily it receives a charge, and *vice verſa;* but it doth not follow from thence, as electricians in general imagined till lately, that, on account of its thinneſs, it is capable of containing a greater charge than a thicker one. The reverſe is actually the caſe: and though a thick glaſs cannot be charged in ſuch a ſhort time as a thin one, it is nevertheleſs capable of containing a greater power of electricity. If the thickneſs of the glaſs be very great, no charge can indeed be given it; but experiments have not yet determined how great the thickneſs muſt be which will prevent any charge. Indeed it is obſerved, that though a thick glaſs cannot be charged by a weak electric machine, it may be ſo by a more powerful one; whence it ſeems reaſonable to ſuppoſe that there is no real limit of this kind; but that if machines could be made ſufficiently powerful, glaſſes of any thickneſs might be charged.

39 Why the jars of a battery are ſometimes apt to break.

40 Mr Brookes's method of conſtructing batteries.

Mr Brookes, an ingenious electrician of Norwich, conſtructed his batteries, which appear to have been very powerful, of green-glaſs bottles. Some of them, like that repreſented in the figure, had only nine of theſe bottles; but when a greater power was wanted, more were added. Jars would have been preferred to bottles on account of their being more eaſily coated by reaſon of their wide mouths; but being leſs eaſily procured, he was content to put up with this inconvenience. The mean ſize of theſe bottles was about eight inches in diameter; they were coated 10 inches high, and made of the thickeſt and ſtrongeſt glaſs that could be procured, weighing from five pounds and an half to ſeven pounds each. In the conſtruction of a battery of 27 bottles, he diſpoſed of them in three rows; nine of the ſtouteſt and beſt compoſing the firſt row, nine of the next in ſtrength being diſpoſed of in the ſecond, and the third containing the nine weakeſt. All of theſe were of green glaſs, but not of the ſame kind. Some which ſtood in the foremoſt row were compoſed of a kind very like that of which Frontiniac wine-bottles are made: and our author remarks, that this kind of glaſs ſeems to be by much the beſt, as being both harder and ſtronger, and leſs liable to break by an high charge. The ſecond and third rows of the battery conſiſted of bottles whoſe diameter was from ſix and an half to ten inches, and which were coated from eight and an half to eleven inches high; none of their mouths being larger than an pparatus

41

ottles
hen bro-
en by a
ſcharge.

an inch and an half, nor leſs than three quarters of an inch. In caſe any of the bottles being broken by the diſcharge of the battery, Mr Brookes found that it could be mended in ſuch a manner as to become ſerviceable by a cement made according to the following receipt: "Take of Spaniſh-white eight ounces; heat it very hot in an iron ladle, to evaporate all the moiſture; and when cool, ſift it through a lawn ſieve: add three ounces of pitch, three quarters of an ounce of roſin, and half an ounce of bees-wax: heat them all together over a gentle fire, ſtirring the whole frequently for near an hour; then take it off the fire, and continue the ſtirring till it is cold and fit for uſe." The bottles cemented with this compoſition, however, were not judged to be ſufficiently ſtrong to ſtand in their original place, but were removed to the ſecond or third row, as it was apprehended they could beſt ſuſtain the charge. All the bottles of this battery, as well as the ſingle ones he commonly made uſe of in his experiments, were coated both on the inſide and outſide with ſlips of tin-foil from three-eighths to three-fourths of an inch wide, laid on with paſte of flour and water, at the diſtance of about the breadth of a ſlip between each.

Fig. 12. repreſents the inſulating ſtool, a very uſeful part of the apparatus, eſpecially for medical purpoſes, where it is often neceſſary to inſulate the human body. In theſe caſes it is proper to have it of a magnitude ſufficient to hold a chair or other ſeat, on which the patient may ſit during the operation. The ſtool itſelf may be conveniently conſtructed of a mahogany board with glaſs feet varniſhed, as already directed. When in uſe, the inſulation will be the more perfect that a piece of dry paper be put upon it.

Theſe are the parts of the electrical apparatus eſſentially neceſſary for exhibiting the ordinary experiments; but as many very curious phenomena are to be obſerved in different ſubſtances, without uſing any part of the apparatus above deſcribed, we ſhall next proceed to give an account of thoſe bodies which naturally exhibit ſigns of electricity, with the various phenomena attending them.

## SECT. IV. *A Catalogue of the different Electric Subſtances, with the general Phenomena attending their Excitation.*

THE liſt of ſubſtances by which electric phenomena may be produced, is ſo very extenſive, that it may perhaps be doubted whether all terreſtrial matters, metals and charcoal only excepted, may not be included in the number. Some, however, have the property much more, or exhibit particular phenomena more obviouſly, than others; and according to this we may divide them into claſſes, as ſhall afterwards be more particularly noticed. The following catalogues enumerate thoſe in which the property in general has been diſcovered.

Phenomena.

| Electric ſubſtances. | Quality of electricity. | Subſtances with which the electric is rubbed |
|---|---|---|
| The back of a cat. | Poſitive | Every ſubſtance hitherto tried. |
| Smooth glaſs | Poſitive | Every ſubſtance, except the back of a cat. |
| Rough glaſs | Poſitive | Dry oiled ſilk, ſulphur, or metals. |
| | Negative | Woollen-cloth, quills, wood, paper, ſealing-wax, white-wax, the human hand. |
| Tourmalin | Poſitive | Amber, or air blown upon it. |
| | Negative | Diamond, the human hand. |
| Hare's ſkin | Poſitive | Metals, ſilk, loadſtone, leather, hand, paper, baked wood. |
| | Negative | Other finer furs. |
| Black ſilk | Poſitive | Sealing-wax. |
| | Negative | Hare's, weaſel's, and ferret's ſkin, loadſtone, braſs, ſilver, iron, hand. |
| White ſilk | Poſitive | Black ſilk, metals, black cloth. |
| | Negative | Paper, hand, hare's, weaſel's ſkin. |
| Sealing-wax | Poſitive | Metals. |
| | Negative | Hare's, weaſel's, and ferret's ſkin, hand, leather, woollen-cloth, paper. |
| Baked wood | Poſitive | Silk. |
| | Negative | Flannel. |

*Phil. Tranſ.*
Vol. lxvii.
Part 1.

This table contains moſt of thoſe ſubſtances that exhibit the ſtrongeſt marks of electricity. The following is compoſed by Mr Henley, and contains a great number of ſubſtances whoſe electricity is much more equivocal. They were fixed or tied on the end of a ſtick of ſealing-wax; and excited by friction againſt a woollen garment, or a piece of ſoft black ſilk, by which means they became electrified as below. The ſtrongeſt in power are diſtinguiſhed by the letter s, and the weakeſt by the letter w.

### METALS.

| | Wool. | Silk. |
|---|---|---|
| A new guinea; a ſmooth ſixpence; a braſs ferule; tin, and tin-foil; enamelled copper, s; gilding on leather, s; lead ore; copper ore; iron ore; ſtream tin. | Neg. | Neg. |
| Milled lead; copper, s; a poliſhed ſteel button, s; a new ſilver ditto; a metal button gilt, s; tutenague ditto, s; iron. | Poſ. | Poſ. |
| Lead from a tea-cheſt, in which there is a mixture of tin, w. | Neg. | Poſ. |
| A gilt button, baſket-pattern; the juncture at the end of a braſs ferule. | Poſ. | Neg. |

### ANIMAL SUBSTANCES.

Tortoiſe-ſhell, w; ivory, s; bone, s; horn; lamb's-tooth; horſe's-hoof; deer's-hoof; muſcle of the leg of a deer, s; cartilage, s; ſpur of a young cock; bill, claw, and ſcale from the leg of

| | Wool. | Silk. |
|---|---|---|
| of a turkey, s; ſcale of a carp; the *chryſalis* of a moth, recent from the earth, cleanſed; *craſſamentum* of the human blood exſiccated, w; quills; claw of an unboiled lobſter; cowrie and ſeveral other ſmooth ſhells, s; ſhell of a hen's egg; tail of a ſmall fiſh; thigh of the elephant beetle; a ſmall beetle, ſmooth ſurface; human hair; red and white horſe's and bullock's hair, s; hog's briſtles, s; wool; ſilk from the worm, w; oyſter-ſhell, ſmooth ſurface; | Poſ. | Poſ. |
| Mother of pearl, and ſeveral other ſhells. | Neg. | Poſ. |
| Muſcle and cockle-ſhells, recent; a recent ſnail-ſhell, rough ſurface; *elytra* of the ſtag-beetle; oyſter-ſhell, rough ſurface. | Neg. | Neg. |
| **Vegetables.** | | |
| Rind of cheſtnut, s; Barcelona nut-ſhell, s; caſhew nut, s; cocoa nut-ſhell poliſhed; Brazil; *lignum vitæ;* black ebony, s; box, w; cane, s; *quinquina*, or Peruvian bark, s; tamarind ſtone; coffee-berry roaſted, s; nutmeg, s; ginger, s; white pepper, freed from the huſk, s; cinnamon, s; cloves, s; mace, s; all-ſpice, s; capſicum, both ſides of the pod, s; hemlock, s; a clove of garlic; ditto of eſchalot, freed from the huſk, s; a green onion, s; rue, s; cork, s; leaves of laurel, bay, yew, holly, roſemary, with their berries, s; parſley, s; leaf of turnip; ditto of Savoy cabbage, s; celery, s; ſago, s; thime, s; carrot; turnip; potato; an acorn, s; rind of Seville orange, s; a large Windſor bean, s; a white pea; root of the white lily; ſnow-drop root; ſeeds of gourd, melon, cucumber, w; a ſpecies of long moſs, w; an apple, s; down of the cotton-ruſh, w; ſea flag; leaf of the American aloe, s; cotton, w. | Neg. | Neg. |
| Hemp; flax; ſtalk of the tobacco-leaf: ſpike, from the leaf of the American aloe; *palma-chriſti* nut; horſe-radiſh. | Neg. | Poſ. |
| A white kidney-bean, ſmooth ſurface; black negroe of the ſame; ſcarlet of the ſame. | Poſ. | Poſ. |
| **Corallines.** | | |
| Sea-fan, the horny part, w; rough coral, w. | Neg. | Poſ. |
| Spunge, w; coral poliſhed, w. | Neg. | Poſ |
| **Salts.** | | |
| Alum, w. - - | Neg. | Neg. |
| *Borax*,<br>Nitre purified, } Smooth ſurfaces; | Poſ. | Poſ. |
| **Fossil and Mineral Substances.** | | |
| Common pebble-ſtones of all colours, s; marble, s; pit-coal, s; black-lead, w; jet, s; *aſbeſtos*; mineralized ſulphur; thunder-bolt ſtone; *cornu-ammonis;* ſhark's-tooth; coat of petrifaction. | Neg. | Neg. |
| Several ſmooth native cryſtals; brown Iceland ditto; *talc*, s; Ceylon pebble, ſmooth and tranſparent; agate, s; cornelian; amethyſt, s. | Poſ. | Poſ. |
| A ſpecimen of *gypſum*. | Neg. | Poſ. |
| **Artificial Substances.** | | |
| Staffordſhire ware glazed; China ware, s; Wedgwood's ware glazed, s; whale's fin prepared, w; writing-paper; parchment, s; ſheep's gut. | Poſ. | Poſ. |
| Tobacco-pipe, s; Wedgwood's ware unglazed; elaſtic gum, s; hard under-cruſt of a leaf; a tallow-candle, w: oiled ſilk; painted paper, s; ſilver, burnt into glaſs, unburniſhed; pearl-barley, w; Indian ink, w; blue vitriol, s. | Neg. | Neg. |
| Dr Lewis's glaſs porcelain. | Neg. | Poſ. |

Here it muſt be obſerved, that a great number of the ſubſtances in Mr Henley's table, particularly metals, would have been totally incapable of excitation had they not been inſulated; and as they were rubbed againſt electrics *per ſe*, it is by no means fair to conclude that the metal was *excited*. It ſeems much more likely that the rubber only was excited, and communicated its electricity to the metal. It muſt alſo be obſerved, that though there is a very remarkable difference between ſubſtances with regard to their non-electric or conducting power, yet there ſeems not to be a perfect electric in nature: for heat will deſtroy the electric power of glaſs, and every other ſubſtance; and, on the contrary, cold, if not attended with moiſture, renders every electric ſubſtance more electric than before. The uſe of warming an electric therefore, before excitation, is only to free it from the moiſture which may adhere to it.

From the above catalogues it will readily be apprehended, that the powers of the electric ſubſtances not only vary prodigiouſly from one another, but likewiſe according to the circumſtances in which they are placed. Thus alſo we find, that, according to the different ſubſtances made uſe of, we may ſometimes produce one phenomenon and ſometimes another, in a manner excluſive of all the reſt. Hence we have a foundation for claſſing electric ſubſtances according to the various powers they occaſionally exhibit, and which we ſhall do in the following manner.

1. Thoſe which exhibit a ſtrong and permanent attractive and repulſive power; of which the moſt remarkable is ſilk.

2. For exhibiting the electric light, attraction and repulſion, and all the other phenomena of electricity in a very vigorous though not durable manner, glaſs is preferable to all other bodies.

3. Thoſe which exhibit electric appearances for a great length of time, and which communicate to conducting bodies the greateſt electric power. Of theſe the ſubſtances called *negative electrics* are the moſt remarkable;

Phenomena.

markable; ſuch as amber, gum-lac, roſin, ſulphur, &c. on the properties of which depend the phenomena of the electrophorus, to be afterwards deſcribed.

4. Thoſe which readily exhibit electrical phenomena by heating and cooling, of which the principal is the tourmalin.

### § 1. *Of the Electrical Phenomena from Silk.*

THIS ſubſtance was firſt diſcovered to be an electric by Mr Grey, in the manner we have already related*; but as it was by no means remarkable for emitting ſparks, which moſt commonly engages the attention, its electric virtues were almoſt entirely overlooked till the year 1759. At that time Mr Symmer preſented to the royal ſociety ſome papers, containing a number of very curious experiments made with ſilk ſtockings, in ſubſtance as follows.

* See n° 5.

He had been accuſtomed to wear two pairs of ſilk ſtockings; a black and a white. When theſe were put off both together, no ſigns of electricity appeared; but on pulling off the black ones from the white, he heard a ſnapping or crackling noiſe, and in the dark perceived ſparks of fire between them. To produce this and the following appearances in great perfection, it was only neceſſary to draw his hand ſeveral times backward and forward over his leg with the ſtockings upon it.

45 o: g at- ction and ulſion ween e- trified ckings.

When the ſtockings were ſeparated and held at a diſtance from each other, both of them appeared to be highly excited; the white ſtocking poſitively, and the black negatively. While they were kept at a diſtance from each other, both of them appeared inflated to ſuch a degree, that they exhibited the entire ſhape of the leg. When two black or two white ſtockings were held in one hand, they would repel one another with conſiderable force, making an angle ſeemingly of 30 or 35 degrees. When a white and black ſtocking were preſented to each other, they were mutually attracted; and if permitted, would ruſh together with ſurpriſing violence. As they approached, the inflation gradually ſubſided, and their attraction of foreign objects diminiſhed, but their attraction of one another increaſed; when they actually met, they became flat, and joined cloſe together like as many folds of ſilk. When ſeparated again, their electric virtue did not ſeem to be in the leaſt impaired for having once met; and the ſame appearances would be exhibited by them for a conſiderable time. When the experiment was made with two black ſtockings in one hand, and two white ones in the other, they were thrown into a ſtrange agitation, owing to the attraction between thoſe of different colours, and the repulſion between thoſe of the ſame colour. This mixture of attractions and repulſions made the ſtockings catch at each other at greater diſtances than otherwiſe they would have done, and afforded a very curious ſpectacle.

When the ſtockings were ſuffered to meet, they ſtuck together with conſiderable force. At firſt Mr Symmer found they required from one to 12 ounces to ſeparate them. Another time they raiſed 17 ounces, which was 20 times the weight of the ſtocking that ſupported them; and this in a direction parallel to its ſurface. When one of the ſtockings was turned inſide out, and put within the other, it required 20 ounces to ſeparate them; though at that time 10 ounces were ſufficient when applied externally. Getting the black ſtockings new dyed, and the white ones waſhed, and whitened in the fumes of ſulphur, and then putting them one within the other, with the rough ſides together, it required three pounds three ounces to ſeparate them. With ſtockings of a more ſubſtantial make, the coheſion was ſtill greater. When the white ſtocking was put within the black one, ſo that the outſide of the white was contiguous to the inſide of the black, they raiſed nine pounds wanting a few ounces; and when the two rough ſurfaces were contiguous, they raiſed 15 pounds one pennyweight and a half. Cutting off the ends of the thread and the tufts of ſilk which had been left in the inſide of the ſtockings, was found to be very unfavourable to theſe experiments.

Mr Symmer alſo obſerved, that pieces of white and black ſilk, when highly electrified, not only cohered with each other, but would alſo adhere to bodies with broad and even poliſhed ſurfaces, though theſe bodies were not electrified. This he diſcovered accidentally; having, without deſign, thrown a ſtocking out of his hand, which ſtuck to the paper-hangings of the room. He repeated the experiment, and found it would continue hanging near an hour. Having ſtuck up the black and white ſtockings in this manner, he came with another pair highly electrified; and applying the white to the black, and the black to the white, he carried them off from the wall, each of them hanging to that which had been brought to it. The ſame experiments held with the painted boards of the room, and likewiſe with the looking-glaſs, to the ſmooth ſurface of which both the white and the black ſilk appeared to adhere more tenaciouſly than to either of the former.

44 Experiments on ribbons by Mr Cigna.

Similar experiments, but with a greater variety of circumſtances, were afterwards made by Mr Cigna of Turin, upon white and black ribbons. He took two white ſilk ribbons juſt dried at the fire, and extended them upon a ſmooth plain, whether a conducting or electric ſubſtance was a matter of indifference. He then drew over them the ſharp edge of an ivory ruler, and found that both ribbons had acquired electricity enough to adhere to the plain; though while they continued there, they ſhowed no other ſign of it. When taken up ſeparately, they were both negatively electrified, and would repel each other. In their ſeparation, electric ſparks were perceived between them; but when again put on the plain, or forced together, no light was perceived without another friction. When by the operation juſt now mentioned they had acquired the negative electricity, if they were placed, not upon the ſmooth body on which they had been rubbed, but on a rough conducting ſubſtance, they would, on their ſeparation, ſhow contrary electricities, which would again diſappear on their being joined together. If they had been made to repel each other, and were afterwards forced together, and placed on the rough ſurface above mentioned, they would in a few minutes be mutually attracted; the lowermoſt being poſitively, and the uppermoſt negatively electrified.

If the two white ribbons received their friction upon the rough ſurface, they always acquired contrary electricities. The upper one was negatively, and the lower one poſitively electrified, in whatever manner they were taken off. The ſame change was inſtantaneouſly done by any pointed conductor. If two ribbons, for inſtance, were made to repel, and the point

Phenomena.

of a needle drawn oppoſite to one of them along its whole length, they would immediately ruſh together.

The ſame means which produced a change of electricity in a ribbon already electrified, would communicate electricity to one which had not as yet received it; viz. laying the unelectrified ribbon upon a rough ſurface, and putting the other upon it; or by holding it parallel to an electrified ribbon, and preſenting a pointed conductor to it. He placed a ribbon that was not quite dry under another that was well dried at the fire, upon a ſmooth plain: and when he had given them the uſual friction with his ruler, he found that in what manner ſoever they were removed from the plain, the upper one was negatively and the lower one poſitively electrified.—If both ribbons were black, all theſe experiments ſucceeded in the ſame manner as with the white. If, inſtead of the ivory ruler, he made uſe of any ſkin or a piece of ſmooth glaſs, the event was the ſame; but if he made uſe of a ſtick of ſulphur, the electricities were in all caſes the reverſe of what they had been before the ribbons were rubbed, having always acquired the poſitive electricity. When he rubbed them with paper either gilt or not gilt, the reſults were uncertain. When the ribbons were wrapped in paper gilt or not gilt, and the friction was made upon the paper laid on the plain above mentioned, the ribbons acquired both of them the negative electricity. If the ribbons were one black and the other white, whichever of them was laid uppermoſt, and in whatever manner the friction was made, the black generally acquired the negative and the white the poſitive electricity.

He alſo obſerved, that when the texture of the upper piece of ſilk was looſe, yielding, and retiform like that of a ſtocking, ſo that it could move and be rubbed againſt the lower one, and the rubber was of ſuch a nature as could communicate but little electricity to glaſs, the electricity which the upper piece of ſilk acquired did not depend upon the rubber, but upon the body on which it was laid. In this caſe, the black was always negative and the white poſitive But when the ſilk was hard, rigid, and of a cloſe texture, and the rubber of ſuch a nature as would have imparted a great degree of electricity to glaſs, the electricity of the upper piece depended on the rubber. Thus, a white ſilk ſtocking rubbed with gilt paper upon glaſs became negatively, and the glaſs poſitively, electrified. But if a piece of ſilk of a firmer texture was laid upon a plate of glaſs, it was *always* electrified poſitively, and the glaſs negatively, if it was rubbed with ſulphur, and for the moſt part if it was rubbed with gilt paper.

If an electrified ribbon was brought near an inſulated plate of lead, it was attracted, but very feebly. On bringing the finger near the lead, a ſpark was obſerved between them. the ribbon was vigorouſly attracted, and both together ſhowed no ſigns of electricity. On the ſeparation of the ribbon, they were again electrified, and a ſpark was perceived between the plate and the finger.

When a number of ribbons of the ſame colour were laid upon a ſmooth conducting ſubſtance, and the ruler was drawn over them, he found, that when they were taken up ſingly, each of them gave ſparks at the place where it was ſeparated from the other, as did alſo the laſt one with the conductor; and all of them were negatively electrified. If they were all taken from the plate together, they cohered in one maſs, which was negatively electrified on both ſides. If they were laid upon the rough conductor, and then ſeparated ſingly, beginning with the lowermoſt, ſparks appeared as before, but all the ribbons were electrified poſitively, except the uppermoſt.—If they received the friction upon the rough conductor, and were all taken up at once, all the intermediate ribbons acquired the electricity, either of the higheſt or loweſt, according as the ſeparation was begun with the higheſt or the loweſt. If two ribbons were ſeparated from the bundle at the ſame time, they clung together, and in that ſtate ſhowed no ſign of electricity, as one of them alone would have done. When they were ſeparated, the outermoſt one had acquired an electricity oppoſite to that of the bundle, but much weaker.

Phenomena.

A number of ribbons were placed upon a plate of metal to which electricity was communicated by means of a glaſs globe, and a pointed conductor held to the other ſide of the ribbons. The conſequence was, that all of them became poſſeſſed of the electricity oppoſite to that of the plate, or of the ſame, according as they were taken off; except the moſt remote, which always kept an electricity oppoſite to that of the plate.

### § 2. *Of the Phenomena produced by excited or electrified Glaſs.*

THAT glaſs is an electric ſubſtance, was firſt diſcovered by Dr Gilbert. It was for a long time, however, thought to poſſeſs but a very weak electric virtue; though now it is found to be one of the beſt, if not the very beſt, electric as yet known. Notwithſtanding the many experiments made upon this ſubſtance, it is not yet aſcertained what kind of glaſs is moſt proper for electrical purpoſes. It has been obſerved, that the hardeſt and moſt completely vitrified glaſs is often a very bad electric, being ſometimes quite a conductor. Glaſs veſſels made for electrical purpoſes are often rendered fit for them by uſe and time, though very bad electrics when new. Mr Bergman of Upſal ſays, that very often, when his glaſs globes could not be excited to a ſufficient degree of ſtrength, he lined them with a thin coating of ſulphur, and that then they gave a much ſtronger poſitive electricity than before. In Italy, and other places, according to Mr Nollet, it is the cuſtom of electricians to put a coating of pitch or other reſinous matter on the inſide of their globes, which they ſay always makes them work well. He gives the preference to the cryſtal glaſs of England, Bohemia, &c. It ſeems doubtful, however, whether the common bottle glaſs does not anſwer equally well, or even better.

45
All kinds
of glaſs u
equally pr
per for ele
t ic exper
n ents.

The moſt remarkable phenomenon producible by excited glaſs is that of the Leyden vial. It depends entirely upon the following property of glaſs, viz. that it is impoſſible to electrify the outſide of a glaſs poſitively, at leaſt to any conſiderable degree, without at the ſame time electrifying the inſide of it negatively: in like manner, it is impoſſible to electrify the outſide negatively; without at the ſame time electrifying the inſide poſitively. It is alſo the nature of glaſs and all other electric ſubſtances, when once electrified either by excitation or communication,

46
Leyden vi
explained.

munication, to part with their electricity very ſlowly and gradually. Thus, ſuppoſing a tube, cylinder, or plate of glaſs, to be highly electrified; if a finger is brought near any part of it, a ſpark will be felt to ſtrike the finger with a ſnapping noiſe. Part of the electricity will then be diſcharged from the glaſs, but not all. If the finger is brought near another part of the glaſs, a ſimilar ſpark will be again produced; and ſo on, by moving the finger to different parts of the glaſs, till all its electricity is exhauſted. It is the nature of conducting ſubſtances to diſcharge all their electricity at once, by a ſingle ſpark, if another conducting ſubſtance is brought near them. This being the caſe, therefore, it follows, that if every part of one ſide of a glaſs plate is covered over with a conducting ſubſtance, every point of the glaſs will give out its electricity to the conductor; and conſequently, if another conducting ſubſtance is brought near to that by which the glaſs is covered, the whole electric power in the glaſs ought to be diſcharged in one ſingle flaſh or large ſpark.

This would no doubt be the caſe, if it was poſſible to electrify the glaſs only on one ſide. But this is found to be impoſſible. No method hath yet been found of electrifying one ſide of a piece of glaſs poſitively, without electrifying the other negatively at the ſame time. There is therefore a neceſſity for taking off the electricity from both ſides of the glaſs at the ſame time. This can only be done by covering both ſides of the glaſs with a conducting ſubſtance, and preſenting other conductors to both ſides at the ſame time: then the electricity of both is diſcharged in an inſtant. A ſtrong ſpark is perceived between both ſides of the coated glaſs and the conducting ſubſtances; and if a perſon holds one in each hand, he will, at the inſtant of the diſcharge, feel a very diſagreeable ſenſation, which cannot well be deſcribed, in his arms and breaſt: and this is ſaid to be receiving the *electric ſhock*.

If, inſtead of preſenting a conducting ſubſtance to both ſides of the plate at once, a finger is preſented to one ſide, ſuppoſe that which is poſitively electrified, and another ſubſtance very highly electrified poſitively is preſented to the negative ſide of the glaſs, a like diſcharge will enſue, but the ſhock will be much gentler than in the former caſe, and probably the electricity of the glaſs will not be all diſcharged. If two conducting ſubſtances, inſulated, ſuppoſe two cylinders of metal fixed upon ſticks of ſealing wax, or ſuſpended by ſilk threads, are brought to the ſides of the coated glaſs at the ſame time; each of them will receive a ſpark of poſitive or negative electricity, according as the ſide to which it was applied is poſitively or negatively electrified. When the metallic cylinders are taken away, they will communicate the electricity they have received to other bodies; and if again applied to the coated glaſs, they will receive ſparks as before; and thus the electricity of both ſides will be gradually diſcharged.

After the diſcharge has been once made, the glaſs is found in a ſhort time to recover its electricity, tho' in a ſmall degree. The ſide which was originally electrified poſitively, becomes electrified in the ſame manner the ſecond time, and ſo of the negative ſide. This ſecond electrification is called the *reſiduum* of a charge; and, where there is a large ſurface of coated glaſs, hath a very conſiderable degree of power. The ſame thing, which we have juſt now obſerved with regard to a flat ſurface of glaſs, takes place with tubes and vials, or glaſs veſſels of any kind; and it is always obſerved, that the thinneſt glaſs anſwers beſt for this purpoſe. The Leyden vial conſiſts of a glaſs vial, jar, or bottle, covered on the outſide and inſide with tin-foil, yet leaving an interval of two or three inches at top without any metallic covering, that the electricity of the one ſide may not be communicated to the other as faſt as it is collected. A more particular deſcription of it will be given when we ſpeak of the electric apparatus. The above will be ſufficient to render the following experiments intelligible.

47
Experiments on glaſs plates by Mr Symmer.

Mr Symmer, when making the experiments we have already related, concerning the ſtrong coheſive power of electrified ſilk, was induced to try the coheſive power of electrified glaſs. For this purpoſe, he got two panes of common window-glaſs, the thinneſt and ſmootheſt he could meet with. He coated one of the ſides with tin-foil, leaving a ſpace uncovered near the edges. The uncovered ſides were then put together, and electricity communicated to one of the coatings by means of a machine. In conſequence of this, the other ſide, which was alſo coated, became electrified with an electricity oppoſite to the firſt, and both panes were charged with the electric power, as if they had been but one. After they had received a conſiderable degree of electric power, they cohered pretty ſtrongly together, but he had no apparatus by which the ſtrength of their coheſion could be meaſured. He then turned the plates upſide down; and diſcharging from his machine poſitive electricity upon the negative ſide of the glaſs, both panes were immediately diſcharged, and their coheſion ceaſed. Placing two panes of glaſs, each of them coated on both ſides, one upon the other, each of them had a poſitive and negative ſide, by communicating electricity to one of them, and they did not cohere.

48
Experiments on glaſs plates by Mr Beccaria.

In conſequence of theſe experiments made by Mr Symmer, and another (which we ſhall preſently give an account of) made at Pekin, Mr Beccaria made the following ones. Having charged a coated plate of glaſs, he took off the coating from the negative ſide, and applied another uncoated and uncharged (or unelectrified) plate of glaſs cloſe to it. After this, putting a coating upon the uncharged glaſs (ſo that the whole reſembled one coated plate conſiſting of two laminæ), he made a communication between the two coatings. The conſequence of this was an exploſion, a diſcharge of the poſitive and negative electricity, and a coheſion of the plates. If the plates were ſeparated before the exploſion, after they had been in conjunction for ſome time, the charged plate was poſitive on both ſides, and the uncharged one negative on both ſides. If after the exploſion he ſeparated and joined them alternately, a ſmall circle of paper, placed under the uncharged plate, adhered to it upon every ſeparation, and was thrown off again upon every conjunction. This could be repeated even 500 times with once charging the plate. This is the experiment made at Pekin as above mentioned.

If, in theſe experiments, the charged plate was inverted, and the poſitive ſide applied to the uncharged plate, all the effects were exactly the reverſe of the former. If it was inverted ever ſo often, after remaining

ing ſome time in contact with the uncharged plate, it would produce a change in the electricity. In the dark, a light was always ſeen upon the ſeparation of theſe plates. Laying the two plates together like one, and coating the outſides of them, he diſcharged them both together; and at the diſtance of about four feet he diſtinguiſhed ſix of the coloured rings mentioned by Sir Iſaac Newton, all parallel to one another, and nearly parallel to the edge of the coating. At the angles of the coatings the rings ſpread to a greater diſtance. Where the coatings did not quite touch the glaſs, the rings bent inwards; and where the coatings adhered very cloſe, they retired farther from them. Upon diſcharging theſe two plates, the coloured rings vaniſhed, and the electric coheſion ceaſed with them. On ſeparating the plates before the exploſion; that which had received the poſitive electricity was poſitive on both ſides, and the other negative on both ſides. If they were ſeparated after the exploſion, each of them was affected in a manner quite the reverſe. Upon inverting the plates, that which was the thinner appeared to be poſſeſſed of the ſtronger electricity, and brought the other plate to correſpond with it. Charging the two plates ſeparately, and taking off two of the coatings, ſo that two poſitive or two negative ſides might be placed together, there was no coheſion nor exploſion. But joining a poſitive and a negative ſide, they immediately cohered; and a communication being formed on the outſide, there was an exploſion which increaſed the coheſion.

49
By Mr Henley.

Mr Henley repeated theſe experiments with ſucceſs when he made uſe of plates of looking-glaſs, or window and crown glaſs; but when two plates of Nuremberg glaſs, commonly called *Dutch plates*, were uſed, the reſult was very different. Eeach of the plates, when ſeparated after charging, had a poſitive and a negative ſurface. When they were replaced, and a diſcharge made, by forming a communication between the two coatings, the electricity of all the ſurfaces was changed. It appeared, however, ſtill to be very ſtrong, and the plates continued to give repeated flaſhes of light when they were alternately cloſed, touched, and ſeparated, like the other plates abovementioned. If a clean, dry, uncoated plate of looking-glaſs was placed between the coated plates, either of looking-glaſs or crown-glaſs, before they were charged, that uncoated plate was always found, upon ſeparating them after charging, to be electrified negatively on both ſides; but if it was put between the Dutch plates, it acquired, like them, a poſitive and negative electricity.

The following obſervation of Mr Æpinus is very remarkable. He preſſed cloſe together two pieces of looking-glaſs, each containing ſome ſquare inches; and found, that when they were ſeparated, and not ſuffered to communicate with any conductor, they acquired a ſtrong electricity, the one poſitive and the other negative. When put together again, the electricity of both diſappeared; but not if either of them had been deprived of their electricity when they were aſunder; for in that caſe, the two, when united, had the electricity of the other.

50
Conducting power of glaſs tubes.

Theſe are the moſt remarkable experiments that have been made with electrified flat plates of glaſs. Tubes of the ſame matter, however, afford a variety of curious phenomena of a different nature. One very remarkable one is the conducting power of new flint-glaſs, which is moſt eaſily perceived in tubes, and on which Dr Prieſtley makes the following obſervations. He ſeveral times got tubes made two or three yards long, terminating in ſolid rods. Theſe he took almoſt warm from the furnace, in the fineſt weather poſſible; and having immediately inſulated them, perceived that the electricity of a charged vial would preſently diffuſe itſelf from one end to the other; and this he thought would have been the caſe at any diſtance at which the experiment could have been made. When the ſame tubes were a few months older, the electricity could not be diffuſed along their ſurface farther than half a yard.

The diffuſive power of glaſs he thought proper to try in a different manner. A tube was procured of about three feet long, but of very unequal width. About three inches of the middle part of it were coated on both ſides. This coated part was afterwards charged, by communicating electricity to the inſide of it by means of a wire. The conſequence of this was, that not only the part through which the wire was introduced became ſtrongly electrical on the outſide, but at the oppoſite end, where there was neither coating nor wire, the fire crackled under the fingers as the tube was drawn through the hand, and a flame ſeemed continually to iſſue out at both ends, while it was at reſt and charged.—One end of this tube was broken and rough, the other was ſmooth.

Another tube was procured about three feet and an half in length, and very thin. It was about an inch in diameter, and cloſed at one end. Three inches of it were coated on both ſides, about nine inches below the mouth. This part being charged, the whole tube, to the very extremity of it, was ſtrongly electrical, crackling very loud when the hand was drawn along it, and emitting ſparks at about an inch diſtance all the way. After drawing the whole tube through the hand, all the electricity on the outſide was diſcharged; but, on putting a finger into the mouth, a light ſtreamed from the coating, both towards the finger and towards the oppoſite end of the tube. After this, all the outſide of the tube was become ſtrongly electrical as before; and this electricity might be taken off and recovered many times without charging the tube anew, only it was weaker each time.—Holding this tube by the coated part, and communicating electricity to the uncoated outſide, both ſides became charged; and, upon introducing a wire, a conſiderable exploſion was made. The diſcharge made the outſide ſtrongly electrical, and by taking off this electricity, the tube became ſenſibly charged. The reſiduum of theſe charges was very conſiderable; and, in one tube, there was a reſiduum after 20 or 30 diſcharges.

By being kept for ſix or ſeven months, moſt of the tubes employed in theſe experiments loſt the above-mentioned properties, and the electricity could no longer diffuſe itſelf upon their ſurfaces. At length they were all broken except one, which had been the moſt remarkable of the whole. With this old tube, the Doctor tried to repeat the above-mentioned experiments:

eno-
:na.

ments; but to no purpoſe. He then took it to a glaſs-houſe; and having made it red all over, its diffuſive property was reſtored as before.

He then tried two other tubes which had been made about ſix weeks, but without being uſed during all that time, and they anſwered exactly as if they had been quite new. The charge from a ſmall coated part diffuſed itſelf all over the tube; ſo that, at the diſtance of a yard from the coating, it gave ſparks to the finger of an inch long. On this occaſion he obſerved, that when his finger was brought to the tube about two inches above the coating, a great quantity of the diffuſing electricity was diſcharged; and his whole arm was violently ſhocked. The old tube, after being heated as above mentioned, ſhowed a prodigious diffuſive power. Upon charging a ſmall coated part, the electricity was diffuſed to the end of the tube; and it gave ſparks at the diſtance of an inch over every part of it. When it was drawn through the hand, in order to take off the diffuſed electricity, it inſtantly returned again, and the extremity of the tube would be highly electrified, even while its communication with the coating was cut off by the hand. The middle part of the tube alſo, which had been ofteneſt heated, had a much greater diffuſive power than any other. It was no ſooner taken off, than it appeared again; ſo that it gave a continual ſtream of fire. The quantity of reſiduum after a diſcharge of this tube was prodigious; ſo that the outſide coating would immediately after give almoſt a conſtant ſtream of fire for ſome time to any conducting ſubſtance placed near it.

The Doctor alſo obſerved, that in all the tubes which had the diffuſion, there was a conſiderable noiſe at the orifice when his hand was drawn from the extremity towards the coating, as if the tube had been gradually diſcharging itſelf. In the dark, the electric matter ſeemed perpetually to pour from the open end, or both ends if they were open; and whenever his hand was drawn over it, the fire ſtreamed from the coating to his hand in a very beautiful manner. The firſt time he charged any of theſe tubes after they had ſtood a while, the diffuſion was the moſt remarkable. It was leſſened by every ſucceſſive charge, and at laſt became exceedingly ſmall; but after the tube had ſtood a few hours uncharged, it was as vigorous as ever.

Mr Cavallo hath alſo made ſome curious diſcoveries concerning glaſs-tubes. He took the hint from obſerving accidentally, that by agitating quickſilver in a glaſs tube hermetically ſealed, and in whoſe cavity the air was very much rarefied, the outſide of the tube was ſenſibly electrified. The electricity, however, was not conſtant, nor in proportion to the agitation of the quickſilver. In order to aſcertain the properties of theſe tubes, he conſtructed ſeveral of them, one of which is repreſented fig. 71. Its length was 31 inches, and its diameter ſomething leſs than half an inch. The quickſilver contained in it was about three fourths of an ounce; and in order to exhauſt it of air, one end of it was cloſed, while the quickſilver boiled in the other. Before this tube is uſed, it muſt be made a little warm and cleaned; then, holding it nearly horizontal, the quickſilver in it is ſuffered to run from one end to the other, by gently and alternately elevating and depreſſing its extremities. This operation immediately renders the outſide electrical; but with the following remarkable property, *viz.* that the end of the tube where the quickſilver actually ſtands is always poſitive, and all the remaining part of it negative. If elevating this poſitive end of the tube a little, the quickſilver runs to the oppoſite end which was negative, then the former inſtantly becomes negative, and the latter poſitive. The poſitive end has always a ſtronger electricity than the negative. If when one end of the tube, for inſtance *A*, is poſitive, *i. e.* when the quickſilver is in it, that electricity is not taken off by touching it; then, on elevating this end *A*, ſo that the quickſilver may run to the oppoſite end *B*, it appears negatively electrified in a very ſmall degree. If by depreſſing it again it is a ſecond time rendered poſitive, and that poſitive electricity is not taken off, then, on elevating the end *A* again, it appears poſitive in a ſmall degree. But if, whilſt it is poſitive, its electricity is taken off, then on being elevated, it appears ſtrongly negative. When about two inches of each extremity of this tube is coated with tin-foil, as repreſented in the figure, that coating renders the electricities at the extremities more perceptible, ſo that ſometimes they will give ſparks to a conductor brought near them. Tubes whoſe glaſs is about one-twentieth of an inch thick anſwer better for theſe experiments than any others.

Phenomena.

52
Durability of the electric virtue in glaſs.

We ſhall cloſe this account of the phenomena of excited glaſs, with ſome experiments which ſhow the durability of the electric virtue in that ſubſtance in certain circumſtances. Mr Canton procured ſome thin glaſs balls of about an inch and a half in diameter, with ſtems or tubes of eight or nine inches in length. He electrified them, ſome poſitively, and others negatively, on the inſide, and then ſealed them hermetically. Soon after, he found that they had loſt all ſigns of electricity: but holding them to the fire at the diſtance of five or ſix inches, they became ſtrongly electrical in a ſhort time, and more ſo as they cooled. Heating them frequently he found would diminiſh their power; but keeping one of them under water a week did not appear in the leaſt to impair it. That which he kept under water was charged on the 22d of September 1760, was heated ſeveral times before it was kept in water, and had been frequently heated afterwards; yet it ſtill retained its virtue to a conſiderable degree till the 31ſt of October following. The breaking of two of his balls gave him an opportunity of obſerving their thickneſs, which he found to be between ſeven and eight parts of a thouſand of an inch. The balls retained their virtue for ſix years, but in a leſs degree. Mr Lullin alſo found, that a glaſs tube charged and hermetically ſealed, would ſhow ſigns of electricity when heated.

The moſt remarkable inſtances of the continuance of this power in glaſs, however, are thoſe given by Mr Henly in the 67th volume of the Phil. Tranſ. One is, of a ſmall bottle, which ſhowed ſigns of electricity for 70 days after it had been charged, and ſtood in a cupboard all that time. The other is of a glaſs cylinder, which after excitation continued to ſhow very ſtrong ſigns of electricity from the 5th day of February to the 10th of March, though various methods had been uſed during that time to deſtroy the electric virtue. Theſe means always proved effectual when they were applied, and the cylinder for ſome time ſhowed

ſhowed no ſigns of electricity. They never failed, however, to return without any freſh excitation; and became ſtronger and weaker, nay, ſometimes quite vaniſhed and returned, without any viſible cauſe. In general, the electricity was weak when a fire was kept in the room, or when the door was kept open. When the wind blew from the north, the electricity was vigorous, and likewiſe after it had been for ſome time deſtroyed by flame. The cylinder, however, did not at all times retain its electric virtue for ſuch a length of time without excitation. Very often it would loſe all ſigns of electricity in 12 hours, and at other times in a fortnight, without returning till it was again excited.

### § 3. *The Phenomena of excited Sulphur, Gum-lac, Amber, Roſin, baked Wood*, &c.

53
Experiments by Mr Wilcke, Æpinus, &c.

THE moſt remarkable property of theſe, as already mentioned, is the durability of their electric virtue when once excited. They are alſo capable of being excited by heat without any friction. This laſt property was diſcovered by Mr Wilcke, who diſtinguiſhes it by the name of *ſpontaneous electricity*. He melted ſulphur in an earthen veſſel, which he placed upon conductors: then, letting them cool, he took out the ſulphur, and found it ſtrongly electrical; but it was not ſo when it ſtood to cool upon electric ſubſtances. He then melted ſulphur in glaſs veſſels, whereby they both acquired a ſtrong electricity whether placed upon electrics or not; but a ſtronger in the former caſe than in the latter: they acquired a ſtronger virtue ſtill, if the glaſs veſſel was coated with metal. In theſe caſes, the glaſs was always poſitive and the ſulphur negative. It was particularly remarkable, that the ſulphur acquired no electricity till it began to cool and contract, and was the ſtrongeſt in the greateſt ſtate of contraction; whereas the electricity of the glaſs was, at the ſame time, the weakeſt; and was the ſtrongeſt of all when the ſulphur was ſhaken out before it began to contract, and acquired any negative electricity.

Purſuing experiments of this kind, he found, that melted ſealing-wax poured into glaſs acquired a negative electricity, but poured into ſulphur a poſitive one, leaving the ſulphur negative. Sealing-wax alſo, poured into wood, was negative, and the wood poſitive; but ſulphur poured into ſulphur, or into rough glaſs, acquired no electricity at all.

Similar experiments were alſo made by Mr Æpinus. He poured melted ſulphur into metal cups; and obſerved, that, when the ſulphur was cold, the cup and ſulphur together ſhowed no ſigns of electricity, but very ſtrong ſigns of it the moment they were ſeparated. The electricity always diſappeared when the ſulphur was replaced in the cup, and revived upon its being taken out. The cup had acquired a negative, and the ſulphur a poſitive electricity; but if the electricity of either of them had been taken off while they were ſeparate, they would both, when united, ſhow ſigns of that electricity which had not been taken off.

Mr Wilcke alſo made ſeveral curious experiments concerning the effects of different rubbers upon electric ſubſtances, the moſt remarkable of which is the following: viz. that ſulphur rubbed againſt metals was always poſitive; and this was the only caſe in which it was ſo. But, being rubbed againſt lead, it became negative, and the metal poſitive.

With regard to the perpetual attractive power of ſulphur, &c. which Mr Grey fancied he had diſcovered *, the moſt remarkable example he gives is of a large cone of ſtone ſulphur, covered with a drinking glaſs in which it was made. This he ſaid would never fail to ſhow an attractive power when the glaſs was taken off. In fair weather, the glaſs would attract alſo; but not ſo ſtrongly as the ſulphur, which never failed to attract, let the wind or weather be ever ſo variable. This experiment has been repeated by Mr Henly; who ſays he has never known the ſulphur to fail of ſhowing ſigns of electricity on the removal of the glaſs. Gum-lac, roſin, &c. agree in the ſame general properties with ſulphur, but do not become ſo ſtrongly electrified ſpontaneouſly, nor are they ſo eaſily excited.

* See n

### § 4. *Phenomena of the Tourmalin.*

THESE have been accurately obſerved by Dr Prieſtley, who gives the following account of the methods he made uſe of for that purpoſe.

54
Dr Pr
ley's m
th
ſervin
elect

1. To aſcertain the kind of electricity produced, he had always at hand a ſtand of baked wood with four arms projecting from it. Three of theſe were of glaſs, having threads of fine ſilk as it comes from the worm faſtened to them, and at the end of each thread a ſmall piece of down. From the other arm hung a fine thread about 9 or 10 inches long, while a braſs arm ſuſpended a pair of pith-balls. At the other extremity of this arm, which was pointed, a jar could be placed, to receive the electricity, and by the repulſive power of it keep the balls equally diverging with poſitive or negative electricity; or ſometimes he ſuſpended the balls in an uninſulated ſtate within the influence of large charged jars: and laſtly, he had always a fine thread of trial at hand, by which he could diſcover whether the ſtone was electrical or not before he began his experiments.

2. Before he began any experiments on the ſtone, alſo, he never failed to try how long the fine threads, which he uſed as electrometers, would retain their virtue; and found this to be various in various caſes. When the threads would retain their electric virtue for a few minutes, he preferred them; but when this was not the caſe, he had recourſe to the feathers, which never failed to retain it for ſeveral hours. They might be touched without any ſenſible loſs of power, though they received their virtue very ſlowly. In the experiments now to be related, he made uſe of Dr Heberden's large tourmalin, whoſe convex ſide became poſitive and the flat ſide negative in cooling; and in all of them, when the poſitive or negative ſide of the tourmalin is mentioned, it is to be underſtood that which is poſitive or negative in cooling.

3. From Mr Wilcke's experiments on the production of ſpontaneous electricity, by melting one ſubſtance within another, he firſt conjectured that the tourmalin might collect its electricity from the neighbouring air: To determine which the following experiment was made. Part of a pane of glaſs was laid on the ſtandard bar of an excellent pyrometer, and upon that glaſs the tourmalin was placed. This bar was

heated

heated by a ſpirit lamp, ſo that the increaſe or decreaſe of heat in the tourmalin could thus be exactly determined. In this ſituation he obſerved, that whenever he examined the tourmalin, the glaſs had acquired an electricity contrary to that ſide of the ſtone which lay upon it, and equally ſtrong with it. If, for example, the flat ſide of the ſtone had been preſented to a feather electrified poſitively, as the heat was increaſing, it would repel it at the diſtance of about two inches, and the glaſs would attract it at the ſame or a greater diſtance; and when the heat was decreaſing, the ſtone would attract, and the glaſs repel it at the diſtance of four or five inches. The caſe was the ſame whichever of the ſides was preſented, as well as when a ſhilling was faſtened with ſealing-wax upon the glaſs; the electricity both of the ſhilling and glaſs being always oppoſite to that of the ſtone. When it came to the turn, the electricity was very quickly reverſed; ſo that in leſs than a minute the electricity would be contrary to what it was before. In ſome caſes, however, viz. where the convex ſurface of the tourmalin was laid upon the glaſs or ſhilling, both of theſe became poſitive as well as the ſtone. This he ſuppoſed to be owing to the ſtone touching the ſurface on which it lay only in a few points, and that its electricity was collected from the air; which ſuppoſition was verified: for, getting a mould of Paris plaſter made for the tourmalin, and heating it in the mould, faſtened to a ſlip of glaſs, he always found the mould and glaſs poſſeſſed of an electricity contrary to that of the ſtone, and equally ſtrong with it. During the time of cooling, the mould ſeemed to be ſometimes more ſtrongly negative than the ſtone was poſitive; for once, when the ſtone repelled the thread at the diſtance of three inches, the mold attracted it at the diſtance of near ſix (A).

4 On ſubſtituting another tourmalin inſtead of the piece of glaſs; it was obſerved, that when one of the tourmalins was heated, both of them were electrified as much as the tourmalin and glaſs had been. If the negative ſide of a hot tourmalin was laid upon the negative ſide of a cold one, the latter became poſitive, as would have been the caſe with a piece of glaſs. On heating both the tourmalins, though faſtened together by cement, they acquired the ſame power that they would have done in the open air.

5. As the tourmalins could not in this caſe touch in a ſufficient number of points, it was now thought proper to vary the experiment by cooling the tourmalin in contact with ſealing-wax, which would fit it with the utmoſt exactneſs. On turning the ſtone, when cold, out of its waxen cell, it was found poſitive, and the wax negative; the electricity of the ſtone being thus contrary to what would have happened in the open air. The other ſide, which was not in contact with the wax, acquired the ſame electricity that it would have done though the ſtone had been heated in the open air; ſo that both ſides now became poſitive. In like manner the poſitive ſide of the ſtone, on being cooled in wax, became negative.

6. On attempting to aſcertain the ſtate of the different ſides of the tourmalin during the time it was heating in wax, many difficulties occurred. It was found impoſſible in theſe caſes to know exactly when the ſtone begins to cool; beſides, that in this method of treatment it muſt neceſſarily be ſome time in the open air before it can be preſented to the electrometer; and the electricity of the ſides in heating is by no means ſo remarkable as in cooling. In the experiments made with the tourmalin, when its poſitive ſide was buried in wax, it was generally found negative, though once or twice it ſeemed to be poſitive. On cooling it in quickſilver contained in a china cup, it always came out poſitive, and left the quickſilver negative; but this effect could not be concluded to be the conſequence of applying the one to the other, becauſe it is almoſt impoſſible to touch quickſilver without ſome degree of friction, which never fails to make both ſides ſtrongly poſitive though it be quite cold, and eſpecially if the ſtone be dipped deep into it. At laſt, ſuppoſing that the ſtone would not be apt to receive any friction by ſimple preſſure againſt the palm of the hand, he was induced to make the experiment, and found it fully to anſwer his expectations; for thus, each ſide of the ſtone was affected in a manner directly contrary to what would have happened in the open air.

Phenomena.

7. Faſtening the convex ſide of the large tourmalin to the end of a ſtick of ſealing-wax, and preſſing it againſt the palm of the hand, it acquired a ſtrong negative electricity, contrary to what would have happened in the open air. Thus it continued till it had acquired all the power it could receive by means of the heat of the hand; after which it began to decreaſe, though it continued ſenſibly negative to the very laſt. On allowing the ſtone to cool in the open air, its negative power conſtantly increaſed till it became quite cold.

8. On heating the ſame flat ſide by means of a hot poker held near it, and then juſt touching it with the palm of the hand when ſo hot that it could not be borne for any length of time, it became poſitive. Letting it cool in the air it became negative, and on touching it again with the hand it became poſitive; and thus it might be made alternately poſitive and negative for a conſiderable time. At laſt, when it became ſo cool that the hand could bear it, it acquired a ſtrong poſitive electricity, which continued till it came to the ſame degree of heat.

9. The wax was removed from the convex, and faſtened to the flat ſide of the ſtone; in which circumſtances it became weakly poſitive after receiving all the heat the hand could give it. On letting it cool in the open air it grew more ſtrongly poſitive, and continued ſo till it was quite cold; and thus the ſame ſide became poſitive both with heating and cooling.

10. On heating the convex ſide by means of a poker, and preſſing it againſt the palm of the hand as ſoon as it could be borne, it became pretty ſtrongly negative; though it is extremely difficult to procure any appearance

5

---

(A) This would probably have been found always the caſe; for here the ſtone and mould acted in a manner ſimilar to the electrophorus and its metal plate; the latter of which always diſcovers a greater electric power than the former.

ance of negative electricity from this ſide; and care muſt be taken that a ſlight attraction of the electrified feather, by a body not electrified, be not miſtaken for negative electricity.

11. On covering the tourmalin when hot with oil and tallow, no new appearances were produced; nor did the heating of it in boiling oil produce any other effect than leſſening the electricity a little; and the event was the ſame when the tourmalin was covered with cement made of bees-wax and turpentine. On making a ſmall tourmalin very hot, and dropping melted ſealing-wax upon it, ſo as to cover it all over to the thickneſs of a crown piece, it was found to act through this coating nearly, if not quite, as well as if it had been expoſed to the open air. Thus a pretty deception may be made; for if a tourmalin be incloſed in a ſtick of wax, the latter will ſeem to have acquired the properties of the ſtone.

12. On letting the ſtone cool in the vacuum of an air-pump, its virtue ſeemed to be diminiſhed about one half, owing no doubt to the vacuum not being ſufficiently perfect.

13. On fixing a thin piece of glaſs oppoſite and parallel to the flat ſide of the tourmalin, and about a quarter of an inch diſtance from it, in an exhauſted receiver, the glaſs was ſo ſlightly electrified, that it could not be diſtinguiſhed whether it was poſitive or negative.

13. On laying the ſtone upon the ſtandard bar of the pyrometer, and communicating the heat to it by means of a ſpirit lamp, it was extremely difficult to determine the nature of the electricity while the heat was increaſing to 70°; during which time the index of the pyrometer moved about one 7200th part of an inch. But if the ſtone was taken off the bar, and an electrified thread or feather preſented to that ſide which had lain next it, the convex ſide was always negative, and the flat one poſitive.

14. To determine what would be the effect of keeping the tourmalin in the very ſame degree of heat for a conſiderable time together, it was laid upon the middle of the bar, to which heat was communicated by two ſpirit lamps, one at each extremity; and making the index move 45 degrees, it was kept in the ſame degree for half an hour without the leaſt ſenſible variation; and it was obſerved, that the upper ſide, which happened to be the convex one, was always electrified in a ſmall degree, attracting a fine thread at the diſtance of about a quarter of an inch. If in that time it was taken off the bar, though ever ſo quick, and an electrified feather preſented to it, the flat ſide, which lay upon the bar, was negative, and the upper ſide very ſlightly poſitive, which appeared only by its not attracting the feather. On putting a piece of glaſs between the ſtone and ſtandard bar, keeping it likewiſe in the ſame degree of heat, and for the ſame ſpace of time as before, the reſult was the ſame; the glaſs was ſlightly electrified, and of a kind oppoſite to that of the ſtone itſelf. To avoid the inconvenience of making one ſide of the ſtone hotter than another, which neceſſarily took place when it was heated on the pyrometer, the following method was uſed. By means of two rough places which happened to be in the ſtone, it was tied with a ſilk thread which touched only the extreme edge of it; and thus being perfectly inſulated, it might be held at any diſtance from a candle, and heated to what degree was thought neceſſary; while, by twiſting the ſtring, it was made to preſent its ſides alternately, and thus the heat was rendered very equal in both. After being made in this manner ſo hot that the hand could ſcarce bear it, it was kept in that ſituation for a quarter of an hour. Then, with a bundle of fine thread held for ſome time before in the ſame heat, the electricity which it had acquired by heating was taken off, and it was found to acquire very little if any; whence appeared the juſtneſs of an obſervation of Mr Canton's, that it is the change of heat, and not the degree of it, that produces the electric property of this ſtone.

15. On heating the ſtone ſuddenly, it may ſometimes be handled and preſſed with the fingers ſeveral times before any change takes place in the electricity which it acquires by heating, though it begins to cool the moment it is removed from the fire. In this caſe, however, the ſtone muſt be heated only to a ſmall degree. When the heat is three or four times as great as is ſufficient to change the electricity of the two ſides, the virtue of the ſtone is the ſtrongeſt, and appears to be ſo when it is tried in the very neighbourhood of the fire. In the very centre of the fire the ſtone never fails to cover itſelf with aſhes attracted to it from every quarter; whence it acquired its name in Dutch.

16. The tourmalin often changes its electricity very ſlowly; and that which it acquires in cooling never fails to remain many hours upon it with very little diminution. It is even poſſible, that in ſome caſes the electricity acquired by heating may be ſo ſtrong as to overpower that which is acquired by cooling; ſo that both ſides may ſhow the ſame power in the whole operation. "I am very certain (ſays the Doctor), that in my hands both the ſides of Dr Heberden's large tourmalin have frequently been poſitive for ſeveral hours together, without any appearance of either of them having been negative at all. At this time I generally heated the tourmalin, by preſenting each ſide alternately to a red hot poker, or a piece of hot glaſs, held at the diſtance of about half an inch, and ſometimes I held it in the focus of a burning mirror; but I have ſince found the ſame appearance when I heated it in the middle of an iron hoop made red hot. The ſtone in all theſe caſes was faſtened by its edge to a ſtick of ſealing-wax. This appearance I have obſerved to happen the ofteneſt when the iron hoop has been exceedingly hot, ſo that the outſide of the ſtone muſt have been heated ſome time before the inſide; and I alſo think there is the greateſt chance of producing this appearance, when the convex ſide of the ſtone is made the hotter of the two. When I heat the large tourmalin in this manner, I ſeldom fail to make both ſides of the ſtone poſitive till it be about blood-warm. I then generally obſerve a ragged part of the flat ſide towards one end of the ſtone become negative firſt, and by degrees the reſt of the flat ſide; but very often one part of the flat ſide will, in this method of treatment, be ſtrongly poſitive half an hour after the other part is become negative."

### SECT. V. *Of the different Theories of Electricity, with the principal Experiments brought in favour of each, and which tend more particularly to ſhow the Nature of the Electric Fluid.*

IT is not to be ſuppoſed, that the phenomena of electricity would long be obſerved without attempts to account for them. In fact, this was attempted by Thales, who firſt obſerved the attractive power of amber. At this property he was ſo much ſurpriſed, that he reckoned the amber to be *animated*. With regard to the ſentiments of Theophraſtus on this ſubject, we are entirely in the dark; but, among the ſucceeding electricians, all the phenomena were derived from *unctuous effluvia* emitted by the excited electric. Theſe were ſuppoſed to faſten upon all bodies in their way, and to carry back with them all that were not too heavy. For, at that time, effluvia of every kind were ſuppoſed to return to the bodies from which they were emitted; ſince nobody could otherwiſe account for the ſubſtance not being ſenſibly waſted by the conſtant emiſſion. When theſe light bodies on which the unctuous effluvia had faſtened were arrived at the excited electric, a freſh emiſſion of the effluvia was ſuppoſed to carry them back again. But this effect of the effluvia was not thought of till electric repulſion, as well as attraction, had been fully obſerved.

55

via.

The diſcovery of a difference between conducting and non-conducting ſubſtances, threw conſiderable difficulties in the way of thoſe who maintained the hypotheſis of unctuous effluvia. When the Newtonian philoſophy began to be pretty generally received, the terms *attraction* and *repulſion* were quickly introduced into electricity, as well as other branches of philoſophy; and the electric effluvia, inſtead of being of an *unctuous* nature, were ſaid to be of an attractive or repulſive one. At the ſame time, the apparent ſtop which is put to the progreſs of theſe effluvia by any electric ſubſtance, introduced a queſtion not yet well decided, viz. Whether electric bodies are penetrable by the fluid or not?

6
elec-
uids
fed by
u Fay.

When Mr Du Fay diſcovered the two oppoſite ſpecies of electricity, at that time diſtinguiſhed by the names of *vitreous* and *reſinous*, and afterwards by thoſe of *plus* and *minus*, or poſitive and negative, he formed the idea of two diſtinct electric fluids. Both theſe were ſuppoſed to have a *repulſive* power with reſpect to themſelves, but an *attractive* one with regard to one another.

As long as electrical attraction and repulſion were the only phenomena to be accounted for, this theory ſerved the purpoſe well enough. To account for attraction and repulſion by an *attractive* and *repulſive* power, was indeed no explication at all; but it afforded a change of terms, which is too frequently miſtaken for an explanation both in electricity and other parts of philoſophy.—At laſt, however, Mr Du Fay dropped his opinion concerning the exiſtence of two electric fluids, and thought that all the phenomena might be accounted for from the action of a ſingle one. The vitreous or poſitive electricity, which was ſuppoſed to be the ſtronger, he thought might attract the negative, or weaker electricity.—It is indeed true, that, in many experiments, the poſitive electricity doth manifeſt a ſuperiority in ſtrength over the negative, ſomething like that ſuperior degree of vigour which is obſerved in one of the poles of a loadſtone over the other. According to Mr Du Fay's own principles, however, had this been the caſe, a body poſitively electrified ought to have attracted one electrified negatively more weakly than one not electrified at all; which is contrary to experience.

57
Electric matter diſcovered to come from the earth.

During all this time, it was imagined, that the electric matter, whether it conſiſted of one or more fluids, was produced from the electric body by friction; but by a diſcovery of Dr Watſon's, it became univerſally believed, that the glaſs globes and tubes ſerved only to ſet the fluid in motion, but by no means to produce it. He was led to this diſcovery by obſerving, that, upon rubbing the glaſs tube, while he was ſtanding upon cakes of wax or roſin (in order, as he expected, to prevent any diſcharge of the electric matter upon the floor), the power was, contrary to his expectation, ſo much leſſened, that no ſnapping could be obſerved upon another perſon's touching any part of his body; but that, if a perſon not electrified held his hand near the tube while it was rubbed, the ſnapping was very ſenſible. The event was the ſame when the globe was whirled in ſimilar circumſtances. For, if the man who turned the wheel, and who, together with the machine, was ſuſpended upon ſilk, touched the floor with one foot, the electric fire appeared upon the conductor; but if he kept himſelf free from any communication with the floor, little or no fire was produced.—He obſerved, that only a ſpark or two would appear between his hand and the inſulated machine, unleſs he at the ſame time formed a communication between the conductor and the floor; but that then there was a conſtant and copious flux of the electric matter obſerved between them. From theſe, and ſome other experiments of a ſimilar kind, the Doctor diſcovered what he called the *complete circulation* of the electric matter. When he found, that, by cutting off the communication of the glaſs globe with the floor, all electric operations were ſtopped, he concluded, that the electric fluid was conveyed from the floor to the rubber, and from thence to the globe. For the ſame reaſon, ſeeing the rubber, or the man who had a communication with it, gave no ſparks but when the conductor was connected with the floor, he as naturally concluded, that the globe was ſupplied from the conductor, as he had before concluded that it was ſupplied from the rubber. From all this he was at laſt led to form a new theory of electricity, namely, that, in electric operations, there was both an *afflux* of electric matter to the globe and the conductor, and likewiſe an *efflux* of the ſame electric matter from them. Finding that a piece of leaf-ſilver was ſuſpended between a plate electrified by the conductor, and another communicating with the floor, he reaſons from it in the following manner. "No body can be ſuſpended in equilibrio but by the joint action of two different directions of power: ſo here the blaſt of electric ether from the floor ſetting through it, drives the ſilver towards the plate electrified. We find from hence, likewiſe, that the draught of electric ether from the floor is always in proportion to the quantity thrown by the globe over the gun-barrel (the prime conductor at that time made uſe of), or the equilibrium by which the ſilver is ſuſpended could not be maintained." Some time after, however, the Doctor retracted this opinion concerning the afflux and efflux, and ſuppoſed that all the electric phenomena might be accounted for from the exceſs or diminution of the quantity of electric matter

58
Dr Watſon's theory of afflux and efflux.

contained in different bodies. This theory was afterwards adopted by Dr Franklin, and continues to be generally received.

59
Difficulty concerning the direction of the electric fluid.

One great difficulty with which the firſt electricians were embarraſſed (and which is yet ſcarcely removed), was to aſcertain the direction of the fluid. At firſt, all electric powers, as we have already obſerved, were ſuppoſed to reſide in the excited globe or glaſs tube. The electric ſpark therefore was imagined to proceed from the electrified body towards any conductor that was preſented towards it. It was never imagined there could be any difference in this reſpect, whether it was amber, glaſs, ſealing-wax, or any thing elſe that was excited. This progreſs of the electric matter was thought to be quite evident to the ſenſes; and therefore the obſervation of electric appearances at an inſulated rubber occaſioned the greateſt aſtoniſhment.—In this caſe, the current could not be ſuppoſed to flow both from the rubber and the conductor, and yet the firſt appearances were the ſame. To provide a ſupply of the electric matter, therefore, philoſophers were obliged to ſuppoſe, that, notwithſtanding appearances were in both caſes much the ſame, the electric fluid was really emitted in one caſe by the electrified body, and received by it in the other. But now being obliged to give up the evidence from ſight for the manner of its progreſs, they were at a loſs, whether, in the uſual method of electrifying by excited glaſs, the fluid proceeded from the rubber to the conductor, or from the conductor to the rubber. It was, however, ſoon found, that the electricity at the rubber was the reverſe of that at the conductor, and in all reſpects the ſame with that which had before been produced by the friction of ſealing-wax, ſulphur, roſin, &c. Seeing, therefore, that both the electricities were produced at the ſame time, by one and the ſame electric, and by the ſame friction, all philoſophers were naturally led to conclude, that both were modifications of one fluid; though in what manner that fluid was modified throughout the immenſe variety of electric phenomena, was a matter not eaſy to be determined.

60
Abbe Nollet's theory.

On this ſubject, the Abbe Nollet adopted the doctrine of *afflux* and *efflux* already mentioned. He ſuppoſed, that, in all electrical operations, the fluid is thrown into two oppoſite motions; that the afflux of this matter drives all light bodies before it by impulſe upon the electrified body, and its efflux carries them back again. He was, however, very much embarraſſed in accounting for facts where both theſe currents muſt be conſidered; as in the quick alternate attraction and repulſion of light bodies by an excited glaſs tube, or other excited electric. To obviate this difficulty, he ſuppoſes that every excited electric, and likewiſe every body to which electricity is communicated, has two orders of pores, one for the emiſſion of the effluvia, and another for the reception of them. Mr de Tour improved upon Nollet's hypotheſis, and ſuppoſed that there is a difference between the affluent and effluent current; and that the particles of the fluid are thrown into vibrations of different qualities, which makes one of theſe currents more copious than the other, according as ſulphur or glaſs is uſed. It is impoſſible, however, that ſuppoſitions ſo very arbitrary could be at all ſatisfactory, or received as proper ſolutions of the electric phenomena.

61
Differe opinion concern the na of the tric flu

No leſs difficult was it for philoſophers to determine the nature of the electric fluid, than its manner of acting. It had been in a manner generally believed, that *fire* was not a diſtinct element, but aroſe from ſome violent repulſions, rarefactions, &c. among the particles of ignited bodies. The great reſemblance of the electric fluid to elementary fire, however, ſeemed ſtrongly to militate againſt this opinion. The hypotheſis therefore of fire as a diſtinct principle or element began to revive. Some maintained, that the electric fluid was really this principle; others thought that it was a fluid *ſui generis*, very much reſembling that of fire; while others, with Mr Boulanger at their head, imagined that it was nothing more than the finer parts of the atmoſphere, which crowded upon the ſurfaces of electric bodies, when the groſſer parts had been driven away by the friction of the rubber.

This laſt opinion, however, ſoon received a full refutation from the experiments of Dr Watſon above-mentioned; by which it was proved, that the electric matter came not from the atmoſphere, but from the earth. About the ſame time the Leyden phial was diſcovered; and the extraordinary effects of it rendered the inquiries into the nature of the electric fluid much more general than before. But ſtill, the violent prejudice againſt the exiſtence of fire as a real element or fluid diſtinct from terreſtrial bodies, continued in its full vigour, and the moſt extravagant theories were acquieſced in, rather than the ſimple poſition above mentioned. It would be tedious, and indeed impoſſible, to give an account of all the theories which were now invented. One of the moſt remarkable, and moſt conſiſtent, was that of Mr Wilſon. According to this gentleman, the chief agent in all the operations of electricity, is Sir Iſaac Newton's ether; which is more or leſs denſe in all bodies in proportion to the ſmallneſs of their pores, except that it is much denſer in ſulphureous and unctuous bodies. To this ether are aſcribed the principal phenomena of attraction and repulſion: the light, the ſulphureous or rather phoſphoreal ſmell with which violent electricity is always attended, and other ſenſible qualities, are aſcribed to the groſſer particles of bodies driven from them by the forcible action of this ether. He alſo endeavours to explain many electrical phenomena by means of a ſubtle medium at the ſurface of all bodies; which is the cauſe of the refraction and reflection of the rays of light, and alſo reſiſts the entrance and exit of this ether. This medium, he ſays, extends to a ſmall diſtance from the body, and is of the ſame nature with what is called the *electric fluid*. On the ſurface of conductors this medium is rare, and eaſily admits the paſſage of the electric fluid; whereas, on the ſurface of electrics, it is denſe and reſiſts it. The ſame medium is rarefied by heat, which thus changes conductors into non-conductors. By far the greater number of philoſophers, however, rejected the opinion of Mr Wilſon; and as they neither choſe to allow the electric fluid to be *fire* nor *ether*, they were obliged to own that it was a fluid *ſui generis*, i. e. one of whoſe nature they were totally ignorant.

62
Mr W ſon's th ry.

But while philoſophers were thus embarraſſed in their electrical theories, a vaſt number of intereſting phenomena were diſcovered by the aſſiduity of a number of different electricians in different countries. Mr Winckler obſerved, that if glaſs was rubbed on the inſide,

ſide, it would ſhow ſtrong appearances of electricity on the outſide; which ſeemed to favour the opinion of the permeability of glaſs to the electric matter. Other German electricians uſed ſeveral globes at a time, and imagined they found effects proportionable; tho' this has ſince been found a miſtake. Such a prodigious force, however, could they excite by means of theſe globes whirled by a large wheel, and rubbed by the hand or with woollen cloth, that, according to their own accounts, blood could be drawn from a finger by means of the electric ſpark, the ſkin would burſt, and a wound appear as if made by a cauſtic. If ſeveral globes or tubes were uſed, they ſaid, that the motion of the heart and arteries would be very perceptibly increaſed in ſuch as were electrified; and that, if a vein was opened in theſe circumſtances, the blood iſſuing from it would appear like lucid phoſphorus, and run out faſter than when the perſon was not electrified. Mr P. Gordon, a Scots Benedictine monk, and profeſſor of philoſophy at Erfurd, increaſed the electric ſparks to ſuch a degree, that they were felt from a man's head to his foot, ſo that he could hardly take them without falling down with giddineſs, and ſmall birds were killed by them. This was effected by conveying the electricity with iron wires to the diſtance of 200 ells from the place of excitation. He alſo found that the ſparks were ſtronger when the wires were thick than when they were ſmall.

s.

While the power of electricity was thus tried, another queſtion of great importance was likewiſe decided, namely, Whether electricity acted according to the largeneſs of the ſurface of bodies? This was found to be in proportion to the ſurface, and not the ſolid contents. The magnetic effluvia alſo were found not to interfere in the leaſt with the electrical ones. An electrified loadſtone attracted light bodies of all kinds by its electric virtue, at the ſame time that it attracted iron and ſteel by its peculiar magnetic virtue. The attractive virtue of electricity was alſo found to pervade glaſs ſo powerfully, that a thread was attracted through five exhauſted receivers, and ſeemingly with more vigour than it would have been by the excited tube alone in the open air.

Such was the ſtate of philoſophical opinions concerning electricity, when Dr Franklin firſt invented his theory concerning poſitive and negative, or *plus* and *minus*, electricity. This had been already ſuggeſted by Dr Watſon, but was not ſo fully explained by him as by Dr Franklin; on which account the latter is generally reckoned to be the ſole inventor. According to this theory, all the operations in electricity depend upon one fluid *ſui generis*, extremely ſubtile and elaſtic. Between the particles of this fluid there ſubſiſts a very ſtrong repulſion with regard to each other, and as ſtrong an attraction with regard to other matter. Thus, according to Dr Franklin's hypotheſis, one quantity of electric matter will repel another quantity of the ſame, but will attract and be attracted by any terreſtrial matter that happens to be near it. The pores of all bodies are ſuppoſed to be full of this ſubtile fluid; and when its equilibrium is not diſturbed, that is, when there is in any body neither more nor leſs than its natural ſhare, or than that quantity which it is capable of retaining by its own attraction, the fluid does not manifeſt itſelf to our ſenſes. The action of the rubber upon an electric diſturbs this equilibrium, occaſioning a deficiency of the fluid in one place, and a redundancy of it in another. This equilibrium being forcibly diſturbed, the mutual repulſion of the particles of the fluid is neceſſarily exerted to reſtore it. If two bodies be both of them overcharged, the electric atmoſpheres repel each other, and both the bodies recede from one another to places where the fluid is leſs denſe. For as there is ſuppoſed to be a mutual attraction between all bodies and the electric fluid, ſuch bodies as are electrified muſt go along with their atmoſpheres. If both the bodies are exhauſted of their natural ſhare of this fluid, they are both attracted by the denſer fluid exiſting either in the atmoſphere contiguous to them, or in other neighbouring bodies; which occaſions them ſtill to recede from one another as if they were overcharged.

66
Difficulty concerning the reaſon why bodies negatively electrified repel one another.

This is the Franklinian doctrine concerning the cauſe of electric attraction and repulſion; but it is evident, that the reaſon juſt now given why bodies negatively attracted ought to repel one another, is by no means ſatisfactory. Dr Franklin himſelf had framed his hypotheſis before he knew that bodies negatively electrified would repel one another; and when he came afterwards to learn it, he was ſurpriſed, and acknowledged that he could not ſatisfactorily account for it *. Other philoſophers therefore invented different ſolutions of this difficulty, of which that above mentioned is one. But by ſome this was rejected. They ſaid, that as the denſer electric fluid, ſurrounding two bodies negatively electrified, acts equally on all ſides of thoſe bodies, it cannot occaſion their repulſion. The repulſion, according to them, is owing rather to an accumulation of the electric on the ſurfaces of the two bodies; which accumulation is produced by the attraction, and the difficulty the fluid finds in entering them. This difficulty is ſuppoſed chiefly to be owing to the air on the ſurface of bodies, which Dr Prieſtley ſays is probably a little condenſed there. This he deduces from an experiment of Mr Wilſon, corrected by Mr Canton. The experiment was made in order to obſerve the courſe of the electric light through a Torricellian vacuum. A ſingular appearance of light was obſerved upon the ſurface of the quickſilver, at which the fluid was ſuppoſed to enter. Mr Wilſon ſuppoſed that this was owing to a ſubtile medium ſpread over the ſurface of the quickſilver, and which prevented the eaſy entrance of the electric fluid. But this was afterwards diſcovered by Mr Canton to be owing to a ſmall quantity of air which had been left in the tube. It is plain, however, that as the attraction is equal all round, and likewiſe the difficulty with which the fluid penetrates the air, bodies negatively electrified ought not to repel one another on this ſuppoſition more than the former. Nay, they ought to attract each other; becauſe, in the place of contact, the reſiſtance of the air would be taken off, and the electric fluid could come from all other quarters by the attraction of the bodies.

67
Different ſolutions of this difficulty.

68
Mr Cavallo's ſolution.

Mr Cavallo, who ſeems to have undertaken the defence of this hypotheſis in all caſes, gives another reaſon why bodies negatively electrified ſhould repel each other. In a chapter intitled, "A Compendious View of the principal properties of Electricity," among others he gives the following: "No electricity can be ob-

---

* *Franklin's Letters.*

obſerved upon the ſurface of any electrified body, except that ſurface is contiguous to an electric, which electric can ſome how or other acquire a contrary electricity at a little diſtance. Otherwiſe:—No electricity can appear upon the ſurface of any electrified body, except that ſurface is oppoſite to another body which has actually acquired the contrary electricity, and theſe contrarily electrified bodies are ſeparated by an electric. On conſidering this principle (adds he), it may be aſked, Why an electricity can be obſerved upon the ſurface of an electrified body that is inſulated at a conſiderable diſtance from other conductors? Or, Which is the electric that is contiguous to the ſurface of an electrified conductor or excited electric, and which has actually acquired a contrary electricity at a little diſtance from the ſaid ſurface? To this queſtion it is anſwered, that the air is, in general, the electric which is oppoſite to the ſurface of any electrified body; which, not being a perfect conductor, does eaſily acquire a contrary electricity on a ſtratum of its ſubſtance that is at a little diſtance from the electrified body; and, in conſequence of this ſtratum, it acquires another ſtratum contrarily electrified, and at a little diſtance from the former: to this other ſtrata ſucceed, alternately poſſeſſed of poſitive and negative electricities, and decreaſing in power till they vaniſh. This aſſertion is eaſily proved by ſeveral experiments, particularly the following. If the end of a pretty long glaſs tube be preſented to a body electrified, for inſtance, poſitively, the tube will be found electrified poſitively alſo for the ſpace of one or two inches at that end; but beyond that ſpace, will be found two or three inches electrified negatively: after that another poſitive electricity will appear; and ſo alternately, a poſitive and a negative zone will follow one another, always weaker and weaker in power, till at laſt they quite vaniſh. This ſhows, that, in general, when an electric ſufficiently denſe is preſented to an electrified body, it acquires ſucceſſive zones or ſtrata of poſitive and negative electricity."

From this fact (which, with the utmoſt impropriety, he terms a *law* of electricity, whereas it is moſt evidently the *effect* of a law, and not the law itſelf), Mr Cavallo gives the following reaſon why bodies negatively electrified repel one another. "As to the repulſion exiſting between bodies poſſeſſed of the ſame electricity; in order to underſtand its explanation thoroughly, the reader muſt be reminded of the principle above-mentioned, which is, that no electricity, *i. e.* the electric fluid proper to a body, can either be augmented or diminiſhed upon the ſurface of that body, except the ſaid ſurface is contiguous to an electric, which can acquire a contrary electricity at a little diſtance: from whence it follows, that no electricity can be diſplayed upon the facing ſurfaces of two bodies that are ſufficiently near to one another, and both poſſeſſed of the ſame electricity; for the air that lies between thoſe contiguous ſurfaces has no liberty of acquiring any contrary electricity. This being premiſed, the explanation of electric repulſion becomes very eaſy. Suppoſe, for inſtance, that two ſmall bodies are freely ſuſpended by inſulated threads; ſo that, when they are not electrified, they may hang contiguous to one another. Now ſuppoſe theſe bodies to be electrified either poſitively or negatively, and then they muſt repel one another: for either the increaſed or the diminiſhed natural quantity of electric fluid in theſe bodies will endeavour to diffuſive itſelf equally over every part of the ſurfaces of theſe bodies; and this endeavour will cauſe the ſaid bodies to recede from each other, ſo that a quantity of air may be interpoſed between their ſurfaces, ſufficient to acquire a contrary electricity at a little diſtance from the ſaid ſurfaces. Otherwiſe: If the bodies poſſeſſed of the ſame electricity do not repel each other, ſo that a ſufficient quantity of air may be interpoſed between their ſurfaces, the increaſed quantity of electric fluid when the bodies are electrified poſitively, or the remnant of it when they are electrified negatively, by the above principle cannot be diffuſed equally throughout or over the ſurfaces of theſe bodies; for no electricity can appear upon the ſurfaces of bodies in contact, or that are very near each other. But the electric fluid, by attracting the particles of matter, endeavours to diffuſe itſelf equally throughout or over the ſurfaces of theſe bodies; therefore the ſaid bodies are, by this endeavour, forced to repel one another."

69 Inſufficie

This theory is evidently no ſolution of the difficulty; ſeeing it is only explaining one fact by another, which requires explanation at leaſt as much as the firſt. But though this ſhould be overlooked, it is ſtill inſufficient; for, granting that bodies negatively electrified ought to repel one another till the electricity is equally diffuſed along their ſurfaces, yet when this is accompliſhed, the repulſion ought to ceaſe. Now, there is no occaſion for ſuppoſing the bodies to be electrified while they are in contact, or nearly ſo. One may be electrified negatively in one corner of a room, and another in the other. The electrification may alſo be continued for any length of time we pleaſe, ſo that it is not poſſible to ſuppoſe but the electric matter muſt have diffuſed itſelf equally along the ſurfaces of both: yet, if we attempt to bring theſe bodies together, we ſhall find that they will repel each other very violently; which ought not to be the caſe, according to Mr Cavallo's ſuppoſition.

70 Dr Franklin's explanation of the phenomena of the Leyden phial.

What gave the greateſt reputation to Dr Franklin's theory, however, is the eaſy ſolution which it affords of all the phenomena of the Leyden phial. The fluid is ſuppoſed to move with the greateſt eaſe in bodies which are conductors, but with extreme difficulty in *electrics per ſe*; inſomuch that glaſs is abſolutely impermeable to it. It is moreover ſuppoſed, that all electrics, and particularly glaſs, on account of the ſmallneſs of their pores, do at all times contain an exceeding great, and always an equal quantity of this fluid; ſo that no more can be thrown into any one part of any electric ſubſtance, except the ſame quantity go out at another, and the gain be exactly equal to the loſs. Theſe things being previouſly ſuppoſed, the phenomena of charging and diſcharging a plate of glaſs admit of an eaſy ſolution. In the uſual manner of electrifying by a ſmooth glaſs globe, all the electric matter is ſupplied by the rubber from all the bodies which communicate with it. If it be made to communicate with nothing but one of the coatings of a plate of glaſs, while the conductor communicates with the other, that ſide of the glaſs which communicates with the rubber muſt neceſſarily be exhauſted in order to ſupply the conductor, which muſt convey the whole of it to the ſide with which it communicates. By this operation, therefore, the electric fluid becomes almoſt entirely exhauſted on one ſide of the plate, while it is as much accumulated on the other; and the diſcharge is made by the electric fluid ruſhing, as ſoon as an opportunity is given it by means of proper conductors, from the ſide which was overloaded to that which is exhauſted.

It is not, however, neceſſary to this theory, that the very ſame individual particles of electric matter which were thrown upon one ſide of the plate, ſhould make the whole circuit of the intervening conductors, eſpecially in very great diſtances, ſo as actually to arrive at the exhauſted ſide. It may be ſufficient to ſuppoſe, that the additional quantity of fluid diſplaces and occupies the ſpace of an equal portion of the natural quantity of fluid belonging to thoſe conductors in the circuit which lay contiguous to the charged ſide of the glaſs. This diſplaced fluid may drive forwards an equal quantity of the ſame matter in the next conductor; and thus the progreſs may continue till the exhauſted ſide of the glaſs is ſupplied by the fluid naturally exiſting in the conductors contiguous to it. In this caſe, the motion of the electric fluid, in an exploſion, will rather reſemble the vibration of the air in ſounds, than a current of it in winds.

It will ſoon be acknowledged (ſays Dr Prieſtley), that while the ſubſtance of the glaſs is ſuppoſed to contain as much as it can poſſibly hold of the electric fluid, no part of it can be forced into one of the ſides, without obliging an equal quantity to quit the other ſide: but it may be thought a difficulty upon this hypotheſis, that one of the ſides of a glaſs plate cannot be exhauſted, without the other receiving more than its natural ſhare; particularly, as the particles of this fluid are ſuppoſed to be repulſive of one another. But it muſt be conſidered, that the attraction of the glaſs is ſufficient to retain even the large quantity of electric fluid which is natural to it, againſt all attempts to withdraw it, unleſs that eager attraction can be ſatisfied by the admiſſion of an equal quantity from ſome other quarter. When this opportunity of a ſupply is given, by connecting one of the coatings with the rubber, and the other with the conductor, the two attempts to introduce more of the fluids into one of the ſides are made, in a manner, at the ſame inſtant. The action of the rubber tends to diſturb the equilibrium of the fluid in the glaſs; and no ſooner has a ſpark quitted one of the ſides, to go to the rubber, than it is ſupplied by the conductor on the other; and the difficulty with which theſe additional particles move in the ſubſtance of the glaſs, effectually prevents its reaching the oppoſite exhauſted ſide. It is not ſaid, however, but that either ſide of the glaſs may give or receive a ſmall quantity of the electric fluid, without altering the quantity on the oppoſite ſide. It is only a very conſiderable part of the charge that is meant, when one ſide is ſaid to be filled while the other is exhauſted.

It is a little remarkable, adds Dr Prieſtley, that the electric fluid, in this and in every other hypotheſis, ſhould ſo much reſemble the ether of Sir Iſaac Newton in ſome reſpects, and yet differ from it ſo eſſentially in others. The electric fluid is ſuppoſed to be, like ether, extremely ſubtile and elaſtic, that is, repulſive of itſelf; but inſtead of being, like the ether, repelled by all other matter, it is ſtrongly attracted by it: ſo that, far from being, like the ether, rarer in the ſmall than in the large pores of bodies, rarer within the bodies than at their ſurfaces, and rarer at their ſurfaces than at any diſtance from them; it muſt be denſer in ſmall than in large pores, denſer within the ſubſtance of bodies than at their ſurfaces, and denſer at their ſurfaces than at a diſtance from them.

71
Attraction and repulſion thro' glaſs accounted for.

To account for the attraction of light bodies, and other electrical appearances, in air of the ſame denſity with the common atmoſphere, when glaſs (which is ſuppoſed to be impermeable to electricity) is interpoſed; it is conceived, that the addition or ſubtraction of the electric fluid, by the action of the excited electric on one ſide of the glaſs, occaſions, as in the experiment of the Leyden phial, a ſubtraction or addition of the fluid on the oppoſite ſide. The ſtate of the fluid, therefore, on the oppoſite ſide being altered, all light bodies within the ſphere of its action muſt be affected in the very ſame manner as if the effluvia of the excited electric had actually penetrated the glaſs, according to the opinions of all electricians before Dr Franklin.

This hypotheſis has been in ſome meaſure improved by Mr Æpinus, in a treatiſe intitled, "Tentamen Theoriæ Electricitatis & Magnetiſmi." He extends the property of impermeability to air, and all electrics, as well as glaſs. He ſuppoſes *impermeability* to conſiſt in the great difficulty with which electric ſubſtances admit the fluid into their pores, and the ſlowneſs with which it moves in them. In conſequence of this impermeability of air to the electric fluid, he denies the exiſtence of electric atmoſpheres, and thinks that Dr Franklin's theory will do much better without them. He alſo imagines, that all the particles of matter are repulſive of one another: for that otherwiſe (ſince all ſubſtances have in them a certain quantity of the electric fluid, the particles of which repel one another and are attracted by all other matter), it could not happen, that bodies in their natural ſtate with reſpect to electricity, ſhould neither attract nor repel one another. He alſo introduces a number of mathematical calculations; the reſult of which (ſays Dr Prieſtley, with a great deal of probability) cannot be depended upon.

72
Principles on which Dr Franklin's theory depends.

The above is a full explanation of the theory of electricity at preſent moſt generally received. It depends on the following principles. 1. All terreſtrial ſubſtances, as well as the atmoſphere which ſurrounds the earth, are full of electric matter. 2. Glaſs, and other electric ſubſtances, though they contain a great deal of electric matter, are nevertheleſs *impermeable* by it. 3. This electric matter violently repels itſelf, and attracts all other matter. 4. By the excitation of an electric, the equilibrium of the fluid contained in it is broken; and one part of it is overloaded with electricity, while the other contains too little. 5. Conducting ſubſtances are permeable to the electric matter through their whole ſubſtance, and do not conduct it merely over their ſurface. 6. Poſitive electricity is when a body has too much of the electric fluid, and negative electricity when it has too little. Of theſe poſitions we ſhall now adduce thoſe proofs drawn from

Theory. different facts, which ſeem in the ſtrongeſt manner to confirm them.

I. "All terreſtrial ſubſtances, as well as the atmoſphere which ſurrounds the earth, are filled with electric fluid."—Of this the proofs are very eaſy. There is no place of the earth or ſea, where the electric fire may not be collected by making a communication between it and the rubber of an electric machine. Therefore, conſidering that the whole earth is moiſt, that moiſture is a conductor of electricity, and that every part of the earth muſt thus communicate with another, it is certain that the electric matter muſt diffuſe itſelf as far as the moiſture of the earth reaches; and this we may reaſonably ſuppoſe to be to the very centre.

73 Proofs of atmoſpherical electricity.

With regard to the atmoſphere, the caſe is equally clear. We have formerly mentioned in general, that Dr Franklin, and others, had collected electricity from the atmoſphere in great quantity during the time of thunder-ſtorms; but it is now found that it may be collected from the air at any time. The beſt inſtrument for this purpoſe is the electrical kite. Mr Cavallo, who hath made a great many experiments in atmoſpherical electricity, obſerves that the whole power of this machine lies in the ſtring. A common ſchool-boy's kite anſwers the purpoſe as well as any other. The beſt method of making the ſtring is by twiſting two threads of common twine with one of that copper-thread which is uſed for trimmings. When a kite conſtructed in this manner was raiſed, he ſays, he always obſerved the ſtring to give ſigns of electricity, except once. The weather was warm, and the wind ſo weak, that the kite was raiſed with difficulty, and could hardly be kept up for a few minutes. Afterwards, however, when the wind increaſed, he obtained, as uſual, a pretty ſtrong poſitive electricity. Concerning the management of this kite he gives the following directions.

74 Mr Cavallo's directions concerning the electrical kite.

"In raiſing the kite, when the weather is very cloudy and rainy, in which time there is danger of meeting with a great quantity of electricity, I generally uſe to hang upon the ſtring *AB* (Plate CLXXVII. fig. 78.) the hook of a chain *C*, the other extremity of which falls on the ground. Sometimes I uſe another caution beſides, which is to ſtand upon an inſulating ſtool; in which ſituation, I think, that if any quantity of electricity, ſuddenly diſcharged by the clouds, ſtrikes the kite, it cannot much affect any perſon. As to inſulated reels, and other ſuch like inſtruments that ſome gentlemen have uſed to raiſe the kite without any danger of receiving a ſhock; fit for the purpoſe as they may appear in theory, they are yet very inconvenient to be managed. Except the kite be raiſed in the time of a thunder-ſtorm, there is no great danger for the operator to receive any ſhock. Although I have raiſed my electrical kite hundreds of times without any caution whatever, I have very ſeldom received a few exceedingly ſlight ſhocks in my arms. In time of a thunder-ſtorm, if the kite has not been raiſed before, I would not adviſe a perſon to raiſe it while the ſtormy clouds are juſt overhead; the danger at ſuch a time being very great, even with the precautions abovementioned: at that time the electricity of the clouds may be obſerved, without raiſing the kite, by a cork-ball electrometer held in the hand in an open place, or, if it rains, by the electrometer for rain, to be deſcribed hereafter.

"By making uſe of this inſtrument, I am obliged to keep the kite up no longer than it is neceſſary to charge the phial, in order to obſerve the quality of the electricity in the atmoſphere; for after the kite has been drawn in, and brought home, I can then examine the electricity of the inſide of the phial, which is the ſame as that of the kite. When the electricity of the kite is very ſtrong, I fix a chain communicating with the ground, at about ſix inches diſtance from the ſtring, which may carry off its electricity in caſe this ſhould increaſe ſo much as to put the byſtanders in danger."

75 Great qu tity of el tricity brought down fr a cloud.

With all his caution, however, it ſeems Mr Cavallo could not always avoid danger, even when there was no thunder; as appears from the following account. "October 18. 1775. After having rained a great deal in the morning and night before, the weather became a little clear in the afternoon, the clouds appearing ſeparated, and pretty well defined. The wind was weſt, and rather ſtrong, and the atmoſphere in a temperate degree of heat. In theſe circumſtances, at three P. M. I raiſed my electrical kite with 360 feet of ſtring. After the end of the ſtring had been inſulated, and a leather ball covered with tin-foil had been hanged to it, I tried the power and quality of the electricity, which appeared to be poſitive and pretty ſtrong. In a ſhort time, a ſmall cloud paſſing over, the electricity increaſed a little; but the cloud being gone, it decreaſed again to its former degree. The ſtring of the kite was now faſtened by the ſilk lace to a poſt in the yard of the houſe, and I was repeatedly charging two coated phials and giving ſhocks with them. While I was ſo doing, the electricity, which was ſtill poſitive, began to decreaſe, and in two or three minutes it became ſo weak that it could hardly be perceived with a very ſenſible cork-ball electrometer. Obſerving at the ſame time, that a large and black cloud was approaching the zenith (which, no doubt, cauſed the decreaſe of electricity), indicating imminent rain, I introduced the end of the ſtring through a window in a firſt-floor room, wherein I faſtened it by the ſilk lace to an old chair. The quadrant electrometer was ſet upon the ſame window, and was by means of a wire connected with the ſtring of the kite. Being now three quarters after three o'clock, the electricity was abſolutely imperceptible: however, in about three minutes time it became again perceptible; but, upon trial, was now found to be negative. It is therefore plain, that its ſtopping was nothing more than a change from poſitive to negative; which was evidently occaſioned by the approach of the cloud, part of which by this time had reached the zenith of the kite, and the rain alſo had begun to fall in large drops. The cloud alſo came farther on; the rain increaſed; and the electricity keeping pace with it, the electrometer ſoon arrived at 15°. Seeing now that the electricity was pretty ſtrong, I began again to charge the two coated phials, and to give ſhocks with them; but the phials had not been charged above three or four times, before I perceived that the index of the electrometer was arrived at 35°, and was keeping ſtill increaſing. The ſhocks being now very ſmart, I deſiſted from charging the phials any longer; and, conſidering the rapid advance of the electricity, thought to take ry.

take off the inſulation of the ſtring, in caſe that, if it ſhould increaſe farther, it might ſilently be conducted to the earth without cauſing any bad accident by being accumulated in the inſulated ſtring. To effect this, as I had no proper apparatus near me, I thought to remove the ſilk lace, and faſten the ſtring itſelf to the chair. Accordingly I diſengaged the wire that connected the electrometer with the ſtring; laid hold of the ſtring; untied it from the ſilk lace, and faſtened it to the chair: but while I effected this, which took up leſs than half a minute of time, I received about 12 or 15 very ſtrong ſhocks, which I felt all along my arms, in my breaſt, and legs; ſhaking me in ſuch a manner, that I had hardly power enough to effect my purpoſe, and to warn the people in the room to keep their diſtance. As ſoon as I took my hands off the ſtring, the electricity (in conſequence of the chair being a bad conductor) began to ſnap between the ſtring and the ſhutter of the window, which was the neareſt body to it. The ſnappings, which were audible at a good diſtance out of the room, were at firſt iſochronous with the ſhocks which I had received; but, in about a minute's time, oftener; ſo that the people of the houſe compared their ſound to the rattling noiſe of a jack going when the fly is off. The cloud now was juſt over the kite; it was black, and well defined, almoſt of a circular form, its diameter appearing to be about 40°. The rain was copious, but not remarkably heavy. As the cloud was going off, the electrical ſnapping began to weaken, and in a ſhort time became inaudible. I went then near the ſtring, and finding the electricity weak, but ſtill negative, I inſulated it again, thinking to keep up the kite ſome time longer: but obſerving that another larger and denſer cloud was approaching towards the zenith, and I had then no proper apparatus at hand to prevent every poſſible bad accident, reſolved to pull the kite in: accordingly a gentleman who was by me began pulling it in, while I was winding up the ſtring. The cloud was now very nearly over the kite; and the gentleman told me that he had received one or two ſlight ſhocks in his arms; and that, if he was to receive another, he would certainly let the ſtring go: upon which I laid hold of the ſtring, and pulled the kite in as faſt as I could without any farther obſervation; being then ten minutes after four o'clock.—N. B. There was neither thunder nor lightning perceived that day, nor indeed for ſome days before or after."

From his obſervations on the electricity of the atmoſphere, Mr Cavallo deduces the following concluſions.

ſions
from
peri-

" 1. That there is in the atmoſphere at all times a quantity of electricity; for whenever I uſe the abovementioned inſtrument, it always acquires ſome electricity.

" 2. That the electricity of the atmoſphere, or fogs, is always of the ſame kind, namely, poſitive; for the electrometer is always negative, except when it is evidently influenced by heavy clouds near the zenith.

" 3. That, in general, the ſtrongeſt electricity is obſervable in thick fogs, and alſo in froſty weather; and the weakeſt, when it is cloudy, warm, and very near raining: but it does not ſeem to be leſs by night than in the day.

Theory.

" 4. That in a more elevated place the electricity is ſtronger than in a lower one; for having tried the atmoſpherical electrometer both in the ſtone and iron gallery on the cupola of St Paul's cathedral, I found that the balls diverged much more in the latter than in the former leſs elevated place. Hence it appears, that if this rule takes place at any diſtance from the earth, the electricity in the upper regions of the atmoſphere muſt be exceedingly ſtrong."

The concluſions drawn from the experiments with the kites, are as follow.

" 1. The air appears to be electrified at all times; its electricity is conſtantly poſitive, and much ſtronger in froſty than in warm weather; but it is by no means leſs in the night than in the day time.

" 2. The preſence of the clouds generally leſſens the electricity of the kite; ſometimes it has no effect upon it; and it is very ſeldom that it increaſes it a little." To this the above mentioned inſtance is a moſt remarkable exception.

" 3 When it rains, the electricity of the kite is generally negative, and very ſeldom poſitive.

" 4. The aurora borealis ſeems not to affect the electricity of the kite.

" 5. The electric ſpark taken from the ſtring of the kite, or from any inſulated conductor connected with it, eſpecially when it does not rain, is very ſeldom longer than a quarter of an inch; but it is exceedingly pungent. When the index of the electrometer is not higher than 20°, the perſon that takes the ſpark will feel the effect of it in his legs; it appearing more like the diſcharge of an electric jar than the ſpark taken from the prime conductor of an electrical machine.

" 6. The electricity of the kite is generally ſtronger or weaker, according as the ſtring is longer or ſhorter; but it does not keep any exact proportion to it. The electricity, for inſtance, brought down by a ſtring of 100 yards, may raiſe the index of the electrometer to 20, when, with double that length of ſtring, the index of the electrometer will not go higher than 25.

" 7. When the weather is damp, and the electricity is pretty ſtrong, the index of the electrometer, after taking a ſpark from the ſtring, or preſenting the knob of a coated phial to it, riſes ſurpriſingly quick to its uſual place; but in dry and warm weather it riſes exceedingly ſlow."

II. The ſecond poſition requiſite for eſtabliſhing Dr Franklin's theory is, " That glaſs and other electric ſubſtances, though they contain a great deal of electric matter, are nevertheleſs *impermeable* by it." This aſſertion evidently has a contradictory appearance. It is very difficult, if not impoſſible, to conceive, that any ſubſtance can be full of a fluid, and yet impermeable by that fluid; eſpecially when we continually talk of putting in an additional quantity into one ſide, and taking out of the other. Nay, what is ſtill more extraordinary, the thinner the glaſs is, *i. e.* the *leſs* quantity of electric matter it can contain, the *more* we are able to put into it; for the thinner a glaſs is, the more eaſily does it receive a high charge.

77
Arguments for the impermeability of glaſs refuted.

The chief arguments for the impermeability of glaſs by the electric fluid are drawn from the phenomena of the Leyden phial. It is indeed very plain, that there is in that caſe an expulſion of fire from the outſide at the

the ſame time that it is thrown upon the inſide. This appears from numberleſs experiments, but is moſt readily obſervable in the following. Let a coated phial be ſet upon an inſulating ſtand, and the knob of another phial brought near the coating of the firſt. As ſoon then as the electric ſparks are diſcharged from the prime conductor to the knob of the firſt bottle, an equal number will be obſerved to proceed from the coating of the firſt to the knob of the ſecond. This is very remarkable, and an unphiloſophical obſerver will ſcarce ever fail to conclude, that the fire runs directly through the ſubſtance of the glaſs. Dr Franklin, however, concludes that it does not, becauſe there is found a very great accumulation of electricity on the inſide of the glaſs, which diſcovers itſelf by a violent flaſh and exploſion when a communication is made between the outſide and inſide coatings. But it muſt be obſerved, that there is here no other reaſon for concluding the glaſs to be impermeable, except that we *ſuppoſe* the electric matter to be *accumulated* on one ſide of the glaſs, and *deficient* on the other. If this ſuppoſition therefore cannot be proved, the evidence of ſenſe, which indeed is very ſtrong in favour of the permeability, muſt undoubtedly preponderate. It is ſaid, indeed, that if the glaſs was permeable by the electric matter, a phial would be diſcharged immediately after being charged, or rather could never be charged at all; becauſe the matter would no ſooner be thrown upon one ſide than it would fly off from the other. This ſuppoſition, however, depends entirely upon the abovementioned one, namely, that in bodies *poſitively* electrified there is an *accumulation*, and in ſuch as are *negatively* electrified there is a *deficiency* of fluid; which never can be proved.

Another argument againſt the permeability of glaſs and other electrics is, that coated phials, it is ſaid, ſtanding upon electric ſubſtances, cannot be charged. This, however, ſeems to be very much exaggerated. A phial, though ever ſo perfectly inſulated, will always receive a charge from a machine that acts very powerfully. Nay, it is certain, that though a phial is placed in ſuch a manner, that both its knob and outſide coating are in contact with the prime conductor, it will ſtill receive a charge; much leſs indeed in this caſe than in any other, but ſtill the ſhock will be perceptible.

In 1759, Mr Wilſon read a paper before the Royal Society, in which the permeability of glaſs by the electric fluid was aſſerted. The experiments from which he deduced this concluſion were the following. He took a very large pane of glaſs, a little warmed; and holding it upright by one edge, while the oppoſite edge reſted upon wax, he rubbed the middle part of the ſurface with his finger, and found both ſides electrified *plus*. He accounted for this from the electrical fluid paſſing through the glaſs from his finger to the oppoſite ſide. But here Dr Prieſtley obſerves, that on Franklin's principles it ought to be ſo. If one ſide be rubbed by the finger, it acquires from it ſome electrical fluid. This being ſpread on the glaſs as far as the rubbing extended, repels an equal quantity of that contained in the other ſide of the glaſs, and drives it out on that ſide, where it ſtands as an atmoſphere, ſo that both ſides are found poſitively electrified. Mr Wilſon alſo tried another experiment, which ſeemed more deciſive than the former: Having by him a pane of glaſs, one ſide of which was rough and the other ſmooth, he rubbed it ſlightly on one ſide; upon doing which, both ſides were electrified *minus*. This alſo Dr Prieſtley attempts to reconcile with Franklin's hypotheſis. "As the electric fluid, contained in the glaſs (ſays he), is kept equal in both ſides by the common repulſion; if the quantity in one ſide is diminiſhed, the fluid in the other ſide, being leſs repelled, retires *inward*, and leaves that ſurface alſo *minus*." But here it is impoſſible to avoid obſerving, that Dr Prieſtley's own words, in the ſtrongeſt manner, militate againſt the doctrine he means to eſtabliſh. The quantity of fluid in one ſide being diminiſhed, that on the other, he ſays, *retires inward*. But into what does it retire? if into the ſubſtance of the glaſs, then the glaſs is undoubtedly permeable by it; and this is the very thing which Dr Prieſtley argues againſt.

7
The e
tric fl
canno
prove
pulſiv
itſelf.

III. "The electric matter violently repels itſelf, and attracts all other matter." The proofs of this poſition are chiefly derived from the following experiment, and others of a ſimilar kind. Let a ſmooth piece of metal be inſulated, and bring an excited glaſs tube near one end of it. A ſpark of poſitive electricity will be obtained from the other end; after which, if the tube is ſuddenly removed, the metal becomes electrified negatively. Here, then, it is ſaid, is a plain repulſion of one part of the electric fluid by another. That contained in the tube repels the fluid contained in the neareſt end of the metal; of conſequence it is accumulated in the other end, and when the tube is removed, the metal is found to be deprived of part of its natural quantity of electricity, or is electrified negatively.—On ſuch experiments as this, however, it is obvious to remark, that we ought firſt to prove that poſitive electricity conſiſts in an *accumulation*, and negative electricity in a *deficiency*, of the electric fluid. But while this is only *ſuppoſed*, it is impoſſible that any proofs drawn from the ſuppoſition can be concluſive.

7
Becc
hypo
conce
excit

IV. "By the excitation of an electric, the equilibrium of the fluid contained in it is broken, and one part is overloaded with electricity, while the other contains too little." This poſition is entirely hypothetical. No electrician hath yet explained, in a ſatisfactory manner, how the fluid is procured by the excitation of glaſs or any other electric ſubſtance. Dr Prieſtley, inſtead of giving an explanation, propoſes ſeveral queries concerning it. Mr Cavallo tells us, that the act of excitation *pumps* as it were the electric fluid from the rubber, and conſequently from the earth. He adds, "By what mechaniſm one body extracts the electric fluid from another, is not yet known. The celebrated Father Beccaria ſuppoſes, that the action of rubbing increaſeth the capacity of the electric, *i. e.* renders that part of the electric which is actually under the rubber, capable of containing a greater quantity of electric fluid: hence it receives from the rubber an additional ſhare of fluid, which is manifeſted upon the ſurface of the electric, when that ſurface is come out from the rubber; in which ſtate it loſes, or, as it were, contracts its capacity. Signior Beccaria's experiment to prove this ſuppoſition is the following. He cauſed a glaſs plate to be rubbed by a rubber applied on one ſide of the plate, while it was turning vertically; and holding at the ſame time a linen thread on the other ſide of the plate

plate juſt oppoſite to the rubber, he obſerved that the thread was not attracted by that part of the glaſs which correſponded to the rubber, but by that which was oppoſite to the ſurface of the glaſs that had juſt come out from the rubber; which ſhows, that the fluid acquired by the glaſs plate did not manifeſt its power until the ſurface of the glaſs was come out from the rubber." But from this experiment it ſeems impoſſible to draw any concluſion concerning the capacity of glaſs either one way or other. It is evident, therefore, that whatever parts of Dr Franklin's hypotheſis reſt on this ſuppoſition concerning excitation, are entirely void of evidence.

V. "Conducting bodies are permeable by the electric fluid through the whole of their ſubſtance, and do not conduct it merely over their ſurface." The proof moſt commonly adduced in favour of this poſition, is the following experiment. Take a wire of any kind of metal, and cover part of it with ſome electric ſubſtance, as roſin, ſealing-wax, &c. then diſcharge a jar through it, and it will be found that it conducts as well with as without the electric coating. This, ſays Mr Cavallo, proves that the electric matter paſſes through the ſubſtance of the metal, and not over its ſurface. A wire, adds he, continued through a vacuum, is alſo a convincing proof of the truth of this aſſertion. Even here, however, the proof, if impartially conſidered, will be found very defective. It is a fact agreed upon by all philoſophers, that bodies which to us are apparently in contact, do nevertheleſs require a very conſiderable degree of force to make them actually touch one another. Dr Prieſtley found that a weight of ſix pounds was neceſſary to preſs 20 ſhillings into cloſe contact, when lying upon one another on a table. A much greater weight was neceſſary to bring the links of a chain into contact with each other. It cannot be at all incredible, therefore, that a wire, though covered with ſealing-wax or roſin, ſhould ſtill remain at ſome little diſtance from the ſubſtance which covers it. The following experiments of Dr Prieſtley alſo ſeem to be much in favour of the ſuppoſition that the electric fluid paſſes chiefly over the ſurface of conducting ſubſtances.

"From the very firſt uſe of my battery (ſays he), I had obſerved a very black ſmoke or duſt to ariſe on every diſcharge, even when no wire was melted; and the braſs chain I made uſe of was of a conſiderable thickneſs. I obſerved, that a piece of white paper, on which lay the chain I was uſing to make the diſcharge, was marked with a black ſtain, as if it had been burnt, wherever it had touched it. I neglected the experiment, till, ſome time after, obſerving a very ſtriking appearance of the ſame kind, I was determined to attend to the circumſtances of it a little more particularly. I made my chain very clean, and wrapping it in white paper, I made a diſcharge of about 40 ſquare feet through it, and found the ſtain wherever it had touched the paper. Some time after I wrapped the paper, in the ſame manner, round a piece of braſs wire; but, making a diſcharge through it, ſaw no ſtain. To aſcertain whether this appearance depended upon the diſcontinuity of the metallic circuit, I ſtretched the chain with a conſiderable weight, and found the paper on which it lay, as the ſhock paſſed through it, hardly marked at all. Finding that it depended upon the diſcontinuity, I laid the chain upon white paper, making each extremity faſt with pins ſtuck through the links; and when I had made the diſcharge, obſerved that the black ſtains were directly oppoſite to the body of the wire that formed the chain, and not to the intervals, as I had ſometimes ſuſpected. A chain five feet four inches long, which weighed one ounce ſeventeen penny-weights four grains, loſt exactly half a grain after each diſcharge.

81
A chain ſhortened by the electric ſhock.

"In making the mark above-mentioned, I once happened to lay the chain ſo as to make it return at a ſharp angle, in order to impreſs the form of a letter upon the paper; and obſerved, that on the diſcharge, the part of the chain that had been doubled was diſplaced, and pulled about two inches towards the reſt of the chain. At this I was ſurpriſed, as I thought it lay ſo, that it could not ſlide by its own weight. Upon this I repeated the experiment with more accuracy. I ſtretched the whole chain along a table, laying it double all the way, and making it return by a very ſharp angle. The conſequence always was, that the chain was ſhortened about two inches, and ſometimes more, as if a ſudden pull had been given to it by both the ends. Suſpecting that the black ſmoke which roſe at every diſcharge, might come, not from the chain, but from the paper, or the table on which it lay, and which was probably burnt by the contact of it, I let the chain hang freely in the air; but, upon making the diſcharge, I obſerved the ſame groſs black ſmoke that had before riſen from the paper or the table. Fig. 76. repreſents the ſpots made upon the paper by a chain laid over it. The breadth of the ſpots is about the mean thickneſs of the wire of the chain, and *a b* marks the place to which that part of the chain which returned was thrown back by the diſcharge.

Plate CLXXVII.

"Being willing to try what would be the effect of laying the chain in contact with non-conductors, I dipped it in melted roſin till it had got a coating of conſiderable thickneſs. When it was quite ſtiff, I laid it carefully, without bending, upon white paper, and made the diſcharge through it. The roſin was inſtantly diſperſed from all the outſide of the chain, it being left as clean as if none had ever been put on. That with which the holes in the chain had been filled having been impelled in almoſt all directions, was beaten to powder; which, however, hung together but was perfectly opaque; whereas it had been quite tranſparent before this ſtroke. I next laid the chain upon a piece of glaſs, which was marked in the moſt beautiful manner wherever the chain had touched it; every ſpot the width and colour of the link. The metal might be ſcraped off the glaſs at the outſide of the marks; but in the middle part it was forced within the pores of the glaſs. On the outſide of this metallic tinge was the black duſt, which was eaſily wiped off.

From theſe experiments it would ſeem, that the electrical flaſh had paſſed over the ſurface of the chain rather than through its ſubſtance; ſeeing it threw off the roſin with ſuch extreme violence. The ſame thing appears from the manner in which electricity generally acts, which is not according to the ſolid contents of any ſubſtance, but according to the dimenſions of its ſurface. It is not to be doubted, however, but that, where a great quantity of electric matter is made to paſs along a very ſmall wire, it will enter the ſubſtance of the metal. This appears from the poſſibility of melting wires by the force of electric batteries, and even totally diſſipating them into ſmall globules. To accompliſh this, it is only neceſſary to connect the hook communicating with the outſide coating of a battery, containing at leaſt 30 ſquare feet of coated ſurface, with a wire that is about one-fiftieth part of an inch thick and about two feet long. The other end of it muſt be faſtened to one end of the diſcharging rod: this done, charge the battery; and then by bringing the diſcharging rod near its wires, ſend the exploſion through the ſmall wire, which by this means will be made red hot and melted. ſo as to fall upon the floor in different glowing pieces. When a wire is melted in this manner, ſparks are frequently ſeen at a conſiderable diſtance from it, which are red hot particles of the metal, that, by the violence of the exploſion, are ſcattered in all directions. If the force of the battery is very great, the wire will be entirely diſperſed by the exploſion, ſo that none of it can be afterwards found. If it is required to melt ſuch particles as cannot eaſily be drawn into wires, ores, for inſtance, or grain-gold, they may be ſet in a train upon a piece of wax: they are then to be put into the circuit, and an exploſion ſent through them, which, if ſufficiently ſtrong, will melt them as well as the wires. If a wire is ſtretched by weights, and a ſhock is ſent through it which renders it juſt red hot, the wire, after the exploſion, is found to be conſiderably lengthened.

82 Dr Franklin's hypotheſis concerning poſitive and nagative electricity cannot be proved.

VI. The laſt poſition on which Dr Franklin's theory depends, and which indeed may be called the foundation of the whole, is, "That poſitive electricity is an accumulation, or too great a quantity, of electric matter contained in a body; and negative electricity is when there is too little." Of this, however, there is not one ſolid proof; and all attempts that have hitherto been made to prove it, are only arguing in a circle, or proving the thing by itſelf. Thus, for inſtance, a body electrified poſitively, attracts one that is electrified negatively; becauſe the firſt has too much, and the other too little, electric matter. But how do we know that one has too much, and the other too little, electricity? Becauſe they attract each other. Again it has been proved, that when a phial is electrified poſitively, there is as conſtant a ſtream of fire from the outſide coating, as there is from the conductor to the inſide coating. Therefore, it is ſaid, the outſide of the glaſs has too little, and the inſide too much, electricity. But how is this known to be the caſe? Becauſe glaſs is impermeable by the electric fluid. And how is glaſs known to be impermeable? Becauſe, in the above experiment, one ſide has too much, and the other too little, electricity. Thus in every inſtance, the arguments for Dr Franklin's hypotheſis return into themſelves, and no concluſion can be drawn from them. In the ſubſequent ſection, the nature of the electric fluid is particularly conſidered, where the improbability of its ever being accumulated in the ſubſtance of ſolid bodies will more plainly appear.

## SECT. VI. *An Inquiry into the Nature of the Electric Fluid; with an Attempt to explain the principal Phenomena of Electricity, from the known Laws by which other Fluids are obſerved to act upon one another.*

In making this inquiry, or indeed any other, it is proper to take for granted as little as poſſible. No poſition ſhould be aſſumed as the baſis of any reaſoning whatever, except what has been proved by inconteſtable facts. In the preſent caſe, therefore, it is ſufficient to aſſume as a fact what hath been already proved by innumerable experiments, namely, That the air, the earth, and ſea, all contain great quantities of electric fluid. The queſtion which moſt naturally ſuggeſts itſelf when this is once admitted, is, Whence hath the electric fluid come? is it eſſentially inherent in theſe bodies, or hath it come from without? This cannot be reſolved, without conſidering the nature of the fluid itſelf, and whether it is analogous to any other which is more generally known.

### § 1. *Proofs of the Identity of the Electric Fluid and Elementary Fire or Light of the Sun.*

The ſimilarity between the electric matter and fire, naturally ſuggeſted to the firſt obſervers, that it was no other than elementary fire, which pervaded all ſubſtances, as we have already mentioned. This, however, was objected to; and the principal objection was, that though the electric matter emitted light, and had the appearance of fire, it nevertheleſs wanted its moſt eſſential quality, namely, *burning*. In particular, the blaſt which comes from an electrified point, feels cold inſtead of being hot; and where great quantities of the fluid are forced with violence through certain ſubſtances, and thus ſet them on fire, it was thought that the fire might be occaſioned by the internal commotion excited among their ſmall particles. This objection, however, ſeems now to be totally removed. The diſpute concerning the preferable utility of pointed or knobbed conductors for ſecuring buildings from lightning, occaſioned the fitting up of a more magnificent apparatus than had ever appeared before. An immenſe conductor was conſtructed at the expence of the board of ordnance, and ſuſpended in the *Pantheon*. It conſiſted of a great number of drums covered with tin-foil, which formed a cylinder of above 155 feet in length, and more than 16 inches in diameter; and to this vaſt conductor were occaſionally added 4800 yards of wire. The electric blaſt from this machine fired gun-powder in the moſt unfavourable circumſtances that can be imagined, namely, when it was drawn off by a ſharp point, in which caſe it has generally leſs force than in any other. The method of doing this was as follows. Upon a ſtaff of baked wood a ſtem of braſs was fixed, which terminated in an iron point at the top. This point was put into the end of a ſmall tube of Indian paper, made ſomewhat in form of a cartridge, about an inch and a quarter long, and two-tenths of an inch in diameter. When the cartridge was filled with common gun-powder, unbruiſed, a wire communicating with the earth was then faſtened to the bottom of the braſs ſtem. The charge in the great cylinder being continually kept up by the motion of the wheel, the top of the cartridge was brought

83 Gun-po der fire the ele blaſt.

very near the drums, ſo that it frequently even touched the tin-foil with which they were covered. In this ſituation a ſmall faint luminous ſtream was frequently obſerved between the top of the cartridge and the metal. Sometimes this ſtream would ſet fire to the gun-powder the moment it was applied; at others, it would require half a minute or more before it took effect. But this difference in time was ſuppoſed to be owing to ſome ſmall degree of moiſture in the powder or the paper, which was always unfavourable to the experiment. Tinder was fired much more readily.

As it therefore appears, that the electric fluid, when it moves through bodies either with great rapidity, or in very great quantity, will ſet them on fire, it ſeems ſcarce diſputable, that this fluid is the ſame with the element of fire. For further proofs of this opinion, which is now adopted by ſome very eminent philoſophers, ſee the articles Fire and Heat. See alſo Chemistry-*Index*. This being once admitted, the ſource from whence the electric fluid is derived into the earth and atmoſphere, muſt be exceedingly evident, being no other than the ſun, or ſource of light itſelf. The vaſt quantity of light which continually comes from him to the earth muſt of neceſſity be abſorbed by that opaque body, at leaſt in great part. It is impoſſible it can remain there, becauſe there is a perpetual ſucceſſion of new quantities coming from the ſun. It muſt be obſerved, however, that as this fluid receives a great number of different directions after once it enters the earth, it cannot appear in its natural form of fire or light, till it receives a new motion ſimilar to what it had when proceeding from the ſun. The ſolar light only burns, or produces heat, when diverging from a centre, or converging towards one. The heat is always greateſt at the central point; and even there, no heat is produced except where the light paſſes through a reſiſting medium. In thoſe caſes likewiſe the electric fluid burns. When diſcharged with violence from an electrified bottle, it flies out on all ſides, and then will fire gun-powder, or other combuſtible ſubſtances. The ſame thing it will do when converging towards a point, if in ſufficient quantity, as was obſerved in the experiment with the large conductor above mentioned. But when the electric fluid neither meets with any conſiderable reſiſtance, diverges from a centre, nor converges towards one, it is almoſt always inviſible, and without heat. A moſt remarkable proof of this we have, even when a vaſt quantity of electric matter is forced to go through a very ſmall wire. Dr Prieſtley tells us he had once an opportunity of obſerving what part of the conductors which form an electric circuit are moſt affected by the exploſion. Upon diſcharging a battery of 51 ſquare feet thro' an iron wire nine inches long, the whole of it was glowing hot, and continued ſo for ſome ſeconds. The middle part grew cool firſt, while both the extremities were ſenſibly red. When the wire was afterwards examined, both the extremities were found quite melted; an inch or two of the part next to them was extremely brittle, and crumbled into ſmall pieces on being handled; while the middle part remained pretty firm, but had quite loſt its poliſh, ſo that it looked darker than before. This is preciſely what would have happened, had both ends been put into a common fire. We are very ſure, that the ſame quantity of electric matter paſſed through the middle of the wire, that entered one end of it and went out at the other. Why then did it not produce the ſame degree of heat in the middle that it did at each end? The reaſon is plain: At one end it was in a ſtate of *convergence* from the battery to the point of the wire; at the other, it was in a ſtate of *divergence* from the point of the wire to the battery. At the points, therefore, an intenſe heat was produced; but in the middle, where the fluid neither converged nor diverged, but moved forwards in a parallel direction, the heat was much leſs. Now we know that this is the caſe with the ſolar light itſelf. At the focus of a burning-glaſs there is an intenſe heat both where the convergence ends and the divergence begins. But where this divergence conſiderably ceaſes, and the motion of the light becomes more parallel, the heat is vaſtly diminiſhed. The caſe is the ſame with a common fire, and with all burning bodies; for heat never acts but from a centre, and is always greateſt at the central point. It is true, that we can never produce electric fire without at the ſame time producing a violent ſhock exceedingly different from the *burning* of common fire. But the reaſon of this is, that we cannot produce a divergence in a ſtream of electric matter, without at the ſame time giving it ſuch a motion in ſome other direction, that its impetus becomes very perceptible. If it was in our power to make the flaſh produced by an electric bottle keep its place, we cannot ſuppoſe that any ſhock, or other ſenſation than heat, would be felt. But there is no poſſibility of hindering it from flying with prodigious celerity from one ſide of the bottle to the other. Therefore, as it is neither in a ſtate of divergence nor convergence, except where it comes out from and enters into the bottle, no ſenſation is perceived except what ariſes from its change of place; and hence it is ſaid, that the electric matter hath no heat.

34 on of lectric er and com- 1.

### § 2. *The Identity of Electric Matter and Light farther conſidered; with ſome poſitive Proofs, that Electric Subſtances are actually penetrated by the Electric Fluid.*

85 Objection concerning the impenetrability of glaſs anſwered.

The only objection of any ſtrength which can ariſe to the identity of the electric fluid and light is, the ſurpriſing eaſe with which the latter penetrates glaſs, and the ſeeming ſtop which is put to the motions of the former when a piece of glaſs or any other electric ſubſtance is preſented to it. Here, however, it muſt be obſerved, that light, as proceeding from a luminous body, muſt be regulated by very different laws from light which is abſorbed by opaque bodies, and conſequently ſubjected to motions quite different from what it originally had. Water, the only fluid with which we are very well acquainted (tho' all others we know ſeem to be regulated by the ſame laws), is capable of two very different motions. The one is a rectilinear one, by which great quantities of it run from one place to another. The other is not ſo eaſily explained. It may, however, be very readily obſerved, by throwing a ſmall ſtone into a pool of water. A great number of concentric circles will be propagated from the place where the ſtone fell, as from a centre, which will gradually grow larger and larger. If another ſtone is thrown in at ſome diſtance, ſimilar circles will proceed from the place where it fell. Theſe will meet with the former, and croſs them without interfering with each other in the leaſt. It is certain, however, that two ſtreams of water ruſhing oppoſite to one another, would ſhatter and deſtroy each other. If, therefore, there is a difference in the motion of the electric fluid when it burns, and when it does not (which there certainly is), we may eaſily ſuppoſe it poſſible, that glaſs ſhould obſtruct one kind of motion and not another: In which caſe, the glaſs would ſeem to be permeable by the fluid when manifeſting itſelf by the firſt kind of motion, and not ſo when it manifeſts itſelf by the other.

86 Surpriſing experiments concerning the tranſparency of bodies.

It hath commonly been thought, that the tranſparency of bodies depends upon the rectilinear direction of their pores, and opacity upon the ſituation of them in ſome other direction. Electrical experiments, however, have ſhown that this is not the caſe. Sealing-wax and pitch are as opaque bodies as we are acquainted with; yet in Mr Haukſbee's experiments, mentioned n° 4. theſe ſubſtances were both rendered tranſparent by the action of the electric fluid. Theſe experiments are confirmed by ſome others ſtill more ſurpriſing, mentioned by Dr Prieſtley. See alſo below Sect. VIII. One was made by S. Beccaria. He diſcharged an electric ſhock through ſome braſs duſt ſprinkled between two plates of ſealing-wax. The whole was perfectly luminous and tranſparent. The moſt extraordinary experiment, however, was made by Dr Prieſtley himſelf, of which he gives the following account. "I laid a chain in contact with the outſide of a jar lightly on my finger, and ſometimes kept it at a ſmall diſtance by means of a thin piece of glaſs; and, if I made the diſcharge at the diſtance of about three inches, the electric fire was viſible on the ſurface of the finger, giving it a ſudden concuſſion, which ſeemed to make it vibrate to the very bone; and when it happened to paſs on that ſide of the finger which was oppoſite to the eye, the whole ſeemed perfectly *tranſparent* in the dark."

87 Conſequences from them.

Experiments of this kind, though they have not hitherto been much purſued by electricians, ſeem to be more worthy of notice than almoſt all others. One conſequence which may be derived from them is, that there is in bodies, whether electric or non electric, a certain ſubtile medium, on the motion of which tranſparency depends. That is, when the medium is at reſt, the body is opaque; but when ſet in motion, it becomes tranſparent. This motion, we ſee, may be given in two different ways. One is by ſimple electrification *in vacuo*, according to Mr Haukſbee's experiments. The other is, by ſending the flaſh of an electrified bottle over their ſurface. In Dr Prieſtley's experiment, he could determine the motion to be of the vibratory kind; and hence we may eaſily conclude, that ſome bodies may be conſtructed in ſuch a manner, that they are capable of tranſmitting the vibrations of this fluid, but not any other kind of motion. Such kinds of bodies will be naturally tranſparent: but others, whoſe particles are diſpoſed in ſuch a manner that the vibrations cannot be propagated thro' them without conſiderable violence, are naturally opaque. The queſtion then only is, What is this ſubtile medium, the vibrations of which occaſion tranſparency? It is ſcarce poſſible to anſwer this queſtion in another manner than by ſaying, that it is the electric fluid. That it is this fluid which gives the power to electric ſubſtances, has never been denied. That the motion of this fluid along the ſurfaces of bodies throws another fluid within them into vibrations, is alſo evident from the experiments above mentioned. All bodies are confeſſed to have much of this fluid in their pores: therefore, if a quantity of the ſame matter paſſes over the ſurface of any body, it muſt affect what is within its ſubſtance with a motion of ſome kind or other; becauſe it affects that which lies on the outſide, and this cannot fail to affect all the reſt. This motion Dr Prieſtley's experiment determines to be of the vibratory or tremulous kind; and, indeed, it is natural to think it ſhould be ſo. The vibrations of the electrical fluid, therefore, conduct light through opaque bodies. But whatever fluid is conducted by the vibration of another, muſt itſelf alſo vibrate while it is ſo conducted. Light, therefore, vibrates when emitted from luminous bodies. In the preſent caſe, theſe vibrations are originally occaſioned by the electric flaſh. They are conducted thro' opaque bodies by the vibrations of the electric fluid. The air is alſo full of the ſame fluid. The air is naturally tranſparent; but we have ſeen that tranſparency conſiſts only in the eaſy tranſmiſſion of a vibratory motion of the electric fluid. The light, therefore, is perpetually conducted by means of the vibrations of this fluid: therefore, the vibrations of the electric fluid and light are the ſame; for no two fluids are always capable of ſetting one another in motion preciſely in the ſame manner, unleſs their nature is in all reſpects exactly the ſame.

88 Light pr ved to b vibrati the elect fluid.

Theſe experiments ſeem in the ſtrongeſt manner to prove the identity of the electric fluid and light, and that both are tranſmitted through electric as well as other ſubſtances. The reaſon, therefore, of the ſeeming ſtop, which is obſerved in our electrical operations by the intervention of glaſs, is, that in all artificial electricity, the fluid has a very conſiderable progreſſive motion, which cannot be eaſily propagated through the ſolid ſubſtance of any body, eſpecially where there is a pretty ſtrong reſiſtance on the other ſide; which ſhall afterwards be ſhown to be the caſe with this fluid when paſſing through electric ſubſtances.

### § 3. *Of the Paſſage of the Electric Fluid over the Surface, and through the Subſtance, of different Bodies.*

89 Dr Prie ley's exp riments vith ice

Dr Priestley hath made many very curious experiments concerning the diſcharging of electric ſhocks over the ſurface of different bodies; and finds, that by this means a battery may be made to diſcharge itſelf at a much greater diſtance than it would do if ſent directly through the air. The experiments were begun with ice; and he firſt accidentally diſcovered, that, when the ſhock of a common jar was diſcharged on a plate of ice, it would ſometimes run over the ſurface and ſtrike the chain directly on the other ſide. With a ſingle jar, however, the diſtance was not much greater than what it would have paſſed over in the uſual way; but, with a battery, it exceeded the uſual diſtance in a very great degree. Endeavouring to make a circular ſpot, ſuch as he had formerly made on metals, upon a piece of raw fleſh, he took a leg of mutton, and laying the chain that communicated with the outſide of the battery over the ſhank, he took the exploſion on the outward membrane, about ſeven inches from the chain; but was greatly ſurpriſed to obſerve the electric fire not

90 With ra fleſh;

to enter the fleſh, but to paſs in a body along the ſurface of it to come to the chain. Thinking that this might be occaſioned by the fatty membrane on which the exploſion was made, he again laid the chain in the ſame manner over the ſhank, and took the exploſion upon the muſcular fibres, where they had been cut off from the reſt of the body; but ſtill the fire avoided entering the fleſh, made a circuit of near an inch round the edge of the joint, and paſſed along the ſurface to come to the chain as before, though the diſtance was near 11 inches. Imagining that this effect was promoted by the chain lying lightly on the ſurface of the fleſh, and therefore not actually in contact with it, he took another exploſion upon the hook of the chain, which was thruſt into the fleſh. On this the fire entered the mutton; and as he held it in his hands, both his arms were violently ſhocked up to his ſhoulders.

The Doctor next determined to try the effect of different conducting ſubſtances in the ſame manner; and of theſe water was the moſt obvious. "Next day, (ſays he) I laid a braſs rod communicating with the outſide of the battery, very near the ſurface of a quantity of water (to reſemble the chain lying upon the ſurface of the fleſh, without being in contact with it), and, by means of another rod furniſhed with knobs, made a diſcharge on the ſurface of the water, at the diſtance of ſeveral inches from any part of the rod; when the electric fire ſtruck down to the water, and, without entering it, paſſed viſibly over its ſurface till it arrived at that part of the rod which was neareſt the water, and the exploſion was exceedingly loud. If the diſtance at which I made the diſcharge exceeded ſeven or eight inches, the electric fire entered the water, making a beautiful ſtar upon its ſurface, and yielding a very dull ſound. When I firſt made this experiment of the electric flaſh paſſing over the ſurface of water, I thought it neceſſary, that neither the piece of metal communicating with the outſide, nor that communicating with the inſide, of the jars, ſhould touch the water immediately before the diſcharge. But I afterwards found, that the experiment would anſwer, tho' either, or even both of them, were dipped in the water: for, in this caſe, the exploſion would ſtill prefer the ſurface to the water itſelf, if the diſtance was not very great; and would even paſs at a greater diſtance along the ſurface, when there was a nearer paſſage from one rod to the other in the water."

He afterwards tried to paſs the electric flaſh over the ſurfaces of a great number of different bodies, but found it impoſſible with many of them. He therefore imagined that this property of conducting a ſhock over its ſurface was peculiar to water and raw fleſh. It was found, however, that the flaſh paſſed over the ſurface of a touch-ſtone, and likewiſe over a piece of the beſt kind of iron ore, exceedingly ſmooth on ſome of its ſides. The piece was about an inch thick, and three inches in its other dimenſions. The full charge of a jar of three ſquare feet would not enter it. The exploſion paſſed over the ſurface of oil of vitriol, with a dull ſound and a red colour; but in all other caſes, if it paſſed at all, it was in a bright flame, and with a report peculiarly loud. It paſſed over the ſurface of the moſt highly rectified ſpirit of wine without firing it; but when too great a diſtance was taken, the electric fire entered the ſpirit, and the whole was in a blaze in a moment.

This was the caſe when ſuch ſubſtances were employed as are but indifferent conductors of electricity; raw fleſh, for inſtance, water, &c. When good conductors were uſed, ſuch as charcoal of different kinds, no remarkable appearances were produced. So far was the ſhock from paſſing viſibly over the ſurface of any metal, that, if the diſtance through the air, in order to a paſſage through the metal, was ever ſo little nearer than the diſtance between the two ſurfaces, it never failed to enter the metal; ſo that its entering the ſurface of the metal, and its coming out again, ſeemed to be made without obſtruction. If as much water was laid on a ſmooth piece of braſs as could lie upon it, it would not go over the ſurface of the water, but always ſtruck thro' the water into the metal. But if the metal lay at any conſiderable depth under the water, it would prefer the ſurface. It even paſſed over three or four inches of the ſurface of water as it was boiling in a braſs pot, amidſt the ſteam and bubbles, which ſeemed to be no hindrance to it. Animal fluids, however, of all kinds, ſeemed peculiarly to favour this paſſage of the electric matter over their ſurface; and the report of theſe exploſions was manifeſtly louder than when water was uſed. In all caſes of this kind, the report was conſiderably louder than when the diſcharge was made in the common way. The exploſions were obſerved by perſons out of the houſe, and in a neighbouring houſe, very much to reſemble the ſmart cracking of a whip. "But (ſays Dr Prieſtley) the ſound made by theſe exploſions, though by far the loudeſt that ever I heard of the kind, fell much ſhort of the report made by a ſingle jar, of no very great ſize, of Mr Rackſtrow's; who ſays, that it was as loud as that of a piſtol." He alſo obſerves, that when the electrical exploſion does not paſs over the ſurface of the water, but enters it, a regular ſtar is made upon the ſurface, conſiſting of ten or a dozen rays: and what is very remarkable, thoſe rays which ſtretch towards the braſs rod that communicates with the outſide of the battery are always longer than the reſt; and if the exploſion is made at ſuch a diſtance as to be very near taking the ſurface, thoſe rays will be four or five times longer than the reſt, and a line bounding the whole appearance will be an ellipſis, one of whoſe foci is perpendicularly under the braſs knob with which the diſcharge is made.

93
Circular ſpots produced by electrical exploſions.

When an electric battery is diſcharged upon ſmooth pieces of metal, the effects are very different from any of thoſe we have yet mentioned. Dr Prieſtley having conſtructed ſome large batteries, determined to try what would be the effects of a very great electric power diſcharged upon metals and other ſubſtances; and, in the courſe of his random experiments, he made the following diſcoveries. "June 13. 1766 (ſays he), after having diſcharged a battery of about 40 ſquare feet with a ſmooth braſs knob, I accidentally obſerved upon it a pretty large circular ſpot, the centre of which ſeemed to be ſuperficially melted, in a great number of dots; larger near the centre, and ſmaller at a diſtance from it. Beyond this ſpot was a circle of black duſt which was eaſily wiped off: but what I was moſt ſtruck with was, that after an interruption of melted places, there was an entire and exact circle of ſhining dots, conſiſting of places ſuperficially melted like thoſe at

Theory.

the centre. The appearance of the whole, excluſive of the black duſt, is repreſented Plate CLXXVII. fig. 75. n° 1.

"June 14th, I took the ſpot upon ſmooth pieces of lead and ſilver. It was in both caſes like that on the braſs knob; only the central ſpot on the ſilver conſiſted of dots diſpoſed with the utmoſt exactneſs, like radii from the centre of a circle, each of which terminated a little ſhort of the external circle. I took the circular ſpot upon poliſhed pieces of ſeveral metals with the charge of the ſame battery, and obſerved that the cavities in ſome of them were deeper than in others; as I thought in the following order, beginning with the deepeſt, tin, lead, braſs, gold, ſteel, iron, copper, ſilver. I will not be poſitive as to the order of ſome of the metals; but ſilver was evidently not affected a fourth part ſo much as gold, and much leſs than any of the others. The circles were marked as plain, but the impreſſion was more ſuperficial.

"I alſo made the exploſion between a piece of lead juſt ſolid after melting, and another ſmooth piece that I had kept a conſiderable time. The piece of freſh lead was melted more than the other, but there was no other difference between them. The ſemimetals, as biſmuth and zinc, received the ſame impreſſion as the proper metals; being melted nearly as much as iron. I made three diſcharges between a piece of highly poliſhed ſteel and a piece of very ſmooth iron, and in all caſes thought the ſteel was more deeply melted than the iron.

"Preſently after I had obſerved the ſingle circle, I imagined, that, whatever was the cauſe of the appearance, it was not improbable but that two or more concentric circles might be procured, if a greater quantity of coated glaſs was uſed, or perhaps if the exploſion was received upon metals that were more eaſily fuſed than braſs. Accordingly, June 27, taking the moderate charge of a battery, conſiſting of about 38 ſquare feet, upon a piece of tin, I firſt obſerved a ſecond outer circle, at the ſame diſtance from the firſt, as the firſt was from the central ſpot. It conſiſted of very fine points hardly viſible, except when held in an advantageous light; but the appearance of the whole was very beautiful, and was ſuch as is repreſented Plate CLXXVII. fig. 75. n° 2.

"Having hitherto found the circles the moſt diſtinct on metals that melt with the leaſt degree of heat, I ſoon after procured a piece of that compoſition which melts in boiling water; and having charged 60 ſquare feet of coated glaſs, I received the exploſion with it, and found three concentric circles; the outermoſt of which was not quite ſo far from the next to it, as that was from the innermoſt. All the ſpace within the firſt circle was melted; but the ſpace was very well defined, and by no means like a central ſpot, which in this caſe was quite obliterated. The appearance of theſe three concentric circles is repreſented Plate CLXXVII fig. 75. n° 3. The diſtance at which the diſcharge was made occaſioned no difference in the diameter of theſe circular ſpots. When, by putting a drop of water upon the braſs rod communicating with the inſide of the battery, I made the diſcharge at the diſtance of two inches; the ſpot was juſt the ſame as if it had been received at the diſtance of half an inch, *i. e.* about a quarter of an inch in diameter. Attempting to ſend an electric ſhock over the ſurface of quickſilver or melted lead, I found that it would not paſs; though neither of the rods with which the diſcharge was made touched the metals. A dark impreſſion was made on the ſurfaces of both the quickſilver and the lead of the uſual ſize of the circular ſpot; and remained very viſible notwithſtanding the ſtate of fuſion in which the metals were."

Theo

### § 4. *The Electric Fluid moves through the Subſtance of Electrics, though with difficulty. In moſt Caſes, it paſſes over the Surface of good Conductors.*

THIS will appear from a conſideration of the phenomena above mentioned, and ſome others. The electric moſt univerſally preſent is *air*. That the fluid pervades its ſubſtance is evident to our eye-ſight; for if a pointed body is placed on the prime conductor, and at the ſame time the cylinder is briſkly turned, a continual ſtream of blue fire will be obſerved to iſſue from the point. This is undoubtedly the fluid itſelf made viſible by the reſiſtance it meets with from the air. That the electric fluid in this caſe pervades the air to a conſiderable diſtance, is alſo evident from the different methods by which the air of a room may be electrified. One method is that above mentioned: One or more needles are fixed on the prime conductor, which is kept ſtrongly electrified for about 10 minutes. If, afterwards, an electrometer is brought into the room, the air will ſhow that it has received a conſiderable quantity of electricity; for the balls will ſeparate, and continue to do ſo even after the apparatus has been quite removed out of the room. Another method of electrifying the air is to charge a large jar and inſulate it; then connect a ſharp-pointed wire, or a number of them, with the knob of the jar; and make a communication from the outſide coating to the table. If the jar is charged poſitively, the air of the room will likewiſe ſoon become electrified poſitively; but if the jar is charged negatively, the air will alſo become negative. To this it may be replied, that the air is always full of conducting ſubſtances, and that by means of them the electricity is propagated from one part of the air to another. But whether this is the caſe or not, it is certain that the air, notwithſtanding all the conducting ſubſtances it may contain, is in fact an electric, and capable of receiving a charge like glaſs or any other electric ſubſtance. To this purpoſe there is a very curious experiment made in the following manner. Take two ſmooth boards, of a circular form, and each about three or four feet in diameter. Coat one ſide of each with tin-foil, which ſhould be paſted down and burniſhed, and turned over the edge of the board. Theſe boards muſt be both inſulated, parallel to one another, in a horizontal poſition. They muſt be turned with their coated ſides towards each other; and ſhould be placed in ſuch a manner as to be eaſily moved to or from each other; to do which, it will be proper to fix to one of the boards a ſtrong ſupporter of glaſs or baked wood, and to ſuſpend the other by ſilk ſtrings from the ceiling of the room; from which it may be lowered at pleaſure by means of a pulley. When theſe boards are placed in the manner above deſcribed, and about an inch diſtant from one another, they may be uſed exactly as the coatings of a pane of glaſs. If a ſpark is given from the conductor to the upper board, a ſpark will in-

94
Metho
electr-
the air
room.

9
To ch
a plat
air.

inſtantly be diſcharged from the lower one, if any conducting ſubſtance is preſented to it. By continuing to give ſparks to the upper board, and to take them from the lower one, the air between them will at laſt become charged like a piece of glaſs; and if a communication is made between them, they will explode, give the ſhock, &c. like glaſs.

In this experiment it ſeems impoſſible to deny that the air is penetrated by electric fluid. The diſtance of an inch is ſo ſmall, that it muſt appear ridiculous to ſay that this ſpace is penetrated only by a *repulſive power*, when in other caſes we plainly ſee the fluid penetrating it to three or four times that diſtance. The flat ſurface of the boards indeed makes the motion of the electric fluid through the plate of air gradual and equal, ſo that it is not ſeen to paſs in ſparks or otherwiſe; but this is neceſſary to its receiving a charge, as will be afterwards explained.

If one electric ſubſtance is penetrable by the electric fluid, we muſt be led ſtrongly to ſuſpect at leaſt, that all the reſt are ſo too. That roſin, pitch, ſealing-wax, &c. are ſo, hath been already proved; and from thence, if we reaſon analogically, we muſt conclude, that glaſs is likewiſe penetrable by it. A very ſtrong additional proof of this is, that the electric ſhock cannot be ſent over the ſurface of glaſs. If this ſubſtance was altogether impenetrable to the fluid, it is natural to think, that it would run over the ſurface of glaſs very eaſily. But inſtead of this, ſo great is its propenſity to enter, that a ſhock ſent through between two glaſs plates, if they are preſſed pretty cloſe together, always breaks them to pieces, and even reduces part of them to a powder like ſand. This laſt effect cannot be attributed to any other cauſe than the electric fluid entering the pores of the glaſs; and, meeting with reſiſtance, the impetus of its progreſſive motion violently forces the vitreous particles aſunder in all directions.

To this violent impetus of the electric fluid, when once it is ſet in motion, we may alſo with ſome probability aſcribe the burſting of electric globes, both ſuch as are made of glaſs, and other materials, in the act of excitation. Dr Prieſtley hath given ſeveral inſtances of this accident. "The fragments (ſays he) have been thrown with great violence in every direction, ſo as to be very dangerous to the byſtanders. This accident happened to Mr Sabbatelli in Italy, Mr Nollet in France, Mr Beraud at Lyons, Mr Boze at Wittemberg, Mr Le Cat at Rouen, and Mr Robein at Rennes. The air in the inſide of Mr Sabbatelli's globe had no communication with the external air, but that of the Abbe Nollet had. This laſt, which was of Engliſh flint glaſs, had been uſed for more than two years, and was above a line thick. It burſt like a bomb in the hands of a ſervant who was rubbing it, and the fragments, none of which were above an inch in diameter, were thrown to a conſiderable diſtance. The Abbe ſays, that all the globes which were burſt in that manner, exploded after five or ſix turns of the wheel; and he aſcribes this effect to the action of the electric matter making the particles of glaſs vibrate in a manner he could not conceive.

"When Mr Beraud's globe burſt (and he was the firſt to whom this accident was ever known to happen), he was making ſome experiments in the dark on the 8th of February 1750. A noiſe was firſt heard as of ſomething rending to pieces; then followed the exploſion; and when the lights were brought in, it was obſerved that thoſe places of the floor which were oppoſite to the equatorial diameter of the globe were ſtrewed with ſmaller pieces, and in greater numbers, than thoſe which were oppoſite to other parts of it. This globe had been cracked, but it had been in conſtant uſe in that ſtate above a year; and the crack had extended itſelf from the pole quite to the equator. The proprietor aſcribed the accident to the vibrations of the glaſs, and thought the crack had ſome way impeded theſe vibrations. When Mr Boze's globe broke, he ſays that the whole of it appeared, in the act of breaking, like a flaming coal. Mr Boulanger ſays, that glaſs globes have ſometimes burſt like bombs, and have wounded many perſons, and that their fragments have even penetrated ſeveral inches into a wall. He alſo ſays, that if globes burſt in whirling by the gun-barrel's touching them, they burſt with the ſame violence, the ſplinters often entering into the wall. The Abbe Nollet had a globe of ſulphur which burſt as he was rubbing it with his naked hands, after two or three turns of the wheel, having firſt cracked inwardly. It broke into very ſmall pieces, which flew to a great diſtance, and into a fine duſt; of which part flew againſt his naked breaſt, where it entered the ſkin ſo deep, that it could not be got off without the edge of a knife."

97
Proofs of the electric fluid's paſſing over the ſurface of conductors.

From theſe appearances we muſt neceſſarily conclude, not only that the electric fluid moves within the ſubſtance of electric bodies, but that it ſometimes moves with extreme violence; ſo that its repulſive power ſeparates even the minuteſt particles from each other; and this could not happen without a thorough penetration of the electric body. It ſeems more difficult to prove, that the electric matter does not generally paſs directly through the ſubſtance of metals, but over their ſurface. A little conſideration, however, will ſhow, that this muſt very probably be the caſe. If we compare Dr Prieſtley's experiments on metals related in § 3. with the effects of the ſolar light collected in the focus of a burning-glaſs upon the ſame metals, we ſhall find a conſiderable degree of reſemblance. Under the article Burning-glass, it is obſerved, that, notwithſtanding the prodigious power of that concave mirror with which Mr Macquer melted platina, all bodies did not melt equally ſoon in the focus. In particular, poliſhed ſilver, though a very fuſible metal, did not melt at all. It is not to be doubted, that this was owing to the complete reflection of the light by the ſilver; and had poliſhed pieces of all the metals been tried, it is equally certain, that the difficulty of melting them would have been found exactly proportioned to their reflective power. Something like this happened with Dr Prieſtley; for ſilver was leſs touched by the electric exploſion than any other metal. The violent progreſſive motion of the fluid indeed forced it into the metal, but at the ſame time the reflective power of the ſilver hindered it from going ſo deep as it had done in the others. The caſe was ſtill more evident when melted lead and quickſilver were uſed. Theſe have a very great reflective power; and though by reaſon of the extreme violence wherewith the fluid ſtruck them, part of their ſubſtance might naturally have

have been ſuppoſed to be diſſipated in the hard metals, yet we find this was not the caſe. Only a black ſpot was made on the ſurface, and the fluid was immediately diſperſed, moſt probably over the ſurface of the metal.

It is not indeed eaſy to bring a deciſive proof in favour of this hypotheſis. The extreme ſubtility, and, in moſt caſes, inviſibility, of the electric fluid, render all reaſoning about its motions precarious. It is incredible, however, that this fluid ſhould paſs through the very ſubſtance of metallic bodies, and not be in the leaſt retarded by their ſolid particles. In thoſe caſes, where the ſolid parts of metals are evidently penetrated, i. e. when wires are exploded, there is a very manifeſt reſiſtance; for the parts of the wire are ſcattered about with violence in all directions. The like happened in Dr Prieſtley's circles made on ſmooth pieces of metal. Part of the metal was alſo diſperſed and thrown off, for the circular ſpots were compoſed of little cavities. If therefore the fluid was diſperſed throughout the ſubſtance; and not over the ſurface of the metal, it is plain, that a wire whoſe diameter was equal to one of thoſe circular ſpots, ought alſo to have been deſtroyed by an exploſion of equal ſtrength ſent through it. But this would not have been the caſe. A wire whoſe diameter is equal to one of thoſe circular ſpots repreſented in n° 1, 2, 3. fig. 75. Plate CLXXVII. would without injury conduct a ſhock much greater than any battery hitherto conſtructed could give. It is moſt probable therefore, that though violent flaſhes of electricity, which act alſo as fire, will enter into the ſubſtance of metals and conſume them; yet it immediately diſperſes itſelf over their ſurface, without entering the ſubſtance any more, till being forced to collect itſelf into a narrow compaſs it again acts as fire.

In many caſes, the electric fluid will be conducted very well by metals reduced to a mere ſurface, ſo that we can ſcarce ſay they have any thickneſs at all. A piece of white paper will not conduct a ſhock without being torn in pieces, as it is an electric ſubſtance. But a line drawn upon it with a black-lead pencil will ſafely convey the charge of ſeveral jars. It is impoſſible we can think that the fire here paſſes through the ſubſtance of the black-lead ſtroke. It muſt run over its ſurface; and if we conſider ſome of the properties of metals, we ſhall find, that there is very great reaſon for believing that their conducting power lies at their ſurface.

The metals are, of all terreſtrial ſubſtances, thoſe which reflect the light moſt powerfully. Sir Iſaac Newton hath ſhown that this reflective power they have not from their ſubſtance as metals, but from what he calls a *repulſive power*, ſpread equally over their ſurface. The exiſtence of this repulſive power hath already been taken notice of in ſeveral inſtances, particularly in that of a chain, whoſe links cannot be brought into contact with each other without a conſiderable degree of force. It is exceedingly probable, that the repulſive power by which the links of the chain are kept aſunder, and that by which the rays of light are reflected, are one and the ſame. As the electric fluid is known to pervade all ſubſtances, and metals as well as others, it ſeems alſo probable, that the repulſive and reflective power on the ſubſtance of metals is no other than the electric fluid itſelf in a quieſcent ſtate. Perhaps it may be thought abſurd to aſcribe the reflection of light to a ſubſtance of ſuch extreme fluidity and tenuity as the electric fluid is; but we find that the vacuum of an air-pump, a medium of nearly equal tenuity with the electric fluid (as will elſewhere be proved), is in ſome caſes capable of reflecting light very powerfully. Now it is certain, that nothing can be ſuppoſed to give ſuch an eaſy paſſage to the electric fluid as itſelf; becauſe it is the thinneſt and moſt ſubtile of all the ſubſtances we know, and therefore muſt make the leaſt reſiſtance. Hence the fluid ſlides over the ſurface of a piece of metal with ſurpriſing eaſe; and when a large ſurface of metal is electrified, the effect is proportionable to the extent of it, becauſe all that quantity of electric fluid which is ſpread over the ſurface, eaſily receives the motion communicated by the electrical machine.

The vacuum of an air-pump is found to be a very good conductor, and by means of it the motion of the fluid is rendered viſible. Hence this is brought as an argument that the electric fluid *always* paſſes through the ſubſtance of conductors. That it doth ſo in ſome caſes is indeed very evident, but it then meets with conſiderable reſiſtance; and, even in the preſent inſtance, the paſſing through the vacuum of an air-pump, where it is oppoſed by a conſiderable quantity of the ſame kind of fluid, gives ſuch a conſiderable reſiſtance, that it will prefer a paſſage along a metalline rod to one through a vacuum. With regard to charcoal, and other conductors of that kind, as they are very porous, and likewiſe compoſed of fine ſpiculæ, it is probable the fluid may run along the ſurface of the ſpiculæ, and at the ſame time through the ſubſtance of the coal. Even in paſſing over the beſt conductors, however, this fluid meets with ſome reſiſtance, as it will prefer a ſhort paſſage through the air to a long one through the beſt conductors.

### § 5. *The exceeding great Velocity and Strength of the Electric Fluid are not owing to a repulſive Power among its Particles, but to the mutual Action of the Air and Electric Fluid upon themſelves and one another.*

98
Electric
fluid ſho
to be no
repulſiv
itſelf.

The arguments for a repulſive power exiſting between the particles of the electric fluid are very inconcluſive. Some of them have been already taken notice of. The ſtrongeſt is that drawn from the appearance of the electric fire iſſuing from a point, or from any body highly electrified. In the open air this diverges exceſſively; and very often divides into ſeveral diſtinct rays, which by avoiding each other ſeem to be violently repulſive. That they are not ſo in reality, however, is plain from the appearance they have *in vacuo*; when, the reſiſtance of the atmoſphere being taken off, the electric light would have room to ſpread more widely. Fig. 27. Plate CLXXIV. repreſents an exhauſted receiver with an electrified wire diſcharging a ſtream of this fluid from itſelf, by means of its communication with a machine. If the electric matter then was really elaſtic, or endowed with a power repulſive of itſelf, it is impoſſible it could paſs in an uninterrupted column through an exhauſted receiver as in the figure. A column of air, if blown ſwiftly through the orifice of a ſmall pipe, will go forward a conſiderable way, if it is counterbalanced by air like itſelf on every ſide. But if ſuch a column enters a vacuum, what

what we call its *elaſticity*, occaſions it to be diſſipated in a moment, and equally diffuſed through the whole exhauſted receiver. But this by no means happens to the electric fluid; for even the ſmall divergency repreſented in the figure ſeems entirely owing to ſome quantity of air left in the air-pump. Dr Watſon, by means of a long bent tube of glaſs filled with mercury, and inverted, made all the bended part which was above the mercury the moſt perfect vacuum that could be made. This vacuum he inſulated; and one of the baſons of mercury being made to communicate with the prime conductor, when ſome non-electric ſubſtance touched the other, the electric matter pervaded the vacuum in a continued arch of lambent flame, and, as far as the eye could follow it, without the leaſt divergency. From theſe experiments it appears, that there is in the vacuum of an air-pump, as well as in the Torricellian vacuum, a fluid of nearly the ſame denſity with the electric one: that the electric fluid is not repulſive of itſelf, but is reſiſted by the atmoſphere; and therefore all appearances of electrical light are leſs bright *in vacuo* than in the open air; becauſe, the more reſiſtance the matter meets with, the brighter is the flaſh.

Thus, as long as a ſtream of electric fluid is moved through a medium of an equal denſity with itſelf, the equable preſſure of the fluid all round will keep the luminous ſtreams from diverging; but if the preſſure is taken off from any part of the receiver, the preſſure of the reſt will immediately force the ſtream to that place, as repreſented fig. 28. That it is by a preſſure of this kind, and not by any obſcure *attractive power*, that this is occaſioned, will be rendered very probable from the following example. Suppoſe a pot or kettle is boiling violently over a fire, and in ſuch a ſituation that there is very little agitation in the ſurrounding air. The equal preſſure of the atmoſphere will then force the ſteam ſtraight upwards in a cylindrical column; but if any object is brought near the edge of the pot, ſo that the preſſure of the atmoſphere is taken off on one ſide, the ſteam will be directly forced upon that body, or ſeemingly attracted by it. The electric matter therefore, being capable of having its motions reſiſted by the air, muſt immediately fly to that place where the reſiſtance is leaſt; but in the caſe above mentioned, this is beſt done by applying a conducting ſubſtance to the ſide of the receiver, or one along which the fluid can run downward to the earth. This, however, will be more fully explained when we ſpeak of the phenomena of the Leyden phial.

From this ſimple principle, *viz.* that fluids impelled by any force will always tend towards that place where there is the leaſt reſiſtance, moſt of the phenomena of electricity may be explained. The firſt thing to be conſidered is, From what ſource it originally derives the aſtoniſhing agility and ſtrength diſplayed in its motions. If it is granted that the electric fluid is the ſame with the ſolar light, the ultimate cauſe of its momentum muſt be the power by which the light of the ſun is emitted. As this power extends through regions of ſpace which to our conceptions are truly *infinite*, ſo muſt the power itſelf be; and it is plain, that by its equable action all round, throughout the whole ſpace thro' which the ſun's light is propagated, the preſſure of it upon all bodies muſt be equal all round, and conſequently it can neither move them one way nor another. But if, by the intervention of ſome other power, the preſſure is leſſened upon any particular part, a current of electric matter will ſet towards that part, with a force exactly proportioned to the diminution of the preſſure. Thus, in the common experiments of the air pump, when the air is exhauſted from a glaſs veſſel, the preſſure of the ſuperincumbent atmoſphere is directed towards every part of the glaſs; ſo that if it is of a flat ſquare ſhape, and not very ſtrong, it will certainly be broken. But after the air is exhauſted, the veſſel is diſcovered to be full of another ſubtile fluid of the ſame nature with the electric one *. If this could alſo be extracted from the veſſel, the preſſure on its ſides would neceſſarily be much greater, becauſe not only the atmoſphere, but the whole ſurrounding ether or electric matter, would urge towards the place; and it is not probable, that this preſſure could be reſiſted by any terreſtrial power whatever. The momentum of the electric matter therefore, in our experiments, depends on two cauſes, *viz.* the preſſure of the atmoſphere upon the electric matter, and the preſſure of one part of this matter upon another. The celerity with which it moves may be explained from its parts lying in contact with each other throughout the wide immenſity of ſpace. Hence the great tendency of the fluid to circulate; becauſe, from whatever point a ſtream of it is ſent off, there the preſſure is leſſened, and the ſtream, finding no place empty for its reception, muſt neceſſarily have a tendency to return to the place from whence it came, as there it meets with the leaſt reſiſtance; and hence, when a paſſage is opened for it, by which it can return to this point, it is urged thither with great violence, the equable preſſure is reſtored, and the artificial motion ceaſes.

### § 6. *The Manner in which an Electric Subſtance becomes excited, or diffuſes its Electric Virtue.*

THIS will eaſily appear from conſidering the means taken for the excitation of a common cylinder for electric experiments. The glaſs is a ſubſtance, as we have already ſeen, into which the electric matter is very apt to enter. To the ſurface of the glaſs is applied ſome amalgam ſpread on leather. This is a metallic ſubſtance which has an exceeding great reflective power, being that which is employed for ſilverizing looking-glaſſes. The electric fluid therefore runs over its ſurface with great eaſe, and there is always a certain quantity of this fluid in a ſtate of ſtagnation on its ſurface. At the place where the cylinder touches the amalgam, the air is excluded, and conſequently the electric fluid hath there a tendency to riſe more than at any other part of the ſurface where the atmoſphere preſſes with its full force. When the cylinder begins to turn, it neceſſarily forces before it a ſmall quantity of that electric matter which lay upon the ſurface of the amalgam. To underſtand this the more eaſily, we muſt conſider that property which glaſs has of tranſmitting the electric fluid through it, and refuſing it a paſſage along its ſurface. Thus we may conceive it to be formed of a vaſt number of exceedingly ſmall tubes placed cloſe to each other. If we ſuppoſe any ſubſtance made by art of ſuch a texture, we would find it impoſſible to pour water along its ſurface, though it would very eaſily run through it. If ſuch a ſubſtance was

* See Vacuum.

was made in the ſhape of a cylinder, and turned briſkly round, with its ſurface juſt touching a quantity of water contained in a veſſel, the conſequence would be, that the water would be ſcattered around in all directions. The caſe ſeems to be the ſame with the more ſubtile electric fluid. The glaſs cylinder throws out part of the electric fluid lying on the ſurface of the amalgam. This quantity is perpetually renewed from the conducting ſide of the rubber. The quantity which is thrown out cannot be conducted over the ſurface of the glaſs, nor can it paſs through it; becauſe it is reſiſted by the air in the inſide, and, in ſome meaſure, by the glaſs itſelf. It is alſo reſiſted by the air on the outſide; but as that reſiſtance is leſs than what is made by the air and glaſs both put together, the fluid naturally forces itſelf into the open air. Still, however, there neither is, nor can be, any *accumulation* of the matter itſelf. It cannot enter the air without diſplacing the electric matter which was there before. This will diſplace more of the ſame kind, and ſo on, till at laſt the motion is communicated to the electric matter lodged in ſome part of the earth. From thence it is propagated to the rubber of the electric machine, and thus a kind of circulatory motion is carried on. By the excitation of an electric ſubſtance, therefore, the fluid is not accumulated, but only ſet in motion. The reaſon of that ſeeming accumulation obſervable about the excited cylinder is, the reſiſtance which the fluid meets with from the air. This inſtantly produces a divergency in the ſtream of electric matter, and a vibratory ſtruggle betwixt it and the air; which again produces the appearances of fire and light, for the reaſons already given.

100 Proofs of the vibratory motion of the electric fluid.

That this kind of vibratory motion or ſtruggle between the electric fluid and air always takes place when the latter is ſet in motion, ſeems evident from the ſenſation which is felt when a ſtrongly excited electric is brought near any part of the human body. This is ſuch as would be occaſioned by a ſpider's web drawn lightly along the ſkin, or rather by a multitude of ſmall inſects crawling upon the body. It is, however, more clearly proved by an experiment made by Dr Prieſtley. He was deſirous to know whether the electric fluid was concerned in the freezing of water or not. For this purpoſe, he expoſed two diſhes of water to the open air in the time of a ſevere froſt. One of them he kept pretty ſtrongly electrified; but could obſerve no difference in the time either when it began to freeze, which was in about three minutes, or in the thickneſs of the ice, when both had been frozen for ſome time. Happening to look out at the window through which he had put the diſhes, he obſerved on each ſide of the electrified wire the ſame dancing vapour which is ſeen near the ſurface of the earth in a hot day, or at any time near a body ſtrongly heated.

101 When an exhauſted cylinder cannot be excited;

If the glaſs cylinder which we want to excite is exhauſted of air, the electric matter, inſtead of flying off into the air, runs directly through the glaſs; and, meeting with ſome reſiſtance from the *vacuum* as it is called, a weak light is produced in the inſide, but no ſigns of electricity are perceived on the outſide of the glaſs. The ſame thing happens by giving the cylinder or tube a metallic coating. The fluid collected from the rubber runs directly through the glaſs, and along the ſurface of the metallic coating, which keeps off the preſſure of the air contained in the glaſs. If an electric lining is uſed, and the glaſs is exhauſted of air, the motion of the fluid becomes viſible through both, and the whole is tranſparent, as already obſerved. If the cylinder is lined with an electric ſubſtance, and the air is not exhauſted, the electricity on the outſide is often conſiderably increaſed; but the reaſon of this is not evident. Moſt probably it is owing to the different kind of electricity acquired by the inſide lining; for electricity of any kind always produces its oppoſite at a ſmall diſtance, the reaſon of which ſhall be afterwards given.

10 Nor on filled w condenſ air.

If the air within the cylinder is condenſed, the electrical appearances on the outſide are leſſened in proportion. The reaſon of this ſeems to be, that though it is neceſſary that the fluid ſhould not go through the ſubſtance of the glaſs very eaſily, yet it is requiſite that its paſſage ſhould not be totally obſtructed; and therefore the electric experiments ſucceed beſt when the air within the glaſs is a little rarefied. We muſt alſo conſider, that when an additional quantity of air is forced into the cylinder, an equal bulk of electric matter is forced out. The reſt of the matter, therefore, which is contained all round the glaſs, preſſes violently into its pores; but this preſſure, being directly oppoſite to what happens when the glaſs is excited, muſt of conſequence hinder the excitation. If the glaſs is now made very hot, the preſſure of the atmoſphere is kept off, and the paſſage of the electric fluid through the glaſs and condenſed air is rendered eaſier, and therefore the electric appearances on the outſide return.

On the ſame principles may we explain the excitation of a ſolid ſtick of glaſs, ſealing-wax, or ſulphur. Though theſe have no air within them, yet they have a very conſiderable quantity of electric matter, which reſiſts an expulſion from its place: and therefore, tho' it may yield a little when the rubber is applied to the outſide, yet it will inſtantly throw off into the atmoſphere what the rubber has left on the ſurface; becauſe the reſiſtance is leaſt towards that place, as ſoon as the electric has come out from under the rubber. Hence alſo we ſee the reaſon why no ſigns of electricity are obſerved on glaſs to which the rubber is immediately applied; namely, becauſe the preſſure being equally great all round, no part of the electric fluid can be thrown off into the atmoſphere, in order to ſet the reſt in motion.

The only thing neceſſary to be added in confirmation of this theory of excitation is, that electric ſubſtances of the ſame kind cannot be excited by rubbing them againſt one another. Thus glaſs cannot be excited by rubbing it againſt glaſs, &c. Mr Wilcke obſerved, that when two pieces of glaſs were rubbed upon each other in the dark, a very vivid light appeared upon them; which, however, threw out no rays, but adhered to the place where it was excited. It was attended with a ſtrong phoſphoreal ſmell, but no attraction or repulſion. From this experiment he inferred, that friction alone would not excite electricity; but that to produce this effect, the bodies rubbed together muſt be of different natures with reſpect to their attracting the electric fluid.

## § 7. *Of Poſitive and Negative Electricity.*

FROM what hath been already advanced, it will pretty plainly appear, that to increaſe the quantity of electric fluid in any body is a thing impoſſible, unleſs we alſo augment the ſize of the body. All the fine pores of every terreſtrial fluid are exceedingly full, and unleſs we ſeparate the minuteſt particles of the body farther from one another than they are naturally, we cannot introduce more of the electric fluid into it than there was before. This fluid, we have already ſeen, is not, like the air, endued with a repulſive force between its particles; and therefore it muſt be incompreſſible. If it is incompreſſible, all the phenomena attending it muſt be owing to its various motions, and the ſeeming accumulations of it muſt be owing only to its more briſk action in ſome places than in others. But before a complete ſolution of the phenomena of poſitive and negative electricity can be given, it is neceſſary to ſhow that theſe are not ſo eſſentially diſtinct and oppoſite as they have been thought to be, but may be converted into each other in ſuch caſes as we cannot poſſibly ſuppoſe either an addition or ſubtraction of the electric fluid.

03
ods of
ing
ve and
ive
icity
ne
er.

This poſition, however oppoſite to the common opinions on the ſubject, may be proved by the following experiments. 1. Let a coated phial be ſet upon an inſulating ſtand, and let its knob be touched by the knob of another phial negatively electrified. A ſmall ſpark will be obſerved between them, and both ſides of the inſulated phial will inſtantly be electrified negatively. Now, though we may ſuppoſe the one ſide of the phial which is touched by the negatively electrified one to loſe part of its fire, yet this cannot be the caſe with the other, becauſe there is nothing to take it away, and therefore it ought to appear in its natural ſtate. 2. Let a phial, having a pith-ball electrometer faſtened to its outſide coating, be ſlightly charged poſitively, and then ſet upon an inſulating ſtand. The outſide is then negatively electrified, or, according to Dr Franklin's theory, has too little electric matter in it. The pith-balls, however, will touch each other, or ſeparate but in a very ſmall degree: but let the knob of another bottle, which hath received a ſtrong charge of poſitive electricity, be brought near to the knob of the firſt, and the pith-balls on the outſide will diverge with poſitive electricity. Now, it is impoſſible that any ſubſtance can have both too much and too little electric matter at the ſame inſtant: yet we ſee that negative electricity may thus inſtantaneouſly be converted into the poſitive kind, in circumſtances where no addition of fire to the outſide can be ſuppoſed. 3. Let the ſame phial, with the pith-balls affixed to its outſide coating, be ſlightly charged negatively, and then inſulated. The outſide is now electrified poſitively, or, according to Dr Franklin's hypotheſis, has too great a quantity of electric fluid. Nevertheleſs, upon bringing the knob of a phial ſtrongly electrified negatively to that of the inſulated one, the pith-balls will inſtantly diverge with *negative* electricity. 4. Let a phial receive as full a charge of poſitive electricity as it can contain, and then inſulate it. Charge another very highly with negative electricity. Bring the knob of the negative bottle near that of the poſitive one, and a thread will play briſkly between them. But when the knobs touch each other, the thread after being attracted will be repelled by both. The negative electricity is ſomehow or other ſuperinduced upon the poſitive; and, for a few moments after the bottles are ſeparated, both will ſeem to be electrified negatively. But if the finger is brought near the knob of that bottle on which the negative electricity was ſuperinduced, it will inſtantly be diſſipated, a ſmall ſpark ſtrikes the finger, and the bottle appears poſitively charged as before.

From theſe metamorphoſes of poſitive into negative, or negative into poſitive, electricity, it ſeems proven in the moſt deciſive manner, that poſitive electricity doth not conſiſt in an *accumulation*, nor the negative kind in a *deficiency*, of the electric fluid. We are obliged, therefore, to adopt the only probable ſuppoſition, namely, that both of them ariſe entirely from the different directions into which the fluid is thrown in different circumſtances; and of conſequence, the only method of giving an intelligible explanation of poſitive and negative electricity is by conſidering the different direction of the fluid in each.

174
Method of
determining the direction of
the fluid.

A great variety of methods have been contrived to aſcertain the direction of the electric fluid, but all of them ſeem uncertain except that which is drawn from the appearance of electric light. The luminous matter appearing on a point negatively electrified is very ſmall, reſembling a globule; it makes little noiſe, and has a kind of hiſſing ſound. The poſitive electricity, on the other hand, appears in a diverging luminous ſtream, which darts a conſiderable way into the air, with a crackling noiſe. Now, it is certain, that in whatever caſe the electric fluid darts from the point into the air, in that caſe it muſt be the moſt reſiſted by it; and this is evident in the poſitive electricity. In this, the rays evidently *diverge* from the points. We may, indeed, ſuppoſe them to be *converging* from many points in the ſurrounding air towards the metallic point. But why ſhould we imagine that a viſible ray would break out from one place of the atmoſphere more than another? The air, we know, reſiſts the motion of the electric fluid, and it certainly muſt reſiſt it equally. Of conſequence, when this fluid is coming from the air towards a pointed conductor, it muſt percolate ſlowly and inviſibly through the air on all ſides equally, till it comes ſo near that it is able to break through the intermediate ſpace; and as this will likewiſe be equal, or nearly ſo, all round, the negative electricity muſt appear like a ſteady luminous globule on the point, not lengthening or ſhortening by flaſhes as the poſitive kind does. Electricians have therefore determined with a great deal of reaſon, that when a point is electrified poſitively the matter flows out from it.

It is to be remarked, however, that in moſt caſes, if not in all, a body cannot be electrified negatively till it has firſt become poſitively electrified; and it is in the act of diſcharging its poſitive electricity that it becomes negative. Thus, ſuppoſe a coated phial to be ſet upon an inſulated ſtand, and its knob is approached by that of another bottle charged poſitively: a ſmall ſpark is obſerved between them, and both ſides of the inſulated bottle are electrified poſitively; but as ſoon as the finger is brought near to the outſide, the poſitive electricity is diſcharged by a ſpark, and a negative one appears. But from what hath been already advanced,

it

it is evident, that poſitive electricity is when the fluid hath a tendency to leave any body, and the negative electricity when it hath the ſame tendency to enter it. Therefore, as the electric fluid is ſubject to mechanical laws as well as other fluids, it muſt follow, that theſe tendencies are produced and kept up by the motions excited originally in the air, and electric fluid in the air, ſurrounding theſe bodies. If this principle is kept in view, it will lead us to an eaſy explanation of many electrical phenomena, for which no ſatisfactory reaſon hath hitherto been given.

### § 8. *Of Electric Attraction and Repulſion.*

IT hath now been ſhown, that, in bodies electrified poſitively, there is a flux of electric matter from their ſurface all round; that is, the fluid contained in their pores puſhes out on every ſide, and communicates a ſimilar motion to the electric fluid contained in the adjacent atmoſphere. This muſt of neceſſity very ſoon exhauſt the body of its electric matter altogether, if it was not inſtantaneouſly ſupplied after every emiſſion. But this ſupply is immediately procured from the ſurrounding atmoſphere. The quantity ſent off is inſtantly returned from the air, and the vibratory motion or ſtruggle between the air and electric fluid, which hath been often mentioned, immediately takes place. The poſitive electricity therefore conſiſts in a vibratory motion in the air and electric fluid; and the force of this vibration is directed outwards from the electrified body. In bodies negatively electrified, the fluid contained in the neighbouring atmoſphere is directed towards the body ſo electrified. But it is certain, that this motion inwards cannot be continued unleſs there is alſo a motion of the fluid outwards from the body. In this caſe alſo there is a vibratory motion, but the force of it is directed inwards, and as the ſource of it lies not in the body, but in the ſurrounding atmoſphere, it manifeſts itſelf ſomewhat leſs vigorouſly.

105
Why electric appearances continue ſo long.

The reaſon why theſe motions are continued for ſuch a length of time as we ſee they are, is, the extreme mobility of the electric fluid. It doth not indeed appear from any experiments, that this fluid hath the leaſt friction among its parts. A motion once induced into it muſt therefore continue for ever, until it is counteracted by ſome other motion of the ſame fluid. Hence, when a vibratory motion is once introduced among the particles of the electric fluid contained in any ſubſtance, that motion will be kept up by the ſurrounding fluid, let the body be removed to what place we pleaſe. There is no occaſion indeed for ſuppoſing any thing like an electric atmoſphere round the electrified body. The caſe is exactly the ſame as with a burning body. Let a candle be carried to what place we will, it will ſtill burn; but it would be abſurd to ſay, that the fire ſurrounded it like an atmoſphere, as we know the fire is kept up by the air only, which is changed every moment. In like manner, the poſitive and negative electricities, which are two different motions of the electric fluid, are kept up by the air and electric matter contained in it; and, wherever the electrified body is carried, theſe fluids are equally capable of continuing them.

The phenomena of attraction and repulſion are now eaſily explained. Let us ſuppoſe a body poſitively electrified ſuſpended by a ſmall thread, at a diſtance from any other. The vibration above-mentioned, in which poſitive electricity conſiſts, being kept up by the equable preſſure on all ſides, the body is neither moved to one ſide nor another. But when a negatively electrified body is brought near, the force of the vibration being directed outwards in the one, and inwards in the other, the preſſure of the fluid in the intermediate ſpace between them is greatly leſſened; and of conſequence the preſſure on the other ſides drives them together, and they are ſaid to *attract* each other. If another body, electrified alſo poſitively, is brought near to the firſt, the force of the vibrations are directly oppoſed to one another, and therefore the bodies recede from each other, and are ſaid to *repel* one another. The caſe is the ſame with two bodies negatively electrified: for there the electricity, as far as it extends round the bodies, conſiſts of a vibratory motion of the electric fluid; and the vibrations being directed towards both the bodies, as towards two different centres, muſt neceſſarily cauſe them recede from each other; becauſe, if they remained in contact, the vibratory motions would interfere with and deſtroy one another.

When a ſmall body is brought within the ſphere of another's electricity, the equable preſſure of that vibratory or electrical ſphere is ſomewhat leſſened upon the ſide near which the ſecond body is brought; and therefore it is immediately impelled towards the firſt by the action of the ſurrounding fluid, in order to keep up the equilibrium. As ſoon as it arrives there, the vibrations of the fluid around the firſt body being communicated to that within the pores of the ſecond, it immediately acquires a ſphere of electricity as well as the firſt, and is conſequently repelled. The repulſion continues till the vibration ceaſes either by the action of the air, or by the body coming in contact with another much larger than itſelf; in which caſe the electricity is ſaid to be *diſcharged*. If, after this diſcharge of electricity, the ſecond body is ſtill within the electric ſphere of the firſt, it will immediately be attracted, and very ſoon after repelled, and ſo on alternately till the electricity of the former totally ceaſes.

### § 9. *Of the Diſcharge of Electricity by Sparks upon blunt Conductors, and ſilently by pointed Ones.*

10
Electr
only ſ
itſelf i
air.

THE manner in which this is accompliſhed will beſt appear from conſidering the nature of what is commonly called *electricity*. This cannot appear but in an electric ſubſtance; and the ſubſtance in which it doth appear is the air. The prime conductor of an electrical machine diſcovers no other properties in itſelf, when electrified, than it had before. The metal is equally hard, ſhining, and impenetrable. The electricity, or properties of attracting, repelling, &c are all lodged in the air; and if the conductor is placed *in vacuo*, they inſtantly ceaſe. It hath already been ſhown, that the electric matter runs over the ſurface of conducting ſubſtances in great quantities, like a ſtream of water running from one place to another. In this manner it will not paſs over the ſurface of electrics. It enters their ſubſtance, and paſſes through it with a vibratory motion. This vibratory motion always ſhows a reſiſtance; nor is it in any caſe poſſible to induce a vibration without firſt impreſſing a motion in one direction, and then reſiſting it by a contrary motion

Round the ſurface of an electrified body ſuſpended in the air, therefore, there is always an equable preſſure, by which the emiſſion of the electric fluid is every moment checked, and by which its vibrations are occaſioned. When a metallic ſubſtance is brought near the electrified body, the fluid has an opportunity of making its eſcape, provided it could get at the metal, becauſe it could run along its ſurface. The preſſure of the air is alſo leſſened on that ſide which the conducting ſubſtance approaches. The whole effort of the electric matter contained in the vibratory ſphere is exerted againſt that ſingle place, becauſe the reſiſtance is leaſt. If the body has a broad ſurface, however, the diſproportion between theſe reſiſtances is not ſo great as when its ſurface is leſs. Let us ſuppoſe, for inſtance, that the ſurface of the conducting ſubſtance contains an inch ſquare, and that the whole ſurface of the electrified ſphere contains only ſix ſquare inches. When the conducting ſubſtance approaches, all the preſſure is directed towards that place; and the effort made by the electric matter to eſcape there, is five times as great as what it is any where elſe. Nevertheleſs, though it has a vibratory motion in the ſubſtance of the air, it cannot have a progreſſive motion through it without violently diſplacing its parts; and an inch ſquare of air makes a conſiderable reſiſtance. At laſt, however, if this reſiſtance is every moment made leſs by approaching the conducting ſubſtance nearer to the electrified body, the electric matter breaks through the thin plate of air, ſtrikes the conductor, and runs along it. The ſpark is produced by the reſiſtance it meets with from the air. But if, inſtead of a body with a broad ſurface, we preſent the point of a needle, whoſe ſurface is perhaps not above the ten-thouſandth part of a ſquare inch, the effort of the electric matter to diſcharge itſelf there will be 60,000 times greater than at any other place, becauſe the whole effort of the ſix ſquare inches, of which we ſuppoſe the ſurface of the electric ſphere to conſiſt, is exerted againſt that ſingle point. The air alſo reſiſts, as in the former caſe; but it can reſiſt only in proportion to the extent of its ſurface which covers the conducting body; and this, being only the ten-thouſandth part of a ſquare inch, muſt be exceedingly little. As ſoon therefore as a needle, or any other fine pointed body, is preſented to an electrified ſubſtance, the electric matter is urged thither with great velocity; and as it hath an opportunity of running along the needle, its vibrations quickly ceaſe, and the electricity is ſaid to be *drawn off.*—This drawing off, however, does not extend all round the electrified body, if means are uſed to keep up the electricity perpetually. Thus, if, on the end of the prime conductor, there are faſtened a number of fine threads, hairs, &c. when the cylinder is turned, the threads on the end will diverge, and ſpread out like as many rays proceeding from a centre. If a point is preſented on one ſide of the conductor, though at a conſiderable diſtance, the threads on one ſide will loſe their divergency and hang down, but thoſe on the other ſide will continue to diverge. The reaſon of this is, the difficulty with which the electric fluid gets through the atmoſphere, even where the reſiſtance of it is made as little as poſſible; and hence alſo we may ſee why more conductors than one may be neceſſary for the ſafety of large buildings. See LIGHTNING.

### § 10. *Why Poſitive Electricity hath a Tendency to induce the Negative Kind on any Body kept within its Sphere of Action, and why Negative Electricity produces the Poſitive Kind in ſimilar Circumſtances.*

THIS is one of the electrical phenomena moſt difficult to be ſolved; and indeed ſeems totally inſolvable, unleſs we give up the idea of *accumulation* and *deficiency* of the electric fluid in different bodies. On Dr Franklin's principles, no ſolution hath been attempted. Mr Cavallo places this among the *properties* of electricity for which he doth not pretend to account, but gives as the *cauſes* of other phenomena. It is indeed certain, that if a body hath already *too much* electricity or any thing elſe, it cannot be continually taking from thoſe around it; and if it hath *too little*, it cannot be continually giving them. By attending to the principles above laid down, however, this phenomenon admits of an eaſy ſolution. As poſitive electricity conſiſts in a vibratory motion of the electric matter in the pores of any body, and to ſome diſtance through the air, while at the ſame time the force is directed outwards from the body, it is plain, that if any other body is brought within this ſphere, the direction of the vibration is changed; for what is *outwards* from the one is *inwards* to the other. But a vibratory motion, the force of which is directed *inwards*, is what conſtitutes negative electricity; and, therefore, no ſooner is any body placed at ſome diſtance from one poſitively electrified, than it immediately becomes negatively ſo. The ſame reaſon may be given why negative electricity produces the poſitive kind on a body placed near it. In the negative kind, the force of the vibration is directed inwards. If another body is brought near, the vibration which is *inwards* to the firſt muſt be *outwards* from the ſecond, which thus becomes poſitively electrified. The only difficulty here, is to account for this motion, which is only inward or outward to one ſide of the body brought near the electrified one, being ſo ſuddenly propagated all round. This, however, muſt eaſily be ſeen to ariſe from the extreme ſubtility of the electric fluid, and its effort to keep up an equilibrium in all parts, which it will never ſuffer to be broken. When this fluid puſhes inward to one ſide of a body, the fluid contained in that body would immediately yield, and allow a free paſſage to what came after, if its yielding was not obſtructed by ſomething on the other ſide. This obſtruction ariſes from the air, which cannot admit a progreſſive motion of electric matter through it. No ſooner, therefore, is a puſh made againſt one ſide than a contrary one is made againſt the other; and thus the body inſtantly becomes electrified all round.

167
Why a motion of the electric fluid on one ſide is ſuddenly propagated round a body.

168
Zones of poſitive and negative electricity accounted for.

On theſe principles, alſo, may we account for the zones of poſitive and negative electricity which are to be found on the ſurface of glaſs tubes *; and eſpecially in electrified air. When the prime conductor of a machine is ſtrongly electrified poſitively, it is throwing out the fluid from it in all directions. The air cannot receive this fluid without throwing out that which it alſo contains; and this ſhows, that ſimple electrification can neither increaſe nor diminiſh the denſity of the air, which is alſo vouched by numberleſs experiments. But if the air throws out its electric fluid in all directions, it muſt throw part of it back upon the conductor;

---

* See n° 68,

tor, and conſequently obſtruct its operations. This likewiſe is found to be the caſe; for it is impoſſible to make an electric machine act long with the ſame degree of ſtrength, owing to the electricity communicated from it to the air. But if the conductor and air are thus reciprocally throwing the electric matter back upon one another, it is impoſſible but another zone of air which lies at a greater diſtance muſt be continually receiving it, or be electrified negatively. But this cannot receive, without alſo emitting the fluid it contains; which, therefore, will be thrown upon another zone behind it, and partly back upon the firſt. The original force of the fluid being now ſpread over a large ſpace. will conſequently be diminiſhed; and the ſucceeding zone will be electrified weakly, though poſitively. In like manner, a ſucceeding zone muſt yield, and receive the fluid from this; which will conſequently be electrified negatively, though weaker than the former: and thus zones of poſitive and negative electricity will gradually ſucceed each other in the air, till no traces of either are to be found.—In theſe zones, it muſt be remembered, that there is a centre peculiar to each, and from this centre the vibrations proceed either inward or outward. Thus, when the machine is firſt ſet in motion, a vibration is propagated from it as from a centre to ſome diſtance in the air, and the air is at firſt negatively electrified. But as this vibratory motion cannot be extended far in one direction. vibrations begin to be propagated in all directions from another centre at ſome diſtance. The conductor becomes then leſs poſitively electrified than before; however, by means of the machine, its electricity is ſtill kept up, though weaker; but a zone of air beyond the firſt, where the reſiſtance is much leſs, becomes negatively electrified. This again cannot continue long till vibrations outwards ariſe from another centre, and ſo on. It is ſcarce needful to add here, that the longer the electrification is continued, and the ſtronger it is, the broader theſe zones muſt be.

### § 11. *Of the Leyden Phial.*

The phenomena of the Leyden phial are eaſily explained from what hath been already advanced. Glaſs and other electric ſubſtances are ſo conſtituted, that they can tranſmit the vibratory motions of the electric matter, though they cannot admit of any conſiderable progreſſive one. Conducting ſubſtances, on the other hand, admit of a progreſſive motion, but not ſo eaſily of a vibratory one. When the electric fluid is procured from the earth by an electric machine, if the conductor had a communication with the earth, all the matter collected by the cylinder would run along the conductor into the earth, and not a ſpark or other appearance of electricity would be procured in the air. But when the conductor is inſulated, the matter is forced to go off into the air, and there produces the vibratory motions already mentioned. If a pane of glaſs which has no metallic coating touches the conductor, though it is permeable by the vibratory motion of the fluid, yet a conſiderable reſiſtance is made, and the fluid cannot eaſily diffuſe itſelf over its ſurface. Nevertheleſs, it will ſoon ſhow ſigns of having received electricity, that is of having the fluid within its pores thrown into a vibratory motion. This motion is directed outwards, from the middle of the ſubſtance of the glaſs, to the ſurface, and a conſiderable way beyond it on both ſides. Both ſides of the glaſs are then poſitively electrified. If a conducting ſubſtance touches one of the ſides of the glaſs, the vibrations on that ſide are deſtroyed; becauſe the fluid which occaſioned them yields to the reſiſtance it met with, and runs along the conductor into the earth. But no ſooner is this done, than the power which reſiſted the vibration outward from the glaſs having got the better in the manner juſt now explained, a new vibration is produced by that reſiſting power; and the force of this vibration is directed towards the ſide from whence the electricity was drawn off, which therefore becomes electrified negatively. Thus may we underſtand how a pane of glaſs, or any other electric, may receive poſitive electricity on the one ſide and negative on the other. to as high a degree as we pleaſe. But there is found to be a limit to every charge of electricity we can give; and this limit is the reſiſtance of the air. A phial will contain double the charge in air doubly condenſed that it does in the common atmoſphere; and when once the vibration becomes too great to be borne, the poſitive ſide of the glaſs throws out pencils of light, and will receive no more electricity in that ſtate of the atmoſphere.

come
ged.

II
Why
tains i
charg

Thus, in every charged phial, there is a violent impulſe or vibration of the fluid, *outward* from the poſitive, and *inward* to the negative, ſide. As long as theſe continue, the phial continues charged. As the electric fluid ſeems to be ſubject to no other natural power, but controls all its own actions only by moving in oppoſite directions, it is plain, that if a charged phial is carefully kept from any of thoſe means by which it is known to be diſcharged, it muſt keep its charge for a long time; and thus. by keeping phials within glaſs caſes, their charge will be retained for ſix or eight weeks, or perhaps a great deal longer. The only method of diſcharging a phial, is by making a communication between its coatings. The fluid preſſing out of the poſitive ſide. now yields to the preſſure of that from the negative ſide, and runs along the conductor. But no ſooner does it come near the negative ſide of the phial, than, meeting with more of the ſame kind, the current of which is directed the ſame way, both together break through the air with a violent flaſh and crack, and all appearances of electricity ceaſe. —In this, as in all other electrical experiments, it is eaſy to ſee, that the force, velocity, &c. of the fluid depends entirely on the preſſure of that which ſurrounds us. Nature hath appointed a certain conſtitution or modification of the electric fluid in all terreſtrial bodies, and likewiſe all round the earth. In our electrical experiments, we violate this conſtitution in ſome degree. When this violation is but ſmall. the powers of nature operate gently in repairing the diſorder we have introduced; but when any conſiderable deviation is occaſioned, the natural powers reſtore the original conſtitution with extreme violence.

### § 12. *The Phenomena of the Electrophorus accounted for.*

The electrophorus is a machine repreſented Plate CLXXVII. fig. 74. It conſiſts of two plates, A and B, uſually of a circular form; though they may be made ſquare, or of the figure of a parallelogram, with more eaſe, and with equal advantage. At firſt the under plate was of ry

2 uc- the pho-

Theory.

of glaſs, covered over with ſealing-wax; but there is little occaſion for being particular either with regard to the ſubſtance of the lower plate, or the electric which is put upon it. A metallic plate, however, is perhaps preferable to a wooden one, though the latter will anſwer the purpoſe very well This plate is to be covered with ſome electric ſubſtance. Pure ſulphur anſwers very near as well as the dearer electrics, ſealing-wax, gum-lac, &c.; but it hath this bad quality, that, by rubbing it, ſome exceeding ſubtile ſteams are produced, which infect the perſon's clothes, and even his whole body, with a very diſagreeable ſmell, and will change ſilver in his pocket to a blackiſh colour.—The upper plate of the electrophorus is a braſs plate, or a board or piece of paſteboard covered with tin-foil or gilt paper. nearly of the ſame ſize with the electric plate though it will not be the worſe that it is ſomewhat larger. It is furniſhed with a glaſs handle (I), which ought to be ſcrewed into the centre. The manner of uſing this machine is as follows. Firſt, the plate B is excited by rubbing its coated ſide with a piece of new white flannel, or a piece of hare's ſkin. Even a common hard ſhoe-bruſh, having the hair a little greaſed, will excite ſulphur extremely well. When this plate is excited as much as poſſible, it is ſet upon the table with the electric ſide uppermoſt Secondly, the metal plate is laid upon the excited electric, as repreſented in the figure. Thirdly, the metal plate is touched with the finger or any other conductor, which, on touching the plate, receives a ſpark from it. Laſtly, the metal plate A, being held by the extremity of its glaſs handle (I), is ſeparated from the electric plate; and, after it is elevated above that plate, it will be found ſtrongly electrified with an electricity contrary to that of the electric plate; in which caſe, it will give a very ſtrong ſpark to any conductor brought near it. By ſetting the metal upon the electric plate, touching it with the finger, and ſeparating it ſucceſſively, a great number of ſparks may be obtained apparently of the ſame ſtrength, and that without exciting again the electric plate. If theſe ſparks are repeatedly given to the knob of a coated phial, it will preſently become charged.

3 val- er- .

" As to the continuance of the virtue of this electric plate (ſays Mr Cavallo), when once excited, without repeating the excitation, I think there is not the leaſt foundation for believing it perpetual, as ſome gentlemen have ſuppoſed; it being nothing more than an excited electric, it muſt gradually loſe its power by imparting continually ſome of its electricity to the air, or other ſubſtances contiguous to it. Indeed its electricity, although it could never be proved to be perpetual by experiments, laſts a very long time, it having been obſerved to be pretty ſtrong ſeveral days, and even weeks, after excitation. The great duration of the electricity of this plate, I think, depends upon two cauſes: firſt, becauſe it does not loſe any electricity by the operation of putting the metal plate upon it, &c. and, ſecondly, becauſe of its flat figure, which expoſes it to a leſs quantity of air, in compariſon with a ſtick of ſealing-wax, or the like, which, being cylindrical, expoſes its ſurface to a greater quantity of air, which is continually robbing the excited electrics of their virtue.

" The firſt experiments that I made, relative to this machine, were with a view to diſcover which ſubſtance would anſwer beſt for coating the glaſs plate, in order to produce the greateſt effect. I tried ſeveral ſubſtances either ſimple or mixed; and at laſt I obſerved, that the ſtrongeſt in power, as well as the eaſieſt, I could conſtruct, were thoſe made with the ſecond ſort of ſealing-wax, ſpread upon a thick plate of glaſs. A plate that I made after this manner, and no more than ſix inches in diameter, when once excited, could charge a coated phial ſeveral times ſucceſſively, ſo ſtrongly as to pierce a hole through a card with the diſcharge. Sometimes the metal plate, when ſeparated from it, was ſo ſtrongly electrified, that it darted ſtrong flaſhes to the table upon which the electric plate was laid, and even into the air, beſides cauſing the ſenſation of the ſpider's web upon the face brought near it, like an electric ſtrongly excited. The power of ſome of my plates is ſo ſtrong, that ſometimes the electric plate adheres to the metal when this is lifted up, nor will they ſeparate even if the metal plate is touched with the finger or other conductor. It is remarkable, that ſometimes they will not act well at firſt, but they may be rendered very good by ſcraping with the edge of a knife the ſhining or gloſſy ſurface of the wax. This ſeems analogous to the well-known property of glaſs, which is, that new cylinders or globes, made for electrical purpoſes, are often very bad electrics at firſt; but that they improve by being worked, *i. e.* by having their ſurface a little worn. Paper alſo has this property.

114 Experiments with the electrophorus.

" If, after having excited the ſealing-wax, I lay the plate with the wax upon the table, and the glaſs uppermoſt, *i. e.* contrary to the common method; then, on making the uſual experiments of putting the metal plate on it, and taking the ſpark, &c. I obſerve it to be attended with the contrary electricity: that is, if I lay the metal plate upon the electric one, and, while in that ſituation, touch it with an inſulated body, that body acquires the poſitive electricity; and the metallic, removed from the electric plate, appears to be negative; whereas it would become poſitive, if laid upon the excited wax. This experiment, I find, anſwers in the ſame manner if an electric plate is uſed which has the ſealing-wax coating on both ſides, or one which has no glaſs plate.

" If the braſs plate, after being ſeparated from, be preſented with the edge toward the wax, lightly touching it, and thus be drawn over its ſurface, I find that the electricity of the metal is abſorbed by the ſealing-wax, and thus the electric plate loſes part of its power; and if this operation is repeated five or ſix times, the electric plate loſes its power entirely, ſo that a new excitation is neceſſary in order to revive it.

" If, inſtead of laying the electric plate upon the table, it is placed upon an electric ſtand, ſo as to be accurately inſulated, then the metal plate ſet on it acquires ſo little electricity, that it can only be diſcovered with an electrometer; which ſhows, that the electricity of this plate will not be conſpicuous on one ſide of it, if the oppoſite ſide is not at liberty either to part with or acquire more of the electric fluid. In conſequence of this experiment, and in order to aſcertain how the oppoſite ſides of the electric plate would be affected in different circumſtances, I made the following experiments.

" Upon an electric ſtand E, (Plate CLXXVII. fig. 74.)

I placed a circular tin-plate, nearly ſix inches in diameter, which by a ſlender wire H communicated with an electrometer of pith-balls G, which was alſo inſulated upon the electric ſtand F I then placed the excited electric plate D of ſix inches and a quarter in diameter, upon the tin-plate, with the wax uppermoſt; and on removing my hand from it, the electrometer G, which communicated with the tin-plate, *i. e.* with the under ſide of the electric plate, immediately opened with negative electricity. If, by touching the electrometer, I took that electricity off, the electrometer did not afterwards diverge. But if now, or when the electrometer diverged, I preſented my hand open, or any other uninſulated conductor, at the diſtance of about one or two inches, over the electric plate, without touching it, then the pith-balls diverged; or, if they diverged before, came together, and immediately diverged again with poſitive electricity:—I removed the hand, and the balls came together;—approached the hand, and they diverged: and ſo on.

"If, while the pith-balls diverged with negative electricity, I laid the metal plate, holding it by the extremity K of its glaſs handle, upon the wax, the balls came, for a little time, towards one another, but ſoon opened again with the ſame, *i. e.* negative electricity.

"If, whilſt the metallic reſted upon the electric plate, I touched the former, the electrometer immediately diverged with poſitive electricity; which if, by touching the electrometer, I took off, the electrometer continued without divergence.—I touched the metal plate again, and the electrometer opened again; and ſo on for a conſiderable number of times, until the metal plate had acquired its full charge. On taking now the metal plate up, the electrometer G inſtantly diverged with ſtrong negative electricity.

"I repeated the above-deſcribed experiments, with this only difference in the diſpoſition of the apparatus, *i. e.* I laid the electric plate D with the excited ſealing-wax upon the circular tin-plate, and the glaſs uppermoſt; and the difference in their reſult was, that where the electricity had been poſitive in the former diſpoſition of the apparatus, it now became negative, and *vice verſa*; except that, when I firſt laid the electric plate upon the tin, the electrometer G diverged with negative electricity, as well in this as in the other diſpoſition of the apparatus.

"I repeated all the above experiments with an electric plate, which, beſides the ſealing-wax coating on one ſide, had a ſtrong coat of varniſh on the other ſide, and their reſult was ſimilar to that of thoſe made with the above-deſcribed plate."

115 Miſtakes in Mr Cavallo's obſervations.

This is Mr Cavallo's account of the electrophorus; but there is one part of it in which he muſt certainly be miſtaken. He tells us, that "if inſtead of laying the electric plate upon the table, it is ſet upon an electric ſtand, ſo as to be accurately inſulated, then the metal plate ſet on it acquires ſo little electricity, that it can only be diſcovered by an electrometer." In what manner this gentleman came to miſtake a plain fact ſo egregiouſly, is not eaſy to determine; but it is certain, than an electrophorus, inſtead of having its virtue impaired by being inſulated, has it greatly increaſed, at leaſt the ſphere of its activity is greatly enlarged. When lying on the table, if the upper plate is put upon it without being touched with the finger, it will not ſhow much ſign of electricity. But as ſoon as it is put on the electric ſtand, both the upper and under ſide appear ſtrongly negative. A thread will be attracted at the diſtance of eight or ten inches. If both the upper and under ſide are touched at the ſame time, a ſtrong ſpark will be obtained from both, but always of the ſame kind of electricity, namely, the negative kind. If the upper plate is now lifted up, a ſtrong ſpark of poſitive electricity will be obtained from it; and on putting it down again, two ſparks of negative electricity will be produced.

116 Singular appearan on inſulating an electroph rus.

The ſingularity of this experiment is, that it produces always double the quantity of negative electricity that it doth of the poſitive kind; which cannot be done by any other method yet known Another very ſurpriſing circumſtance is, that when the electrophorus remains in its inſulated ſituation, you need not always touch the upper and under ſide of the plates at once, in order to procure poſitive electricity from the upper plate: It is ſufficient to touch both ſides only once. On lifting up the upper plate, a ſpark of poſitive electricity is obtained as already mentioned. On putting it down again, a ſpark of the negative kind is obtained from the upper plate, even though you do not touch the lower one. On lifting up the upper plate, a ſpark of poſitive electricity is obtained, but weaker than it would have been had both ſides been touched at once. Putting down the upper plate again without touching both, a ſtill weaker ſpark firſt of negative and then of poſitite electricity will be obtained from the upper one. Thus the ſparks will go on continually diminiſhing, to the number perhaps of two or three hundred. But at laſt, when the electricity of the whole machine ſeems to be totally loſt, if both ſides are touched at once, it will inſtantly be reſtored to its full ſtrength, and the double ſpark of negative, with the ſingle one of poſitive electricity, will be obtained without intermiſſion as before.

11 General reaſon of all the ph nomena.

To account for all theſe phenomena very particularly, is perhaps impoſſible, without a greater degree of knowledge concerning the internal fabric of bodies than we have acceſs to attain. In general, however, it is evident, that the phenomena of the electrophorus ariſe from the diſpoſition that the electric matter hath to keep up an equilibrium within itſelf throughout every part of the univerſe. In conſequence of this, no motion of the electric matter can be produced upon the one ſide of a body, but it muſt immediately be balanced by a correſponding one on the oppoſite ſide; and in proportion to the ſtrength of the one, ſo will the ſtrength of the other be. When the under plate of the electrophorus is excited, the negative electricity or vibratory action of the electric matter towards the excited ſide, is produced; and the moment that ſuch an action is produced on one ſide, it is reſiſted by a ſimilar one on the oppoſite ſide, and thus the electrophorus becomes negatively electrified on both ſides. As long as the under part of the machine communicates with the earth, the vibratory motion is impeded by the progreſſive one towards the earth. This makes the reſiſtance on the under ſide leſs, and therefore the vibratory motion on the upper part extends but a ſmall way. When the plate is inſulated, the electric matter has not an opportunity of eſcaping to the earth as before, becauſe it is ſtrongly reſiſted by the air; a vibration

bration therefore takes place on both ſides, and extends to a great diſtance from the plate. When the upper plate is ſet upon the electrophorus, the ſame kind of electricity, *viz.* the negative kind, is communicated to it. When both ſides are touched with the finger, or with any other conducting ſubſtance, both electricities are ſuddenly taken off, becauſe the electric matter running along the conducting ſubſtance on both ſides, puts an end to the vibratory motion in the air, which conſtitutes the very eſſence of what we call *electricity*. There is now a quiet and equal balance of the electric matter on both ſides, and therefore no ſigns of electricity are ſhown. But as ſoon as the upper plate is taken off, this balance is deſtroyed. The fluid in the metal plate had not been able to penetrate the electric ſubſtance in ſuch a manner as to put a ſtop to the vibrations of what was within it. As ſoon then as the plate is taken off, the electricity or vibratory motion towards the electric breaks out at that ſide. But this motion *inwards* to the electric, which conſtitutes negative electricity, neceſſarily becomes *outward* from the plate; and as no motion of the fluid can be produced on one ſide of a body, but what is immediately communicated to the other, the upper plate becomes electrified poſitively, and the under one negatively on both ſides.

### SECT. VII. *Of the Method of uſing the Electrical Apparatus already deſcribed, with ſome practical Rules for performing Experiments with it to the beſt Advantage.*

Method of uſing the Electrical Apparatus, &c.

THE machines already deſcribed are calculated for exhibiting the phenomena of electricity in a very high degree; and in general the following effects may be expected from them.

1. On whirling the cylinder in contact with the rubber, without bringing any conducting body near the former, or inſulating the latter, we will perceive in the dark a ſtream of fire ſeemingly iſſuing from the place of contact between the rubber and cylinder, and adapting itſelf to the form of the cylinder ſo as to involve it in a blue flame mixed with bright ſparks; the whole making a very perceptible whizzing and ſnapping noiſe. If the finger is brought near the cylinder in this ſituation, the flame and ſparks will leave the cylinder and ſtrike it; and this phenomenon will continue as long as the globe is whirled round.

2. On applying the prime conductor, the light will in a great meaſure vaniſh, and be perceptible only upon the points preſented by it to the cylinder: but if the finger is now brought near the conductor, a very ſmart ſpark will ſtrike it, and that at a greater or ſmaller diſtance according to the ſtrength of the machine. This ſpark, when the electricity is not very ſtrong, appears like a ſtraight line of fire; but if the machine acts very powerfully, it will put on the appearance of zigzag lightning, throwing out other ſparks from the corners, and ſtrike with ſuch force as to give conſiderable pain to thoſe who receive it. Theſe ſparks in certain circumſtances will ſet fire to ſpirits, tinder, gunpowder, &c.

120 Method of drawing ſparks.

3. If inſtead of the hand or any part of the human body, we hold the knob of a coated phial near the conductor, a vaſt number of ſparks will appear between them, firſt with a loud ſnapping noiſe, but gradually diminiſhing until at laſt it ceaſes, and pencils of blue flame intermixed with ſmall ſparks will be thrown out by the phial; and if the latter is ſtill kept near the conductor, it will in a little time diſcharge itſelf with a violent flaſh and crack; after which, if the phial has not been broke by the diſcharge, the ſparks from the conductor will begin as before, and the ſame phenomena be repeated as long as the cylinder is turned, or till the phial breaks.

121 On applying the battery, &c.

4. On applying the battery, though the accumulation of electricity be much greater than in a ſingle phial, the ſigns of it are much leſs apparent; and ſparks will always paſs between the conductor and knob leading to the battery, by reaſon of the great evaporation from the latter into the air. But here, if one of the jars diſcharges itſelf, all the reſt are likewiſe diſcharged in the ſame moment, and ſome of them generally broken.

5. A thread or other light body ſuſpended near the conductor will be attracted at a conſiderable diſtance; and the force of attraction will be greater or leſs according to the power of the machine.

6. The electricity in all caſes will be poſitive if the rubber be not inſulated, and negative if it is ſo: and by Mr Nairne's contrivance of having a conductor connected with the inſulated rubber, and another with the cylinder, both kinds of electricity may be had with equal eaſe.

122 Effects of the great machine in Teyler's muſeum.

All theſe phenomena are the more remarkable in proportion to the power of the machine. That uſed in Teyler's muſeum is the ſtrongeſt of which we have yet heard; and its effects are as follow.

On preſenting a very ſharp ſteel point to the prime conductor, a luminous ſtream of about half an inch was perceived between them. On fixing the point to the conductor ſo as to project three inches from it, ſtreams of light were thrown out from the point ſix inches long when a ball of three inches in diameter was preſented, but only two inches in length on preſenting another point.

The ſenſation called the *ſpider's web* on the face of the byſtanders (B) is often felt at the diſtance of eight feet from the prime conductor. A thread ſix feet long was ſenſibly attracted at the diſtance of 30 from the prime conductor, and a pointed wire appeared luminous at the diſtance of 28 feet; a cork-ball electrometer diverged at the diſtance of 40 feet.

A ſingle ſpark from the conductor melted a conſiderable length of gold-leaf; gunpowder and other combuſtibles, incloſed in a paper cartridge, with a ſharp point in the middle, were fired; and when another conductor communicating with the earth was placed at the diſtance of 21, or ſometimes 24 inches

---

(B) This is a kind of ſenſation always produced by ſtrong electricity, ſomething reſembling the creeping of inſects or the motion of a light body, ſuch as a ſpider's web, over the ſkin, as already mentioned. It ſeems to proceed from the attraction and electrification of the ſmall hairs with which the body is covered.

from the prime conductor of the machine, a ſtream of fire was perceived between them. This was crooked, and darting out many lateral bruſhes of a very large ſize, in the manner already mentioned. A Leyden phial, containing about one ſquare foot of coated ſurface, was fully charged by about half a turn of the winch ſo as to diſcharge itſelf: and by repeated trials it was found, that in one minute it diſcharged itſelf 76, 78, and frequently 80 times. Laſtly, it was found, that though the conductor, which received the ſparks from the prime one of the machine, communicated with the earth by a wire $\frac{1}{8}$ths of an inch in diameter, this wire would give ſmall ſparks to any conducting body brought near it, as if even this wire had not been ſufficient to conduct the quantity of electricity it received from the machine very readily to the earth.

Though theſe effects are not to be expected from our ordinary electrical machines, yet it is certain, that by taking proper care of them they will be found to act much more powerfully than if neglected. The following directions therefore will be found uſeful for ſuch as wiſh to make electrical experiments.

1. The firſt thing to be obſerved is, the preſervation and care of the inſtruments. The electrical machine, the coated jars, and in ſhort every part of the electrical apparatus, ſhould be kept clean, and as free as poſſible from duſt and moiſture.

2. When the weather is clear, and the air dry, eſpecially in clear and froſty weather, the electrical machine will always work well. But when the weather is very hot, the electrical machine is not ſo powerful; nor in damp weather, except it be brought into a warm room, and the cylinder, the ſtands, the jars, &c. be made thoroughly dry.

3. Before the machine be uſed, the cylinder ſhould be firſt wiped very clean with a ſoft linen cloth that is dry, clean, and warm; and afterwards with a clean hot flannel, or an old ſilk handkerchief: this done, if the winch be turned when the prime conductor and other inſtruments are removed from the electrical machine, and the knuckle be held at a little diſtance from the ſurface of the cylinder, it will be ſoon perceived, that the electric fluid comes like a wind from the cylinder to the knuckle; and, if the motion be a little continued, ſparks and crackling will ſoon follow. This indicates that the machine is in good order, and the electrician may proceed to perform his experiments. But if, when the winch is turned for ſome time, no wind is felt upon the knuckle, then the fault is, very likely, in the rubber: and to remedy that, uſe the following directions: By looſening the ſcrews on the back of the rubber, remove it from its glaſs pillar, and keep it a little near the fire, ſo that its ſilk part may be dried; take now a dry piece of mutton ſuet, or a little tallow from a candle, and juſt paſs it over the leather of the rubber; then ſpread a ſmall quantity of the above deſcribed amalgam over it, and force it as much as poſſible into the leather. This done, replace the rubber upon the glaſs pillar; let the glaſs cylinder be wiped once more, and then the machine is fit for uſe.

4. Sometimes the machine will not work well becauſe the rubber is not ſufficiently ſupplied with electric fluid; which happens when the table, upon which the machine ſtands, and to which the chain of the rubber is connected, is very dry, and conſequently in a bad conducting ſtate. Even the floor and the walls of the room are, in very dry weather, bad conductors, and they cannot ſupply the rubber ſufficiently. In this caſe the beſt expedient is, to connect the chain of the rubber, by means of a long wire, with ſome moiſt ground, a piece of water, or with the iron work of a water-pump; by which means the rubber will be ſupplied with as much electric fluid as is required.

5. When a ſufficient quantity of amalgam has been accumulated upon the leather of the rubber, and the machine does not work very well, then, inſtead of putting on more amalgam, it will be ſufficient to take the rubber off, and to ſcrape a little that which is already upon the leather.

6. It will be often obſerved, that the cylinder, after being uſed ſome time, contracts ſome black ſpots, occaſioned by the amalgam, or ſome foulneſs of the rubber, which grow continually larger, and greatly obſtruct its electric power. Theſe ſpots muſt be carefully taken off, and the cylinder muſt be frequently wiped in order to prevent its contracting them.

7. In charging electric jars in general, it muſt be obſerved, that not every machine will charge them equally high. That machine whoſe electric power is the ſtrongeſt, will always charge the jars higheſt. If the coated jars, before they are uſed, be made a little warm, they will receive and hold the charge the better.

8. If ſeveral jars are connected together, among which there is one that is apt to diſcharge itſelf very ſoon, then the other jars will ſoon be diſcharged with that; although they may be capable of holding a very great charge by themſelves. When electric jars are to be diſcharged, the electrician muſt be cautious, leſt by ſome circumſtance not adverted to, the ſhock ſhould paſs through any part of his body; for an unexpected ſhock, though not very ſtrong, may occaſion ſeveral diſagreeable accidents. In making the diſcharge, care muſt be taken that the diſcharging rod be not placed on the thinneſt part of the glaſs, for that may cauſe the breaking of the jar.

9. When large batteries are diſcharged, jars will be often found broken in it, which burſt at the time of the diſcharge. To remedy this inconvenience, Mr Nairne ſays, he has found a very effectual method, which is, never to diſcharge the battery through a good conductor, except the circuit be at leaſt five feet long. Mr Nairne ſays, that ever ſince he made uſe of this precaution, he has diſcharged a large battery near a hundred times without ever breaking a ſingle jar, whereas before he was continually breaking them. But here it muſt be conſidered, that the length of the circuit weakens the force of the ſhock proportionably; the higheſt degree of which is in many experiments required.

10. It is adviſable, when a jar, and eſpecially a battery, has been diſcharged, not to touch its wires with the hand, before the diſcharging rod be applied to its ſides a ſecond and even a third time; as there generally remains a reſiduum of the charge, which is ſometimes very conſiderable.

11. When any experiment is to be performed which requires but a ſmall part of the apparatus, the remaining part of it ſhould be placed at a diſtance from the machine,

Entertaining Experiments.

machine, the prime conductor, and even from the table, if that is not very large. Candles, particularly, ſhould be placed at a conſiderable diſtance from the prime conductor, for the effluvia of their flames carry off much of the electric fluid.

## Sect. VIII. *Entertaining Experiments.*

### I. *The Electrified Cork-ball Electrometer.*

Fix at the end of the prime conductor a knobbed rod, and hang on it two ſmall cork-balls ſuſpended by threads of equal length. The balls will now touch one another, the threads hanging perpendicularly, and parallel to each other. But if the cylinder of the machine be whirled by turning the winch, then the cork-balls will repel one another; and more or leſs according as the electricity is more or leſs powerful.—If the electrometer be hung to a prime conductor negatively electrified, *i. e.* connected with the inſulated rubber of the machine, the cork-balls will alſo repel each other. If, in this ſtate of repulſion, the prime conductor is touched with ſome conducting ſubſtance not inſulated, the cork-balls will immediately come together. But if, inſtead of the conducting ſubſtance, the prime conductor is touched with an electric, as for inſtance a ſtick of ſealing-wax, a piece of glaſs, &c. then the cork-balls will continue to repel each other; becauſe the electric fluid cannot be conducted through that electric: hence we have an eaſy method of determining what bodies are conductors and what electrics. This electrical repulſion is alſo ſhown by a large downy feather, or ſtill more agreeably by the repreſentation of a human head with hair, as ſhown fig. 47. for there the electric repulſion will make the hair erect itſelf in a ſtrange manner. If the feather is uſed, it will appear beautifully ſwelled by the divergency of its down.

### II. *Attraction and Repulſion of light Bodies.*

Connect with the prime conductor, by means of the hook *H*, the two parallel braſs plates *F*, *G*, as repreſented in fig. 38. at about three inches diſtance from one another; and upon the lower plate put any kind of light bodies, as bran, bits of paper, bits of leaf-gold, &c.; then work the machine, and the light bodies will ſoon move between the two plates, leaping alternately from one to the other with great velocity. If, inſtead of bran or irregular pieces of other matter, ſmall figures of men or other things cut in paper and painted, or rather made of the pith of alder, be put upon the plate, they will generally move in an erect poſition, but will ſometimes leap one upon another, or exhibit different poſtures, ſo as to afford a pleaſing ſpectacle to an obſerving company. When bran or other ſubſtances of that kind are made uſe of, it will be proper to incloſe both plates in a glaſs cylinder, by which the bran will be kept from diſperſing and flying about the room.

The phenomena of electric attraction and repulſion may be repreſented alſo with a glaſs tube, or a charged bottle, and ſome of them in a manner more ſatiſfactory than with the machine.

### III. *The Flying-feather, or Shuttle-cock.*

Take a glaſs tube (whether ſmooth or rough is not material); and after having rubbed it, let a ſmall light feather be let out of your fingers at the diſtance of about eight or nine inches from it. This feather will be immediately attracted by the tube, and will ſtick very cloſe to its ſurface for about two or three ſeconds, and ſometimes longer; after which time it will be repelled; and if the tube be kept under it, the feather will continue floating in the air at a conſiderable diſtance from the tube, without coming near it again, except it firſt touches ſome conducting ſubſtance; and if you manage the tube dexterouſly, you may drive the feather through the air of a room at pleaſure.

There is a remarkable circumſtance attending this experiment; which is, that if the feather be kept at a diſtance from the tube by the force of electric repulſion, it always preſents the ſame part towards the tube:—You may move the excited tube about the feather very ſwiftly, and yet the ſame ſide of the feather will always be preſented to the tube.

This experiment may be agreeably varied in the following manner: A perſon may hold in his hand an excited tube of ſmooth glaſs, and another perſon may hold an excited rough glaſs tube, a ſtick of ſealing-wax, or in ſhort another electric negatively electrified, at about one foot and a half diſtance from the ſmooth glaſs tube: a feather now may be let go between theſe two differently excited-electrics, and it will leap alternately from one electric to the other; and the two perſons will ſeem to drive a ſhuttle-cock from one to the other by the force of electricity.

### IV. *The Electric Well.*

Place upon an electric ſtool a metal quart mug, or ſome other conducting body nearly of the ſame form and dimenſion; then tie a ſhort cork-ball electrometer, at the end of a ſilk thread proceeding from the ceiling of the room, or from any other ſupport, ſo that the electrometer may be ſuſpended within the mug, and no part of it may be above the mouth: this done, electrify the mug by giving it a ſpark with an excited electric or otherwiſe; and you will ſee that the electrometer, whilſt it remains in that inſulated ſituation, even if it be made to touch the ſides of the mug, is not attracted by it, nor does it acquire any electricity; but if, whilſt it ſtands ſuſpended within the mug, a conductor, ſtanding out of the mug, be made to communicate with or only preſented to it, then the electrometer is immediately attracted by the mug.

The following experiments require to be made in the dark: for although the electric light in ſeveral circumſtances may be ſeen in the day-light, yet its appearance in this manner is very confuſed; and that the electrician may form a better idea of its different appearances, it is abſolutely neceſſary to perform ſuch experiments in a darkened room.

### V. *The Star and Pencil of Electric Light.*

When the electrical machine is in good order, and the prime conductor is ſituated with the collector ſufficiently near the glaſs cylinder, turn the winch, and you will ſee a lucid ſtar at each of the points of the collector. This ſtar is the conſtant appearance of the electric fluid that is entering a point. At the ſame time you will ſee a ſtrong light proceeding from the rubber;

Entertaining Experiments.

rubber, and ſpreading itſelf over the ſurface of the cylinder; and if the excitation of the cylinder is very powerful, denſe ſtreams of fire will proceed from the rubber, and, darting round almoſt half the circumference of the cylinder, will reach the points of the collector. If the prime conductor is removed, the denſe ſtreams of fire will go quite round the cylinder; reaching from one ſide of the rubber to the other. If the chain of the rubber is taken off, and a pointed body, as for inſtance the point of a needle or a pin, is preſented to the back of the rubber, at the diſtance of about two inches, a lucid pencil of rays will appear to proceed from the point preſented, and diverge towards the rubber. If another pointed body be preſented to the prime conductor, it will appear illuminated with a ſtar; but if a pointed wire or other pointed conducting body be connected with the prime conductor, it will throw out a pencil of rays.

### VI. *Drawing Sparks.*

Let the prime conductor be ſituated in its proper place, and electrify it by working the machine; then bring a metallic rod with a round knob at each end, or the knuckle of a finger, within a proper diſtance of the prime conductor, and a ſpark will be ſeen between that and the knuckle or knobbed wire. The longer and ſtronger ſpark is drawn from that end of the prime conductor which is fartheſt from the cylinder, or rather from the extremity of the knobbed rod fixed at its end; for the electric fluid ſeems to acquire an impetus by going through a long conductor, when electrified by a powerful machine. This ſpark appears like a long line of fire, reaching from the conductor to the oppoſed body, and often (particularly when the ſpark is long, and different conducting ſubſtances are near the line of its direction) it will have the appearance of being bended to ſharp angles in different places, exactly reſembling a flaſh of lightning. It often darts bruſhes of light ſidewiſe in every direction.

### VII. *The Electric Light flaſhing between two Metallic Plates.*

Let two perſons, one ſtanding upon an inſulated ſtool, and communicating with the prime conductor, and another ſtanding upon the floor, each hold in one of his hands a metal plate, in ſuch a manner that the plates may ſtand back to back in a parallel ſituation, and about two inches aſunder. Let the winch of the machine be turned, and you will ſee the flaſhes of light between the two plates ſo denſe and frequent, that you may eaſily diſtinguiſh any thing in the room. By this experiment the electric light is exhibited in a very copious and beautiful manner, and it bears a ſtriking reſemblance to lightning.

### VIII. *To fire Inflammable Spirits.*

The power of the electric ſpark to ſet fire to inflammable ſpirits, may be exhibited by ſeveral different methods, but more eaſily thus: Hang to the prime conductor a ſhort rod having a ſmall knob at its end; then pour ſome ſpirits of wine, a little warmed, into a ſpoon of metal; hold the ſpoon by the handle, and place it in ſuch a manner, that the ſmall knob on the rod may be about one inch above the ſurface of the ſpirits. In this ſituation, if, by turning the winch, a ſpark be made to come from the knob, it will ſet the ſpirits on fire. It will generally be found more advantageous to fix the diſh containing the ſpirits upon the prime conductor, as repreſented fig. 48.

Entert ing Ex riment

This experiment may be varied different ways, and may be rendered very agreeable to a company of ſpectators. A perſon, for inſtance, ſtanding upon an electric ſtool, and communicating with the prime conductor, may hold the ſpoon with the ſpirits in his hand, and another perſon, ſtanding upon the floor, may ſet the ſpirits on fire by bringing his finger within a ſmall diſtance of it. Inſtead of his finger, he may fire the ſpirits with a piece of ice, when the experiment will ſeem much more ſurpriſing. If the ſpoon is held by the perſon ſtanding upon the floor, and the inſulated perſon brings ſome conducting ſubſtance over the ſurface of the ſpirits, the experiment ſucceeds as well.

### IX. *The artificial Bolognian Stone illuminated by the Electric Light.*

The moſt curious experiment to ſhow the penetrability of the electric light, is made with the real, or more eaſily with the artificial, Bolognian ſtone, invented by the late Mr J. Canton. This phoſphorus is a calcareous ſubſtance, generally uſed in the form of a powder, which has the property of abſorbing light when expoſed to it, and afterwards appearing lucid when brought into the dark *. Take ſome of this powder, and, by means of ſpirits of wine or ether, ſtick it all over the inſide of a clear glaſs phial, and ſtop it with a glaſs ſtopper, or a cork and ſealing-wax. If this phial be kept in a darkened room (which for this experiment muſt be very dark), it will give no light; but let two or three ſtrong ſparks be drawn from the prime conductor, when the phial is kept at about two inches diſtance from the ſparks, ſo that it may be expoſed to that light, and this phial will receive that light, and afterwards will appear illuminated for a conſiderable time. The powder may be ſtuck upon a board by means of the white of an egg, ſo as to repreſent figures of planets, letters, or any thing elſe at the pleaſure of the operator; and the figures may be illuminated in the dark, in the ſame manner as the above-deſcribed phial.

A beautiful method to expreſs geometrical figures with the above phoſphorus, is to bend ſmall glaſs tubes of about the tenth part of an inch diameter, in the ſhape and figure deſired, and then fill them with the phoſphorus powder. Theſe may be illuminated in the manner deſcribed, and they are not ſo ſubject to be ſpoiled as the figures repreſented upon the board frequently are. The beſt method of illuminating this phoſphorus, and which Mr W. Canton generally uſed, is to diſcharge a ſmall electric jar near it.

### X. *The Luminous Conductor.*

Plate CLXX

Fig. 24. repreſents a prime conductor invented by Mr Henley, which ſhows clearly the direction of the electric fluid paſſing through it, from whence it is called the *luminous conductor*. The middle part *E F* of this conductor is a glaſs tube about 18 inches long and three or four inches in diameter. To both ends of this tube the hollow braſs pieces *F D*, *B E*, are cemented air-tight, one of which has a point *C*, by which

* See mistry, n° 141

ertain- Expe- ents.

which it receives the electric fluid, when ſet near the excited cylinder of the electrical machine, and the other has a knobbed wire $G$, from which a ſtrong ſpark may be drawn; and from each of the pieces $F D$, $B E$, a knobbed wire proceeds within the cavity of the glaſs tube. The braſs piece $F D$, or $B E$, is compoſed of two parts; *i. e.* a cap $F$ cemented to the glaſs tube, and having a hole with a valve, by which the cavity of the glaſs tube is exhauſted of air; and the ball $D$, which is ſcrewed upon the cap $F$. The ſupporters of this inſtrument are two glaſs pillars faſtened in the bottom-board $H$, like the ſupporters of the prime conductor. When the glaſs tube of this conductor is exhauſted of air by means of an air-pump, and the braſs ball is ſcrewed on, as repreſented in the figure, then it is fit for uſe, and may ſerve for a prime conductor to an electrical machine. If the point $C$ of this conductor is ſet near the excited cylinder of the machine, it will appear illuminated with a ſtar; at the ſame time the glaſs tube will appear all illuminated with a weak light; but from the knobbed wire that proceeds within the glaſs from the piece $F D$, a lucid pencil will iſſue out, and the oppoſite knob will appear illuminated with a ſtar, which, as well as the pencil of rays, is very clear, and diſcernible among the other light that occupies the greateſt part of the cavity of the tube. If the point $C$, inſtead of being preſented to the cylinder, be connected with the rubber of the machine, the appearance of light within the tube will be reverſed; the knob which communicates with the piece $F D$ appearing illuminated with a ſtar, and the oppoſite with a pencil of rays; becauſe in this caſe the direction of the electric fluid is juſt the contrary of what it was before; it then going from $D$ to $B$, and now coming from $B$ and going to $D$. If the wires within the tube $E F$, inſtead of being furniſhed with knobs, be pointed, the appearance of light is the ſame; but it ſeems not ſo ſtrong in this as in the other caſe.

### XI. *The Conducting Glaſs Tube.*

Take a glaſs tube of about two inches diameter, and about two feet long; fix to one of its ends a braſs cap, and to the other a ſtop-cock or a valve; then, by means of an air-pump, exhauſt it of air. If this tube be held by one end, and its other end be brought near the electrified prime conductor, it will appear to be full of light whenever a ſpark is taken by it from the prime conductor, and much more ſo if an electric jar be diſcharged through it. This experiment may alſo be made with the receiver of an air-pump: take, for inſtance, a tall receiver, clean and dry; and through a hole at its top inſert a wire, which muſt be cemented air tight. The end of the wire that is within the tube muſt be pointed, but not very ſharp; and the other end muſt be furniſhed with a knob. Put this receiver upon the plate of the air-pump, and exhauſt it. If now the knob of the wire at the top of the receiver be touched with the prime conductor, every ſpark will paſs through the receiver in a denſe and large body of light, from the wire to the plate of the air-pump. When any thing is to be touched with the prime conductor that is not very portable, as the air-pump above mentioned, the communication between the former and the latter may be made by means of a rod furniſhed with an electric handle, or the like.

### XII. *The Aurora Borealis.*

Entertaining Experiments.

Plate CLXXIV. fig. 21.

Take a phial nearly of the ſhape and ſize of a Florence flaſk; fix a ſtop-cock or a valve to its neck, and exhauſt it of air as much as poſſible with a good air-pump. If this glaſs is rubbed in the common manner uſed to excite electrics, it will appear luminous within, being full of a flaſhing light, which plainly reſembles the aurora borealis or northern light. This phial may alſo be made luminous, by holding it by either end, and bringing the other end to the prime conductor; in this caſe, all the cavity of the glaſs will inſtantly appear full of flaſhing light, which remains in it for a conſiderable time after it has been removed from the prime conductor. Inſtead of the above-deſcribed glaſs veſſel, a glaſs tube exhauſted of air and hermetically ſealed may be uſed, and perhaps with better advantage. The moſt remarkable circumſtance of this experiment is, that if the phial, or tube, after it has been removed from the prime conductor (and even ſeveral hours after its flaſhing light hath ceaſed to appear), be graſped with the hand, ſtrong flaſhes of light will immediately appear within the glaſs, which often reach from one of its ends to the other.

### XIII. *The Viſible Electric Atmoſphere.*

Plate CLXXIV.

$G I$, fig. 26. repreſents the receiver with the plate of an air-pump. In the middle of the plate $I F$, a ſhort rod is fixed, having at its top a metal ball $B$ nicely poliſhed, whoſe diameter is nearly two inches. From the top of the receiver, another rod $A D$, with a like ball $A$, proceeds, and is cemented air-tight in the neck $C$; the diſtance of the balls from one another being about four inches, or rather more. If, when the receiver is exhauſted of air, the ball $A$ be electrified poſitively, by touching the top $D$ of the rod $A D$ with the prime conductor, or an excited glaſs tube, a lucid atmoſphere appears about it, which although it conſiſts of a feeble light, is yet very conſpicuous, and very well defined; at the ſame time, the ball $B$ has not the leaſt light. This atmoſphere does not exiſt all round the ball $A$; but reaches from about the middle of it, to a ſmall diſtance beyond that ſide of its ſurface which is towards the oppoſite ball $B$. If the rod with the ball $A$ be electrified negatively, then a lucid atmoſphere, like the above deſcribed, will appear upon the ball $B$, reaching from its middle to a ſmall diſtance beyond that ſide of it that is towards the ball $A$; at the ſame time, the negatively electrified ball $A$ remains without any light. The operator in this experiment muſt be careful not to electrify the ball $A$ too much; for then the electric fluid will paſs in a ſpark from one ball to the other, and the experiment will not have the deſired effect. A little practice, however, will render the operation very eaſy and familiar.

### XIV. *Of charging and diſcharging a Phial in general.*

Plate CLXXIV.

Take a coated jar, and place it upon the table near the prime conductor, ſo that the knob of its wire, and that only, may be in contact with it: fix the quadrant electrometer fig. 15. upon the prime conductor, and then turn the winch of the machine. You will obſerve, that as the jar is charging, the index of the electrometer will riſe gradually as far as 90°, or thereabouts, and then reſt: when this happens, you may conclude that the jar has received its full charge. If now you take a diſcharging rod, and holding it by the glaſs handle, apply firſt one of its knobs to the outſide coating of the jar, and then bring the other knob near the knob of the wire of the jar, or near the prime conductor that communicates with it, you will hear a report, and ſee very vivid ſparks between the diſcharging rod and the conducting ſubſtances, communicating with the ſides of the jar. This operation diſcharges the jar. If, inſtead of uſing the diſcharging rod, you touch the outſide of the jar with one hand, and bring the other hand near the wire of the jar, the ſame ſpark and report will follow; but now you will feel a ſhock which affects your wriſts, elbows, and if ſtrong, your breaſt alſo. If a number of perſons join hands, and the firſt of them touches the outſide of the jar, and the laſt touches the wire communicating with the inſide, they will all feel the ſhock, and preciſely at the ſame perceivable time. This ſhock, bearing no reſemblance to any ſenſation otherwiſe felt, cannot conſequently be deſcribed; and in order that a perſon may form a juſt idea of it, he muſt abſolutely feel it. A ſhock may be given to any ſingle part of the body, if that part only be brought into the circuit.

### XV. *The Leyden Vacuum.*

Plate CLXXIV.

Fig. 22. 23. repreſent a ſmall phial coated on the outſide, about three inches up the ſides, with tin-foil; at the top of the neck of this phial, a braſs cap is cemented, having a hole with a valve, and from the cap a wire proceeds a few inches within the phial, terminating in a blunt point. When this phial is exhauſted of air, a braſs ball is ſcrewed upon the braſs cap, which is cemented into its neck, ſo as to defend the valve, and prevent any air from getting into the exhauſted glaſs. This phial exhibits clearly the direction of the electric fluid, both in charging and diſcharging; for if it be held by its bottom, and its braſs knob be preſented to the prime conductor poſitively electrified, you will ſee that the electric fluid cauſeth the pencil of rays to proceed from the wire within the phial, as repreſented fig. 22; and if it is diſcharged, a ſtar will appear in the place of the pencil, as repreſented in fig. 23. But if the phial is held by the braſs cap, and its bottom be touched with the prime conductor, then the point of the wire on its inſide will appear illuminated with a ſtar when charging, and with a pencil when diſcharging. If it be preſented to a prime conductor electrified negatively, all theſe appearances, both in charging and diſcharging, will be reverſed.

The apparatus repreſented fig. 25. will be found very convenient for the various experiments upon the luminous conductor, Leyden vacuum, jars charged poſitively or negatively, with their different ſtates of inſulation. *A* is an inſulating pillar of glaſs, which is ſcrewed to the wooden foot *B*; and on this pillar all the apparatus may be ſcrewed alternately. *CD* is an exhauſted tube of glaſs, furniſhed at each end with braſs caps; at the end *D* is a valve properly ſecured under the braſs plate; a braſs wire with a ball projects from the upper cap; a pointed wire proceeds from the bottom plate; and this tube is called the *luminous conductor*. The flaſk repreſented at *E* is called the *Leyden vacuum*. It is furniſhed with a valve under the ball *E*; to come at which the more readily, the ball may be unſcrewed: a wire, with a blunt end, projects to within a little of the bottom of the flaſk, the latter being coated with tin-foil; and a female ſcrew is cemented to the bottom, in order to ſcrew it on the pillar *A*. *F* is a ſyringe to exhauſt the air occaſionally, either from the luminous conductor or the Leyden vacuum. To do this, unſcrew the ball of the Leyden vacuum, or the plate of the luminous conductor, and then ſcrew the ſyringe in the place of either of theſe pieces, being careful that the bottom of the female ſcrew *G* bears cloſe againſt the leather which covers the ſhoulders *a b c d*; then work the ſyringe, and in a few minutes the glaſſes will be ſufficiently exhauſted. *H* and *I* are two Leyden bottles; each of which has a female ſcrew fitted to the bottom, in order that they may be conveniently ſcrewed on the pillar *A*; and the bottle *H* is furniſhed with a belt by which it may be ſcrewed ſidewiſe to the ſame. *K* and *L* are two ſmall wires, to be ſcrewed occaſionally either into the ball *E*, the knobs *e* or *f*, the cap *c*, or the ſocket *g* on the top of the pillar: the balls may be unſcrewed from theſe wires, which will then exhibit a blunt point. *M* is a wooden table to be ſcrewed occaſionally on the glaſs pillar.

### XVI. *To pierce a Card and other Subſtances with the Electric Exploſion.*

Take a card, a quire of paper, or the cover of a book, and keep it cloſe to the outſide coating of a charged jar; put one knob of the diſcharging rod upon the card, quire of paper, &c. ſo that between the knob and coating of the jar the thickneſs of that card, or quire of paper, only is interpoſed; laſtly, by bringing the other knob of the diſcharging rod near the knob of the jar, make the diſcharge, and the electric matter will pierce a hole (or perhaps ſeveral) quite through the card or quire of paper. This hole has a bur raiſed on each ſide, except the card, &c. be preſſed hard between the diſcharging rod and the jar; which ſhows that the hole is not made in the direction of the paſſage of the fluid, but in every direction from the centre of the reſiſting body. If this experiment be made with two cards inſtead of one, which however muſt be kept very little diſtant from one another, each of the cards, after the exploſion, will be found pierced with one or more holes, and each hole will have burs on both ſurfaces of each card. The hole, or holes, are larger or ſmaller, according as the card, &c. is more damp or more dry. It is remarkable, that if the noſtrils are preſented to it, they will be affected with a ſulphureous, or rather a phoſphoreal ſmell, juſt like that produced by an excited electric.

If, inſtead of paper, a very thin plate of glaſs, roſin, ſealing-wax, or the like, be interpoſed between the knob of the diſcharging rod and the outſide coating of the jar, on making the diſcharge, this will be broken in ſeveral pieces. Small inſects may alſo be killed in this manner. They may be held between the outſide coating of the jar and the knob of the diſcharging rod, like the above card; and a ſhock of a common phial ſent through them, will inſtantly deprive them of life, if they are pretty ſmall: but if larger, they will be affected in ſuch a manner, as to appear quite dead on firſt receiving the ſtroke; but will, after ſome time, recover: this, however, depends on the quantity of the charge ſent through them.

### XVII. *To ſhow the Effect of the Shock ſent over the Surface of a Card or other Subſtances.*

PUT the extremities of two wires upon the ſurface of a card, or other body of an electric nature, ſo that they may be in one direction, and about one inch diſtance from one another; then, by connecting one of the wires with the outſide of a charged jar, and the other wire with the knob of the jar, the ſhock will be made to paſs over the card or other body. If the card be made very dry, the lucid track between the wires will be viſible upon the card for a conſiderable time after the exploſion. If a piece of common writing paper be uſed inſtead of the card, it will be torn by the exploſion into very ſmall bits.

If, inſtead of the card, the exploſion is ſent over the ſurface of a piece of glaſs, this will be marked with an indelible track, which generally reaches from the extremity of one of the wires to the extremity of the other. In this manner, the piece of glaſs is very ſeldom broken by the exploſion. But Mr Henley has diſcovered a very remarkable method to increaſe the effect of the exploſion upon the glaſs; which is by preſſing with weights that part of the glaſs which lies between the two wires (*i. e.* that part over which the ſhock is to paſs). He puts firſt a thick piece of ivory upon the glaſs, and places upon that ivory a weight at pleaſure, from one quarter of an ounce to ſix pounds: The glaſs in this manner is generally broken by the exploſion into innumerable fragments, and ſome of it is abſolutely reduced into an impalpable powder. If the glaſs is very thick, and reſiſts the force of the exploſion, ſo as not to be broken by it, it will be found marked with the moſt lively priſmatic colours, which are thought to be occaſioned by very thin laminæ of the glaſs, in part ſeparated from it by the ſhock. The weight laid upon the glaſs is always ſhook by the exploſion, and ſometimes it is thrown quite off from the ivory. This experiment may be moſt conveniently made with the univerſal diſcharger, fig. 8.

### XVIII. *To ſwell Clay, and break ſmall Tubes, by the Electric Exploſion.*

ROLL up a piece of ſoft tobacco-pipe clay in a ſmall cylinder, and inſert in it two wires, ſo that their ends without the clay may be about a fifth part of an inch from one another. If a ſhock be ſent through this clay, by connecting one of the wires with the outſide of a charged jar, and the other with the inſide, it will be inflated by the ſhock, *i. e.* by the ſpark, that paſſes between the two wires, and, after the exploſion, will appear ſwelled in the middle. If the ſhock ſent through it is too ſtrong, and the clay not very moiſt, it will be broken by the exploſion, and its fragments ſcattered in every direction. To make this experiment with a little variation, take a piece of the tube of a tobacco-pipe, about one inch long, and fill its bore with moiſt clay; then inſert in it two wires, as in the above rolled clay; and ſend a ſhock through it. This tube will not fail to burſt by the force of the exploſion, and its fragments will be ſcattered about to a great diſtance. If, inſtead of clay, the above-mentioned tube of the tobacco-pipe, or a glaſs tube (which will anſwer as well), be filled with any other ſubſtance, either electric or non-electric, inferior to metal, on making the diſcharge, it will be broken in pieces with nearly the ſame force. This experiment is the invention of Mr Lane, F. R. S.

### XIX. *To make the Electric Spark viſible in Water.*

FILL a glaſs tube of about half an inch diameter, and ſix inches long, with water; and to each extremity of the tube adapt a cork, which may confine the water; through each cork inſert a blunt wire, ſo that the extremities of the wires within the tube may be very near one another; laſtly, connect one of theſe wires with the coating of a ſmall charged phial, and touch the other wire with the knob of it; by which means the ſhock will paſs through the wires, and cauſe a vivid ſpark to appear between their extremities within the tube. In performing this experiment, care muſt be taken that the charge be exceedingly weak, otherwiſe the tube will burſt. If we place in a common drinking glaſs, almoſt full of water, two knobbed wires, ſo bent, that their knobs may be within a little diſtance of one another in the water, and if one of theſe wires be connected with the outſide coating of a pretty large jar, and the other wire be touched with the knob of it; the exploſion which muſt paſs through the water from the kob of one of the wires to that of the other, will diſperſe the water, and break the glaſs with a ſurpriſing violence. This experiment is very dangerous if not conducted with great caution.

### XX. *To fire Gun-powder.*

MAKE a ſmall cartridge of paper, and fill it with gun-powder, or elſe fill the tube of a quill with it; inſert two wires, one at each extremity, ſo that their ends within the quill, or cartridge, may be about one fifth of an inch from one another: this done, ſend the charge of a phial through the wires; and the ſpark between their extremities, that are within the cartridge, or quill, will ſet fire to the gun-powder. If the gun-powder be mixed with ſteel-filings, it will take fire more readily, and with a very ſmall ſhock.

### XXI. *To ſtrike Metals into Glaſs.*

TAKE two ſlips of common window-glaſs about three inches long, and half an inch wide; put a ſmall ſlip of gold, ſilver, or braſs leaf, between them, and tie them together, or elſe preſs them together between the boards of the preſs *H*, belonging to the univerſal diſcharger fig. 9. Plate CLXXIV. leaving a little of the metallic leaf out between the glaſſes at each end; then ſend a ſhock through this metallic leaf, and the force of the exploſion will drive part of the metal into ſo cloſe a contact with the glaſs, that it cannot be wiped off, or even be affected by the common menſtrua which otherwiſe would diſſolve it. In this experiment the glaſſes are often ſhattered to pieces; but whether they are broken or not, the indelible metallic tinge will always be found in ſeveral places, and ſometimes thro' the whole length of both glaſſes.

Entertaining Experiments.

### XXII. *To ſtain Paper or Glaſs.*

LAY a chain, which forms a part of the circuit between the two ſides of a charged jar, upon a ſheet of white paper; and if a ſhock be ſent through it, the paper will be found ſtained with a blackiſh tinge at the very juncture of the links. If the charge be very large, the paper, inſtead of being ſtained with ſpots, is brunt through. If the chain be laid upon a pane of glaſs inſtead of paper, the glaſs will often be found ſtained with ſpots in ſeveral places, but (as might be expected) not ſo deep as the paper. If this experiment be made in the dark, a ſpark will be ſeen at every juncture of the links; and if the links are ſmall, and the ſhock pretty ſtrong, the chain will appear illuminated like a line of fire.

### XXIII. *The Lateral Exploſion.*

IF a jar be diſcharged with a diſcharging rod that has no electric handle, the hand that holds it, in making the diſcharge, feels ſome kind of ſhock, eſpecially when the charge is conſiderable. In other words: A perſon, or any conducting ſubſtance, that is connected with one ſide of a jar, but forms no part of the circuit, will feel a kind of ſhock, *i. e.* ſome effect of the diſcharge. This may be rendered viſible in the following manner. Connect with the outſide of a charged jar a piece of chain; then diſcharge the jar thro' another circuit, as for inſtance with a diſcharging rod in the common way, and the chain that communicates with the outſide of the jar, and which makes no part of the circuit, will appear lucid in the dark, *i. e.* ſparks will appear between the links; which ſhows, that the electric fluid, natural to that chain, muſt by ſome means have been diſturbed. This chain will alſo appear luminous, if it is not in contact with the outſide of the jar, but only very near it; and on making the diſcharge, a ſpark will be ſeen between the jar and the end of the chain near it. This electrical appearance out of the circuit of a diſcharging jar, is that which we call the *lateral exploſion;* and to make it appear in the moſt conſpicuous manner, obſerve the following method, which is that of Dr Prieſtley.

When a jar is charged, and ſtands upon the table as uſual, inſulate a thick metallic rod, and place it ſo that one of its ends may be contiguous to the outſide coating of the jar; and within about half an inch of its other end place a body of about ſix or ſeven feet in length, and a few inches in breadth: then put a chain upon the table, ſo that one of its ends may be about an inch and a half diſtant from the coating of the jar: at the other end of the chain apply one knob of the diſcharging rod, and bring the other knob to the wire of the jar, in order to make the exploſion. On making the diſcharge in this manner; a ſtrong ſpark will be ſeen between the inſulated rod, which communicates with the coating of the jar and the body near its extremity, which ſpark does not alter the ſtate of that body in reſpect to electricity. Whether this lateral exploſion is received on flat and ſmooth ſurfaces, or upon ſharp points, the ſpark is always equally long and vivid.

### XXIV. *To diſcharge a Jar ſilently.*

WHEN a large jar is fully charged, which would give a terrible ſhock, put one of your hands in contact with its outſide coating; with the other hold a ſharp pointed needle, and keeping the point directed towards the knob of the jar, proceed gradually near it, until the point of the needle touches the knob. This operation diſcharges the jar entirely; and you will either receive no ſhock at all, or ſo ſmall a one as can hardly be perceived. The point of the needle, therefore, has ſilently and gradually drawn all the ſuperfluous fluid from the inſide ſurface of the electric jar.

### XXV. *Drawing the Electricity from the Prime Conductor by a Point.*

LET a perſon hold the knob of a braſs rod at ſuch a diſtance from the prime conductor, that ſparks may eaſily fly from the latter to the former, when the machine is in motion. Then let the winch be turned; and while the ſparks are following one another, preſent the ſharp point of a needle at nearly twice the diſtance from the prime conductor, that the knobbed rod is held; and you will obſerve that no more ſparks will go to the rod:—remove the needle entirely, and the ſparks will be ſeen again;—preſent the needle, and the ſparks diſappear: which evidently ſhows, that the point of the needle draws off ſilently almoſt all the fluid that the cylinder throws upon the prime conductor.

If the needle be fixed upon the prime conductor with the point outward, and the knob of a diſcharging rod, or the knuckle of a finger, be brought very near the prime conductor, though the excitation of the cylinder may be very ſtrong, yet you will perceive that no ſpark, or an exceeding ſmall one, can be obtained from the prime conductor.

### XXVI. *The Electrified Cotton.*

TAKE a ſmall lock of cotton, extended in every direction as much as conveniently can be done; and by a linen thread about five or ſix inches long, or by a thread drawn out of the ſame cotton, tie it to the end of the prime conductor: then let the winch of the machine be turned, and the lock of cotton, on being electrified, will immediately ſwell, by repelling its filaments from one another, and will ſtretch itſelf towards the neareſt conductor. In this ſituation let the winch be kept turning, and preſent the end of your finger, or the knob of a wire, towards the lock of cotton, which will then immediately move towards the finger, and endeavour to touch it; but take with the other hand a pointed needle, and preſent its point towards the cotton, a little above the end of the finger, and you will obſerve the cotton immediately to ſhrink upward, and move towards the prime conductor.—Remove the needle, and the cotton will come again towards the finger. Preſent the needle, and the cotton will ſhrink again.

### XXVII. *The Electrified Bladder.*

TAKE a large bladder well blown, and cover it with gold, ſilver, or braſs leaf, ſticking it with gum-water: ſuſpend this bladder at the end of a ſilk thread, at leaſt ſix or ſeven feet long, hanging from the ceiling of the room; and electrify the bladder, by giving it a ſtrong ſpark with the knob of a charged bottle: this done, take a knobed wire, and preſent it to the bladder when motionleſs; and you will perceive, that as the knob ap-

# ELECTRICITY.

approaches the bladder, the bladder alſo moves towards the knob, and, when nearly touching it, gives it the ſpark which it received from the charged phial, and thus it becomes unelectrified. Give it another ſpark, and, inſtead of the knobbed wire, preſent the point of a needle towards it, and you will perceive that the bladder will not be attracted by, but rather recede from, the point, eſpecially if the needle be very ſuddenly preſented towards it.

### XXVIII. *The Spider ſeemingly animated by Electricity.*

late XXV.

Fig. 51. repreſents an electric jar, having a wire *C D E* faſtened on its outſide, which is bended ſo as to have its knob *E* as high as the knob *A*.—*B* is a ſpider made of cork, with a few ſhort threads run thro' it to repreſent its legs. This ſpider is faſtened at the end of a ſilk thread, proceeding from the ceiling of the room, or from any other ſupport, ſo that the ſpider may hang mid-way between the two knobs *A*, *E*, when the jar is not charged. Let the place of the jar upon the table be marked; then charge the jar, by bringing its knob *A* in contact with the prime conductor, and replace it in its marked place. The ſpider will now begin to move from knob to knob, and continue this motion for a conſiderable time, ſometimes for ſeveral hours.

The inſide of the jar being charged poſitively, the ſpider is attracted by the knob *A*, which communicates to it a ſmall quantity of electricity; the ſpider then becoming poſſeſſed of the ſame electricity with the knob *A*, is repelled by it, and runs to the knob *E*, where it diſcharges its electricity, and is then attracted by the knob *A*, and ſo on. In this manner the jar is gradually diſcharged; and when the diſcharge is nearly completed, the ſpider finiſhes its motion.

### XXIX. *The Dancing Balls.*

Fix a pointed wire upon the prime conductor, with the point outward; then take a glaſs tumbler, graſp it with your hands, and preſent its inſide ſurface to the point of the wire upon the prime conductor while the machine is in motion: the glaſs in this manner will ſoon become charged; for its inſide ſurface acquires the electricity from the point, and the hands ſerve as a coating for the outſide. This done, put a few pith balls upon the table, and cover them with this charged glaſs tumbler. The balls will immediately begin to leap up along the ſides of the glaſs as repreſented fig. 39. and will continue their motion for a conſiderable time.

### XXX. *The Electrical Jack.*

This is an invention of Dr Franklin's, and turns with conſiderable force, ſo that it may ſometimes be uſed for the purpoſes of a common jack. A ſmall upright ſhaft of wood paſſes at right angles through a thin round board of about 12 inches diameter, and turns on a ſharp point of iron fixed in the lower end, while a ſtrong wire in the upper end, paſſing through a ſmall hole in a thin braſs plate, keeps the ſhaft truly vertical. About 30 radii, of equal length, made of ſaſh-glaſs cut into narrow ſlips, iſſue horizontally from the circumference of the board, the ends moſt diſtant from the centre being about four inches apart. On the end of every one a braſs thimble is fixed. If now the wire of a bottle electrified in the common way be brought near the circumference of this wheel, it will attract the neareſt thimble, and ſo put the wheel in motion. That thimble, in paſſing by, receives a ſpark; and thereby being electrified, is repelled, and ſo driven forwards; while a ſecond, being attracted, approaches the wire, receives a ſpark, and is driven after the firſt; and ſo on, till the wheel has gone once round; when the thimbles before electrified approaching the wire, inſtead of being attracted, as they were at firſt, are repelled, and the motion preſently ceaſes. But if another bottle which had been charged through the coating, or otherwiſe negatively electrified, is placed near the ſame wheel, its wire will attract the thimble repelled by the firſt, and thereby double the force that carries the wheel round. The wheel therefore moves very ſwiftly, turning round 12 or 15 times in a minute, and with ſuch force, that a large fowl ſpitted on the upper ſhaft may be roaſted by means of it.

### XXXI. *The Self-moving Wheel.*

This appears more ſurpriſing than the former, tho' conſtructed upon the ſame principles. It is made of a thin round plate of window-glaſs 17 inches in diameter, well gilt on both ſides, all but two inches next the edge. Two ſmall hemiſpheres of wood are then fixed with cement to the middle of the upper and under ſides, centrally oppoſite; and in each of them a ſtrong thick wire eight or ten inches long, which together make the axis of the wheel. It turns horizontally on a point at the lower end of its axis, which reſts on a bit of braſs cemented within a glaſs ſalt-celler. The upper end of its axis paſſes through a hole in a thin braſs plate, cemented to a long and ſtrong piece of glaſs; which keeps it ſix or eight inches diſtant from any non-electric, and has a ſmall ball of wax or metal on its top to keep in the fire.

In a circle on the table which ſupports the wheel, are fixed 12 ſmall pillars of glaſs, at about 11 inches diſtance, with a thimble on the top of each. On the edge of the wheel is a ſmall leaden bullet, communicating by a wire with the gilding of the upper ſurface of the wheel; and about ſix inches from it is another bullet communicating in like manner with the under ſurface. When the wheel is to be charged by the upper ſurface, a communication muſt be made from the under ſurface to the table. As ſoon as it is well charged, it begins to move. The bullet neareſt to a pillar moves towards the thimble on that pillar; and, paſſing by, electrifies it, and is then repelled from it. The ſucceeding bullet, which communicates with the other ſurface of the glaſs, more ſtrongly attracts that thimble on account of its being electrified before by the other bullet; and thus the wheel increaſes its motion, till the reſiſtance of the air regulates it. It will go half an hour; and make, one minute with another, 20 turns in a minute, which is 600 turns in the whole; the bullet in the upper ſurface giving in each turn 12 ſparks to the thimbles, making in all 2500 ſparks; while the ſame quantity of fire is thought to be received by the under bullet. The whole ſpace moved over by theſe bullets in the mean time is 2500 feet. If;

inſtead of two bullets, you put eight, four communicating with the upper and four with the under ſurface, the force and ſwiftneſs will be greatly increaſed, and the wheel will make about 50 turns in a minute; but then it will not continue moving for ſuch a long time. Theſe wheels may be applied to the ringing of chimes, and the moving of ſmall orreries, &c.

### XXXII. *The Magic Picture.*

Plate CLXXVI. fig. 57.

THIS is a contrivance of Mr Kinnerſley; and is perhaps more calculated to give ſurpriſe than any other experiment in electricity. It is made in the following manner: Having a large mezzotinto, with a frame and glaſs (ſuppoſe of the king), take out the print, and cut a pannel out of it near two inches diſtant from the frame all round. If the cut be through the picture, it is nothing the worſe. With thin paſte, or gum-water, fix the board that is cut off on the inſide of the glaſs, preſſing it ſmooth and cloſe; then fill up the vacancy, by gilding the glaſs well with leaf-gold or braſs. Gild likewiſe the inner edge of the back of the frame all round, except the top part, and form a communication between that gilding and the gilding behind the glaſs; then put in the board, and that ſide is finiſhed. Turn up the glaſs, and gild the foreſide exactly over the back gilding; and when it is dry, cover it, by paſting on the pannel of the picture that has been cut out; obſerving to bring the correſponding parts of the board and picture together, by which the picture will appear of a piece as at firſt; only part is behind the glaſs and part before. Laſtly, hold the picture horizontally by the top, and place a little moveable gilt crown on the king's head. If now the picture is moderately electrified, and another perſon take hold of the frame with one hand, ſo that his fingers touch its inſide gilding, and with the other endeavour to take off the crown, he will receive a terrible blow, and fail in the attempt. The operator, who holds the picture by the upper end, where the inſide of the frame is not gilt, to prevent its falling, feels nothing of the ſhock; and may touch the face of the picture without danger, which he pretends to be a teſt of his loyalty.

### XXXIII. *The Thunder-houſe.*

Fig. 52. is an inſtrument repreſenting the ſide of a houſe, either furniſhed with a metallic conductor, or not; by which both the bad effects of lightning ſtriking upon a houſe not properly ſecured, and the uſefulneſs of metallic conductors, may be clearly repreſented. *A* is a board about three quarters of an inch thick, and ſhaped like the gable-end of a houſe. This board is fixed perpendicularly upon the bottom-board *B*, upon which the perpendicular glaſs pillar *C D* is alſo fixed in a hole about eight inches diſtant from the baſis of the board *A*. A ſquare hole *I L M K*, about a quarter of an inch deep, and nearly one inch wide, is made in the board *A*, and is filled with a ſquare piece of wood nearly of the ſame dimenſions. It is mentioned nearly of the ſame dimenſions, becauſe it muſt go ſo eaſily into the hole, that it may drop off by the leaſt ſhaking of the inſtrument. A wire *L K* is faſtened diagonally to this ſquare piece of wood. Another wire *I H* of the ſame thickneſs, having a braſs ball *H*, ſcrewed on its pointed extremity, is faſtened upon the board *A*; ſo alſo is the wire *M N*, which is ſhaped in a ring at *O*. From the upper extremity of the glaſs pillar *C D*, a crooked wire proceeds, having a ſpring ſocket *F*, through which a double knobbed wire ſlips perpendicularly, the lower knob *G* of which falls juſt above the knob *H*. The glaſs pillar *D C* muſt not be made very faſt into the bottom board; but it muſt be fixed ſo as it may be pretty eaſily moved round its own axis; by which means the braſs ball *G* may be brought nearer or farther from the ball *H*, without touching the part *E F G*. Now when the ſquare piece of wood *L M I K* (which may repreſent the ſhutter of a window or the like) is fixed into the hole ſo, that the wire *L K* ſtands in the dotted repreſentation *I M*, then the metallic communication from *H* to *O* is complete, and the inſtrument repreſents a houſe furniſhed with a proper metallic conductor: but if the ſquare piece of wood *L M I K* is fixed ſo, that the wire *L K* ſtands in the direction *L K*, as repreſented in the figure, then the metallic conductor *H O*, from the top of the houſe to its bottom, is interrupted at *I M*, in which caſe the houſe is not properly ſecured.

Fix the piece of wood *L M I K* ſo, that its wire may be as repreſented in the figure, in which caſe the metallic conductor *H O* is diſcontinued. Let the ball *G* be fixed at about half an inch perpendicular diſtance from the ball *H*; then, by turning the glaſs pillar *D C*, remove the former ball from the latter; by a wire or chain connect the wire *E F* with the wire *Q* of the jar *P*, and let another wire or chain, faſtened to the hook *O*, touch the outſide coating of the jar. Connect the wire *Q* with the prime conductor, and charge the jar; then, by turning the glaſs pillar *D C*, let the ball *G* come gradually near the ball *H*; and when they are arrived ſufficiently near one another, you will obſerve that the jar explodes, and the piece of wood *L M I K* is puſhed out of the hole to a conſiderable diſtance from the thunder-houſe. Now the ball *G*, in this experiment, repreſents an electrified cloud, which, when it is arrived ſufficiently near the top of the houſe *A*, the electricity ſtrikes it; and as this houſe is not ſecured with a proper conductor, the exploſion breaks off a part, *i. e.* knocks off the piece of wood *I M*.

Repeat the experiment with only this variation, *viz.* that this piece of wood *I M* is ſituated ſo, that the wire *L K* may ſtand in the ſituation *I M*, in which caſe the conductor *H O* is not diſcontinued; and you will obſerve, that the exploſion will have no effect upon the piece of wood *L M*, this remaining in the hole unmoved; which ſhows the uſefulneſs of the metallic conductor.

Further. Unſcrew the braſs ball *H* from the wire *H I*, ſo that this may remain pointed. With this difference only in the apparatus, repeat both the above experiments; and you will find that the piece of wood *I M* is in neither caſe moved from its place, nor any exploſion will be heard; which not only demonſtrates the preference of the conductors with pointed termination to thoſe with blunted ones; but alſo ſhows that a houſe furniſhed with ſharp terminations, although not furniſhed with a regular conductor, is almoſt ſufficiently guarded againſt the effects of lightning.

This apparatus is ſometimes made in the ſhape of a houſe, as repreſented fig. 53. where, for the ſake of

Plate XXVI.

diſtinctneſs, the ſide and part of the roof next the eye are not repreſented. The gable-end *AC* repreſents that of the thunder-houſe, and may be uſed in the ſame manner with that above deſcribed, or more readily by the following method. Let one ball of the diſcharging rod touch the ball of the charged jar, and the other the knob *A* of the conductor *AC* of the thunder-houſe; the jar will then of courſe explode, and the fluid will act upon the conductor juſt mentioned. The conducting wire at the windows *hh* muſt be placed in a line. The ſides and gable *AC* of the houſe, are connected with the bottom by hinges; and the building is kept together by a ridge on the roof. To uſe this model, fill the ſmall tube *a* with gunpowder, and ram the wire *c* a little way into the tube; then connect the tube *e* with the bottom of a large jar or battery. When the jar is charged, form a communication from the hook at *C*, on the outſide, to the top of the jar, by the diſcharging rod; the diſcharge will fire the powder, and the exploſion of the latter will throw off the roof, with the ſides, back, and front, ſo that they will all fall down together. The figures *f* and *g* in the ſide of the houſe repreſent a ſmall ramrod for the tube *a*, and a pricker for the touch-hole at *C*. Fig. 54. repreſents a mahogany pyramid, by means of which the ſame experiment may be exhibited. It is uſed in a manner ſimilar to that juſt now deſcribed, the piece at *a* being thrown out by the diſcharge; by which means the upper part falls down in three pieces.

Mr Jones of Holborn makes the front of the common thunder-houſes, as well as the powder-houſe above deſcribed, with two pieces of wood or windows *hh*, which, by being placed in proper ſituations, the one to conduct and the other to reſiſt the fluid, will illuſtrate by one diſcharge the uſefulneſs of good conductors for ſecuring buildings or magazines from the exploſion of thunder, as well as the danger of uſing imperfect ones.

### XXXIV. *The Electric Fly.*

This fly is compoſed of ſmall braſs wires, fig. 49. fixed into a cap of braſs alſo, eaſily moveable upon an axis of the ſame metal, and exactly balanced, ſo that they may turn with the ſmalleſt force. The ends, which ought to be very ſharp, are all bent one way, with regard to one another, as thoſe belonging to *a*, *b*, in the figure; though the two ſets of points conſtituting the two flies there repreſented, are contrary to each other; ſo that the whole flies muſt have a contrary motion. Fixing the axle with the two flies upon the prime conductor, and working the machine, both will begin to turn very ſwiftly, each in a direction contrary to that of the points. In this manner, with a powerful machine, a great many flies may be made to turn either in the ſame or in contrary directions; and by their gradual increaſe or decreaſe in ſize may repreſent a cone or other figure; for the courſe of each will be marked by a line of fire, and thus the whole will exhibit a beautiful appearance in the dark. The light is ſaid to be more brilliant when the ends are ſlightly covered with ſealing-wax, greaſe, or other electric matter.

In this experiment the fly will turn the ſame way whether the electricity be poſitive or negative; the reaſon of which will eaſily be conceived from the theory already laid down, viz. that in poſitive electricity the fluid iſſues from the body electrified, and that in negative electricity it enters into it. In the former caſe, the recoil of the fluid, which acts equally on the air and on the point from whence it iſſues, muſt continually put the point the contrary way; and in negative electricity, when the point ſolicits a continual draught of electric matter from the air, the direct impulſe of the former muſt alſo produce a motion in the point in the courſe in which the fluid itſelf moves. In vacuo no motion is produced; becauſe there is no air on which the fluid may act when it iſſues from the point. In like manner, when air is incloſed in a glaſs veſſel, the motion of the electric fly ſoon ſtops; becauſe the fluid cannot eaſily get through the air and the glaſs, and therefore its motions are impeded ſo that it cannot preſs with force ſufficient to produce motion. On applying a conductor to the outſide of the glaſs, the fly renews its motion; becauſe an opportunity is now given to the fluid to eſcape, by running through the glaſs. But this, for the reaſons already given, muſt ſoon ceaſe, becauſe a contrary action of the fluid inſtantly begins to take place; and in a ſhort time becomes equal to that which urges it forward from the machine. The motion of the fly, therefore, ſtops for the ſame reaſon that a Leyden phial becomes at laſt ſaturated and cannot receive a greater charge; and which has been already ſo fully diſcuſſed, that it would be ſuperfluous to ſay more on the ſubject. Fig. 50. ſhows another fly which turns perpendicularly, and which will be readily underſtood from what has been already ſaid.

### XXXV. *The Electrified Bells.*

Plate CLXXV.

Fig. 35. repreſents an inſtrument having three bells, which are made to ring by electric attraction and repulſion. *B* is a braſs rod, furniſhed with a ring *A* of the ſame metal, by which it is ſuſpended from another rod fixed in the prime conductor. The outer bells *C* and *E* are ſuſpended by braſs chains; but the middle bell *D* and the two ſmall braſs clappers between *CD* and *DE* are ſuſpended by ſilk threads. From the concave under part of the bell *D* a chain proceeds, which falls upon the table, and has a ſilk thread *E* at its extremity. When this apparatus is hung to the conductor by the ring *A*, and the cylinder of the machine gently turned, the clappers will fly from bell to bell with a rapid motion, and the bells will ring as long as they are kept electrified. The two bells *C* and *E* being ſuſpended by braſs chains, are firſt electrified: hence they attract the clappers, communicate to them a little electricity, and repel them to the unelectrified bell *D*; upon which the clappers depoſit their electricity, and move again to the bells *CE*, from which they acquire more, and ſo on. If, by holding the ſilk thread *F*, the chain of the middle bell be raiſed from the table, the bells after ringing a little while will ſtop; becauſe the bell *D* will have no opportunity of conveying the electricity it receives from the clappers to the ground, being inſulated by the ſilk thread. In the dark, ſparks will be ſeen between the clappers and bells.

Fig. 36. repreſents a ſet of bells more elegantly mounted, and which produce a better ſound. In theſe the knob *a* muſt communicate with the conductor when the apparatus is made uſe of. Fig. 37. repreſents

Entertaining Experiments

Plate CLXXV.

a ſet of eight bells otherwiſe conſtructed. The clapper *h* is here ſuſpended by a ſilken thread from the fly *a b c d*: the axis of the fly reſts in a ſmall hole on the top of a glaſs pillar; and its upper part moves freely in, and is confined by a hole in the braſs arm *g*. To make uſe of theſe bells they muſt be applied to the cylinder of the machine, or at leaſt brought very near it when the conductor is removed; ſo that the fly *a b c d* may be about the height of the centre of the cylinder. The latter being then put in motion, the electricity from it proceeding to the fly, will cauſe it to turn round in the manner deſcribed in the foregoing experiment, and the clapper attracted by each of the bells alternately in its rotation; which, if they are properly turned, will produce a pleaſing and harmonious ſound.

### XXXVI. *To fire a Piſtol or Cannon by Inflammable Air.*

Fig. 40. repreſents a braſs piſtol for inflammable air. It conſiſts principally of a chamber, to the mouth *D* of which a cork is fitted: a glaſs tube *F* is cemented into the top of the chamber, through which a braſs wire paſſes, and is bent within ſide ſo as to approach within an eighth part of an inch of the ſide. On the outſide end of this wire is ſcrewed a braſs ball *A*, which ſerves to receive a ſpark from the conductor of the machine, and conduct it in that form to the inſide of the piſtol. The inflammable air with which the piſtol is to be charged may be made in a common ſtone-ware or glaſs bottle, by mixing a handful of iron-filings with about two wine-glaſsfuls of water and near one of oil of vitriol. The air, when thus made, ſhould be kept in a bottle corked up. To make uſe of the piſtol, take out the cork from the bottle, and inſtantly apply the mouth of the piſtol to the mouth of the bottle; and in about ten ſeconds it will be ſufficiently charged: then remove it, and cork both the piſtol and bottle with the utmoſt expedition: then bring the ball *A* near the prime conductor or the knob of a charged jar; and the ſpark that paſſes through the ball, and between the end of the wire withinſide and the ſide of the chamber, will fire the inflammable air with a loud report, and drive the cork to a conſiderable diſtance. Inſtruments to fire inflammable air are often made in the form of a cannon with its carriage, as in fig. 41.

### XXXVII. *The Spiral Tube.*

Fig. 42. repreſents an inſtrument compoſed of two glaſs tubes *C D*, one within another, and cloſed with two knobbed braſs caps *A* and *B*. The innermoſt of theſe has a ſpiral row of ſmall round pieces of tin-foil ſtuck upon its outſide ſurface, and lying at about one-thirtieth of an inch from each other. If this inſtrument be held by one of its extremities, and its other extremity be preſented to the prime conductor, every ſpark that it receives from the prime conductor will cauſe ſmall ſparks to appear between all the round pieces of tin-foil ſtuck upon the innermoſt tube; which in the dark affords a pleaſing ſpectacle, the inſtrument appearing encompaſſed by a ſpiral line of fire.

Fig. 43. repreſents ſeveral ſpiral tubes placed round a board, in the middle of which is ſcrewed a glaſs pillar, and on the top of this pillar is cemented a braſs cap with a fine ſteel point. In this a braſs wire turns, having a braſs ball at each end, nicely balanced on the wire. To make uſe of this apparatus, place the middle of the turning wire under a ball proceeding from the conductor, ſo that it may receive a ſucceſſion of ſparks from the ball; then puſh the wire gently round; and the balls in their relative motions will give a ſpark to each tube, and thereby illuminate them down to the board, which from its brilliancy and rapid motion affords a moſt beautiful and pleaſing ſight.

Enter-air ing Expe ments.

The ſmall pieces of tin-foil are ſometimes ſtuck on a flat piece of glaſs *ABCD*, fig. 44. ſo as to repreſent various fanciful figures. Upon the ſame principle is the luminous word *light* produced. It is formed by the ſmall ſeparations of the tin-foil paſted on a piece of glaſs fixed in a frame of baked wood, as repreſented fig. 45. To uſe this, the frame muſt be held in the hand, and the ball *G* preſented to the conductor. The ſpark then will be exhibited in the intervals compoſing the word; from whence it paſſes to the hook at *b*, and thence to the ground by a chain. The brilliancy of this is equal to that of the ſpirals.

### XXXVIII. *To fire a Piece of Iron-wire in Dephlogiſticated Air.*

Plate CLXXI

The apparatus for this is repreſented fig. 28. n° 2. where the wire is twiſted into a ſpiral figure. When this is done, it may eaſily be inſerted in the braſs knob *D*. The jar comes out of the bottom *C*, and is filled with the dephlogiſticated air, as directed under the article Aerology. The electricity of a common jar being then inſtantly ſent down through the ball and wire at *A*, an exploſion takes place betwixt the end of the ſmall wire and the lower ball *B*, which ſets the end of the former on fire. It burns with remarkable brightneſs; and by reaſon of the ſpiral ſhape into which it is twiſted, ſhows the appearance of a ſmall ſun moving from the top to the bottom of the jar, and ſlowly moving round as the wire, which is of a ſpiral ſhape, gradually burns away.

### XXXIX. *The Electrified Capillary Syphon.*

Plate CLXX

Let a ſmall bucket of metal filled with water be ſuſpended from the prime conductor, and put in a glaſs ſyphon ſo narrow in the extremity that the water may juſt drop from it. If in this diſpoſition of the apparatus the winch of the machine be turned, the water, which when not electrified run out only by drops, will now run in a full ſtream, or even be ſubdivided into ſmaller ſtreams; and if the experiment be made in the dark, the appearance will be very beautiful. The ſame phenomenon will be exhibited by a ſmall bucket with a jet, as repreſented fig. 46. or the experiment may be agreeably varied, by hanging one bucket from a poſitive conductor and another from a negative one; ſo that the ends of the tubes or jets may be about three or four inches from each other. The ſtream iſſuing from the one will be attracted by that iſſuing from the other, and both will unite into one; but though both are luminous in the dark before meeting, the united ſtream will not be ſo unleſs the one electricity has been ſtronger than the other.

### XL. *To illuminate Eggs.*

Plate CLXX

Fig. 55. repreſents a mahogany ſtand ſo conſtructed as to hold three eggs at a greater or ſmaller diſtance, according to the poſition of the ſliding pieces. A chain *C* is placed at the bottom in ſuch a manner as to

rtain.
Exper
s.

to touch the bottom of the egg at $B$ with one end, and with its other the outſide coating of a charged jar. The ſliding wire $A$ at top is made to touch the upper egg; and the diſtance of the eggs aſunder ſhould not exceed the quarter or eighth part of an inch. The electricity being by means of the diſcharging rod ſent down the ball and wire at $A$, will in a darkened room render the eggs very luminous and tranſparent, as has already been mentioned.

### XLI. *To render Ivory or Boxwood luminous.*

Place an ivory ball on the prime conductor of the machine, and take a ſtrong ſpark, or ſend the charge of a Leyden bottle through its centre, the ball will appear perfectly luminous; but if the charge be not taken through the centre, it will paſs over the ſurface of the ball and corrode it. A ſpark taken through a ball of boxwood not only illuminates the whole, but makes it appear of a beautiful crimſon or rather fine ſcarlet colour.

### XLII. *To illuminate Water.*

Connect one end of a chain with the outſide of a charged jar, and let the other lie upon the table. Place the end of another piece of chain at about one quarter of an inch from the former; then ſet a decanter of water on theſe ſeparated ends; and on making a diſcharge, the water will appear perfectly and beautifully luminous.

### XLIII. *To make a beautiful Appearance* in vacuo.

late
XVI.

Fig. 58. repreſents a glaſs barometer tube, having on the end $B$ a ſteel cap faſtened to the glaſs with cement. From this proceed a wire and ball $c\,d$. Fill this tube with quickſilver; and then by ſending up a large bubble of air, and repeatedly inverting the tube, free the quickſilver and iron ball from air: then put a ſmall drop of ether on the quickſilver, and put the finger on the end of the glaſs tube; and then invert the end $f$ in a baſon of quickſilver, taking care not to remove the finger from the end of the tube till the latter be immerged under the ſurface of the quickſilver. When the finger is removed, the mercury will deſcend, and the ether expand itſelf; preſent the metallic top of the tube to a large charged conductor, and a beautiful green ſpark will paſs through the vapour of the ether from the ball $d$ to the quickſilver. By admitting a ſmall quantity of air into the tube, an appearance ſomething like a falling ſtar is produced.

### XLIV. *To render Gold-leaf or Dutch-metal luminous.*

This is done by diſcharging the contents of a ſmall Leyden jar over it. A ſtrip of gold leaf one-eighth of an inch in breadth and a yard long, will frequently be illuminated throughout its whole extent, by the exploſion of a jar containing two gallons. This experiment may be beautifully diverſified, by laying the gold or ſilver leaf on a piece of glaſs, and then placing the glaſs in water; for the whole gold-leaf will appear moſt brilliantly luminous in the water, by expoſing it thus circumſtanced to the exploſion of a battery.

### XLV. *To perforate a Glaſs Tube.*

Entertaining Experiments

Fig. 59. repreſents a ſmall glaſs tube ſtopped at one end with a piece of cork; $k$ is a wire with a ball, at one end of which is a braſs ball; the other paſſes thro' a cork fitted to the upper part of the tube. This end of the wire is bent at right angles, in ſuch a manner as to approach the ſide of the tube. To perform the experiment, take out the upper cork and wire, and then pour ſome ſallad oil into the tube; replace the cork, and puſh down the wire, ſo that the end of it may be near or rather below the ſurface of the oil; preſent the ball to the electrified conductor, holding the finger or any other conducting ſubſtance oppoſite to the bent end of the wire; and when the ſpark paſſes from the conductor to the braſs ball, the ſame will paſs along the wire, perforating the tube in order to get at the finger, and produce a curious agitation of the oil.

### XLVI. *The Inflammable Air-lamp.*

Fig. 60. repreſents this machine, which is an invention of M. Volta. $A$ is a glaſs globe to contain the inflammable air; $B$, a glaſs baſon or reſervoir to hold water; $D$, a cock to form occaſionally a communication between the reſervoir of water and that of air. The water paſſes into the latter through the metal pipe $gg$, which is fixed to the upper part of the reſervoir $A$; as $s$ is a ſmall cock to cut off or open a communication with the air in the ball and the jet $K$. — $N$ is a ſmall pipe to hold a piece of wax taper; $L$, a braſs pillar, on the top of which is a ball of the ſame metal; $a$ is a pillar of glaſs with a ſocket at top, in which the wire $b$ ſlides, having a ball ſcrewed on the end of it. $F$ is a cock by which the ball $A$ is filled with inflammable air, and which afterwards ſerves to confine the air, and what water falls from the baſon $B$ into the ball $A$.

To uſe this inſtrument, after having filled the reſervoir $A$ with pure inflammable air and the baſon with water, turn the cocks $D$ and $s$, and the water which falls from the baſon $B$ will force out ſome of the inflammable air, and cauſe it to paſs through the jet $K$ into the air. If an electric ſpark be made to paſs from the braſs ball $m$ to that marked $n$, the inflammable jet which paſſes through the pipe $K$ will be fired. To extinguiſh the lamp, firſt ſhut the cock $s$, and then the cock $D$. The inflammable air is made of the uſual ingredients, *viz.* iron-filings and vitriolic acid; and the reſervoir is filled in the following manner: Having previouſly filled $A$ with water, place the foot $R$ in a tub of that fluid which may cover it, ſo that the bent glaſs tube through which the air paſſes may paſs commodiouſly below the foot of the lamp. When the air has nearly driven out all the water, turn the cock $F$, and the apparatus is ready for uſe. This inſtrument is convenient for preſerving a quantity of inflammable air ready for any occaſional experiment, as charging the inflammable air-piſtol, &c. It is alſo convenient for lighting a candle for economical purpoſes, as the leaſt ſpark from an electrophorus or a ſmall bottle is ſufficient to fire the air.

### XLVII. *Imitations of the Planetary Motions.*

See below, *Uſes of the Electric Fluid in the Syſtem of Nature.*

### XLVIII. *Beautiful Figures produced in Powdered Roſin, &c. ſtrewed over an Electric Subſtance.* Ibid.

Sect.

## SECT. IX. *Experiments of a Miſcellaneous Nature,* viz. *thoſe relating to the Effects of the Electric Fluid on Colours; on its Velocity; the Changes of Electric into Conducting Subſtances; the impoſſibility of forcing the Fluid through a perfect Vacuum; the Power of Batteries; its Direction in various Caſes; Improvements in the Method of Excitation, &c.*

These experiments, though far from being unentertaining, we have thought proper to claſs under a different title, as many might wiſh to amuſe themſelves with producing an agreeable and beautiful phenomenon who would not chooſe to make experiments for the ſake of inveſtigating unknown ſubjects, where perhaps little elſe than the labour of making the experiment might be the reward of the operator. Theſe experiments alſo may be truly ſaid to be of an anomalous nature; as not being founded upon any known laws of electricity, but rather a collection of facts; from ſome of which we may afterwards deduce the laws by which this ſubtile fluid is occaſionally governed. We ſhall begin with experiments made by Mr Cavallo upon ſubſtances painted over with colours of different kinds. They were occaſioned by his having obſerved that an electric ſhock, ſent over the ſurface of a card, made a black ſtroke upon a red ſpot, from which he was induced to try the effect of ſending ſhocks over cards painted with different water-colours. The force employed was generally about one foot and an half of charged glaſs; and the ſhocks were ſent over the cards while the latter were in a very dry ſtate.

"Vermilion was marked with a ſtrong black track, about one-tenth of an inch wide. This ſtroke is generally ſingle, as repreſented by *A B*, fig. 74. n° 2. of Plate CLXXVII. Sometimes it is divided in two towards the middle, like *E F*; and ſometimes, particularly when the wires are ſet very diſtant from one another, the ſtroke is not continued, but interrupted in the middle, like *G H*. It often, although not always, happens, that the impreſſion is marked ſtronger at the extremity of that wire from which the electric fluid iſſues, as it appears at *E*, ſuppoſing that the wire *C* communicates with the poſitive ſide of the jar; whereas the extremity of the ſtroke, contiguous to the point of the wire *D*, is neither ſo ſtrongly marked, nor ſurrounds the wire ſo much, as the other extremity *E*.

"Carmine received a faint and ſlender impreſſion of a purple colour.

"Verdigis was ſhaken off from the ſurface of the card; except when it had been mixed with ſtrong gum-water, in which caſe it received a very faint impreſſion.

"White-lead was marked with a long black track, not ſo broad as that on vermilion.

"Red lead was marked with a faint mark much like carmine.

"The other colours I tried were orpiment, gamboge, ſap-green, red-ink, ultramarine, Pruſſian blue, and a few others, which were compounds of the above; but they received no impreſſion.

"It having been inſinuated, that the ſtrong black mark, which vermilion receives from the electric ſhock, might poſſibly be owing to the great quantity of ſulphur contained in that mineral, I was induced to make the following experiment. I mixed together equal quantities of orpiment and flower of ſulphur; and with this mixture, by the help, as uſual, of very diluted gum-water, I painted a card; but the electric ſhock ſent over it left not the leaſt impreſſion.

"Deſirous of carrying this inveſtigation on colours a little further, with a particular view to determine ſomething relative to the properties of lamp-black and oil (c), I procured ſome pieces of paper painted on both ſides with oil colours; and ſending the charge of two feet of coated glaſs over each of them, by making the interruption of the circuit upon their ſurfaces, I obſerved that the pieces of paper painted with lamp-black, Pruſſian blue, vermilion, and purple brown, were torn by the exploſion; but white lead, Naples yellow, Engliſh ochre, and verdigris, remained unhurt.

"The ſame ſhock ſent over a piece of paper painted very thickly with lamp-black and oil left not the leaſt impreſſion. I ſent the ſhock alſo over a piece of paper unequally painted with purple brown, and the paper was torn where the paint lay very thin, but remained unhurt where the paint was evidently thicker. Theſe experiments I repeated ſeveral times and with ſome little variation, which naturally produced different effects; however, they all ſeem to point out the following propoſitions.

"I. A coat of oil-paint over any ſubſtance, defends it from the effects of ſuch an electric ſhock as would otherwiſe injure it; but by no means defends it from any electric ſhock whatever. II. No one colour ſeems preferable to the others, if they are equal in ſubſtance, and equally well mixed with oil; but a thick coating does certainly afford a better defence than a thinner one.

"By rubbing the above mentioned pieces of paper, I find that the paper painted with lamp-black and oil is more eaſily excited, and acquires a ſtronger electricity, than the papers painted with the other colours; and, perhaps, on this account it may be, that lamp-black and oil might reſiſt the ſhock ſomewhat better than the other paints.

"It is remarkable, that vermilion receives the black impreſſion, when painted with lintſeed oil, nearly as well as when painted with water. The paper painted with white lead and oil receives alſo a black mark; but its nature is very ſingular. The track, when firſt made, is almoſt as dark as that marked on white-lead painted

---

(c) "It has often been obſerved, that when lightning has ſtruck the maſts of ſhips, it has paſſed over ſuch parts of the maſts as were covered with lamp-black and tar, or painted with lamp-black and oil, without the leaſt injury, at the ſame time that it has ſhivered the uncoated parts in ſuch a manner as to render the maſts uſeleſs."

painted with water; but it gradually loſes its blackneſs, and in about an hour's time (or longer, if the paint is not freſh) it appears without any darkneſs; and when the painted paper is laid in a proper light, appears only marked with a colourleſs track, as if made by a finger-nail. I ſent the ſhock alſo over a piece of board which had been painted with white-lead and oil about four years before, and the exploſion marked the black track upon this alſo: this track, however, was not ſo ſtrong, nor vaniſhed ſo ſoon, as that marked upon the painted paper; but in about two days time it alſo vaniſhed entirely."

123 tric c cal- , vitri- and re- ies me-

Another very remarkable property of the electric fluid is, that it both calcines, vitrifies, and revivifies, metals. The calcination of them appears from Dr Prieſtley's experiments with the braſs chain, formerly mentioned, where the black duſt was plainly a calx of the metal. The vitrification is performed by exploding ſmall wires of any kind with the ſhock of a battery. In this caſe, the ſmall globules of metal, even though gold, ſilver, or platina, are found to be completely vitrified. The revivification is an experiment of Mr Beccaria. This he did by making the exploſion between two pieces of the calces; and thus he revivified ſeveral metallic ſubſtances, particularly zinc, and even produced real quickſilver from cinnabar. In this caſe, he always obſerved ſtreaks of black beyond the coloured metallic ſtains; owing, as he ſuppoſed, to the phlogiſton driven from the parts that were vitrified, when the other part revivified the calx.

124 Becca- s expe- nts to that electric er ws con ing ances e it.

Mr Beccaria alſo diſcovered another very remarkable property of the electric matter; namely, that when it is obliged to paſs through air, or any other ſubſtance through which it makes its way with difficulty, it throws before it all light conducting ſubſtances it can find, in order to facilitate its own paſſage; and thus it will paſs through a greater quantity of reſiſting medium than it would otherwiſe be able to do. The experiments from which Mr Beccaria drew this concluſion, were the following. He put a narrow piece of leaf-ſilver between two plates of wax, laying it acroſs them, but ſo that it did not quite reach one of the ſides. The diſcharge being made through this ſtrip of metal, by bringing a wire oppoſite to the ſilver, at the place where it was diſcontinued; the ſilver was found melted, and part of it diſperſed all along the track that the electric matter took between the plates of wax, from the ſilver to the wire. Happening once to receive, inadvertently, the charge of a ſmall jar through ſome ſmoke of ſpirit of nitre, a hole was made in his thumb, where the fire entered, and which he thought could only have been made by the acid carried along by the electric fluid. Dr Prieſtley hath made ſeveral more experiments, in order to aſcertain this remarkable property; and of which he gives the following account.

25 Prieſt- expe- nts on ubject.

"I diſcharged frequent ſhocks, both of a common jar, and another of three ſquare feet, through trains of braſs duſt, laid on a ſtool of baked wood, making interruptions in various parts of the train; and always found the braſs duſt ſcattered in the intervals, ſo as to connect the two disjoined ends of the train; but then it was likewiſe ſcattered nearly as much from almoſt all other parts of the train, and in all directions. The ſcattering from the train itſelf was probably occaſioned by ſmall electric ſparks between the particles of the duſt; which, cauſing a vacuum in the air, drove all that light matter to a conſiderable diſtance. But the particles of the duſt, which were ſtrowed in the intervals of the train, ſome of which were at leaſt three inches, could hardly be conveyed in that manner.

Miſcellaneous Experiments.

"When ſmall trains were laid, the diſperſion was the moſt conſiderable, and a light was very viſible in the dark, illuminating the whole circuit. It made no difference, in any of theſe experiments, which way the ſhock was diſcharged.

"When I laid a conſiderable quantity of the duſt at the ends of two pieces of chain, through which the ſhock paſſed, at the diſtance of about three inches from one another, the duſt was always diſperſed over the whole interval, but chiefly laterally; ſo that the greateſt quantity of it lay in arches, extending both ways, and leaving very little of it in the middle of the path. It is probable, that the electric power would have ſpread it equably, but that the vacuum made in the air, by the paſſage of the fluid from one heap of duſt to the other, diſperſed it from the middle part.

"I then inſulated a jar of three ſquare feet, and upon an adjoining glaſs-ſtand laid a heap of braſs duſt; and at the diſtance of ſeven or eight inches a braſs rod communicating with the outſide of the jar. Upon bringing another rod, communicating with the inſide, upon the heap of duſt, it was diſperſed in a beautiful manner, but not one way more than another. However, it preſently reached the rod communicating with the outſide.

"Making two heaps, about eight inches aſunder, I brought one rod communicating with the inſide upon one of them, and another rod communicating with the outſide upon the other. Both the heaps were diſperſed in all directions, and ſoon met; preſently after which the jar was diſcharged, by means of this diſperſed duſt, in one full exploſion. When the two heaps were too far aſunder to promote a full diſcharge at once, a gradual diſcharge was made through the ſcattered particles of the duſt.

"When one heap of duſt was laid in the centre of the ſtand, and the two rods were made to approach on each ſide of it, they each attracted the duſt from the ſide of the heap next to them, and repelled it again in all directions. When they came very near the heap, the diſcharge was made through it, without giving it any particular motion.

"All theſe experiments ſhow, that light bodies poſſeſſed of a conſiderable ſhare of electricity, diſperſe in all directions, carrying the electric matter to places not abounding with it; and that they ſometimes promote a ſudden diſcharge of great quantities of that matter from places where it was lodged, to places where there was a defect of it. But an accident led me to a much more beautiful, and perhaps a more ſatisfactory, manner of demonſtrating the laſt part of this propoſition, than any that I hit upon while I was purſuing my experiments with that deſign.

"Hanging a drop of water upon the knob of a braſs rod communicating with the inſide of my battery, in order to obſerve what variety it might occaſion in the circular ſpots above mentioned, I was greatly ſurpriſed to find the exploſion made all at once, at the diſtance of two inches.

"I

“I afterwards put ſome braſs duſt upon a plate of metal communicating with the inſide of the battery; and making the diſcharge through the duſt, it exploded at the diſtance of an inch and a half. The duſt roſe towards the diſcharged rod, and from thence was diſperſed in all directions.

“Theſe experiments are the more remarkable, as they demonſtrate ſo great a difference between the diſtance at which the battery may be made to diſcharge at once, by the help of theſe light bodies, and without them. When the diſcharge of a battery by the knobs of braſs rods, in the open air, is at the diſtance of about half an inch; it will, by this means, be made at about two inches.”

126
Experiments concerning the velocity of the electric fluid.

The motions of the electric fluid, though prodigiouſly quick, are not inſtantaneous. The ſhock of the Leyden phial, indeed, hath been tranſmitted through wires of ſeveral miles in length, without taking up any ſenſible ſpace of time. That is, ſuppoſing two perſons to hold the ends of the wire, one communicating with the knob, and the other with the outſide coating of the phial, both would feel the ſhock at the ſame inſtant; nor would it make any alteration though a conſiderable part of the ſurface of the ground was made part of the conductor. Dr Prieſtley relates ſeveral very curious experiments made with a view to aſcertain this point ſoon after the Lyden phial was diſcovered. Theſe experiments were planned and directed by Dr Watſon, who was preſent at every one of them. His chief aſſiſtants were Martin Folkes, Eſq; preſident of the royal ſociety, Lord Charles Cavendiſh, Dr Bevis, Mr Graham, Dr Birch, Mr Peter Daval, Mr Trembley, Mr Ellicott, Mr Robins, and Mr Short. Many other perſons, and ſome of diſtinction, gave their attendance occaſionally.

Dr Watſon, who wrote the hiſtory of their proceedings, in order to lay them before the royal ſociety, begins with obſerving (what was verified in all their experiments), that the electric ſhock is not, ſtrictly ſpeaking, conducted in the ſhorteſt manner poſſible, unleſs the bodies through which it paſſes conduct equally well; for that, if they conduct unequally, the circuit is always formed through the beſt conductor, though the length of it be ever ſo great.

The firſt attempt theſe gentlemen made, was to convey the electric ſhock acroſs the river Thames, making uſe of the water of the river for one part of the chain of communication. This they accompliſhed on the 14th and 18th of July 1747, by faſtening a wire all along Weſtminſter bridge, at a conſiderable height above the water. One end of this wire communicated with the coating of a charged phial, the other being held by an obſerver, who, in his other hand, held an iron rod, which he dipped into the river. On the oppoſite ſide of the river ſtood a gentleman, who likewiſe dipped an iron rod in the river with one hand; and in the other held a wire, the extremity of which might be brought into contact with the wire of the phial.

Upon making the diſcharge, the ſhock was felt by the obſervers on both ſides the river, but more ſenſibly by thoſe who were ſtationed on the ſame ſide with the machine; part of the electric fire having gone from the wire down the moiſt ſtones of the bridge, thereby making ſeveral ſhorter circuits to the phial, but ſtill all paſſing through the gentlemen who were ſtationed on the ſame ſide with the machine. This was, in a manner, demonſtrated by ſome perſons feeling a ſenſible ſhock in their arms and feet, who only happened to touch the wire at the time of one of the diſcharges, when they were ſtanding upon the wet ſteps which led to the river. In one of the diſcharges made upon this occaſion, ſpirits were kindled by the fire which had gone through the river.

Upon this, and the ſubſequent occaſions, the gentlemen made uſe of wires in preference to chains; for this, among other reaſons, that the electricity which was conducted by chains was not ſo ſtrong as that which was conducted by wires. This, as they well obſerved, was occaſioned by the junctures of the links not being ſufficiently cloſe, as appeared by the ſnapping and flaſhing at every juncture where there was the leaſt ſeparation. Theſe leſſer ſnappings, being numerous in the whole length of a chain, very ſenſibly leſſened the great diſcharge at the gun-barrel.

Their next attempt was to force the electrical ſhock to make a circuit of two miles, at the New River at Stoke Newington. This they performed on the 24th of July 1747, at two places; at one of which the diſtance by land was 800 feet, and by water 2000: in the other, the diſtance by land was 2800 feet, and by water 8000. The diſpoſition of the apparatus was ſimilar to what they before uſed at Weſtminſter bridge, and the effect anſwered their utmoſt expectations. But as, in both caſes, the obſervers at both extremities of the chain, which terminated in the water, felt the ſhock as well when they ſtood with their rods fixed into the earth 20 feet from the water, as when they were put into the river; it occaſioned a doubt, whether the electric circuit was formed through the windings of the river, or a much ſhorter way, by the ground of the meadow: for the experiment plainly ſhowed, that the meadow-ground, with the graſs on it, conducted the electricity very well.

By ſubſequent experiments they were fully convinced, that the electricity had not in this caſe been conveyed by the water of the river, which was two miles in length, but by land, where the diſtance was only one mile; in which ſpace, however, the electric matter muſt neceſſarily have paſſed over the New River twice, have gone through ſeveral gravel pits, and a large ſtubble field.

July 28th, they repeated the experiment at the ſame place, with the following variation of circumſtances. The iron wire was, in its whole length, ſupported by dry ſticks, and the obſervers ſtood upon original electrics; the effect of which was, that they felt the ſhock much more ſenſibly than when the conducting wire had lain upon the ground, and when the obſervers had likewiſe ſtood upon the ground, as in the former experiment.

Afterwards, every thing elſe remaining as before, the obſervers were directed, inſtead of dipping their rods into the water, to put them into the ground, each 150 feet from the water. They were both ſmartly ſtruck, though they were diſtant from each other above 500 feet.

The ſame gentlemen, pleaſed with the ſucceſs of their former experiments, undertook another, the object of which was, to determine whether the electric virtue could be conveyed through dry ground; and, at the ſame time, to carry it through water to a greater diſtance than they had done before. For this purpoſe they pitched upon Highbury-barn beyond Iſlington, where they carried it into execution on the 5th of Auguſt 1747. They choſe a ſtation for their machine almoſt equally diſtant from two other ſtations for obſervers upon the New River; which were ſomewhat more than a mile aſunder by land and two miles by water. They had found the ſtreets of London, when dry, to conduct very ſtrongly for about 40 yards; and the dry road at Newington about the ſame diſtance. The event of this trial anſwered their expectations. The electric fire made the circuit of the water, when both the wires and the obſervers were ſupported upon original electrics, and the rods dipped into the river. They alſo both felt the ſhock, when one of the obſervers was placed in a dry gravelly pit, about 300 yards nearer the machine than the former ſtation, and 100 yards diſtant from the river: from which the gentlemen were ſatisfied, that the dry gravelly ground had conducted the electricity as ſtrongly as water.

From the ſhocks which the obſervers received in their bodies, when the electric power was conducted upon dry ſticks, they were of opinion, that, from the difference of diſtance ſimply conſidered, the force of the ſhock, as far as they had yet experienced, was very little if at all impaired. When the obſervers ſtood upon electrics, and touched the water or the ground with the iron rods, the ſhock was always felt in their arms or wriſts; when they ſtood upon the ground with their iron rods, they felt the ſhock in their elbows, wriſts, and ankles; and when they ſtood upon the ground without rods, the ſhock was always felt in the elbow and wriſt of that hand which held the conducting wire, and in both ankles.

The laſt attempt of this kind which theſe gentlemen made, and which required all their ſagacity and addreſs in the conduct of it, was to try whether the electric ſhock was perceptible at twice the diſtance to which they had before carried it, in ground perfectly dry, and where no water was near; and alſo to diſtinguiſh, if poſſible, the reſpective velocity of electricity and ſound.

For this purpoſe they fixed upon Shooter's-hill, and made their firſt experiments on the 14th of Auguſt 1747; a time when, as it happened, but one ſhower of rain had fallen during five preceding weeks. The wire communicating with the iron rod which made the diſcharge, was 6732 feet in length, and was ſupported all the way upon baked ſticks; as was alſo the wire which communicated with the coating of the phial, which was 3868 feet long, and the obſervers were diſtant from each other two miles. The reſult of the exploſion demonſtrated, to the ſatisfaction of the gentlemen preſent, that the circuit performed by the electric matter was four miles, *viz.* two miles of wire and two of dry ground, the ſpace between the extremities of the wires; a diſtance which, without trial, as they juſtly obſerved, was too great to be credited. A gun was diſcharged at the inſtant of the exploſion, and the obſervers had ſtop-watches in their hands, to note the moment when they felt the ſhock: but, as far as they could diſtinguiſh, the time in which the electric matter performed that vaſt circuit might have been inſtantaneous.

Miſcellaneous Experiments.

In all the exploſions where the circuit was made of conſiderable length, it was obſerved, that though the phial was very well charged, yet that the ſnap at the gun-barrel, made by the exploſion, was not near ſo loud as when the circuit was formed in a room; ſo that a by-ſtander, ſays Dr Watſon, though verſed in theſe operations, would not imagine, from ſeeing the flaſh, and hearing the report, that the ſtroke at the extremity of the conducting wire could have been conſiderable; the contrary whereof, when the wires were properly managed, he ſays, always happened.

Still the gentlemen, unwearied in theſe purſuits, were deſirous, if poſſible, to aſcertain the abſolute velocity of electricity at a certain diſtance; becauſe, though in the laſt experiment, the time of its progreſs was certainly very ſmall, if any, they were deſirous of knowing, ſmall as that time might be, whether it was meaſurable; and Dr Watſon had contrived an excellent method for that purpoſe.

Accordingly, on the 5th of Auguſt 1748, the gentlemen met once more, and the laſt time, at Shooter's-hill; when it was agreed to make an electric circuit of two miles, by ſeveral turnings of the wire in the ſame field. The middle of this circuit they contrived to be in the ſame room with the machine, where an obſerver took in each hand one of the extremities of the wires, each of which was a mile in length. In this excellent diſpoſition of the apparatus, in which the time between the exploſion and the ſhock might have been obſerved to the greateſt exactneſs, the phial was diſcharged ſeveral times; but the obſerver always felt himſelf ſhocked at the very inſtant of making the exploſion. Upon this the gentlemen were fully ſatisfied, that through the whole length of this wire, which was 12,276 feet, the velocity of the electric matter was inſtantaneous.

127
Sometimes the fluid ſeems to move more ſlowly.

With all this ſurpriſing velocity, however, it is certain, that both ſides of a charged phial may be touched ſo quickly, even by the beſt conductors, that all the electric matter hath not time to make the circuit, and the phial will remain but half diſcharged. If the upper plate of an electrophorus alſo is very ſuddenly touched with the finger, or any other conductor, a very ſmall ſpark will be obtained on lifting it up; though a very ſtrong one would be got if the finger was kept longer upon it. But how this ſeeming ſlowneſs can be reconciled with the immeaſurable velocity above-mentioned, doth not appear. It is certain, indeed, that this fluid is conſiderably reſiſted in its paſſage through or over every ſubſtance. It will even prefer a ſhort paſſage in the air where it is violently reſiſted to one along a wire of very great length; but here, as in every other caſe, it ſeems to divide its force, and to break out through ſeveral different paſſages at once. A method of aſcertaining this hath been contrived by Dr Prieſtley, thus. Bend a wire, about five feet long, ſo that one part may come within half an inch of the other; then connect the extremities of the wire with the hook of the battery, and ſend a ſhock through it. On making the exploſion, a ſpark will be ſeen between the two parts which approach neareſt to each other; which ſhows that the fluid chooſes a ſhort paſſage through the air, rather than the long one through the wire. The charge, however, does not paſs entirely between theſe two parts, but ſome of it goes alſo thro' the wire. This may be proved by putting a ſlender wire

Miſcellaneous Experiments.

between the two approaching parts: for, on making the diſcharge with only this addition in the apparatus, the ſmall wire will hardly be made red hot; whereas, if the large wire be cut ſo as to diſcontinue the circuit, the ſmall wire will be melted, and even exploded, by the ſame ſhock that before made it ſcarcely red hot. But though we can eaſily ſhow that the electric fluid always meets with reſiſtance, it is by no means eaſy to ſhow why the ſame reſiſtance which puts a temporary ſtop to its motions in ſome caſes, doth not ſo in all.

128 Water becomes electric by cold.

Another curious experiment in electricity is the converting of conducting ſubſtances into electrics by cold, and of changing electrics into conductors by heat. The firſt hath yet been done only in the inſtance of water. This is a diſcovery of Mr Achard's at Berlin, who, in the month of January 1776, obſerved, that water frozen to the 20th degree below the freezing point of Reaumur's thermometer, anſwering to the 13th below 0 of Fahrenheit's, is an electric. He tried his experiments in the open air, where he found, that a rod of ice two feet long and two inches thick, was a very imperfect conductor when Reaumur's thermometer was at ſix degrees below 0; and that it would not in the leaſt conduct when the thermometer was ſunk to 20°. By whirling a ſpheroid of ice in a proper machine, he even electrified the prime conductor ſo as to attract, repel, give ſparks, &c. The ice made uſe of was free from air-bubbles, and quite tranſparent; to produce which, he uſed to ſet a veſſel containing diſtilled water to be frozen, upon the window of a room which was rather warm with reſpect to the ambient air; ſo that the water began to freeze on the one ſide of the veſſel, while on the other it was ſtill liquid.

129 Electrics become conductors by heat.

To prove that glaſs and other electrics become conductors when very hot: Take a ſmall glaſs tube of about one twentieth of an inch in diameter, and above a foot long; cloſe it at one end, and introduce a wire into it, ſo that it may be extended through its whole length; let two or three inches of this wire project above the open end of the tube, and there faſten it with a bit of cork; tie round the cloſed end of the tube another wire, which will be ſeparated from the wire within the tube only by the glaſs interpoſed between them. In theſe circumſtances, endeavour to ſend a ſhock through the two wires, *i. e.* the wire inſerted in the glaſs tube and that tied on its outſide, by connecting one of them with the outſide, and touching the other with the knob of a charged jar; and you will find that the diſcharge cannot be made unleſs the tube be broken; becauſe the circuit is interrupted by the glaſs at the end of the tube, which is interpoſed between the two wires. But put that end of the tube to which the wire is tied into the fire, ſo that it may become juſt red-hot, then endeavour to diſcharge the jar again through the wires, and you will find that the exploſion will be eaſily tranſmitted from wire to wire through the ſubſtance of the glaſs, which, by being made red-hot, is become a conductor.

Miſcel neous E periment

In order to aſcertain the conducting quality of hot reſinous ſubſtances, oils, &c. bend a glaſs tube in the form of an arch *CFFD*, fig. 77. Plate CLXXVII; and tie a ſilk ſtring *GCD* to it, which ſerves to hold it by when it is to be ſet near the fire; fill the middle part of this tube with roſin, ſealing-wax, &c. then introduce two wires *AE*, *BF*, through its ends, ſo that they may touch the roſin, or penetrate a little way in it. This done, let a perſon hold the tube over a clear fire, ſo as to melt the roſin within it; at the ſame time, by connecting one of the wires *A* or *B* with the outſide of a charged jar, and touching the other with the knob of the jar, endeavour to make the diſcharge through the roſin, and you will obſerve, that while the roſin is cold, no ſhocks can be tranſmitted through it; but it becomes a conductor according as it melts; and when totally melted, then the ſhocks will paſs through it very freely.

To ſhow that hot air is a conductor, electrify one of the cork-ball electrometers ſuſpended upon the ſtand fig. 13. of Plate CLXXIV. or electrify the prime conductor with the quadrant electrometer; then bring a red-hot iron within a ſufficient diſtance of the electrometer or prime conductor, and you will find that they ſoon loſe their electricity, which is certainly conducted by the hot air contiguous to the iron; for if the experiment be repeated with the ſame iron when cold, *i. e.* by bringing it within the ſame diſtance of the electrified electrometer or prime conductor, their electricity will not be conducted away as before. It has been obſerved, that a battery may be diſcharged by introducing a red-hot iron between two knobs interpoſed, and ſtanding at ſome diſtance from each other in the circuit: but if, inſtead of iron, there be introduced a piece of red-hot glaſs between the knobs (the diſtance between them remaining as at firſt), the battery cannot be diſcharged: whence we may infer, that either hot air is not ſo good a conductor as has been imagined; or elſe, that air heated by iron is ſtronger with reſpect to its conducting power, than when heated by the red-hot glaſs.

130 Non-con ducting power o perfect v cuum.

The impoſſibility of forcing the electric fluid thro' a perfect vacuum, is a doctrine which militates ſo directly againſt the theory laid down in Sect. VI. that we cannot by any means omit a very full conſideration of it. As this, however, would lead us here into a theoretical diſquiſition, we ſhall not enter into any explanation in this place, but defer what is to be ſaid on that ſubject to the laſt ſection, where the uſes of the electric fluid in the ſyſtem of nature are conſidered. The experiment on which this ſuppoſition is founded, was originally made by Mr Walſh; who found that it was poſſible to cleanſe a barometrical tube ſo perfectly of air, that no electric light would be viſible in it upon agitating the mercury, as is the caſe with the common barometers. It has ſince been repeated to more advantage by Mr William Morgan, who from his obſervations has deduced ſome concluſions concerning the action of the electric fluid very inconſiſtent with that extenſive operation which many philoſophers have aſcribed to it, and which is aſcribed to it in various articles of this work. His experiment is publiſhed in the Phil. Tranſ. for 1785, which we ſhall here extract.

131 Mr Mo riment this ſubj

" The non-conducting power of a perfect vacuum, is a fact in electricity which has been much controverted among philoſophers. The experiments made by Mr Walſh, F. R. S. in the double barometer tube clearly demonſtrated the impermeability of the electric light through a vacuum; nor was it, I think, precipitate to to conclude from them the impermeability of the electric fluid itſelf. But this concluſion has not been univerſally admitted; and the following experiments were made with the view of determining its truth or fallacy. When I firſt attended to the ſubject, I was not aware that any other attempts had been made beſides thoſe of Mr Walſh; and though I have ſince found myſelf to have been in part anticipated in one of my experiments, it may not perhaps be improper to give ſome account of them, not only as they are an additional teſtimony in ſupport of this fact, but as they led to the obſervation of ſome phenomena which appear to be new and intereſting.

“ A mercurial gage *B*, about 15 inches long, carefully and accurately boiled till every particle of air was expelled from the inſide, was coated with tin-foil five inches down from its ſealed end *A*, and being inverted into mercury thro' a perforation *D*, in the braſs cap *E*, which covered the mouth of the ciſtern *H*, the whole was cemented together, and the air was exhauſted from the inſide of the ciſtern thro' a valve *C* in the braſs cap *E* juſt mentioned; which producing a perfect vacuum in the gage, afforded an inſtrument peculiarly well adapted for experiments of this kind. Things being thus adjuſted, (a ſmall wire *F* having been previouſly fixed on the inſide of the ciſtern to form a communication between the braſs cap *E* and the mercury *G*, into which the gage was inverted), the coated end was applied to the conductor of an electrical machine; and notwithſtanding every effort, neither the ſmalleſt ray of light, nor the ſlighteſt charge, could ever be procured in this exhauſted gage. I need not obſerve, that if the vacuum on its inſide had been a conductor of electricity, the latter at leaſt muſt have taken place; for it is well known, that if a glaſs tube be exhauſted by an air-pump, and coated on the outſide, both light and a charge may very readily be procured. If the mercury in the gage be imperfectly boiled, the experiment will not ſucceed; but the colour of the electric light, which, in air rarefied by an exhauſter, is always violet or purple, appears in this caſe of a beautiful green; and what is very curious, the degree of the air's rarefaction may be nearly determined by this means: for I have known inſtances, during the courſe of theſe experiments, where a ſmall particle of air having found its way into the tube *B*, the electric light became viſible, and as uſual of a green colour; but the charge being often repeated, the gage has at length cracked at its ſealed end, and in conſequence the external air, by being admitted into the inſide, has gradually produced a change in the electric light from green to blue, from blue to indigo, and ſo on to violet and purple, till the medium has at laſt become ſo denſe as no longer to be a conductor of electricity. I think there can be little doubt from the above experiments, of the non-conducting power of a perfect vacuum; and this fact is ſtill more ſtrongly confirmed by the phenomena which appear upon the admiſſion of a very minute particle of air into the inſide of the gage. In this caſe the whole becomes immediately luminous upon the ſlighteſt application of electricity, and a charge takes place, which continues to grow more and more powerful in proportion as freſh air is admitted, till the denſity of the conducting medium arrives at its maximum, which it always does when the colour of the electric light is indigo or violet. Under theſe circumſtances the charge may be ſo far increaſed as frequently to break the glaſs. In ſome tubes, which have not been completely boiled, I have obſerved that they will not conduct the electric fluid when the mercury is fallen very low in them; yet upon letting in air into the ciſtern, ſo that the mercury ſhall riſe in the gage, the electric fluid, which was before latent in the inſide, ſhall now become viſible; and as the mercury continues to riſe, and of conſequence the medium is rendered leſs rare, the light ſhall grow more and more viſible, and the gage ſhall at laſt be charged, notwithſtanding it has not been near an electrical machine for two or three days. This ſeems to prove, that there is a limit even in the rarefaction of air, which ſets bounds to its conducting power; or, in other words, that the particles of air may be ſo far ſeparated from each other as no longer to be able to tranſmit the electric fluid; that if they are brought within a certain diſtance of each other, their conducting power begins, and continually increaſes till their approach alſo arrives at its limit, when the particles again become ſo near as to reſiſt the paſſage of the fluid entirely, without employing violence, which is the caſe in common and condenſed air, but more particularly in the latter.

Miſcellaneous experiments.

133
Surpriſing eaſe with which an exhauſted tube is charged with electricity.

“ It is ſurpriſing to obſerve how readily an exhauſted tube is charged with electricity. By placing it at 10 or 12 inches from the conductor, the light may be ſeen pervading its inſide, and as ſtrong a charge may ſometimes be procured as if it were in contact with the conductor: nor does it ſignify how narrow the bore of the glaſs may be; for even a thermometer tube, having the minuteſt perforation poſſible, will charge with the utmoſt facility; and in this experiment the phenomena are peculiarly beautiful.

“ Let one end of a thermometer tube be ſealed hermetically; let the other end be cemented into a braſs cap with a valve, or into a braſs cock, ſo that it may be fitted to the plate of an air-pump. When it is exhauſted, let the ſealed end be applied to the conductor of an electrical machine, while the other end is either held in the hand or connected to the floor. Upon the ſlighteſt excitation the electric fluid will accumulate at the ſealed end, and be diſcharged through the inſide in the form of a ſpark, and this accumulation and diſcharge may be inceſſantly repeated till the tube is broken. By this means I have had a ſpark 42 inches long; and had I been provided with a proper tube, I do not doubt but that I might have had a ſpark of four times that length. If, inſtead of the ſealed end, a bulb be blown at that extremity of the tube, the electric light will fill the whole of that bulb, and then paſs through the tube in the form of a brilliant ſpark, as in the foregoing experiment: but in this caſe I have ſeldom been able to repeat the trials above three or four times before the charge has made a ſmall perforation in the bulb. If, again, a thermometer filled with mercury be inverted into a ciſtern, and the air exhauſted in the manner I have deſcribed for making the experiment with the gage, a Torricellian vacuum will be produced; and now the electric light in the bulb, as well as the ſpark in the tube, will be of a vivid green; but the bulb will not bear a frequent repetition of charges before it is perforated in like manner as when it has been exhauſted by an air pump. It can hardly

134
Tube perforated by the electric ſpark.

Miſcellaneous Experiments.

be neceſſary to obſerve, that in theſe caſes the electric fluid aſſumes the appearance of a ſpark (D), from the narrowneſs of the paſſage through which it forces its way. If a tube 40 inches long be fixed into a globe 8 or 9 inches in diameter, and the whole be exhauſted, the electric fluid, after paſſing in the form of a brilliant ſpark throughout the length of the tube, will, when it gets into the inſide of the globe, expand itſelf in all directions, entirely filling it with a violet and purple light, and exhibiting a ſtriking inſtance of the vaſt elaſticity of the electric fluid. 135 Why the fluid aſſumes the form of a ſpark.

"I cannot conclude this paper without acknowledging my obligations to the ingenious Mr Brook of Norwich, who by communicating to me his method of boiling mercury, has been the chief cauſe of my ſucceſs in theſe experiments (E). I have lately learned from him, that he has alſo aſcertained the non-conducting power of a perfect vacuum; but what ſteps he took for that purpoſe, I know not. Of his accuracy, however, I am ſo well convinced, that had I never made an experiment myſelf, I ſhould, upon his teſtimony alone, have been equally aſſured of the fact. To moſt of the preceding experiments Dr Price, Mr Lane, and ſome others of my friends, have been eye-witneſſes; and I believe that they were as thoroughly ſatisfied as myſelf with the reſults of them. I muſt beg leave to obſerve to thoſe who wiſh to repeat them, that the firſt experiment requires ſome nicety, and no inconſiderable degree of labour and patience. I have boiled many gages for ſeveral hours together without ſucceſs, and was for ſome time diſpoſed to believe the contrary of what I am now convinced to be the truth. Indeed, if we reaſon *à priori*, I think we cannot ſuppoſe a perfect vacuum to be a perfect conductor without ſuppoſing an abſurdity: for if this were the caſe, either our atmoſphere muſt have long ago been deprived of all its electric fluid, by being every where ſurrounded by a boundleſs conductor, or this fluid muſt pervade every part of infinite ſpace; and conſequently there can be no ſuch thing as a perfect vacuum in the univerſe. If, on the contrary, the truth of the preceding experiments be admitted, it will follow, that the conducting power of our atmoſphere increaſes only to a certain height, beyond which this power begins to diminiſh, till at laſt it entirely vaniſhes; but in what part of the upper regions of the air theſe limits are placed, I will not preſume to determine. It would not perhaps have been difficult to have applied the reſults of ſome of theſe experiments to the explanation of meteors, which are probably owing to an accumulation of electricity. It is not, however, my preſent deſign to give looſe to my imagination. I am ſenſible, that by indulging it too freely, much harm is done to real knowledge; and therefore, that one fact in philoſophy well aſcertained, is more to be valued than whole volumes of ſpeculative hypotheſes."

136 Great difficulty in making this experiment.

137 Electric fluid ſuppoſed not to reach beyond the atmoſphere of the earth.

Miſcella- neou perime

A fact ſo contrary to the generally received opinion of the conducting powers of a vacuum, could not but excite a general ſurpriſe, and attempts to repeat the experiment would no doubt be ardently wiſhed for Unfortunately, however, the experiment itſelf, as muſt evidently appear from the account given of it by Mr Morgan, is of ſuch a precarious nature, as muſt undoubtedly diſcourage any ordinary electrician from attempting it; for in the firſt place, there is no hope of ſucceſs without a very tedious boiling of mercury in a tube for ſeveral hours; and even when this is done, the inſtrument will not remain in a ſtate of perfection for any length of time. Mr Cavallo, who has greatly improved the air-pump, gives an account of ſome very curious experiments made with this inſtrument, in order to aſcertain the truth of Mr Morgan's poſition; which we ſhall likewiſe give in his own words, with the concluſions he draws from them.

13 Cavall experi ment an impr ved air pump.

"I. In a glaſs receiver, of ſix inches diameter and nine inches in height, having a braſs cap, a braſs wire of two-tenths of an inch in diameter was fixed to its cap, and proceeding through the middle of the receiver, its lower extremity was five inches diſtant from the aperture of the receiver, and of courſe of the plate of

---

(D) "By cementing the ſtring of a guittar into one end of a thermometer tube, a ſpark may be obtained as well as if the tube had been ſealed hermetically."

(E) "Mr Brook's method of making mercurial gages is nearly as follows: Let a glaſs tube *L*, (fig. 81.) ſealed hermetically at one end, be bent into a right angle within two or three inches of the other end. At the diſtance of about an inch or leſs from the angle, let a bulb *K*, of about $\frac{3}{4}$ths of an inch in diameter, be blown in the curved end, and let the remainder of this part of the tube be drawn out *I*, ſo as to be ſufficiently long to take hold of when the mercury is boiling. The bulb *K* is deſigned as a receptacle for the mercury, to prevent its boiling over; and the bent figure of the tube is adapted for its inverſion into the ciſtern: for by breaking off the tube at *M* within $\frac{1}{8}$th or $\frac{1}{4}$th of an inch of the angle, the open end of the gage may be held perpendicular to the horizon when it is dipped into the mercury in the ciſtern, without obliging us to bring our finger or any other ſubſtance into contact with the mercury in the gage, which never fails to render the inſtrument imperfect. It is neceſſary to obſerve, that if the tube be 14 or 15 inches long, I have never been able to boil it effectually for the experiments mentioned in this paper in leſs than three or four hours, although Mr Brook ſeems to preſcribe a much ſhorter time for the purpoſe; nor will it even then ſucceed, unleſs the greateſt attention be paid that no bubbles of air lurk behind, which to my own mortification I have frequently found to have been the caſe: but experience has at length taught me to guard pretty well againſt this diſappointment, particularly by taking care that the tube be completely dry before the mercury is put into it; for if this caution be not obſerved, the inſtrument can never be made perfect. There is, however, one evil which I have not yet been able to remedy; and that is, the introduction of air into the gage, owing to the unboiled mercury in the ciſtern: for when the gage has been a few times exhauſted, the mercury which originally filled it becomes mixed with that into which it is inverted, and in conſequence the vacuum is rendered leſs and leſs perfect, till at laſt the inſtrument is entirely ſpoiled. I have juſt conſtructed a gage ſo as to be able to boil the mercury in the ciſtern, but have not yet aſcertained its ſucceſs."

ila- Ex- en's.

of the air-pump, when the receiver was placed upon it. A fine linen thread was faſtened towards the top of the wire, and about four inches of it hanged freely along the braſs wire, and almoſt in contact with it. The extremity of the wire, which paſſing through the braſs cap projected out of the receiver, was furniſhed with a ball. Thus prepared, the receiver was placed upon the plate of the pump, without any leather, or any thing elſe beſides a little oil on its outſide edge, which muſt be always underſtood in all the other experiments related in the courſe of this chapter. Then the exhauſtion was commenced, and at intervals ſome electricity was communicated, either by the approach of the conductor of an electrical machine, or the knob of a charged jar, to the braſs ball of the wire, in order to obſerve the ſtrength of the repulſion of the thread from the wire in different degrees of rarefaction; which degrees were aſcertained by the ſhort barometrical gage. Proceeding in this manner, it was obſerved, that till the rarefaction did not exceed one hundred, to wit, till the air remaining within the receiver was not leſs than the hundredth part of the original quantity, whenever the electricity was communicated to the braſs ball, the thread firſt adhered to the wire, and then was repelled by it; though this repulſion became ſmaller and ſmaller, according as the exhauſtion came nearer to the above mentioned degree. The clinging of the thread to the wire firſt, was becauſe being dry, it required ſome time before it acquired a ſufficient quantity of electricity from the wire, and conſequently it was not immediately repelled. When the air within the receiver was exhauſted above 100 times, the thread was not firſt attracted and then repelled as before, but only vibrated a little backwards and forwards, and then remained in the ſituation in which it ſtood when electricity was not concerned. By exhauſting the receiver ſtill farther, the vibration of the thread when electrified was gradually diminiſhed; ſo that when the degree of rarefaction was above 500, ſparks and the diſcharge of a jar only made the thread vibrate in a manner juſt ſenſible; but this vibration, however ſmall, did never become quite inſenſible, even when the receiver was exhauſted to the utmoſt power of the pump, which was very near 1000. After this the air was gradually admitted into the receiver, and at various intervals the ball of the braſs wire was electrified, in order to obſerve whether the ſame phenomena appeared at the different degrees of exhauſtion as had done before; and they were found to agree with ſufficient exactneſs.

"II. The braſs wire within the ſame glaſs receiver was made very ſhort, and from its extremity a fine linen thread, fixes inches long, was ſuſpended; and upon the plate of the pump a ſmall braſs ſtand with a braſs pillar was placed: ſo that when the receiver was put upon the plate, and over the braſs ſtand, about one inch length of the thread ſtood parallel to, and at various required diſtances from, the braſs pillar (F). In this diſpoſition of the apparatus, whenever any the leaſt quantity of electricity was communicated to the knob of the braſs wire, the thread was immediately attracted by the braſs pillar, and adhered to it ſome time, becauſe, being dry, it did not immediately part with the acquired electricity. At various degrees of exhauſtion, the electricity being communicated to the braſs ball of the wire, it was found, that the thread was always attracted by the braſs pillar, though from a greater or leſs diſtance, according as a greater or leſs quantity remained within the receiver. Thus when the air was rarefied about 100 times, the thread was attracted from about one inch; when the air was rarefied 200 times, it was attracted from about $\frac{1}{8}$th of an inch; when the air was rarefied 300 times, it was attracted from about $\frac{1}{10}$th; and after this it was always attracted from about $\frac{1}{20}$th, even when the air within the receiver was rarefied about 1000 times. It is remarkable, that when the air in the receiver is rarefied about 300 times, if a jar is diſcharged thro' the vacuum, by touching its knob with the ball of the wire on the receiver, the thread is not in conſequence of it attracted by the braſs pillar: the reaſon of which ſeems to be, becauſe that large quantity of electricity opens a way thro' the vacuum, and paſſes thro' every part of it; whereas a ſmall quantity of electricity, even the action of a ſmall electrical machine in the ſame room, at no very great diſtance from the apparatus, will cauſe the thread being attracted by the braſs pillar.

Miſcellaneous Experiments.

III. "The braſs ſtand, with the pillar, and the thread which proceeded from the wire, being removed from under the receiver, a very ſenſible electrometer was faſtened, inſtead of the thread, to the extremity of the braſs wire. This electrometer conſiſted of two very fine ſilver wires, each about one inch long, and having a ſmall cone of cork at its extremity. The ſenſibility of ſuch an electrometer is really ſurpriſing; for even the electricity of a ſingle hair excited, does ſenſibly affect it; and, as its ſuſpenſion is almoſt without any friction or other impediment, it never deceives one by appearing to be electrified when in reality it is not ſo. With this preparation, the receiver being placed upon the plate of the air-pump, the air was gradually exhauſted, and at intervals ſome electricity was communicated to the ball on the outſide of the receiver, either by an excited electric or by a charged jar; and it was found that the corks of the electrometer were always made to diverge by it, even when the air was exhauſted as much as poſſible. Indeed their divergency was ſmaller and ſmaller, and laſted a ſhorter time, according as the air was more exhauſted, but it was viſible to the laſt.

"In this experiment, analogous to what has been obſerved in the preceding, when the air was exhauſted above 300 times, if a jar was diſcharged through the vacuum, or a ſtrong ſpark was given to the knob on the top of the receiver, the corks of the electrometer diverged very little indeed, and but for an inſtant; whereas a ſmall quantity of electricity made them diverge more, and remain much longer in that ſtate.

139
His concluſions from them.

"It ſeems deducible from thoſe experiments, that electric attraction and repulſion take place in every degree of rarefaction, from the loweſt to about 1000, but that the power diminiſhes in proportion as the air

---

(F) This diſtance was altered by turning the braſs wire which paſſed through a collar of leather in the braſs cap of the receiver.

Miſcellaneous Experiments

air is more and more rarefied; and by following the law, we may perhaps conclude with F. Beccaria, that there is no electric attraction nor repulſion in a perfect vacuum: though this will perhaps be impoſſible to be verified experimentally; becauſe when in an exhauſted receiver no attraction or repulſion is obſerved between bodies to which electricity is communicated, it will be only ſuſpected, that thoſe bodies are not ſufficiently ſmall and light. But if we conſult reaſon, and which alone ought to aſſiſt us when deciſive experiments are not practicable, it ſeems likely that electric attraction and repulſion cannot take place in a perfect vacuum, by which I only mean a perfect abſence of air; becauſe either this vacuum is a conductor or a non-conductor of electricity. If a conductor, and nearer to perfection as it becomes more free from air, it muſt be a perfect conductor at the ſame time that it becomes a perfect vacuum; in which caſe electric attraction or repulſion cannot take place amongſt bodies incloſed in it: for, according to every notion we have of electricity, thoſe motions indicate or are the conſequence of the intervening ſpace in ſome meaſure obſtructing the free paſſage of the electric fluid. And if the perfect vacuum is a perfect non-conductor, then neither electric attraction nor repulſion can happen in it.

140 Electric light always viſible in the moſt perfectly exhauſted receiver.

"IV. In my former experiments, having always obſerved the electric light in the receiver of the air-pump, even when the air was rarefied to the utmoſt power of that machine, I thought proper to repeat that experiment with receivers of various ſizes; and accordingly have uſed receivers of above two feet in height, and ſome of as large a diameter as the plate of the pump could admit, which is about 14 inches; but the light in it was always viſible, only with different colours in different degrees of exhauſtion, and always more diffuſed, and at the ſame time leſs denſe, when the air was more rarefied; which ſeems to render it probable, that when the air is quite removed from any ſpace, the electric light is no longer viſible in it, as muſt have been the caſe with the experiment of Mr Walſh's double barometer; for it is a maxim very well eſtabliſhed in electricity, that the electric light is only viſible when the electric fluid, in paſſing from one body to another, meets with ſome oppoſition in its way; and according to this propoſition, when the air is entirely removed from a given receiver, the electric fluid paſſing through that receiver cannot ſhow any light, becauſe it meets with no oppoſition; but this will not account for the receiver ever becoming a non-conductor.

"Having juſt mentioned, that according as the air is more and more rarefied in a receiver, ſo the electric light becomes gradually more faint, it will be proper to add, that the electric light is more diffuſed and leſs bright in an exhauſted receiver than in air: Thus, when the receiver is not exhauſted, the diſcharge of a jar through ſome part of it will appear like a ſmall globule exceedingly bright; but when the receiver is exhauſted, the diſcharge of the ſame jar will fill the whole receiver with a very faint light: whereas ſome perſons, by ſeeing the whole receiver illuminated, are apt to ſay that the light of electricity is rendered ſtronger and greater by the exhauſtion.

"V. It is mentioned by Mr Nairne, in the 67th vol. of the Phil. Tranſ. that having put a piece of leather, juſt as it comes from the leather-ſellers, into the receiver of an air pump, and afterwards having rarefied the air in it 148 times, the electric light appeared very faint in it; whereas, without the leather, and even when the air was much more rarefied, the light of the electric fluid, when made to paſs through the receiver, was much more apparent. In conſequence of this obſervation, I ſuſpected that a little moiſture in the receiver, or ſome other effluvia of ſubſtances, might perhaps prevent the appearance of the electric light in rarefied air; and with this view I began to put various ſubſtances ſucceſſively into the receiver; and after rarefying the air by working the pump, ſome electric fluid was made to paſs through the receiver.

141 Experiments by introducing various ſubſtances into the receiver.

"When a piece of moiſt leather was put into the receiver, the air could not be rarefied above 100 times, and the electric light appeared divided into a great many branches; though at the ſame time another ſort of faint light filled up the whole cavity of the receiver.

"When a linen rag, moiſtened with a mixture of ſpirit of wine and water, was put into the receiver, the pump could not exhauſt above 40 times, and the light of electricity appeared divided into many branches.

"A wine-glaſs full of olive oil placed under the receiver, prevented very little the exhauſtion of the pump, the air being rarefied above 400 times. The electric light appeared exactly as it uſually does in the ſame degree of rarefaction when no oil is under the receiver, *viz.* a uniform faint light inclining to purple or red.

"Concentrated vitriolic acid placed in a glaſs under the receiver, produced no particular effect. As for the other mineral acids, they were not tried, becauſe, being volatile, they would have damaged the pump.

"Dry ſolids, that had a conſiderable ſmell, as ſulphur, aromatic woods previouſly made very dry, and ſome reſins, produced no particular effect, any more than ſome of them prevented a very great degree of exhauſtion, owing to ſome moiſture which ſtill adhered to them.

142 The light attraction and repulſion, diminiſh in great degree of rarefaction.

"From theſe experiments it appears, firſt, that in the utmoſt rarefaction that can be effected by the beſt air-pump, which amounts to about 1000, both the electric light and the electric attraction, though very weak, are ſtill obſervable: but, ſecondly, that the attraction and repulſion of electricity become weaker in proportion as the air is more rarefied, and in the ſame manner the intenſity of the light is gradually diminiſhed. Now by reaſoning on this analogy we may conclude, that both the attraction and the light will ceaſe in a perfect abſence of air: but this will never account for this perfect vacuum ever becoming a non-conductor of electricity; for ſince the electric fluid is very elaſtic, and expands itſelf with more and more freedom in proportion as the reſiſtance of the air is removed, it ſeems unnatural that it ſhould be incapable of pervading a perfect vacuum: however, the fact ſeems to be fully aſcertained by Mr Walſh and Mr Morgan; and the only thing that remains to be done is to inveſtigate the cauſe of ſo remarkable a property."

With

Miſcellaneous Experiments.

With regard to the power of the electric fluid, we have already had occaſion to ſpeak in various parts of this treatiſe, and particularly to mention the machine in Teyler's Muſeum at Haarlem, as that which was capable of accumulating the greateſt quantity of electricity that had ever been done artificially. Some of the effects of this machine, without any battery, have already been deſcribed; and thoſe which follow are equally calculated to give an idea of its vaſt power. A battery of 135 vials, containing among them about 130 ſquare feet of coated ſurface, was charged by about 100 turns of the glaſs plates; the diſcharge of which melted an iron wire 15 feet long and $\frac{1}{151}$ of an inch diameter; and another time they melted a wire of the ſame metal 25 feet long and $\frac{1}{235}$th of an inch in diameter. With ſuch an extraordinary power they tried to give polarity to needles made out of watch-ſprings of three and even ſix inches in length, and likewiſe to ſteel bars nine inches long, from a quarter to half an inch in breadth, and about the twelfth-part of an inch in thickneſs. The reſult was, that when the bar or needle was placed horizontally in the magnetic meridian, whichever way the ſhock entered, the end of the bar that ſtood towards the north acquired the north polarity, or the power of turning towards the north when freely ſuſpended, and the oppoſite end acquired the ſouth. If the bar, before it received the ſhock, had ſome polarity, and was placed with its poles contrary to the uſual direction, then its natural polarity was always diminiſhed, and often reverſed; ſo that the extremity of it, which in receiving the ſhock looked towards the north, became the north pole, &c.

When the bar or needle was ſtruck ſtanding perpendicularly, its loweſt end became the north pole in any caſe, even when the bar had ſome magnetiſm before, and was placed with the ſouth pole downwards. All other circumſtances being alike, the bars ſeemed to acquire an equal degree of magnetic power, whether they were ſtruck whilſt ſtanding horizontally in the magnetic meridian, or perpendicular to the horizon.

When a bar or needle was placed in the magnetic equator, whichever way the ſhock entered, it never gave it any magnetiſm; but if the ſhock was given through its width, then the needle acquired a conſiderable degree of magnetiſm, and the end of it which lay towards the weſt became the north pole, and the other end the ſouth pole.

If a needle or bar, already magnetic, or a real magnet, was ſtruck in any direction, its power was always diminiſhed. For this experiment, they tried conſiderably large bars; one being 7,08 inches long, 0,26 broad, and 0,05 thick.

When the ſhock was ſo ſtrong, in proportion to the ſize of the needle, as to render it hot, then the needle generally acquired no magnetiſm at all, or very little.

The experiments laſtly tried with this very powerful battery were concerning the calcination of metallic ſubſtances, and the revivification of their calces. It appears that the electric ſhock produced both theſe apparently contradictory effects.

The metallic calces uſed in thoſe experiments were of the pureſt ſort; they were confined between glaſſes whilſt the ſhock was paſſed over them. By this means the calces were ſo far revivified as to exhibit ſeveral grains of the metal, large enough to be diſcerned by the naked eye, and to be eaſily ſeparated from the reſt.

As to the calcination of metals, whenever a ſhock was employed much greater than that which was neceſſary to fuſe the metal, part of the metal was calcined, and diſperſed into ſmoke. It is remarkable, that this calcination or ſmoke generally produced ſeveral filaments, of various lengths and thickneſſes, which ſwam in the air. It was farther obſerved, that thoſe flying filaments of metallic calx, if a conductor was preſented to them, were ſoon attracted by it; but after the firſt contact, they were inſtantly repelled, and generally broke into diverſe parts.

144
The battery augmented.

Even this vaſt power was not the utmoſt effect of the machine. Dr Van Marum, whom we have already mentioned as principally concerned in making the experiments, thinking that it was capable of charging a larger ſurface, added to it 90 jars, each of the ſame ſize with the former; ſo that his grand battery is now a ſquare of 15 jars every way, and contains 225 ſquare feet of coated glaſs. To aſcertain the degree of the charge, he uſes the electrometer invented by Mr Brook, to be afterwards deſcribed, which is fixed in the centre of the battery, at the height of four feet above the knobs of the jars.

His firſt object was to try whether this battery could be fully charged by the machine, and whether its increaſe of power was proportional to the augmentation of its ſurface. In theſe reſpects, his expectations were fully anſwered. The former battery diſcharged itſelf over the uncoated part of the jars after 96 revolutions; and the preſent did the ſame after 160 turns of the machine. With the former battery, the Doctor had ſplit a cylinder of box three inches in diameter and three inches in length, the ſection of which, through its axis, contained nine ſquare inches. With the 225 jars, he ſplit a ſimilar cylinder, four inches in diameter and four inches in height, the ſection of which was 16 ſquare inches. He found that to ſplit a ſquare inch of this wood in the ſame direction, required a force equal to 615 pounds; and hence calculates that the power of this exploſion was not leſs than 9840 pounds.

145
Calculation of the force of its exploſion.

146
Lengths of wire of different kinds melted by it.

The apparent reſemblance between the effects of electricity and of fire, eſpecially in melting metals, has led many to ſuppoſe that they act upon bodies in a ſimilar manner. In order to examine whether this ſuppoſition be juſt, Dr Van Marum cauſed wires of different metals to be drawn through the ſame hole, of one thirty-eighth part of an inch in diameter, and obſerved how many inches of each could be melted by the exploſion of his battery; taking care, in all theſe experiments, to charge it to the ſame degree as aſcertained by his electrometer. The reſults were as follow:

| | | |
|---|---|---|
| Of lead he melted | - | 120 inches. |
| Of tin | - - | 120 |
| Of iron | - - | 5 |
| Of gold | - - | 3½ |

Of ſilver, copper, and braſs, not quite a quarter of an inch.

Theſe ſeveral lengths of wire, of the ſame diameter, melted by equal exploſions, indicate, according to our author, the degree in which each metal is fuſible by the

the electrical diſcharge; and if theſe be compared with the fuſibility of the ſame metals by fire, a very conſiderable difference will be obſerved. According to the experiments of the academicians of Dijon, to melt tin required a heat of 172 degrees of Reaumur's thermometer.

| | |
|---|---|
| Lead | 230 |
| Silver | 430 |
| Gold | 563 |
| Copper | 630 |
| Iron | 696 |

147
Electrical fluid ſuppoſed to act in a different manner from fire.

Thus tin and lead appear to be equally fuſible by electricity, but not by fire: and iron, which by fire is leſs fuſible than gold, is much more ſo by the electrical exploſion. From theſe and ſome other experiments of the ſame kind, Dr Van Marum concludes, that, in melting metals, the electrical fluid acts upon them in a manner very different from the action of fire, and that the ſuppoſed analogy between theſe two powerful agents cannot be proved, either from the fuſion of metals, or the ignition of combuſtible ſubſtances.

148
Comparative efficacy of the different metals as conductors

By theſe experiments on the fuſibility of metals, Dr Van Marum was induced to make trial of the comparative efficacy of lead, iron, braſs, and copper, as conductors to preſerve buildings from lightning. In this reſpect, he found that a leaden conductor ought to be four times the ſize of one of iron, in order to be equal in point of ſafety. He has alſo fully proved the ſuperiority of rods to chains, and of copper to iron, for this important uſe.

When iron wire is melted by the exploſion of the battery, the red-hot globules are thrown to a very conſiderable diſtance, ſometimes to that of 30 feet: this the Doctor juſtly aſcribes to the lateral force exerted by the electrical fluid. It is, however, remarkable, that the thicker the wire is which is melted, the further are the globules diſperſed: but this is accounted for, by obſerving, that the globules, formed by the fuſion of thinner wires, being ſmaller, are leſs able to overcome the reſiſtance of the air, and are therefore ſooner ſtopped in their motion.

Two pieces of iron wire being tied together, the fuſion extended no further than from the end connected with the inſide coating of the jars to the knot; tho' wire of the ſame length and thickneſs, when in one continued piece, had been entirely melted by an equal exploſion.

149
Wires ſhortened by the diſcharge.

When a wire was too long to be melted by the diſcharge of the battery, it was ſometimes broken into ſeveral pieces, the extremities of which bore evident marks of fuſion; and the effect of electricity in ſhortening wire was very ſenſible in an experiment made with 18 inches of iron wire $\frac{1}{37}$th of an inch in diameter, which, by one diſcharge, loſt a quarter of an inch of its length.

150
Very ſmall wires cannot diſcharge the battery entirely.

An exploſion of this battery through very ſmall wires, of nearly the greateſt length that could be melted by it, did not entirely diſcharge the jars. On tranſmitting the charge through 50 feet of iron wire of $\frac{1}{40}$th of an inch diameter, the Doctor found that the reſiduum was ſufficient to melt two feet of the ſame wire; but this reſiduum was much leſs when the wire was of too great a length to be melted by the firſt diſcharge. After an exploſion of the battery through 180 feet of iron wire, of equal diameter with the former, the reſiduum was diſcharged through 12 inches of the ſame wire, which it did not melt, but only blued.

Twenty-four inches of leaden wire $\frac{1}{18}$th of an inch in diameter, were entirely calcined by an exploſion of this battery; the greater part of the lead roſe in a thick ſmoke, the remainder was ſtruck down upon a paper laid beneath it, where it formed a ſtain, which reſembled the painting of a very dark cloud. When ſhorter wires were calcined, the colours were more varied. A plate is given of the ſtain made by the calcination of eight inches of this wire, in which the cloud appears variouſly ſhaded with different tints of green, gray, and brown, in a manner of which no deſcription can give an adequate idea.

151
Curious phenom
wi h tin
wire

On diſcharging the battery through eight inches of tin wire $\frac{1}{38}$th of an inch diameter, extended over a ſheet of paper, a thick cloud of blue ſmoke aroſe, in which many calcareous filaments were diſcernible; at the ſame time a great number of red hot globules of tin, falling upon the paper, were repeatedly thrown up again into the air, and continued thus to rebound from its ſurface for ſeveral ſeconds. The paper was marked with a yellowiſh clouded ſtain immediately under the wire, and with ſtreaks or rays of the ſame colour iſſuing from it in every direction: ſome of theſe formed an uninterrupted line, others were made up of ſeparate ſpots. In order to be certain that the colour of theſe ſtreaks was not cauſed by the paper being ſcorched, the experiment was ſeveral times repeated, when a plate of glaſs and a board covered with tin were placed to receive the globules. Theſe, however, were ſtained exactly like the paper. On calcining five inches of the ſame kind of wire, the red-hot globules were thrown obliquely to the height of four feet, which afforded an opportunity of obſerving that each globule, in its courſe, diffuſed a matter like ſmoke, which continued to appear for a little while in the parabolic line deſcribed by its flight, forming a track in the air of about half an inch in breadth.

152
Account for.

From this phenomenon, Dr Van Marum conjectures, that when the globules approach the paper on which they fall, the matter iſſuing from their lower part ſtrikes againſt its ſurface, and being elaſtic, forces them upwards again by its reaction. The clouded ſtain immediately under the wire, the Doctor attributes to the inſtantaneous calcination of its ſurface; whereas the remainder of the metal is melted into globules, which, while they retain their glowing heat, continue to be ſuperficially calcined, and, during the proceſs, part with this calcareous vapour.

153
With w
compoſe
of equal
parts of
tin and
lead.

Phenomena ſomething ſimilar to the above were obſerved on the calcination of a wire of equal parts of tin and lead, eight inches long, and $\frac{1}{32}$d of an inch in diameter. This alſo was melted into red globules, which were repeatedly driven upwards again from the paper on which they fell, and marked it with ſtreaks of the ſame kind, but of a brown colour, edged with a yellow tinge. Some of theſe globules, though apparently not leſs hot, moved with leſs velocity than others, and were ſoon ſtopped in their courſe by their burning a hole in the paper. In this caſe, a yellow matter was ſeen to riſe from their ſurface to the height of one or two lines, which extended itſelf to the width of a quarter of an inch. This matter continued, during

five

ella- ·Ex- ients.

five or ſix ſeconds, to iſſue from the globules, and formed, on their ſurface, a kind of efflorescence, reſembling the flowers of ſulphur produced by the *ſolfaterra*. The globules, from which theſe calcareous flowers had iſſued, were found to be entirely hollow, and to conſiſt of only a thin ſhell. When this mixed metal is calcined with a leſs charge of the battery, it leaves a ſtain upon the paper, ſomething ſimilar to that made by lead, and does not run into globules.

4 upon by lcina- f me-

The Doctor has alſo given plates of the ſtains made upon paper, by the calcination of iron, copper, braſs, ſilver, and gold. Thoſe made by copper and braſs wires are remarkably beautiful, and are variegated with yellow, green, and a very bright brown. Eight inches of gold-wire, $\frac{1}{85}$th of an inch in diameter, were, by the exploſion, reduced to a purple ſubſtance, of which a part roſe like a thick ſmoke, and the remainder, falling on the paper, left a ſtain diverſified with different ſhades of this colour. Gold, ſilver, and copper, cannot eaſily be melted into globules. Our author has once accidentally ſucceeded in this; but it required a degree of electrical force ſo very particular, that the medium between a charge, which only broke the wire into pieces, and one which entirely calcined it, could not be aſcertained by the electrometer.

5 upon con- in ſtca- r.

Though Dr Van Marum was convinced, by M. Lavoiſier's experiments, that metals, calcined in atmoſpherical air, abſorb from it that principle which renders it fit for reſpiration; yet he reſolved further to inveſtigate this point, by trying what would be the effect of a diſcharge of the battery through a piece of wire confined in phlogiſticated air. For this purpoſe, he took air, in which a burning coal had been extinguiſhed, and which had afterwards ſtood eight days upon water, that it might be entirely cleared from fixed air; with this he filled a glaſs cylinder, four inches in diameter, and ſix inches high, cloſed at the upper end with a braſs-plate; from the centre of this plate the wire was ſuſpended, on which the experiment was made. The cylinder was ſet in a pewter diſh filled with water; and, to prevent its being broken by the expanſion of the air, its lower edges were ſupported by two pieces of wood half an inch high. The lower end of the wire reſted on the diſh, which was connected with the outſide coating of the battery.

6 hlo- ted

On tranſmitting the charge, in this manner, through wires of lead, tin, and iron, of only half the length of thoſe which were calcined by an equal exploſion in atmoſpheric air, no calcination took place. The firſt was reduced to a fine powder, which, upon trial by ſpirit of nitre, appeared to be merely lead; the two other metals were melted into ſmall globules.

The Doctor then tried the ſame experiment in pure or dephlogiſticated air, obtained from red precipitate; thinking that, in this, the metals would be more highly calcined than in common air. His expectation was anſwered only by the lead, which was entirely reduced to a yellow calx, perfectly reſembling maſſicot. The other metals were not more highly calcined in this than in common air; but the globules of iron acquired ſo great a heat, as to retain it for ſome ſeconds, even in the water, and to melt holes in the pewter diſh into which they fell.

In nitrous air, calcination took place as eaſily as in common or in dephlogiſticated air. This was contrary to Dr Van Marum's expectation; but he accounts for it, by obſerving that, from the experiments of Mr Cavendiſh and of M. Lavoiſier, pure air appears to be one of the component parts of the nitrous acid.

Miſcellaneous Experiments.

157 Phenomena in the calcination of metals in water.

In order to illuſtrate M. Lavoiſier's theory, Dr Van Marum reſolved to examine the phenomena reſulting from the calcination of metals in water. This he tried with both iron and lead; and found that, in the moment of the exploſion, a number of air-bubbles appeared on the ſurface, and the calx roſe, like a cloud, through the water. This, he thinks, is not ſo eaſily accounted for by the theory of Stahl as by that of M. Lavoiſier; becauſe, according to the former, water does not readily either receive or part with phlogiſton; whereas the latter ſuppoſes this fluid to be compoſed of the oxigenous principle, united with that of inflammable air. If this be true, nothing more is neceſſary to calcination, than that the metal ſhould acquire a greater affinity with the oxigenous principle, that ſubſiſts between this and that of inflammable air, united with it in the compoſition of water. To collect the air generated by theſe calcinations was no eaſy matter; as the violence of the ſhock broke the glaſs receivers employed for this purpoſe: at laſt, however, the Doctor contrived a method of receiving it in a glazed ſtone baſon. From the firſt calcination of lead, about a quarter of a cubic inch of air was produced, which ſhowed no ſigns of inflammability; but, on every repetition of the experiment, a leſs quantity of air was generated; and on an accurate trial of that produced by the fourth calcination in the ſame water, it was found to conſiſt of one part of inflammable and three of atmoſpherical air. Our author deſigns to repeat theſe experiments with water deprived of its air, by being boiled.

158 Phenomena of earthquakes imitated.

In order to imitate the phenomena of earthquakes, this ingenious philoſopher followed Dr Prieſtley's method, and made the electrical exploſion paſs over a board, floating on water, on which ſeveral columns of wood were erected; but this ſucceeded only once. Reflecting that the electric exploſion exerts the greateſt lateral force when it paſſes through imperfect conductors, and that water is probably its principal ſubterraneous conductor, he laid two ſmooth boards upon each other, moiſtening the ſides in contact with water: upon the uppermoſt, he placed pieces of wood, in imitation of buildings, the baſes of which were 3 inches long and $1\frac{1}{2}$ broad. When the charge of the battery was tranſmitted between the boards, all theſe were thrown down by the tremulous and undulatory motion of that on which they ſtood.

159 Brookes's experiments on the force of batteries.

Mr Brookes, electrician at Norwich, has made a great number of experiments, with a view to determine exactly the force of batteries of an inferior ſize in melting fine wires of different kinds. In theſe he was particularly careful to aſcertain the degree to which his batteries were charged; and this he did by the method which ſhall afterwards be ſhown to be the beſt, viz. that of determining the power of the electricity by the weight which it was capable of raiſing by its repulſive power; and therefore, in the following experiments, the phraſe of batteries being charged to ſo many grains, implies that the repulſive power of the knob of the battery was able to raiſe that weight.

Miſcellaneous Experiments.

Some of the moſt remarkable of theſe experiments were as follow:

" 1. With a battery of nine bottles, containing about 16 ſquare feet of coated ſurface, charged to 32 grains of repulſion, which charge was ſent through a piece of ſteel wire 12 inches long and $\frac{1}{100}$th of an inch thick 11 times; the wire was ſhortened one inch and a half, being then about 10 inches and an half long; the 12th time, the wire was melted to pieces.

" 2. A charge, with the ſame nine bottles, to 32 grains of repulſion, being ſent through a piece of ſteel wire 12 inches long and $\frac{1}{170}$th of an inch thick, the firſt time melted the whole of it into ſmall globules.

" 3. A charge of the ſame nine bottles charged to 32 grains, being ſent through a piece of *braſs* wire 12 inches long, $\frac{1}{170}$th of an inch thick, the whole of it was melted, with much ſmoke, almoſt like gunpowder; but the metallic part of it, after it was melted, formed itſelf, in cooling, chiefly into concave hemiſpherical figures of various ſizes.

" 4. With only eight of the above bottles charged to 32 grains, the charge did but juſt melt 12 inches of the ſteel wire $\frac{1}{170}$th of an inch thick, ſo as to fall into ſeveral pieces; which pieces in cooling formed themſelves into oblong lumps joining to each other by a very ſmall part of the wire between each lump, which was not melted enough to ſeparate, but appeared like oblong beads on a thread at different diſtances.

" 5. The ſame eight bottles charged to 32 grains, ſo perfectly heated 12 inches of braſs wire, about $\frac{1}{170}$th of an inch thick, as to melt it, or ſoften it enough for it to fall down by its own weight (from the forceps with which it was held at each end) upon a ſheet of paper placed under to catch it; and when it fell down, it was ſo perfectly flexible, that by falling, it formed itſelf into a bent, or rather vermicular ſhape, and remained entire its whole length, *i. e.* about 12 inches when it was put into the forceps; but after it was fallen on the paper, it ſagged ſo much as to be ſtretched by its own weight from 12 to about 15 inches long; and by falling on the paper it flattened itſelf the whole length of it, ſo that when it was examined with an half inch magnifier, it appeared about five or ſix times broader than it was in thickneſs.

" 6. With nine bottles again, charged only to 20 grains, the charge was ſent through 12 inches of ſteel wire $\frac{1}{170}$th of an inch thick, which heated it enough to melt it ſo as to be ſeparated in many places; and the pieces formed themſelves into ſtrung-bead-like ſhapes, as in experiment 4.

" 7. With the ſame nine bottles charged to 20 grains, the charge was ſent through 10 inches of braſs wire $\frac{1}{170}$th of an inch thick; the wire was heated ſo red hot as to be very flexible, yet it did not ſeparate, but was ſhortened near $\frac{3}{8}$ths of an inch.

" 8. A charge of nine bottles, charged to 20 grains, ſent a ſecond time through the laſt piece of wire, melted it aſunder in three places.

" 9. Nine bottles charged to 30 grains, and the charge ſent through 12 inches of braſs wire $\frac{1}{170}$th of an inch thick, treated it nearly as in experiment 5. except that it was ſeparated in two places, and the pieces meaſured about 16 inches and an half long; but perfectly flattened by its fall on the paper, as before.

" 10. Nine bottles charged to 30 grains, and the charge being ſent through eight inches and a half of braſs wire the ſize of the laſt, wholly diſperſed it in ſmoke, and left nothing remaining to fall on the ſheet of paper placed under it.

" 11. With 12 bottles, charged to 20 grains, the charge was ſent through ten inches of ſteel wire one-hundredth of an inch thick, which made the wire red hot, but did not melt it.

" 12. A ſecond charge, the ſame as the laſt, was ſent through the ſame piece of wire, which heated it red hot as the firſt did, but it was not ſeparated; this piece of wire was now ſhortened five-ſixteenths of an inch.

" 13. A charge to 25 grains, with the ſame 12 bottles, was ſent through the laſt piece of wire, which melted it into many pieces, and many globules of calcined metal.

" 14. A charge of 15 bottles, charged to 25 grains, was ſent through ten inches of ſteel wire one-hundredth of an inch thick, which melted it the firſt time, and diſperſed a great part of it about the room.

" 15. A charge with the laſt 15 bottles, charged to 20 grains, juſt melted ten inches of ſteel wire the ſize of the former, ſo as to run into beautiful globules, nearly as in exp. 13.

" 16. A charge of 15 bottles, charged to 15 grains, being ſent through ten inches of ſteel wire the ſize of the laſt, it was barely made red hot; but it was ſhortened one-tenth of an inch by the ſtroke paſſing through it.

" 17. The laſt piece of wire having a charge of 15 bottles, charged to twelve and a half grains, ſent thro' it, was not made red hot.

" 18. A charge of the ſame 15 bottles, charged to 25 grains, was ſent through the ſame piece of wire, which ſeemingly tore the wire into ſplinters.

" 19. Four bottles, charged to 30 grains, juſt melted three inches of ſteel wire one hundred and ſeventieth of an inch thick, ſo as to fall into pieces.

" 20. Five bottles, charged to 25 grains, moſt beautifully melted three inches of ſuch wire as the laſt into large globules.

" 21. Eight bottles, charged to 15 grains, melted three inches of ſteel wire one hundred and ſeventieth of an inch thick, ſimilar to the five in the laſt experiment; ſo nearly alike both in appearance and effect, that it might have been ſaid to be the ſame.

" 22. Ten bottles charged to twelve and a half grains, rather exceeded exp. 19. but ſcarcely came up to exp. 20. and 21.

" 23. Suſpecting ſomething in exp. 19. I found, that though my bottles hitherto were as nearly of the ſame ſize as I could procure them, yet ſome of them were a little larger than others, and, which was the caſe in exp. 19. one of the four was ſmaller than the other three; ſo that I repeated the experiment with four bottles more equal in ſize, and charged them to 30 grains, and the fuſion was as perfect as in any.

" 24. A charge to 20 grains, with the laſt eight bottles, very finely melted ſix inches of ſteel wire one hundred and ſeventieth of an inch thick.

“ 25. With two bottles, charged to 45 grains, the charge was ſent through one inch of ſuch ſized ſteel wire as the laſt, which only changed its colour.

“ 26. Three bottles, with a 40 grains charge, diſperſed one inch and a half of ſteel wire, the ſize of the laſt, all about the room.

“ 27. As a ſteel wire of one-hundredth of an inch thick has nearly double the quantity of metal of a wire one hundred and ſeventieth of an inch thick, ſo I took three inches of the former, and ſent a 25 grains charge with ten bottles through it, which melted it juſt as the five bottles did in exp 20.

“ 28. Twenty bottles, charged to twelve grains and a half, melted three inches of ſteel wire, the ſize of the laſt, exactly ſimilar to the foregoing experiment.

“ 29. As a ſteel wire of one-eightieth of an inch thick contains nearly twice the quantity of metal in the ſame length as a ſteel wire of one-hundredth, or four times the quantity of a ſteel wire of one hundred and ſeventieth of an inch thick; ſo it might, from the foregoing experiments, be expected that 20 bottles, charged to 25 grains, would melt three inches of ſteel wire one-eightieth of an inch thick; but on a great many trials 20 bottles could not be procured that would bear the diſcharge, when charged to 25 grains: for at the diſcharge there would be always one or more bottles broken or perforated. I was now reduced to the neceſſity of being content with getting bottles of any ſize that would bear the required charge, from one to three gallons each, or that contained from about 150 to 300, or more, ſquare inches of coated ſurface, each; but all in vain. my only reſource left (as I was not near any glaſs houſe). was to increaſe the quantity of ſurface, and not to charge ſo high, and to proportion the one to the other: a third part was concluded on to be tried; that is, inſtead of about 36 feet of coating, I added one third, or 12 feet, which made it 48 feet: and that, inſtead of charging to 25 grains, or 24 grains, which divides by 3 better, to omit one-third of the height of the charge, which leaves 16 grains: and thus I ſucceeded perfectly well; for 3 inches of ſteel wire one-eightieth of an inch thick was as curiouſly melted with 48 feet of coated ſurface, charged to 16 grains, as any of the former.

“ Theſe bottles, thus broken in large diſcharges, ſeem always to break. or to be ſtruck through, nearly in the thinneſt, but never in the thickeſt place, which ſhows the neceſſity of the ſubſtance in the glaſs.

30. “ As in exp. 19. and 21. where the former is but half the quantity of coated ſurface of the latter, charged to 30, and the latter to 15 grains, to know how high 48 feet of coating muſt be charged to produce the ſame effect exactly: and as the quantity of coating in four bottles, conſiſting of a little more than ſix feet and a half, is contained in 48 feet a little more than ſeven times; ſo I tried by charging 48 feet only to a little more than four grains, or only about one ſeventh part ſo high, as four times ſeven is 28; that is, but two leſs than 30: and this had exactly the ſame effect on the wire, which was one hundred and ſeventieth of an inch thick, and three inches long, as the former.

31. “ As the laſt experiment agreed ſo exactly with exp. 19. and 20. the next thing tried was to ſee the effect of 48 feet of coated ſurface charged to a little more than four grains, upon ſix inches of ſteel wire, the ſize of the laſt; but this was only made very faintly red.

32. “ A repetition of the laſt experiment with the ſame length of the ſame wire, to ſee how often the ſame charge might be ſent through before it would be melted, and to obſerve the appearance of the wire after each ſtroke; the eighth ſtroke melted it into ſeveral pieces. After the firſt ſtroke, the redneſs grew leſs every time, even the laſt time, when it was ſeparated. The firſt ſtroke, though little more than fairly red, made it ſo flexible, that by a little more than its own weight (about a penny-weight more), it was apparently made perfectly ſtraight when it was cooled: about the third or fourth ſtroke it began to appear zigzagged; after the ſixth ſtroke the ſurface of it appeared rough; after the ſeventh ſtroke the ſurface was very roughly ſcorified or ſcaly; and ſome of the ſcales had fallen upon a piece of white paper, placed under it, at about half an inch diſtance below it. The eighth ſtroke melted it in three places; and at thoſe places where the angles appeared the ſharpeſt or moſt acute, a great number of the ſcaly appearances were driven off about the paper, which appeared like ſplinters (ſee exp. 18.); ſome of them were almoſt one-tenth of an inch long, and ſome of them about a third or a fourth part of the diameter of the wire in breadth, and very thin: after the ſeventh ſtroke it was ſhortened ſeven-ſixteenths of an inch: the wire was one hundred and ſeventieth of an inch thick.

“ 33. Repeating exp. 31. again with the ſame ſize and length of wire, and the ſame battery charged the ſame, in order to obſerve the method of the wire ſhortening, having fixed an inſulated gage parallel to and about a quarter of an inch diſtant from it: after the firſt ſtroke, which made the wire fairly red, (it being fixed at one end, that the ſhortening might appear all at the other, which was held ſo as either to contract or dilate), I obſerved that it ſhortened conſiderably as it cooled; repeating the ſtroke, it did the ſame, and ſo on till it was melted, which was by the eighth ſtroke, as before. At the inſtant that the ſtroke paſſed thro' the wire it appeared to dilate a little, and after it was at its hoteſt, it gradually contracted after every ſtroke as it cooled, about one-ſixteenth of an inch each time; the dilating was ſo very little, as to bear but a very ſmall proportion to its contraction, and ſometimes it was doubtful whether or not it did dilate at all; but after all the obſervations it appeared oftener as if it did dilate, than as if it did not.

34. “ The ſame 48 feet, negatively charged to a little more than four grains, melted three inches of ſteel wire one hundred and ſeventieth of an inch thick, the ſame as the poſitive charge did in exp. 30.

“ 35. The ſame battery of 48 feet of coated ſurface, charged to a little more than eight grains, melted three inches of ſteel wire one-hundredth of an inch thick. This is very nearly in proportion to exp. 27. but here the charge was negative, and the fuſion was the moſt pleaſing of any I have hitherto had; probably owing to the charge, by chance, happening to be ſo well adjuſted as to be exactly ſufficient to melt the wire and no more: it held hot the longeſt, and the fuſed metal ran into the largeſt globules: probably the

length

length of the time that the heat continued, was owing to the charge being juſt ſufficient, and to the ſize of the lumps that the fuſed metal formed itſelf into.

"36. A repetition of exp. 1. with twelve inches of ſteel wire, one-hundredth of an inch thick, but with this difference, that as then I uſed only nine bottles, containing about 16 ſquare feet of coated ſurface charged to 32 grains, I here uſed 18 bottles containing about 32 ſquare feet of coating charged to only 16 grains. This was done, to obſerve the progreſs of the deſtruction of the wire, as in exp. 32, as well as to prove the ſimilarity of the effect. The wire being the ſame ſize, ſort of metal, and length, as recited juſt above; the firſt ſtroke made it fairly red-hot the whole length of it with ſmoke and ſmell, changed its colour to a kind of copperiſh hue, and ſhortened it conſiderably; the ſecond ſtroke made it of a fine blue, but it did not appear red, and ſhortened it more; at the third ſtroke, it became zigzagged, many radii were very viſible at the bendings, and continued to ſhorten till the eleventh ſtroke, when one of the bottles in the ſecond row of the battery was ſtruck through: the fracture was covered over with common cement, its place ſupplied by changing place with one in the third row, ſuppoſing the mended one to be the weakeſt; and thus, with the battery in this ſtate, I made the twelfth ſtroke, which ſeparated the wire, as in exp. 1. but this wire was ſhortened only one inch.

"37. A charge of 48 feet to eight grains, ſent through three inches of copper wire one hundred and ſeventieth of an inch thick, ſeven times, made it zigzagged, but not much ſhorter; the eighth ſtroke ſeparated it at one end, cloſe to the forceps which held it, but it did not appear to be made ſenſibly red-hot at all, notwithſtanding it muſt have been often ſo at the place where it was melted: which ſpace was ſo very ſmall as barely to be perceptible, like as when a point is ſet upon any flat ſurface of iron, and a ſtroke from a pound phial being ſent through, both the point and the flat ſurface where the point reſted, if examined with a magnifying glaſs, will be found to have been melted; and a ſpeck may be ſeen; but the redneſs of the metal will ſcarcely be viſible.

"38. A charge of 48 feet, to 16 grains, was ſent through ſix inches of lead wire one-fiftieth of an inch thick, which melted it into many pieces.

"39. A charge of 48 feet, to 15 grains, was ſent through ſix inches of wire like the laſt, which did not ſeparate it, but made it ſmoke.

"40. A charge like the laſt was ſent through the laſt piece of wire a ſecond time; which melted it into ſeveral pieces.

160
Lead more eaſily deſtructible than any other metals.

"The law by which wires reſiſt deſtruction, in proportion to the thickneſs of the wire, does not ſeem to be ſo equable, by much, in the lead as in the ſteel wire. For a charge of four grains, in exp. 34. melted three inches of lead wire one ſixty-ſixth of an inch thick: but it took a charge of about three times that power to deſtroy three inches of lead wire one-fiftieth of an inch thick; which is about double the quantity of metal in the ſame length as in that of one ſixty-ſixth of an inch thick. Thus it is eaſy to find, what different reſiſtance a wire of any of the foregoing metals, of equal ſize and length, will make to the electrical ſtroke or to lightning.

"The length of the electric circuit, in which the different wires were placed, in the foregoing experiments, from the neareſt part of the inſide to the near part of the outſide of the battery, excluſive of the length of the ſaid wires, was about eight feet.

"Notwithſtanding the eaſy deſtruction of the lead wire by the electrical ſtroke, it ſeems greatly to be doubted, whether any thunder ſtrokes happen in any place whatever, ſtrong enough to deſtroy a ſtrip of lead four inches broad and of the thickneſs of about eight pounds to the foot. Whence it may be preſumed, that ſuch a ſtrip of lead may be perfectly ſafe for conductors through buildings of any kind whatever: as it is not much ſubject to decay in any common expoſure.

161
Violent plofionf an elect battery.

"41. Two gentlemen coming in to ſee a piece of wire melted by electricity, I proceeded to ſhow it them, by fixing 12 inches of ſteel wire one-hundred and ſeventieth of an inch thick, in the forceps, and then (ſuppoſing the electrometer and all other things ready placed) to charge the battery, but the electrometer did not move; nevertheleſs I continued charging as I ſuppoſed; but ſtill the electrometer remained as it was, although I had been charging much longer than would have been neceſſary, contrary to my deſign, which was to take a ſmall wire, that a ſmall charge might be ſufficient. Having been charging a long time, I left off to look about the apparatus, in order to ſee if any thing was not right: as I was looking, I found there was no communication to the electrometer, and heard a ſmall crackling in the battery, which convinced me that it was charged. Accordingly I made the diſcharge, expecting nothing unuſual; but the wire was diſperſed ſeemingly in a very violent manner. The report was ſo very loud that our ears were ſtunned, and the flaſh of light ſo very great, that my ſight was quite confuſed for a few ſeconds. The ſingularity of the appearances attending this experiment led me to inſert it."

162
Milner's account the Ley phial.

Though from what has been ſaid under ſection VI. the direction of the electric fluid *outwards* from a body poſitively electrified, and inwards from one negatively ſo, ſeems to be ſufficiently aſcertained, yet ſome experiments related by Mr Nicholſon in the laſt volume of the Philoſophical Tranſactions, which ſeem to militate againſt this doctrine, require a particular conſideration; and for this reaſon we ſhall here not only give an account of theſe, but of ſome others made on the ſubject of excitation, and the ſtate of a charged phial in general, which ſeem to throw ſome light upon the ſubject. Mr Milner, who has been at great pains to inquire into this matter, makes the following obſervations:

"I. In the charged phial, when the inſide has either kind of electricity communicated to it, the outſide is found to poſſeſs a contrary power. It appears alſo from the preceding experiments, that either kind of electricity always produces the other on any conducting ſubſtance placed within the ſphere of influence. And as the ſame effect is alſo produced on electrics themſelves, in the ſame ſituation, and as ſome portion of the air ſuppoſing no other ſubſtance to be near enough, muſt be unavoidably expoſed to ſuch influence, it neceſſarily follows, that neither power can exiſt without the other; and therefore, in every poſſible caſe, poſitive and negative electricity are inſeparably united.

"II. A phial cannot be fully charged, by which the outſide acquires a contrary electricity, unleſs the external coating has a communication by ſome conductor with the earth. In the ſame manner, a full charge of the contrary electricity cannot readily be procured in theſe experiments without a ſimilar communication.

"III. In both caſes the interpoſition of an electric body between the contrary powers is abſolutely neceſſary. In one caſe that body is glaſs, in the other it is air; and the experiment will not ſucceed in either, unleſs both the glaſs and the air be tolerably free from moiſture.

"IV. It appears from the 18th experiment, that the influence of electricity acts in the ſame manner through glaſs as it does through the air, and produces a contrary power in both caſes.

"V. A communication of the electric matter is more eaſily made through the fluid yielding ſubſtance of the air than through glaſs; which is ſo hard and ſolid a body, as to require a very conſiderable degree of power to ſeparate its component particles: this, however, ſometimes happens, and a hole is made thro' the glaſs itſelf, without deſign, in attempting to charge a very thin phial as high as poſſible, in the moſt favourable ſtate of the atmoſphere.

"VI. A conducting body receives the ſtrongeſt charge of the contrary electricity, in theſe experiments when it is brought as near as poſſible to the electric power, without being within the communicating diſtance. And it is well known that the thinneſt phial, if it be ſtrong enough to prevent a communication between the two ſurfaces, will always receive the higheſt charge.

"VII. The electricity of the external ſurface of the charged phial cannot be deſtroyed, ſo long as the internal ſurface remains in force, and continues to exert its influence through the glaſs; becauſe this influence was the cauſe of the contrary electricity on the external ſurface, and muſt therefore preſerve it.

"VIII. If part of the courſe which the electric matter takes in diſcharging a phial be through the air, a ſmall part of the charge will always remain; becauſe the whole of the redundancy on one ſurface is not capable of forcing a paſſage through the reſiſting medium of the air, in order to ſupply the deficiency on the other ſurface. But if every part of the circuit, from the internal to the external coating, conſiſts of the beſt conductors, and if the coated ſurfaces be nearly equal, and directly oppoſite to each other, the phial will then appear to have retained no part of the charge, ſo far as it is covered with tin-foil; but the parts of it above the coating on both ſides will, however, ſtill retain the contrary electricities, after the circuit has been completed (G). A reſidue of the charge may alſo be obſerved in every other inſtance of electrification, in which the degree of electricity is ſufficient to force a communication between the electrified body and a conductor not inſulated, through a ſmall portion of the ai: and if the experiment be carefully made, it will appear, that the whole of the redundancy is not capable of paſſing through the reſiſting intermediate air, in any caſe, and therefore a part of the charge muſt always remain. This may be conveniently ſhown by uſing a well excited electrophorus of about five inches diameter, the metal cover of which may be ſo ſtrongly electrified, as to force a communication through the air, to any good conductor not inſulated, at the diſtance of three quarters of an inch. After this, a ſecond communication much weaker than the firſt may be made at the diſtance of about the twelfth-part of an inch, which is the reſidue of the charge, or rather a part of it: for if the ſecond communication be carefully made through the air, without touching the cover, it will be found ſtill to have retained enough of the firſt charge to electrify a pair of vertical needles.

Miſcellaneous Experiments.

"As it appears from this view, that both theſe caſes are ſimilar in ſo many remarkable particulars, it follows, that they are eſſentially the ſame, notwithſtanding they differ in the degree of power and ſome other circumſtances, which may alter the form of an experiment without changing its nature. It is apprehended, therefore, that the above mentioned diſtinction will not only appear to be unneceſſary, but alſo that either power cannot poſſibly exiſt without the other, as it has been ſhown under the firſt particular, that poſitive and negative electricity were inſeparably united. But here it will be proper to examine more particularly the nature of charged glaſs.

163
A phial is not brought to its natural ſtate by being diſcharged.

"1. When a plate of coated glaſs has been charged, and the circuit between the coatings has been completed, by the mediation of a good conducting ſubſtance, no part of the coated ſurface is ſuppoſed to retain any part of the charge; but, according to the commonly received doctrine, the whole of it is ſaid to be diſcharged; or in other words, to be brought into its natural ſtate. This, however, is not really the caſe, as will evidently appear from the following experiment; the deſign of which is to ſhow the effects produced by charging and diſcharging a plate of glaſs.

"2. Let the middle of a piece of crown window-glaſs, ſeven inches ſquare, be placed between two circular plates of braſs, about the 16th part of an inch thick, and five inches in diameter. In order to enable theſe plates to retain a greater degree of power, it will be proper to terminate each of them with a round bead the third part of an inch thick; and the whole of the bead ſhould be formed on one ſide of the plate, that the other ſide may remain quite flat, and apply well to the ſurface of the glaſs. Let the whole be inſulated:

---

"(G) The whole remainder of the charged phial muſt not, however, be aſcribed to the cauſe above mentioned: for after taking away that part of it belonging to the coated ſurface, which could not force a paſſage through the air, if the phial be allowed to ſtand a ſhort time on the table, the coated ſurface will again gradually acquire ſome power, which muſt be derived from the charge of the phial above the coating. Another ſource of the reſiduum will appear in the next experiment."

Miſcellaneous Experiments

lated about four inches above the table, and in an horizontal poſition, by faſtening one end of a cylindrical piece of ſome good inſulating ſubſtance to the middle of the under plate, the other end of it being fixed in any convenient ſtand. Let a like inſulating ſtem be faſtened to the middle of the upper plate. Let a braſs chain, which may eaſily be removed, reach from the under plate to the table. In the laſt place, bend a piece of braſs wire into ſuch a ſhape that it may ſtand perpendicularly on the upper plate; and let the upper extremity of this wire be formed into an hook, that it may be removed at any time by the aſſiſtance of a ſilk ſtring, without deſtroying the inſulation of the plate.

" 3. The glaſs being thus coated with metal on both ſides, and having alſo a proper communication with the table, will admit of being charged; and both coatings may be ſeparated from the glaſs, and examined apart, without deſtroying the inſulation of either: for the upper coating may be ſeparated by the means of its own proper ſtem; and the under coating may be ſeparated by taking hold of the corners of the glaſs, and lifting the glaſs itſelf. As glaſs readily attracts moiſture from the atmoſphere, it will therefore be neceſſary to warm it in the beginning, and to repeat it ſeveral times in the courſe of the experiment, unleſs the air ſhould be very dry.

" 4. Excite a ſmooth glaſs tube, of the common ſize, by rubbing it with ſilk, and apply it repeatedly to the bent wire until the glaſs be well charged. Then remove the chain, which reaches from the lower plate to the table, and alſo the charging wire from the upper plate, by laying hold of its hook with a ſilk ſtring. It neceſſarily follows, from conſidering the quality of the power employed in the preſent caſe, that the upper ſurface of the glaſs, together with the upper coating, muſt be electrified poſitively; and that the under ſurface and coating muſt be electrified negatively: but as it is deſigned in this experiment to examine the powers of charged glaſs, that no virtue may be imputed to the glaſs but what really belongs to it, let both coatings be ſeparated from it; and after they have been brought to their natural ſtate, by touching them with a conducting body not inſulated, let the glaſs be replaced between them; and whatever effects may now be produced, muſt be aſcribed ſolely to the powers of the charged glaſs. On bringing a finger near the upper coating, a ſmall electrical ſpark will appear between that coating and the finger, attended with a ſnapping noiſe. Apply a finger in the ſame manner to the under coating, and the ſame thing will happen. This effect cannot be produced twice, by two ſucceeding applications to the ſame coating; but it may be repeated ſeveral hundred times over, in a favourable ſtate of the atmoſphere, by alternate applications to the two coatings; and the powers of the glaſs will be thus gradually weakened.

" 5. This part of the experiment may be explained, by obſerving, that the contrary electricities have a natural tendency to produce, and to preſerve each other, on the oppoſite ſides of a plate of glaſs; and therefore, the increaſe or decreaſe of power, on either ſurface, muſt be regulated by the increaſe or decreaſe of the contrary power on the other ſide: and as in charging a plate of glaſs poſitively, no gradual addition of electric matter can be made to the upper ſurface, without a proper conveyance for a proportionable part to paſs away from the lower ſurface; ſo in this method of uncharging it, the electric matter cannot be gradually taken away from the upper ſurface, without adding a proportionable part to the under ſurface: one operation is the reverſe of the other, and ſo are the effects; one caſe being attended with an increaſe and the other with a decreaſe of power.

" 6. Let the glaſs be again fully charged, and after bringing both coatings to their natural ſtate as before, let the glaſs be replaced between them; and on touching the upper coating with a finger, and then ſeparating it from the upper and poſitive ſurface of the glaſs by the inſulating ſtem, this coating will acquire a weak negative power, which will be ſufficient to produce a ſmall ſpark while the glaſs is in full force, though after the power of the glaſs has been reduced, it will give little or no ſpark: but, in both caſes, on touching the coatings alternately two or three times, the negative power of this coating, when ſeparated from the poſitive ſurface of the glaſs, will be ſo conſiderably increaſed, as to produce ſtrong negative ſparks.—This effect may now be repeated ſeveral times, by only touching the upper coating, but the ſparks will grow weaker every time; and they may be reſtored again to nearly their former ſtrength, by alternate applications to both coatings, as before. The ſame things will alſo happen to the under coating, in the ſame circumſtances; but with this difference, that the power of the under coating, on being ſeparated from the under and negative ſurface of the glaſs, will be poſitive. And thus a long ſucceſſion of both poſitive and negative ſparks may be produced in favourable weather; or at any time by keeping the glaſs moderately warm.

" 7. It appears from this part of the experiment, that each of the ſurfaces of the charged glaſs has a power of producing a contrary electricity in the coating in contact with it, by a momentary interruption of the inſulation. It neceſſarily follows in producing theſe effects, that more electrical matter muſt have paſſed away from the upper coating, at the time of touching it, than the ſame coating could receive from the upper ſurface of the glaſs; and therefore, the upper coating, by loſing ſome of its natural quantity, will be negatively electrified: and alſo, that more electric matter muſt have been added to the under coating at the time of touching it, than the under ſurface of the glaſs could receive from it; and therefore the under coating, by receiving ſome addition to its natural quantity, will be poſitively electrified. It appears further, that the greateſt degree of this influential power, which may be conſiſtent with the circumſtances of the caſe, will be produced in either coating, by taking care at the ſame time to bring the oppoſite coating into a like ſtate of influential electricity: and thus it is evident, that the influential powers of the two coatings have the ſame relation to each other as the contrary powers of the glaſs itſelf, and will therefore always increaſe or decreaſe together.

" 8. The glaſs being again well charged as at firſt, let a braſs wire bent in the form of a ſtaple be brought into contact with the upper and lower coating at the ſame time. By this the common diſcharge will be made: but the equilibrium of the coated glaſs will be

only

Miſcellaneous Experiments.

only reſtored in part; for a conſiderable degree of attraction will happen at the ſame time between the upper coating and the glaſs, which has frequently been ſtrong enough to lift a piece of plate-glaſs weighing ten ounces (H). Neither coating will now ſhow the leaſt external ſign of electricity while it is in contact with the glaſs; but on ſeparating either of them from it, if care be taken to preſerve their inſulations, the upper coating will be ſtrongly electrified negatively, and the under coating will be ſtrongly electrified poſitively. Let then both coatings be brought to their natural ſtate, by touching them when ſeparated from the glaſs, with a conducting body not inſulated, and let the glaſs be replaced between them as before. In this ſtate of things, on touching the upper coating only, and ſeparating it from the glaſs, it will not be capable of giving any ſpark; but on touching the coatings alternately five or ſix times, it will then give a weak ſpark; and this may now be repeated ſeveral times by only touching the upper coating: but on a ſecond application of the bent wire to both coatings at the ſame time, a ſecond diſcharge may be perceived, though much weaker than the firſt, and the coatings will be again brought into the ſame electrical ſtate as immediately after the firſt diſcharge. This may frequently be repeated; and a conſiderable number of ſtrong negative ſparks may be taken from the coating when it is ſeparated from the poſitive ſurface of the glaſs. If the glaſs in replacing it between the two plates be turned upſide down, the electrical powers of both coatings will be changed by the next application of the diſcharging wire to complete the circuit; and a ſucceſſion of ſtrong poſitive ſparks may be taken from the coating when it is ſeparated from the negative ſurface of the glaſs.

"9. It appears from this part of the experiment, that the coated part of the charged glaſs was not brought into its natural ſtate by completing the circuit between the coatings; but that it ſtill retained a degree of permanent electricity; that the powers of both coatings were actually changed at the time of the firſt diſcharge; and that a ſucceſſion of the ſame powers may be produced in the coatings, without renewing the leaſt application of electricity to the glaſs itſelf.

"10. The whole quantity of electric matter added to the glaſs in charging it, is evidently diſtinguiſhed into two parts in this experiment. The firſt part, which is by far the moſt conſiderable, appears to have been readily communicated from one ſurface of the glaſs to the other, along the bent wire, when it was firſt brought into contact with both coatings at the ſame time. The ſecond part of the charge appears to be more permanent, and remains ſtill united with the glaſs, notwithſtanding the circuit has been completed (I). This permanent electricity, as well as the other, muſt be poſitive on the upper ſurface, and negative on the lower ſurface; becauſe, in the preſent experiment, the charge was given by a ſmooth glaſs tube excited with a ſilk rubber. Now, the influence of the oppoſite and permanent powers on the different ſides of the glaſs (each ſide having a tendency to bring the coating in contact with it into a ſtate of electricity contrary to its own) muſt aſſiſt each other, in cauſing part of the electric matter naturally belonging to the upper coating to paſs away from it to the under coating, along the diſcharging wire, and at the ſame time the ſurcharge to paſs the ſame way. The upper coating, therefore, by loſing ſome part of its natural quantity, muſt be negatively electrified; and the under coating, by receiving an addition to its natural quantity, muſt be poſitively electrified. The whole quantity of electric matter, which the influence of the permanent electricity of the glaſs is capable of taking from one coating and of adding to the other, bears but a ſmall proportion to the whole charge: and therefore the ſecond and every ſubſequent diſcharge muſt be conſiderably weaker than the firſt.

"11. It appears from ſeveral of the preceding experiments, that a conſiderable degree of influential power may be produced at ſome diſtance by an electric in full force; and therefore a ſmall excited body of a cylindrical ſhape was ſufficient to anſwer that purpoſe: but when the excited electric has been ſo far weakened that it cannot communicate its own power, nor produce this influential power in any body, unleſs it be brought very near or in contact with it, bodies of a cylindrical form muſt then act to great diſadvantage, and a ſmall degree of power only can be produced; becauſe the ſtrength of the influential electricity in this caſe will be in proportion to the ſurfaces of the electric and conducting bodies, which are brought near together, or in contact with each other; and therefore a plate of glaſs in the ſame circumſtances, whether its permanent power be derived from excitation or communication, is enabled from its ſhape to produce a conſiderable degree of the influential powers in the coatings in contact with it.

164
Hypotheſis concerning the electrophorus.

"12. It appears from this experiment, that the ingenious profeſſor Volta's electrophorus is, in reality, a reſinous plate charged with permanent electricity by friction: and becauſe there is a leſs diſpoſition in a body of this kind to attract moiſture from the atmoſphere than there is in glaſs; it will retain the power better, and conſequently be the longer capable of producing a contrary electricity in the inſulated metal cover. If it ſhould be thought neceſſary to ſupport this obſervation by a direct experiment, it may eaſily be done by making a thin flat plate of any reſinous electric ſubſtance, and larger than the inſulated cover, but without faſtening a

---

"(H) The whole of this effect muſt not be aſcribed to the attraction of electricity. Perhaps the paſſage of electric matter between the coating and the glaſs may help to exclude the air; and then the attraction of coheſion, and the preſſure of the external air both above and below, may be ſuppoſed to have the moſt conſiderable ſhare in producing this effect.

"(I) Some new terms ſeem to be wanted in order to expreſs with preciſion the different parts of the charge. And if that part of it which cannot be deſtroyed by completing the circuit, ſhould be called *the permanent part of the charge*, or more ſimply *the charge*: then might the other part, or that which may be deſtroyed by completing the circuit, be named the *ſurcharge*.

a coating to either ſurface; and then, whether this plate be charged by excitation or communication, one of its ſides will be poſitive and the other ſide negative; and a ſucceſſion of poſitive ſparks may be produced on the negative ſide, and of negative ſparks on the poſitive ſide, by a proper application of the inſulated metal cover. It will be alſo found, that this reſinous plate cannot be well charged, either by excitation or communication, unleſs a coating of ſome conducting matter ſhould be kept in contact with the under ſurface; and it ſhould alſo have ſome communication with the floor.

165
How to charge a phial without friction.

“ 13. It has been very properly recommended to uſe a particular kind of rubber, and to attend to the ſtate of it, in order to excite glaſs well; but it will not be neceſſary to pay the leaſt regard to theſe circumſtances in the following experiments, in which a method will be ſhown of charging a ſmall phial and a plate of glaſs at the ſame time, by a gradual accumulation of power; that power being entirely derived from the glaſs itſelf, and with no other degree or kind of friction than is neceſſarily connected with the form of the experiment.

“ 14. Place a circle of tin-foil five inches in diameter on the table, between a ſoft piece of baize and the middle of the ſame plate of glaſs that was uſed in the laſt experiment, which will thus be coated on the under ſide; and in order to preſerve a proper communication with this coating, let a fillet of tin-foil reach from it beyond the extremity of the glaſs. The ſame inſulated metal cover is to be uſed for the upper coating as before. Let a thin ounce-phial of glaſs be filled with braſs-filings, and coated with tin-foil on the outſide to about one inch from the top. Let a large braſs wire, the fifth part of an inch in diameter, paſs through the cork of the phial into the filings, about an inch of it being left above the cork, and let the upper extremity of this wire be well rounded. This experiment requires, that the whole conſtruction ſhould be well warmed at firſt; and it will be neceſſary to repeat it at proper intervals, unleſs the atmoſphere ſhould be very dry.

“ 15. Taking hold of the wire of the phial with one hand, let it be placed on the upper ſurface of the glaſs, and its bottom carried in contact over the middle of the upper ſurface, as far as the tin-foil coating reaches on the under ſide: and during this part of the operation, a finger of the other hand muſt be kept in contact with the fillet of tin-foil. Then lifting the phial by the wire with one hand, let it be placed on the inſulated metal cover, ſuſpended in the air with the other hand; and after ſhifting the hand from the wire to the coating, let the bottom of the phial be placed on the end of the tin-foil fillet. Place the inſulated metal cover on the middle of the glaſs, and touch it with a finger of one hand, while the other hand touches the tin-foil fillet. Now lift the inſulated cover by its ſtem, and bring the head of the cover in contact with the wire of the phial, and a very ſmall ſpark of light will appear between them. Let this be repeated in the ſame manner about 15 times, taking care to preſerve a proper communication between the coating and the floor. Then taking hold of the phial by the coating, let it be replaced on the inſulated cover while it is ſuſpended in the air; and after ſhifting the hand from the coating to the wire, let it be again placed on the middle of the glaſs, and let the bottom be again carried in contact over the middle of the glaſs, holding the wire in one hand, while the other has a proper communication with the tin-foil coating. Let the phial be again returned to the tin-foil fillet as before, and let the inſulated cover be applied repeatedly to the wire, immediately after every ſeparation from the glaſs; and a brighter ſpark, together with a weak ſnapping, will now attend each application, if it be carefully obſerved to touch the cover with one hand before every ſeparation, while the other hand reſts on the fillet of tin-foil. By proceeding in this manner, after the third application of the phial to the glaſs, a very weak ſhock will be felt in thoſe fingers which are uſed in completing the circuit of the glaſs; and after repeating two rounds more in the manner before mentioned, the phial will be fully charged. By applying the coating of the phial when it is in full force to the upper ſurface as before, the glaſs plate will get the greateſt power it is thus capable of receiving, and will then give a ſhock as high as the elbows. After this, on attempting to lift the inſulated cover, the glaſs itſelf will generally be lifted at the ſame time, with the tin-foil coating adhering to the under ſurface: but by continuing the ſeparations of the cover from the glaſs, a ſucceſſion of ſtrong negative ſparks may be produced by the influence of the upper ſurface; and by turning the glaſs over, and leaving the tin-foil coating on the baize, a ſucceſſion of ſtrong poſitive ſparks may be produced by the influence of the other ſide.

“ 16. This experiment may be performed more ſteadily by placing the glaſs, together with the tin-foil coating and baize, on a plate of metal about $\frac{1}{10}$th of an inch thick, and of the ſame ſquare as the glaſs. The whole may be faſtened together by two ſmall holdfaſts placed at the oppoſite corners, which will prevent the glaſs from being lifted. This plate of metal will be uſeful in another view; for after it has been ſufficiently warmed, by retaining heat well, it will help to keep the glaſs dry, and conſequently fit for uſe ſo much the longer. But when it ſhall be required to ſhow the contrary powers of the oppoſite ſides of the glaſs, it will be more convenient not to faſten the parts together, and the whole may be kept ſufficiently ſteady, by the operator's keeping down one corner of the glaſs with a finger, and by placing a proper weight on the oppoſite corner.

“ 17. The bottom of the phial cannot be carried in contact over the glaſs without producing ſome little degree of friction; from which the power in this experiment is originally derived. The cover will appear on examination to be electrified negatively after every ſeparation from the glaſs: but as it was touched in completing the circuit between the coatings before every ſeparation, it neceſſarily follows, that the cover can have only an influential electricity, and conſequently that the permanent power of the upper ſurface of the glaſs muſt be poſitive. The negative power of the cover is communicated to the wire of the phial, by which the inſide is electrified negatively and the outſide poſitively; and both theſe powers will increaſe with every application, becauſe the circumſtances of the phial are favourable to its charging. The phial muſt be inſulated every time it is required to ſhift the hand from the wire to the coating, or from the coating to the wire; for a- Ex- nts.

for without this precaution the phial would be diſcharged. By applying the outſide of the phial to the upper ſurface of the glaſs, in the manner above mentioned, the phial will be partly diſcharged on that ſurface: and though it muſt be therefore weakened, the power of the glaſs will be increaſed, and conſequently enabled to produce a proportionably ſtronger effect on the braſs cover, which by the next round of applications will give the phial a ſtronger charge than it had before. And thus a very ſmall degree of original power is firſt generated, and then employed in forming two different accumulations: and by making each of theſe ſubſervient to the increaſe of the other, the phial is at laſt fully charged, and the glaſs plate acquires ſuch a degree of the ſurcharge, as to give a pretty ſmart ſhock; and after that, it remains capable, by the influence of its permanent powers, of producing a ſucceſſion of poſitive and negative ſparks on the oppoſite ſurfaces.

“18. The contrary charge may be given to the phial by taking hold of the coating, and carrying the wire in contact over the middle of the upper ſurface of the glaſs, and by applying the power of the inſulated cover to the coating; for if the operation be conducted in every other reſpect in the ſame manner as before, then will the inſide be electrified poſitively, and the outſide negatively. The powers of the glaſs plate will be the ſame as they were in the former caſe.

“19 After the phial has been fully charged negatively, by the proceſs of the laſt experiment, let it be inſulated; and taking hold of the wire, let the bottom be held uppermoſt, and let the hand which holds it reſt on the fillet of tin-foil. Apply the inſulated cover to the glaſs, and after touching it with a finger of the other hand, ſeparate it from the glaſs; and on bringing it towards the coating of the phial, a ſtrong ſpark will paſs between them. After repeating this between 20 and 30 times, the powers of the phial will be deſtroyed; and by continuing the ſame operation, they will be inverted; for the inſide will be at laſt fully charged poſitively, and the outſide negatively.

“20. The ſame effect may be produced, by turning the glaſs over, and by repeatedly applying the influential electricity, produced on that ſide, to the wire of the phial.

“21. When the phial has been fully charged negatively, as in the laſt experiment, take hold of the coating of the phial with one hand, and while the other hand reſts on the tin-foil fillet, apply the wire to the middle of the upper ſurface of the glaſs, as far as the tin-foil coating extends on the other ſide. By this the powers of the glaſs plate will be changed.

“22 Another, and perhaps a better method of applying the phial, is to place the inſulated cover on the ſurface of the glaſs, and then holding the phial by the coating in one hand, to apply the wire to the cover, while the other hand touches the fillet of tin-foil; by which a ſhock will be given, and the ſame change of powers will be produced in an inſtant, which before took up ſome little time. On lifting the inſulated cover by its ſtem immediately after the ſhock, it will be negative, or have the ſame power as the inſide of the phial; but on replacing the cover, and completing the circuit of the glaſs plate, the ſurcharge will be deſtroyed; another ſhock will be felt; and the power of the cover, after the next ſeparation, will be poſitive, or contrary to that of the inſide of the phial. Apply this poſitive power to the wire of the phial as before; and after 15 applications, the powers of the phial will be deſtroyed: and by ſtill proceeding in the ſame manner, the powers of the phial will be changed, and the inſide will be fully charged poſitively and the outſide negatively, by 60 applications.

Miſcellaneous Experiments.

“23. Theſe effects may alſo be produced by a ſingle application of the coating of the phial to the other ſide of the glaſs plate; and by repeated applications of the influential electricity, produced on the ſame ſide, to the coating of the phial.

“24. If it were ſimply the object in this experiment to change the powers of the phial, the operation might then be conſiderably ſhortened, by completing the circuit of the phial, and conſequently deſtroying the whole ſurcharge: but it was intended to ſhow what effects might be produced, by oppoſing the contrary powers to each other; and by doing this it appears that either ſide of the glaſs plate can deſtroy the powers of the phial, and give it a contrary charge; that either ſide of the phial can alſo change the powers of the glaſs plate; and that the powers of the glaſs plate, thus inverted, can again deſtroy the powers of the phial, and give it a full charge of the contrary electricity.

“25. Here it may be obſerved, that, in ſome caſes, the quality of the power may be determined by obſervation alone. When the phial employed in the two laſt experiments has been fully charged, it may be known whether the inſide be poſitive or negative from the light which appears at the wire, or from the hiſſing noiſe which attends it: for when the phial has been fully charged poſitively, if the room be ſufficiently darkened, a bright luminous appearance may be ſeen, diverging in ſeparate rays to the diſtance of an inch, attended with an interrupted hiſſing noiſe; and both the light and the noiſe continue a very ſhort time. But when the phial is fully charged negatively, a weaker and more uniform light appears, which does not extend itſelf more than the ſixth part of an inch, and is attended with a cloſer and more uniform hiſſing; and this noiſe and light always continue longer than the former. Even poſitive and negative ſparks, paſſing between the inſulated cover and a finger, may be diſtinguiſhed from each other: for the poſitive ſparks are more divided, give leſs light, make a weaker ſnapping noiſe, and affect the finger leſs ſenſibly than the negative.

“26. The ſtrongeſt ſparks which can be produced in theſe experiments, are thoſe that paſs between the coating of the phial and the inſulated cover, when they poſſeſs contrary powers; but they will be more particularly vigorous, if the coating be poſitive and the inſulated cover negative.”

157 Mr Brookes's experiments on the Leyden-phial.

In Sect. vi. of this treatiſe we have related ſome experiments, tending to ſhow, that in the act of charging a phial with poſitive electricity, both became poſitive; and in the act of charging one negatively, both became negative. Theſe were inſerted in the former edition of this work; ſince which time Mr Brookes at Norwich has publiſhed a treatiſe; in which he not only adopts the opinion, but lays claim to it as his diſcovery, from ſome letters wrote in the year 1775. His experiments are extremely well adapted to elucidate the point intended; and the moſt remarkable of them are as follow:

Miſcellaneous Experiments.

“ 1. Let two pound phials be coated with tin-foil on their outſides, and filled to a convenient height with common ſhot. to ſerve as a coating within-ſide, as well as to keep a wire ſteady in the phials without a ſtopple in the mouth of them. Let each phial be furniſhed with a wire about the ſize of a gooſe-quill, and about ten inches long, and let each wire be ſharpened a little at one end, that it may the more eaſily be thruſt down into the ſhot, ſo as not to touch the glaſs any where at the mouth of the phials, yet ſo as to ſtand ſteadily in them. Let a metallic ball about ſix or ſeven eighths of an inch diameter be ſcrewed on at the other end of each wire: alſo let there be in readineſs a third wire, fitted up like thoſe for the phials, except that another ball of nearly the ſame ſize as the former may occaſionally be ſcrewed on over the ſharpened end of it. I ſay, inſtead of ſuſpending the phials from the prime conductor as before, let one of thoſe above deſcribed be charged at the prime conductor, and then ſet it aſide, but let it be in readineſs in its charged ſtate: then let the other be placed upon a good inſulating ſtand, and let the third wire alſo be laid upon the ſtand, ſo that its ball, or ſome part of the wire, may touch the coating of the phial. Let the ſharpened end of this wire project five or ſix inches over the edge of the ſtand: all of theſe being now placed cloſe to the edge of a table, hang a pair of cork balls on the ſharpened end of the wire, and make a communication from the prime conductor to the ball on the wire on the bottle: on working the machine, the ſharpened end of the wire will permit the bottle to be charged although it be inſulated; and if the wire be very finely pointed, the bottle may be charged nearly as well as if it were not inſulated: I ſay, on working the machine, the phial will charge, and the cork balls will immediately repel each other; but whilſt this phial is charging, take the firſt phial, which having been previouſly charged at the ſame prime conductor in the hand, and while the ſecond phial is charging, preſent the ball of the firſt to the cork balls, and they will all repel each other. This plainly proves that the outſide of the ſecond bottle is electrified plus at the time that it is charging, the ſame as the inſide of the firſt; and the inſide of both the bottles will readily be allowed to be charged alike, that is, plus or poſitive.

“ 2. Let the ſecond bottle in the laſt experiment be wholly diſcharged, and charge it again as before (the firſt bottle yet remaining charged), and whilſt it is charging, let the ball of the firſt approach the cork balls contiguous with the ſecond, and they will, as before, all repel each other: withdraw the ball of the firſt, and ſo long as the machine continues to charge the ſecond bottle higher, the cork balls will continue to repel each other; but ceaſe working the machine, and the cork balls will ceaſe to repel each other till they touch, and will then very ſoon repel each other again; then let the ball in the firſt phial approach the cork balls, and they will now be attracted by it, inſtead of being repelled as above, as in the laſt experiment. This alſo plainly ſhows, that both ſides of a Leyden phial are alike at the time it is charging; and at the ſame time evidently ſhows, that the difference of the two ſides does not take place till after the bottle is charged, or till the machine ceaſes to charge it higher.

Miſcell ous Ex ments.

“ 3. In this experiment, let both the former bottles be diſcharged, then let one of them be placed upon the inſulating ſtand. Let a ball be put on over the ſharpened end of the third wire, and let it be laid on the ſtand as before, ſo as to touch the coating of the phial: place the other phial on the table, ſo that its ball or wire may touch the ball on the third wire, or any part of the wire itſelf: make a communication from the ball on the wire of the firſt phial to the prime conductor: then, by working the machine, both bottles will ſoon become charged. As ſoon as they are pretty well charged, and before the machine ceaſe working, remove the ſecond phial from the third wire; after the ſecond phial is removed, ceaſe working the machine as ſoon as poſſible: take the third wire, with its two balls, off the ſtand with the hand, and lay it on the table, ſo that one of its balls may touch the outſide coating of the ſecond phial: remove the firſt phial off the ſtand, and place it on the table ſo as to touch the ball at the other end of the third wire; then, with an inſulated diſcharging rod, make a communication from the ball in one bottle to the ball in the other: if the outſide of the firſt phial be negative at the time it is charging, the inſide of the ſecond will be the ſame, and making the above communication would produce an exploſion, and both bottles would be diſcharged; but the contrary will happen, for there will be no exploſion, nor will either of the bottles be diſcharged, although there be a complete communication between their outſides, becauſe the inſide of them both will be poſitive. This is a proof, that conſidering one ſide of a phial to be poſitive and the other negative at the time they are charging, is a miſtake: as well as that, if any number of bottles be ſuſpended at the tail of each other, all the intermediate ſurfaces or ſides do not continue ſo.

“ 4. Here alſo let the apparatus be diſpoſed as in the laſt experiment, till the bottles are highly charged: then, with a clean ſtick of glaſs, or the like, remove the communication between the ball of the firſt phial and the prime conductor before the machine ceaſes working; then, with an inſulated diſcharging rod, make a communication from the outſide to the inſide of the firſt phial; a ſtrong exploſion will take place on account of the exceſs within-ſide, notwithſtanding they are both poſitive.

“ 5. This experiment being ſomething of a continuation of the preceding one, immediately after the laſt exploſion takes place, diſcharge the prime conductor of its electricity and atmoſphere; then touch the ball in the firſt phial with the hand, or any conducting ſubſtance that is not inſulated; then will the inſide coating of the firſt phial, which at firſt was ſo ſtrongly poſitive, be in the ſame ſtate as the outſide coating of the ſecond, having a communication by the hand, the floor, &c. with each other; that is, negative, if any thing can properly be called negative or poſitive that has a communication with the common ſtock: but a pair of cork balls that are electrified either plus or minus, will no more be attracted by either the inſide coating of the firſt phial or the outſide coating of the ſecond, than they will by the table on which they ſtand, or a common chair in the room, while they continue in that ſituation. Remove the aforeſaid communication from the ball of the firſt phial;

llane-
peri

phial; touch the ball in the ſecond, as before in the firſt, or diſcharge the bottle with the diſcharging rod, and the ball in the firſt bottle will immediately become negative: with a pair of cork balls, electrified negatively, approach the ball in the firſt phial, and they will all repel each other, or, if the cork balls be electrified poſitively, they will be attracted. All theſe circumſtances together ſeem fully to prove what has already been ſaid, not only that the inſide of the firſt phial, which was ſo ſtrongly poſitive, may be altered ſo as to become in the ſame ſtate as the outſide of the ſecond, without diſcharging the phial, or any more working the machine; but that it may be fairly changed, from being poſitively charged to being negatively charged. If a pair of cork balls are now hanged on to the ball of the wire in this phial, by the help of a ſtick of glaſs, they will repel each other, being negatively electrified. Make a communication from the outſide of the bottle to the table, and replace the communication from the prime conductor to the ball in the bottle; then, upon moderately working the machine to charge the bottle, the cork balls will ceaſe to repel each other till they touch, and will ſoon repel each other again by being electrified poſitively. Here the working the machine anew, plainly ſhows that the inſide of the firſt bottle, which was poſitive, was likewiſe changed to negative.

"In making electrical experiments, and in particular thoſe in which the Leyden phial is concerned (a number of which together compoſe moſt electrical batteries), a method to preſerve the bottles or jars from being ſtruck through by the electric charge is very deſirable; but I do not know that it has hitherto been accompliſhed. The number of them that have been deſtroyed in the foregoing, as well as in many experiments made long before, have led me to various conjectures to preſerve them: at the ſame time I have been obliged to make uſe of bottles inſtead of open mouthed jars. And as coating the former within-ſide is very troubleſome, it has put me on thinking of ſome method more eaſy, quicker, and equally firm and good, as with the tin-foil. With reſpect to the new method of coating, I failed; though ſomething elſe preſented itſelf rather in behalf of the former: therefore introducing the proceſs here will not be of very great uſe; unleſs in ſaving another the trouble of making uſe of the ſame method, or giving a hint towards the former, ſo as to ſucceed with certainty. My aim was, to find ſomething that ſhould be quick and clean, and not eaſy to come off with the rubbing of wires againſt it, and yet a good conductor. My firſt eſſay was with a cement of pitch, roſin, and wax, melted together; into which, to make it a good conductor, I put a large proportion of finely ſifted braſs filings. When this mixture was cold, I put broken pieces of it into the bottle, and warmed the bottle till it was hot enough to melt the cement in it ſo as to run, and cover the bottle within-ſide; then I coated the outſide with tin-foil as is commonly done, and now it was fit for uſe, or ready to be charged: to which I next proceeded; and I believe I had not made more than four or five turns of the winch before it ſpontaneouſly ſtruck through the glaſs with a very ſmall charge. I then took off the outſide coating, and ſtopped the fracture with ſome of my common cement, after which I put the coating on again; and, in as little time as before, it was ſtruck through again in a different place: and thus I did with this bottle five or ſix times; ſometimes it ſtruck through the cement, but it ſtruck through the glaſs in four different places. This made me conſider what it might be that facilitated the ſpontaneous ſtriking through the glaſs, and likewiſe what might retard it. I had long before thought that jars or bottles appeared to be ſtruck through with a much leſs charge, juſt after their being coated, or before they were dry, than when they had been coated long enough for the moiſture to be evaporated from the paſte with which I moſtly lay on the tin-foil; and could only conſider the dry paſte as a kind of mediator between the tin-foil and the glaſs, or, in other words, that the moiſture in the paſte was a better conductor, and more in actual contact with the glaſs, than the paſte itſelf when dry. And the coating the bottles with the heated cement, though long afterward, did not alter my former idea; for it appeared as if the hot cement, with the conducting ſubſtance in it, might be ſtill more in actual contact with the glaſs than the moiſture in the paſte. On theſe probabilities I had to conſider what might act as a kind of mediator more effectually than the dry paſte between the glaſs and the tin-foil. It occurred, that common writing-paper, as being neither a good conductor nor inſulator, might be ſerviceable by being firſt paſted ſmoothly to the tin-foil and left to dry. The paper then being paſted on one ſide, having the tin-foil on the other, I put them on the glaſs together with the tin-foil outward, and rubbed them down ſmooth. This ſucceeded ſo well that I have never ſince had any ſtruck through that were thus done, either common phials, or large bottles which contain near three gallons each, though ſome of the latter have ſtood in the battery in common uſe with the other a long time. And as I have never had one ſtruck through that has been prepared in this way, I am much leſs able at preſent to tell how great a charge they will bear before they are ſtruck through, or whether they will be ſtruck through at all."

Miſcellaneous Experiments.

159
Glaſs eaſily broke by electricity when covered with cement.

160
Nicholſon's experiments on excitation, &c.

In the laſt part of the Philoſophical Tranſactions for 1789, we have the following experiments by Mr Nicholſon, on an improved method of excitation, as well as the action of points, and the direction of the fluid in poſitive and negative electricity.

"1. A glaſs cylinder was mounted, and a cuſhion applied with a ſilk flap, proceeding from the edge of the cuſhion over its ſurface, and thence half round the cylinder. The cylinder was then excited by applying an amalgamed leather in the uſual manner. The electricity was received by a conductor, and paſſed off in ſparks to Lane's electrometer. By the frequency of theſe ſparks, or by the number of turns required to cauſe ſpontaneous exploſion of a jar, the ſtrength of the excitation was aſcertained.

"2. The cuſhion was withdrawn about one inch from the cylinder, and the excitation performed by the ſilk only. A ſtream of fire was ſeen between the cuſhion and the ſilk; and much fewer ſparks paſſed between the balls of the electrometer.

" 3. A roll of dry ſilk was interpoſed, to prevent the ſtream from paſſing between the cuſhion and the ſilk. Very few ſparks then appeared at the electrometer.

" 4. A metallic rod, not inſulated, was then interpoſed inſtead of the roll of ſilk, ſo as not to touch any part of the apparatus. A denſe ſtream of electricity appeared between the rod and the ſilk, and the conductor gave very many ſparks.

" 5. The knob of a jar being ſubſtituted in the place of the metallic rod, it became charged negatively.

" 6. The ſilk alone, with a piece of tin-foil applied behind it, afforded much electricity, though leſs than when the cuſhion was applied with a light preſſure. The hand being applied to the ſilk as a cuſhion, produced a degree of excitation ſeldom equalled by any other cuſhion.

" 7. The edge of the hand anſwered as well as the palm.

" 8. When the excitation by a cuſhion was weak, a line of light appeared at the anterior part of the cuſhion, and the ſilk was ſtrongly diſpoſed to receive electricity from any uninſulated conductor. Theſe appearances did not obtain when the excitation was by any means made very ſtrong.

" 9. A thick ſilk, or two or more folds of ſilk, excited worſe than a ſingle very thin flap. I uſe the ſilk which the milliners call Perſian.

" 10. When the ſilk was ſeparated from the cylinder, ſparks paſſed between them; the ſilk was found to be in a weak negative, and the cylinder in a poſitive, ſtate.

161 The ſilk flap the principal cauſe of excitation.

" The foregoing experiments ſhow that the office of the ſilk is not merely to prevent the return of electricity from the cylinder to the cuſhion, but that it is the chief agent in the excitation; while the cuſhion ſerves only to ſupply the electricity, and perhaps increaſe the preſſure at the entering part. There likewiſe ſeems to be little reaſon to doubt but that the diſpoſition of the electricity to eſcape from the ſurface of the cylinder is not prevented by the interpoſition of the ſilk, but by a compenſation after the manner of a charge; the ſilk being then as ſtrongly negative as the cylinder is poſitive; and, laſtly, that the line of light between the ſilk and cuſhion in weak excitations does not conſiſt of returning electricity, but of electricity which paſſes to the cylinder, in conſequence of its not having been ſufficiently ſupplied during its contact with the rubbing ſurface.

" 11. When the excitation was very ſtrong in a cylinder newly mounted, flaſhes of light were ſeen to fly acroſs its inſide, from the receiving ſurface to the ſurface in contact with the cuſhion, as indicated by the bruſh figure. Theſe made the cylinder ring as if ſtruck with a bundle of ſmall twigs. They ſeem to have ariſen from part of the electricity of the cylinder taking the form of a charge. This appearance was obſerved in a 9-inch and a 12-inch cylinder, and the property went off in a few weeks. Whence it appears to have been chiefly occaſioned by the rarity of the internal air produced by handling, and probably reſtored by gradual leaking of the cement.

162 State of the inſide of a cylinder during excitation determined.

" 12. With a view to determine what happens in the inſide of the cylinder, recourſe was had to a plate machine. One cuſhion was applied with its ſilken flap. The plate was 9 inches in diameter and $\frac{2}{10}$ths of an inch thick. During the excitation, the ſurface oppoſite to the cuſhion ſtrongly attracted electricity, which it gave out when it arrived oppoſite to the extremity of the flap: ſo that a continual ſtream of electricity paſſed through an inſulated metallic bow terminating in balls, which were oppoſed, the one to the ſurface oppoſite the extremity of the ſilk, and the other oppoſite to the cuſhion; the former ball ſhowing poſitive and the latter negative ſigns. The knobs of two jars being ſubſtituted in the place of theſe balls, the jar applied to the ſurface oppoſed to the cuſhion was charged negatively, and the other poſitively. This diſpoſition of the back ſurface ſeemed, by a few trials, to be weaker the ſtronger the action of the cuſhion, as judged by the electricity on the cuſhion ſide.

" Hence it follows, that the internal ſurface of a cylinder is ſo far from being diſpoſed to give out electricity during the friction by which the external ſurface acquires it, that it even greedily attracts it.

" 13. A plate of glaſs was applied to the revolving plate, and thruſt under the cuſhion in ſuch a manner as to ſupply the place of the ſilk flap It rendered the electricity ſtronger, and appears to be an improvement of the plate machine; to be admitted if there were not eſſential objections againſt the machine itſelf.

" 14. Two cuſhions were then applied on the oppoſite ſurfaces with their ſilk flaps, ſo as to claſp the plate between them. The electricity was received from both by applying the finger and thumb to the oppoſite ſurfaces of the plate. When the finger was advanced a little towards its correſpondent cuſhion, ſo that its diſtance was leſs than between the thumb and its cuſhion, the finger received ſtrong electricity, and the thumb none; and, contrariwiſe, if the thumb were advanced beyond the finger, it received all the electricity, and none paſſed to the finger. This electricity was not ſtronger than was produced by the good action of one cuſhion applied ſingly.

" 15. The cuſhion in experiment 12. gave moſt electricity when the back ſurface was ſupplied, provided that ſurface was ſuffered to retain its electricity till the rubbed ſurface had given out its electricity.

163 No adv tage g by rubl two ſid of the plate m chine.

" From the two laſt paragraphs it appears, that no advantage is gained by rubbing both ſurfaces; but that a well managed friction on one ſurface will accumulate as much electricity as the preſent methods of excitation ſeem capable of collecting; but that, when the excitation is weak, on account of the electric matter not paſſing with ſufficient facility to the rubbed ſurface, the friction enables the oppoſite ſurface to attract or receive it, and if it be ſupplied, both ſurfaces will paſs off in the poſitive ſtate; and either ſurface will give out more electricity than is really induced upon it, becauſe the electricity of the oppoſite ſurface forms a charge. It may be neceſſary to obſerve, that I am ſpeaking of the facts or effects produced by friction; but how the rubbing ſurfaces act upon each other to produce them, whether by attraction or otherwiſe, we do not here enquire.

" It will hereafter be ſeen, that plate machines do not collect more electricity than cylinders (in the hands of the electrical operators of this metropolis) do with half the rubbed ſurface; which is a corroboration of the inference here made.

" 16. When a cylinder is weakly excited, the appearances mentioned (par. 8.) are more evident the more rapid

rapid the turning. In this caſe, the avidity of the ſurface of the cylinder beneath the ſilk is partly ſupplied from the edge of the ſilk, which throws back a broad caſcade of fire, ſometimes to the diſtance of above 12 inches. From theſe cauſes it is that there is a determinate velocity of turning required to produce the maximum of intenſity in the conductor. The ſtronger the excitation, the quicker may be the velocity; but it rarely exceeds five feet of the glaſs to paſs the cuſhion in a ſecond.

“ 17. If a piece of ſilk be applied to a cylinder, by drawing down the ends ſo that it may touch half the circumference, and the cylinder be then turned and excited by applying the amalgamed leather, it will become very greedy of electricity during the time it paſſes under the ſilk. And if the entering ſurface of the glaſs be ſupplied with electricity, it will give it out at the other extremity of contact; that is to ſay, if inſulated conductors be applied at the touching ends of the ſilk, the one will give, and the other receive, electricity, until the intenſities of their oppoſite ſtates are as high as the power of the apparatus can bring them; and theſe ſtates will be inſtantly reverſed by turning the cylinder in the oppoſite direction.

“ As this diſcovery promiſes to be of the greateſt uſe in electrical experiments, becauſe it affords the means of producing either the plus or minus ſtates in one and the ſame conductor, and of inſtantly repeating experiments with either power, and without any change of poſition or adjuſtment of the apparatus, it evidently deſerved the moſt minute examination.

“ 18. There was little hope (par. 6.) that cuſhions could be diſpenſed with. They were therefore added; and it was then ſeen, that the electrified conductors were ſupplied by the difference between the action of the cuſhion which had the advantage of the ſilk, and that which had not; ſo that the naked face of the cylinder was always in a ſtrong electric ſtate. Methods were uſed for taking off the preſſure of the receiving cuſhion; but the extremity of the ſilk, by the conſtruction, not being immediately under that cuſhion, gave out large flaſhes of electricity with the power that was uſed. Neither did it appear practicable to preſent a row of points or other apparatus to intercept the electricity which flew round the cylinder; becauſe ſuch an addition would have materially diminiſhed the intenſity of the conductor, which in the uſual way was ſuch as to flaſh into the air from rounded extremities of four inches diameter, and made an inch and half ball become luminous and blow like a point. But the greateſt inconvenience was, that the two ſtates with the backward and forward turn were ſeldom equal; becauſe the diſpoſition of the amalgam on the ſilk, produced by applying the leather to the cylinder in one direction of turning, was the reverſe of what muſt take place when the contrary operation was performed.

“ Notwithſtanding all this, as the intenſity with the two cuſhions was ſuch as moſt operators would have called ſtrong, the method may be of uſe, and I ſtill mean to make more experiments when I get poſſeſſion of a very large machine which is now in hand.

“ 19. The more immediate advantage of this diſcovery is, that it ſuggeſted the idea of two fixed cuſhions with a moveable ſilk flap and rubber. Upon this principle, which is ſo ſimple and obvious, that it is wonderful it ſhould have been ſo long overlooked, I have conſtructed a machine with one conductor, in which the two oppoſite and equal ſtates are produced by the ſimple proceſs of looſening the leather-rubber, and letting it paſs round with the cylinder (to which it adheres) until it arrives at the oppoſite ſide, where it is again faſtened. A wiſh to avoid prolixity prevents my deſcribing the mechaniſm by which it is let go and faſtened in an inſtant, at the ſame time that the cuſhion is made either to preſs or is withdrawn, as occaſion requires.

Miſcellaneous Experiments.

“ 20. Although the foregoing ſeries of experiments naturally lead us to conſider the ſilk as the chief agent in excitation; yet as this buſineſs was originally performed by a cuſhion only, it becomes an object of enquiry to determine what happens in this caſe.

167
In what manner excitation is performed by a ſimple rubber without a ſilk flap.

“ 21. The great Beccaria inferred, that in a ſimple cuſhion, the line of fire, which is ſeen at the extremity of contact from which the ſurface of the glaſs recedes, conſiſts of returning electricity; and Dr Nooth grounded his happy invention of the ſilk flap upon the ſame ſuppoſition. The former aſſerts, that the lines of light both at the entering and departing parts of the ſurface are abſolutely ſimilar; and thence infers, that the cuſhion receives on the one ſide, as it certainly does on the other. I find, however, that the fact is directly contrary to this aſſertion; and that the oppoſite inference ought to be made, as far as this indication can be reckoned concluſive: for the entering ſurface exhibits many luminous perpendiculars to the cuſhion, and the departing ſurface exhibits a neat uniform line of light. This circumſtance, together with the conſideration that the line of light behind the ſilk in par. 8. could not conſiſt of returning electricity, ſhowed the neceſſity of farther examination. I therefore applied the edge of the hand as a rubber, and by occaſionally bringing forward the palm, I varied the quantity of electricity which paſſed near the departing ſurface. When this was the greateſt, the ſparks at the electrometer were the moſt numerous. But as the experiment was liable to the objection that the rubbing ſurface was variable, I paſted a piece of leather upon a thin flat piece of wood, then amalgamed its whole ſurface, and cut its extremity off in a neat right line cloſe to the wood. This being applied by the conſtant action of a ſpring againſt the cylinder, produced a weak excitation; and the line where the contact of the cylinder and leather ceaſed (as abruptly as poſſible) exhibited a very narrow fringe of light. Another piece of wood was prepared of the ſame width as the rubber, but one quarter of an inch thick, with its edges rounded, and its whole ſurface covered with tin-foil. This was laid on the back of the rubber, and was there held by a ſmall ſpring, in ſuch a manner as that it could be ſlided onward, ſo as occaſionally to project beyond the rubber, and cover the departing and excited ſurface of the cylinder without touching it. The ſparks at the electrometer were four times as numerous when this metallic piece was thus projected; but no electricity was obſerved to paſs between it and the cylinder. The metallic piece was then held in the hand to regulate its diſtance from the glaſs; and it was found, that the ſparks at the electrometer increaſed in number as it was brought nearer, until light appeared between the metal and the cylinder; at which time they became fewer the nearer it was brought, and at laſt ceaſed when it was in contact.

Miſcellaneous Experiments.

168 Concluſions from theſe experiments.

The following concluſions appear to be deducible from theſe experiments. 1. The line of light on a cylinder departing from a ſimple cuſhion conſiſts of returning electricity: 2. The projecting part of the cuſhion compenſates the electricity upon the cylinder, and by diminiſhing its intenſity prevents its ſtriking back in ſuch large quantities as it would otherwiſe do. 3. That if there was no ſuch compenſation, very little of the excited electricity would be carried off: And, 4. That the compenſation is diminiſhed, or the intenſity increaſed, in an higher ratio than that of the diſtance of the compenſating ſubſtance; becauſe if it were not, the electricity which has been carried off from an indefinitely ſmall diſtance, would never fly back from a greater diſtance and form the edge of light.

169 How to increaſe the intenſity of electricity to a great degree.

"22. I hope the conſiderable intenſity I ſhall ſpeak of will be an apology for deſcribing the manner in which I produce it. I wiſh the theory of this very obſcure proceſs were better known; but no conjecture of mine is worth mentioning. The method is as follows:

"Clean the cylinder, and wipe the ſilk.

"Greaſe the cylinder by turning it againſt a greaſed leather till it is uniformly obſcured. I uſe the tallow of a candle.

"Turn the cylinder till the ſilk flap has wiped off ſo much of the greaſe as to render it ſemitranſparent.

"Put ſome amalgam on a piece of leather, and ſpread it well, ſo that it may be uniformly bright. Apply this againſt the turning cylinder. The friction will immediately increaſe, and the leather muſt not be removed until it ceaſes to become greater.

"Remove the leather, and the action of the machine will be very ſtrong.

"My rubber, as before obſerved, conſiſts of the ſilk flap paſted to a leather, and the cuſhion is preſſed againſt the ſilk by a ſlender ſpiral ſpring in the middle of its back. The cuſhion is looſely retained in a groove, and reſts againſt the ſpring only, in ſuch a manner that by a ſort of libration upon it as a fulcrum, it adapts itſelf to all the irregularities of the cylinder, and never fails to touch it in its whole length. There is no adjuſtment to vary the preſſure, becauſe the preſſure cannot be too ſmall when the excitation is properly made. Indeed, the actual withdrawing of the cuſhion to the diſtance of $\frac{1}{10}$th of an inch from the ſilk, as in par. 2. will not materially affect a good excitation.

"The amalgam is that of Dr Higgins, compoſed of zinc and mercury. If a little mercury be added to melted zinc, it renders it eaſily pulverable, and more mercury may be added to the powder to make a very ſoft amalgam. It is apt to cryſtallize by repoſe, which ſeems in ſome meaſure to be prevented by triturating it with a ſmall proportion of greaſe; and it is always of advantage to triturate it before uſing.

"A very ſtrong excitation may be produced by applying the amalgamed leather to a clean cylinder with a clean ſilk: but it ſoon goes off, and is not ſo ſtrong as the foregoing, which laſts ſeveral days.

170 Effects of different cylinders excited in this manner.

"23. To give ſome diſtinctive criterions by which other electricians may determine whether the intenſity they produce exceeds or falls ſhort of that which this method affords, I ſhall mention a few facts.

"With a cylinder 7 inches diameter and cuſhion 8 inches long, three bruſhes at a time conſtantly flew out of a 3-inch ball in a ſucceſſion too quick to be counted, and a ball of $1\frac{1}{2}$ inch diameter was rendered luminous, and produced a ſtrong wind like a point. A 9 inch cylinder with an 8-inch cuſhion occaſioned frequent flaſhes from the round end of a conductor 4 inches diameter: with a ball of $2\frac{1}{3}$ inches diameter the flaſhes ceaſed now and then, and it began to appear luminous: a ball of $1\frac{1}{2}$ inch diameter firſt gave the uſual flaſhes; then, by quicker turning, it became luminous with a bright ſpeck moving about on its ſurface, while a conſtant ſtream of air ruſhed from it; and, laſtly, when the intenſity was greateſt, bruſhes of a different kind from the former appeared. Theſe were leſs luminous but better defined in the branches; many ſtarted out at once with a hoarſe ſound. They were reddiſh at the ſtem, ſooner divided, and were greeniſh at the point next the ball, which was braſs. A ball of $\frac{4}{10}$ths of an inch diameter was ſurrounded by a ſteady faint light, enveloping its exterior hemiſphere, and ſometimes a flaſh ſtruck out at top. When the excitation was ſtrongeſt, a few flaſhes ſtruck out ſideways. The horizontal diameter of the light was longeſt, and might meaſure one inch, the ſtem of the ball being vertical.

171 Surpriſi appeara on raiſi an elect cal kite.

"This laſt phenomenon is ſimilar to a natural event related by M. Loammi Baldwin*, who raiſed an electrical kite in July 1771 during the approach of a ſevere thunder-ſtorm, and obſerved himſelf to be ſurrounded by a rare medium of fire, which as the cloud roſe nearer the zenith, and the kite roſe higher, continued to extend itſelf with ſome gentle faint flaſhes. Mr Baldwin felt no other effect than a general weakneſs in his joints and limbs, and a kind of liſtleſs feeling; all which he obſerves might poſſibly be the effect of ſurpriſe, though it was ſufficient to diſcourage him from perſiſting in any farther attempt at that time. He therefore drew in his kite, and retired to a ſhop till the ſtorm was over, and then went to his houſe, where he found his parents and friends much more ſurpriſed than he had been himſelf; who, after expreſſing their aſtoniſhment, informed him, that he appeared to them (during the time he was raiſing the kite) to be in the midſt of a large bright flame of fire, attended with flaſhings: and that they expected every moment to ſee him fall a ſacrifice to the flame. The ſame was obſerved by ſome of his neighbours, who lived near the place where he ſtood.

"This fact is ſimilar to another obſerved by M. de Sauſſure on the Alps, and both are referable to my luminous ball with the ſecond kind of bruſh. The cloud muſt have been negative.

"With a 12-inch cylinder and rubber of $7\frac{1}{2}$ inches, a five-inch ball gave frequent flaſhes, upwards of 14 inches long, and ſometimes a 6 inch ball would flaſh. I do not mention the long ſpark, becauſe I was not provided with a favourable apparatus for the two larger cylinders. The 7-inch cylinder affords a ſpark of $10\frac{1}{2}$ inches at beſt. The 9-inch cylinder, not having its conductor inſulated on a ſupport ſufficiently high, afforded flaſhes to the table which was 14 inches diſtant. And the 12-inch cylinder, being mounted only as a model or trial for conſtructing a larger apparatus, is defective in ſeveral reſpects which I have not thought fit to alter. When the five-inch ball gives flaſhes, the cylinder is enveloped on all ſides with fire which ruſhes from the receiving part of the conductor. I

---

* Memo of the A rican A demy, Vol. I. p 257.

I never uſe points, but in a ſimple machine bring the conductor almoſt in contact with the cylinder. In this apparatus that cuſhion to which the rubber is not applied ſerves that purpoſe.

"24. Theſe marks exhibit the intenſity as deduced from ſimple electriſying. I will now mention the rate of charging, which was nearly the ſame in all the three cylinders.

"A large jar of 350 ſquare inches, or near $2\frac{1}{2}$ ſquare feet, with an uncoated varniſhed rim of more than four inches in height, was made to explode ſpontaneouſly over the rim. The jar, when broken, proved to be 0.082 inches thick on an average; and the number of ſquare feet of the ſurface of the cylinder which was rubbed to produce the charge of one foot, was, when leaſt, 18.03, and when moſt, with good excitation, 19.34. The great machine at Haarlem charges a ſingle jar of one foot ſquare by the friction of 66.6 ſquare feet, and charges its battery of 225 ſquare feet at the rate of 94.8 ſquare feet rubbed for each foot. The intenſity of electricity on the ſurface of the glaſs is therefore conſiderably leſs than $\frac{1}{4}$th of that here ſpoken of; but if we take the moſt favourable number 66.6 at the commencement of turning, and halve it on account of the unavoidable imperfection of a plate machine (as ſhown in par. 14.), it will be found, that the management applied to that machine would cauſe a cylinder to charge one ſquare foot by the friction of $33\frac{1}{3}$ ſquare feet. It muſt be obſerved, however, that M. Van Marum's own machine, conſiſting of two plates 33 inches diameter, has only half the intenſity, though he reckons it a very good one. This machine is about equal in abſolute power to my 9-inch cylinder, with its ſhort rubber; but it is near 30 times as dear in price. In all theſe deductions I omit the computations, for the ſake of brevity, and becauſe they are eaſily made. The data are found in the deſcription of the Teylerian machine, and its continuation publiſhed at Haarlem in the years 1785 and 1787.

"I ſhall here take the liberty of obſerving, that the action of the cylinder, by a ſimple cuſhion or the hand, which excited the aſtoniſhment of all Europe, in the memory of our cotemporaries, was firſt improved by the addition of a leathern flap; then by moiſtening the rubber; afterwards by applying the amalgam; and, laſtly, by the addition of a ſilk flap. Now I find by experiment, that we at preſent obtain upwards of 40 times the intenſity which the bare hand produces; and conſequently, that, ſince 18 times our preſent intenſity will equal the utmoſt we can now condenſe on ſtrong glaſs even in the form of a charge, we have a leſs ſtep to take before we arrive at that amazing power than our immediate predeceſſors have already made. My 9-inch cylinder, when broken, proved to be $\frac{1}{21}$ of an inch thick.

"25. Some of the luminous appearances with balls in the poſitive ſtate, have been ſlightly noticed as criterions of intenſity. I ſhall here add, that the eſcape of negative electricity from a ball is attended with the appearance of ſtraight ſharp ſparks with a hoarſe or chirping noiſe. When the ball was leſs than two inches in diameter, it was uſually covered with ſhort flames of this kind, which were very numerous.

"26. When two equal balls were preſented to each other, and one of them was rendered ſtrongly poſitive, while the other remained in connection with the earth, the poſitive bruſh or ramified ſpark was ſeen to paſs from the electrified ball: when the other ball was electrified negatively, and the ball, which before had been poſitive, was connected with the ground, the electricity (paſſing the ſame way according to Franklin) exhibited the negative flame, or denſe, ſtraight, and more luminous ſpark, from the negative ball; and when the one ball was electrified plus and the other minus, the ſigns of both electricities appeared. If the interval was not too great, the long zig-zag ſpark of the plus ball ſtruck the ſtraight flame of the minus ball, uſually at the diſtance of about $\frac{1}{3}$d of the length of the latter from its point, rendering the other $\frac{2}{3}$ds very bright. Sometimes, however, the poſitive ſpark ſtruck the ball at a diſtance from the negative flame. Theſe effects are repreſented in Plate CLXXVIII. fig. 86, 87, 88.

Miſcellaneous Experiments.

"27. Two conductors of three-quarters of an inch diameter, with ſpherical ends of the ſame diameter, were laid parallel to each other, at the diſtance of about two inches, in ſuch a manner as that the ends pointed in oppoſite directions, and were ſix or eight inches aſunder. Theſe, which may be diſtinguiſhed by the letters *P* and *M*, were ſucceſſively electrified as the balls were in the laſt paragraph. When one conductor *P* was poſitive, fig. 90. it exhibited the ſpark of that electricity at its extremity, and ſtruck the ſide of the other conductor *M*. When the laſt mentioned conductor *M* was electrified negatively, fig. 89. the former being in its turn connected with the earth, the ſparks ceaſed to ſtrike as before, and the extremity of the electrified conductor *M* exhibited negative ſigns, and ſtruck the ſide of the other conductor. And when one conductor was electrified *plus* and the other *minus*, fig. 91. both ſigns appeared at the ſame time, and continual ſtreams of electricity paſſed between the extremities of each conductor to the ſide of the other conductor oppoſed to it. In each of theſe three caſes, the current of electricity, on the hypotheſis of a ſingle fluid, paſſed the ſame way.

176
Of the diſpoſition of balls to receive electricity as their ſtems are long or ſhort.

"28. In drawing the long ſpark from a ball of four inches diameter, I found it of ſome conſequence that the ſtem ſhould not be too ſhort, becauſe the vicinity of the large prime conductor altered the diſpoſition of the electricity to eſcape: I therefore made a ſet of experiments, the reſult of which ſhowed, that the diſpoſition of balls to receive or emit electricity is greateſt when they ſtand remote from other ſurfaces in the ſame ſtate; and that between this greateſt diſpoſition in any ball, whatever may be its diameter, every poſſible leſs degree may be obtained by withdrawing the ball towards the broader or leſs convex ſurface out of which its ſtem projects, until at length the ball, being wholly depreſſed beneath that ſurface, loſes the diſpoſition entirely. From theſe experiments it follows, that a variety of balls is unneceſſary in electricity; becauſe any ſmall ball, if near the prime conductor, will be equivalent to a larger ball whoſe ſtem is longer.

177
Of the action of points.

"29. From comparing ſome experiments made by myſelf many years ago with the preſent ſet, I conſidered a point as a ball of an indefinitely ſmall diameter, and conſtructed an inſtrument conſiſting of a braſs ball of ſix inches diameter, through the axis of which a ſtem, carrying a fine point, was ſcrewed. When this ſtem

ſtem is fixed in the prime conductor, if the ball be moved on its axis in either direction, it cauſes the fine point either to protrude through a ſmall hole in its external ſurface, or to withdraw itſelf; becauſe by this means the ball runs along the ſtem. The diſpoſition of the point to tranſmit electricity may thus be made equal to that of any ball whatever, from the minuteſt ſize to the diameter of ſix inches. See fig. 92. *A*.

" 30. The action of pointed bodies has been a ſubject of diſcuſſion ever ſince it was firſt diſcovered, and is not yet well explained. To thoſe who aſcribe this effect to the figure of electric atmoſpheres, and their diſpoſition to fly off, it may be anſwered, that they ought firſt to prove their exiſtence, and then ſhow why the cauſe which accumulated them does not prevent their eſcape; not to mention the difficulty of explaining the nature of negative atmoſpheres. If theſe be ſuppoſed to conſiſt of electrified air, it will not be eaſy to ſhow why a current of air paſſing near a prime conductor does not deſtroy its effects. The opinion ſupported by the celebrated Volta and others, that a point is the coating to an infinitely ſmall plate of air, does not appear better founded: for ſuch a plate muſt be broken through at a greater diſtance only becauſe higher charged; whence it would follow, that points ſhould not act but at high intenſities I muſt likewiſe take notice, as a proof that the charge has little to do here, that if a ball be preſented to the prime conductor, at the ſame time that a point proceeds from the oppoſite ſide of the ball, the electricity will paſs by the point, though it is obliged to go round the ball for that purpoſe; but it can hardly be doubted, that whatever charge obtains in this caſe is on the ſurface of the ball next the conductor, and not on the remote ſide to which the electricity directs its courſe.

" 31. The pointed apparatus deſcribed (par. 29.) ſhows that the effect of points depends on the remoteneſs of their extremities from the other parts of the conductor. This leads to the following general law: *In any electrified conductor, the tranſition or eſcape of electricity will be made chiefly from that part of the ſurface which is the moſt remote from the natural ſtate.* Thus in the apparatus of the ball and ſtem, the point having a communication with the reſt of the whole conductor, conſtantly poſſeſſes the ſame intenſity; but the influence of the ſurrounding ſurface of the ball diminiſhes its capacity. This diminution is leſs the farther the ball is withdrawn, and conſequently the point will really poſſeſs more electricity, and be more diſpoſed to give it out when it is prominent than when depreſſed. The ſame explanation ſerves for negative electricity.

" 32. The effect of a poſitive ſurface appears to extend farther than that of a negative: for the point acts like a ball when conſiderably more prominent if it be poſitive than it will if negative.

" For the ſake of conciſeneſs, I paſs over many facts which have preſented themſelves in the courſe of my experiments on the two electricities, and content myſelf with obſerving, that there is ſcarcely any experiment made with the poſitive power, which will not afford a reſult worthy of notice, if repeated with the negative."

With regard to the direction of the electric fluid, we ſhall only farther take notice of two experiments, which have been thought to prove directly the paſſage of the fluid outward from the poſitive and inward to the negative ſide of the phial. Fig. 18. repreſents an electric jar, whoſe exterior coating is made up of ſmall pieces of tin-foil placed at a ſmall diſtance from each other. This jar is to be charged in the uſual manner, when ſmall ſparks of the electric fluid will paſs from one piece of tin-foil to the other, in various directions, forming a very pleaſing ſpectacle. The ſeparation of the tin-foil is the cauſe of this viſible paſſage of the fluid from the outſide to the table; and the experiment is ſimilar in appearance to that of the ſpiral tube mentioned in the foregoing ſection. If the jar be diſcharged by bringing a pointed wire gradually to the knob *I*, the unſealed part of the glaſs between the wire and knob will be agreeably illuminated with a crackling noiſe of the ſparks. If the jar be ſuddenly diſcharged, the whole outſide will be illuminated. The jar, in this experiment, muſt be very dry when uſed.

Plate CLXXI
178
Conſtru tion of j to ſhow courſe c the elect fluid.

Fig. 19. repreſents two jars, or Leyden phials, placed one over the other, by which various experiments may be made in order to elucidate the common theory. Bring the outſide coating of the bottle *A* in contact with the prime conductor, and turn the machine till the bottle is charged; then place one ball of the diſcharging rod upon the coating of *B*, and with the other touch the knob of the jar *A*, which will cauſe an exploſion; now place one ball of the diſcharger on the knob *A*, and bring the other ball to its coating, and you have a ſecond diſcharge. Again, apply one ball of the diſcharger to the coating of *B*, and carry the other to the coating of *A*, and it will produce a third diſcharge. A fourth is obtained by applying the diſcharger from the coating of *A* to its knob. The outer coating of the under jar communicating with the inſide of the under one, conveys the fluid from the conductor to the large jar, which is therefore charged poſitively: the upper jar does not charge, becauſe the inſide cannot part with any of its electric fluid; but when a communication is formed from the outſide of *A* to the inſide of *B*, part of the fire on the inſide of *A* will be conveyed to the negative coating of *B*, and the jar will be diſcharged. The ſecond exploſion is occaſioned by the diſcharge of the jar *A*; but as the outſide of this communicates, by conducting ſubſtances, with the poſitive inſide of the jar *B*, if the ball of the diſcharging rod remains for a little time after the diſcharge on the knob of *A*, part of the fire of the inſide of *A* will eſcape, and be replaced by an equal quantity on the outſide from the jar *B*, by which means *A* is charged a ſecond time; the diſcharge of this produces the third, and of *B* the fourth exploſion.

Fig. 20. is an electric jar, which ſerves to illuſtrate the contrary ſtates of the ſide of a Leyden phial while charging. *B B* is the tin-foil coating; *C* a ſtand which ſupports the jar; *D* a ſocket of metal, carrying the glaſs rod *E*, a bent braſs wire pointed at each end, and fixed at the end of the rod *G*; which rod is moveable in the ſpring tube *N* at pleaſure: that tube being fixed by a ſocket on the top of the glaſs rod *E*, the jar is charged by the inſide wire, which communicates with the different diviſions of the inſide coating by horizontal wires.

Ex-
m's

Place the jar to the conductor as uſual; and, when charging, a luminous ſpeck will appear upon the upper point of the wire at *F*, clearly ſhowing, according to the commonly received opinion, that the point is then receiving the electric fluid. From the upper ring of coating *B*, on the outſide of the jar, a fine ſtream or pencil of rays will at the ſame time fly off, beautifully diverging from the lower point of the wire *F* upon the bottom ring of the coating of the jar. When the appearances ceaſe, which they do when the jar is charged, let a pointed wire be preſented towards the conductor: this will ſoon diſcharge the jar ſilently; during which the point will be illuminated with a ſmall ſpark, while the upper point of the wire will throw off a pencil of rays diverging towards the upper ring of the coating.

Ma-
great
cal
ne.

We ſhall conclude this ſection with an account of ſome effects of the electrical fluid upon various elaſtic vapours. Theſe were tried to the greateſt advantage by Dr Van Marum with the great machine already mentioned: and for this purpoſe he uſed a cylindrical glaſs receiver five inches long and an inch and a quarter in diameter, into which different ſorts of elaſtic fluids were ſucceſſively inſerted, and were confined by quickſilver or water. To a hole made in the bottom of the inverted glaſs receiver an iron wire was faſtened, the external part of which communicated with a conductor, which being preſented to the prime conductor of the machine, received the ſparks from it. In this diſpoſition of the apparatus it evidently appears, that the ſparks paſſed through the elaſtic fluid contained in the receiver, by going from the inner extremity of the wire to the quickſilver or water in which the receiver was inverted. With this apparatus it was found, that dephlogiſticated air, obtained from mercurial red precipitate, loſt $\frac{1}{20}$th of its bulk; but its quality was not ſenſibly altered, as it appeared from examining it with the eudiometer. This experiment being repeated when the receiver was inverted in lime-water, and likewiſe in the infuſion of turnſole, there enſued no precipitation, no change of colour, nor any phlogiſtication of the air. On pouring out this air, the uſual ſmell of the electric fluid was perceived very ſenſibly.

Nitrous air was diminiſhed of more than the half of its original bulk; and in that diminiſhed ſtate, being mixed with common air, it occaſioned no red colour, nor any ſenſible diminution. It had loſt its uſual ſmell, and it extinguiſhed a candle. In paſſing the ſparks through the nitrous air, a powder is formed on the ſurface of the quickſilver, which is a part of that metallic ſubſtance diſſolved by the nitrous acid.

Inflammable air, obtained from iron and diluted vitriolic acid, communicated a little redneſs to the tincture of turnſole. The ſtream of electric fluid through this air appeared more red, and much larger, than in common air, being every where ſurrounded by a faint blue light.

The inflammable air, obtained from ſpirit of wine and vitriolic acid, was increaſed to about three times its original bulk, and loſt a little of its inflammability.

Fixed air, from chalk and vitriolic acid, was a little increaſed in bulk by the action of electricity; but it was rendered leſs abſorbable by water.

Miſcellaneous Experiments.

Vitriolic acid air, obtained from vitriolic acid and charcoal, was diminiſhed a little, and black ſpots were formed on the inſide of the glaſs receiver. Afterwards it was obſerved, that only one-eighth part of the electrified elaſtic fluid was abſorbed by water. It extinguiſhed a candle, and had very little ſmell.

Marine acid air ſeemed to oppoſe in great meaſure the paſſage of the electric fluid; ſince the ſparks would not paſs through a greater length than 2½th inches of this air. It was conſiderably diminiſhed, but the reſt was readily abſorbed by water.

Spathous air was neither diminiſhed, nor any other way ſenſibly altered, by the electric ſparks.

Alkaline air, extracted from ſpirit of ſal ammoniac, was at firſt almoſt doubled in bulk; then it was diminiſhed a little; after which it remained without any augmentation or diminution. It became unabſorbable by water, and by the contact of flame it exploded, like a mixture of inflammable air and a good deal of common air.

Common air was laſtly tried, and it was found to give a little faint redneſs to the tincture of turnſole; becoming at the ſame time ſenſibly phlogiſticated. The experiment was repeated thrice at different times, and in each time after the electrization it was examined by the admixture of nitrous air in Mr Fontana's eudiometer, and it was compared with the ſame air not electrified; the latter always ſuffering the greateſt diminution. In the firſt experiment the diminutions were $\frac{145}{500}$ and $\frac{175}{500}$; in the ſecond, $\frac{159}{500}$ and $\frac{194}{500}$; and in the laſt, $\frac{149}{500}$ and $\frac{178}{500}$.

See *Aerology*, n° 77.

On attempting to repeat Mr Cavendiſh's experiment,* in which he produced the nitrous acid by a mixture of pure with phlogiſticated air; inſtead of a ſyphon, the Doctor made uſe of a glaſs tube $\frac{1}{6}$th part of an inch in diameter, cloſed at one end, into which an iron wire, $\frac{1}{150}$th of an inch in diameter, had been inſerted: into this tube, filled with mercury, and fixed in a vertical poſition, was introduced the air with which the experiment was to be tried. The dephlogiſticated air was obtained from red precipitate, and had been thoroughly purified by alkaline ſalts, from any acid it might have contained. With a mixture of 5 parts of this and 3 of common air, the tube was filled to the height of 3 inches, to which was added $\frac{5}{12}$ths of an inch of lixivium, of the ſame kind with that uſed by Mr Cavendiſh. The reſult was, that, after tranſmitting through the tube a continued ſtream of the electrical fluid during 15 minutes, 2 inches of the air were abſorbed by the lixivium: more air being introduced into the tube till it was filled to the height of 3 inches, when it was again electrified. This proceſs was repeated till 8$\frac{3}{4}$ths inches of air had been abſorbed by the lixivium: this was now examined, and found to be, in ſome degree, impregnated with the nitrous acid; but it was very far from being ſaturated. With the ſame lixivium, of which a quarter of an inch remained in the tube, the experiment was continued till 14 inches more of air had been abſorbed; but its diminution was not perceived to decreaſe, though the lixivium had now abſorbed 77 meaſures of air, each equal to its own; whereas, in the experiment related by Mr Cavendiſh, only 38 meaſures of air were abſorbed by the alkali. But notwithſtanding this

Miſcellaneous Experiments.

greater abſorption, the lixivium was yet far from being ſaturated.

The experiment was repeated with pure air, produced by minium, moiſtened with the vitriolic acid, and deprived of its fixed air; ſeven parts of this were mixed with three of phlogiſticated air, and lixivium added to the height of ⅛th of an inch. Here, as in the former experiment, the diminution continued without any decreaſe; and the lixivium, after it had abſorbed 22¼th inches, and conſequently 178 times its own meaſure of air, was very far from being ſaturated with the nitrous acid.

On this Dr Van Marum wrote to Mr Cavendiſh; and finding, by his anſwer, that this gentleman had uſed pure air, obtained from a black powder produced by ſhaking mercury with lead, he requeſted to be informed of the proceſs by which it is generated: but Mr Cavendiſh, not chooſing to communicate this at preſent, he determined to defer the repetition of the experiment till this ingenious philoſopher ſhall have publiſhed his mode of obtaining the pure air uſed in it.

Our author then goes on to ſome experiments made by ſuffering the electric fluid to paſs in a continued ſtream through various kinds of air, incloſed for this purpoſe in the little glaſs tube uſed in the laſt experiments.

Pure air obtained the week before from red precipitate, being placed over mercury, and electrified for 30 minutes, was diminiſhed by ⅕th, the ſurface of the quickſilver ſoon began to be calcined, and towards the end of the experiment the glaſs tube was ſo lined with the calx as to ceaſe to be tranſparent. By introducing a piece of iron, the electric ſtream was made to paſs through the air without immediately touching the mercury; yet this was equally calcined. This phenomenon the Doctor aſcribes ſolely to the diſſolution of the pure air, the principle of which unites itſelf with the metal; as in theſe experiments the mercury had not acquired any ſenſible heat. Two inches and 3 quarters of the ſame kind of air being placed over water, and electrified in the ſame manner during half an hour, loſt a quarter of an inch; and being ſuffered to ſtand 12 hours in the tube, was found to have loſt ⅛th of an inch more. This was very nearly the ſame diminution of the air that had taken place when it was electrified over mercury; but, in this caſe, the proceſs appears to be more ſlow, and the detached principle not ſo readily abſorbed. The air remaining after theſe experiments, being tried by the eudiometer, did not differ from unelectrified pure air taken from the ſame receiver.

To determine whether the pure air retained any of the acid employed in its production, the Doctor repeated the experiment with air obtained from red precipitate, confined by an infuſion of turnſole, but could not perceive in it the leaſt change of colour. He alſo electrified air obtained from minium and the vitriolic acid, placed over ſome diluted vinegar of lead; but this was not rendered at all turbid.

Three inches of phlogiſticated air being electrified, during the firſt 5 minutes were augmented to 3⅛th inches, and in the next 10 minutes to 3¼th inches: ſome lixivium was then introduced to try whether this would abſorb it; but upon being electrified 15 minutes, the column roſe to the height of 3⅜th inches. It was ſuffered to ſtand in the tube till the next day, when it was found to have ſunk to its original dimenſions.

Miſcell neous perimen

Nitrous air, confined by lixivium, being electrified during half an hour, loſt 3 quarters of its bulk; the lixivium appeared to have abſorbed a great deal of nitrous acid; and the air remaining in the tube did not ſeem to differ from common phlogiſticated air. Some of the ſame nitrous air, confined by lixivium, was, by ſtanding 3 weeks, diminiſhed to half its bulk, and this reſiduum alſo proved to be phlogiſticated air. Thus electricity very ſpeedily effects that ſeparation of the nitrous acid from nitrous air, which is ſlowly produced by the lixivium alone.

Inflammable air obtained from ſteel-filings and the diluted vitriolic acid, being confined by an infuſion of turnſole, was electrified for 10 minutes without any change of colour in the infuſion, or any alteration in the bulk of the air. The tube being filled with the ſame air to the heighth of 2½ inches, and placed in diluted vinegar of lead, was expoſed to the electric ſtream during 12 minutes, in which time the incloſed air roſe to 5 inches; but the vinegar remained perfectly clear. Three inches of inflammable air obtained from a mixture of ſpirits of wine with oil of vitriol, on being electrified for 15 minutes, roſe to 10 inches; thus dilated, it loſt all its inflammability, and when nitrous air was added, no diminution enſued.

A column of alkaline air obtained by heat from ſpirit of ſal ammoniac, 3 inches high, was electrified 4 minutes, and roſe to 6 inches, but did not riſe higher when electrified 10 minutes longer. It appears that this air is not expanded more by the powerful electric ſtream from this machine than by the common ſpark. Water would not abſorb this electrified air, which was in part inflammable.

The tube, being filled to the height of an inch with ſpirit of ſal ammoniac, and inverted in mercury, was electrified 4 minutes; in which time the tube was filled with 8 inches of air, which proved to be equally inflammable, and as little abſorbed by water as the alkaline air. Hence Dr Van Marum conjectures that this air is only the volatile alkali rendered elaſtic.

180 Curi perimen with ba loon- fil with in fl mmal air.

The following experiment is very curious, and may ſerve to illuſtrate ſome phenomena obſerved in thunder-ſtorms. Two balloons, made of the allantoides of a calf, were filled with inflammable air, of which each contained about 2 cubic feet. To each of theſe was ſuſpended, by a ſilken thread about 8 feet long, ſuch a weight as was juſt ſufficient to prevent it from riſing higher in the air; they were connected, the one with the poſitive, the other with the negative conductor, by ſmall wires about 30 feet in length, and being kept near 20 feet aſunder, were placed as far from the machine as the length of the wires would admit. On being electrified, theſe balloons roſe up in the air as high as the wire allowed, attracted each other, and uniting as it were into one cloud, gently deſcended. The riſing of theſe artificial clouds is aſcribed to the expanſion of the air they contained, in conſequence of the repulſive force communicated to its particles by elec-

electricity: when in contact, their oppoſite electrical powers deſtroyed each other, and they recovered their ſpecific gravity by loſing the cauſe of its diminution. In order to render this experiment more perfectly imitative, the Doctor ſuſpended to the balloon which was connected with the negative conductor, a bladder filled with a mixture of inflammable and atmoſpherical air, which, being kindled by the ſpark that took place on the union of theſe clouds, gave a conſiderable exploſion. From theſe experiments, the Doctor explains the ſudden elevation of the clouds, and the violent ſhowers of rain and hail, which often accompany thunder-ſtorms.

In the courſe of his experiments upon air and electric fluid, Dr Prieſtley found, that, by means of the ſpark, he was able to turn vegetable blues to a red colour; though we are not to imagine that this was any indication of the acidity of the electric fluid, but merely of the decompoſition of the air, and its converſion into fixed air or aerial acid. The inſtrument uſed in this experiment is a glaſs tube about 4 or 5 inches long and 1 or $\frac{2}{10}$ths of an inch diameter in the inſide; a piece of wire is put into one end of the tube, and fixed there with cement; a braſs ball is placed on the top of this wire; the lower part of the tube is to be filled with water, tinged blue with a piece of turnſole or archil. This is eaſily effected, by ſetting the tube in a veſſel of the tinged water, then placing it under a receiver on the plate of the air-pump; exhauſt the receiver in part, and then, on letting in the air, the tinged liquor will riſe in the tube, and the elevation will be in proportion to the accuracy of the vacuum; now take the tube and veſſel from under the receiver, and throw ſtrong ſparks on the braſs ball from the prime conductor.

When Dr Prieſtely made this experiment, he perceived, that after the electric ſpark had been taken between the wire and the liquor about a minute, the upper part of it began to look red; in 2 minutes it was manifeſtly ſo, and the red part did not readily mix with the liquor. If the tube was inclined when the ſparks were taken, the redneſs extended twice as far on the lower ſide as on the upper. In proportion as the liquor became red, it advanced nearer to the wire, ſo that the air in which the ſparks were taken was diminiſhed; the diameter amounted to about $\frac{1}{5}$th of the whole ſpace; after which, a continuance of the electrification produced no ſenſible effect.

To determine whether the cauſe of the change of colour was in the air or in the electric matter, Dr Prieſtley expanded the air in the tube by means of an air-pump, till it expelled all the liquor, and admitted freſh blue liquor in its place: but after this, electricity produced no ſenſible effect on the air or on the liquor; ſo that it was clear, that the electric matter had decompoſed the air, and made it depoſit ſomething of an acid nature. The reſult was the ſame with wires of different metals. It was alſo the ſame when, by means of a bent tube, the ſpark was made to paſs from the liquor in one leg to the liquor in the other. The air thus diminiſhed was in the higheſt degree noxious.

In paſſing the electric ſpark through different elaſtic fluids, it appears of different colours. In fixed air, the ſpark is very white; in inflammable and alkaline air, it appears of a purple or red colour. From hence we may infer, that the conducting power of theſe airs is different, and that fixed air is a more perfect non-conductor than inflammable air.

Miſcellaneous Experiments.

The ſpark was not viſible in air from a cauſtic alkali made by M. Lane, nor in air from ſpirit of ſalt; ſo that they ſeem to be more perfect conductors of electricity than water or other fluid ſubſtances.

The electric ſpark, taken in any kind of oil, produces inflammable air. Dr Prieſtley tried it with ether, oil of olives, oil of turpentine, and eſſential oil of mint, taking the electric ſpark in them without any air to begin with; inflammable air was produced in them all.

Dr Prieſtley found, that on taking a ſmall electric exploſion for an hour, in the ſpace of an inch of fixed air, confined in a glaſs tube $\frac{1}{10}$th of an inch diameter, when water was admitted to it, only $\frac{1}{4}$th of the air was imbibed. Probably the whole would have been rendered immiſcible in water, if the electrical operation had been continued a ſufficient time.

The electric ſpark, when taken in alkaline air, appears of a red colour; the electric exploſions, which paſs through this air, increaſe its bulk; ſo that, by making about 200 exploſions in a quantity of it, the original quantity will be ſometimes increaſed $\frac{1}{4}$th. If water is admitted to this air, it will abſorb the original quantity, and leave about as much elaſtic fluid as was generated by the electricity, and this elaſtic fluid is a ſtrong inflammable air.

Dr Prieſtley found, when the electric ſpark was taken in vitriolic acid air, that the inſide of the tube in which it was confined was covered with a blackiſh ſubſtance. He ſeems to think, that the whole of the vitriolic acid air is convertible into this black matter, not by means of any union which it forms with the electric fluid, but in conſequence of the concuſſion given to it by the exploſion; and that, if it be the calx of the metal which ſupplied the phlogiſton, it is not to be diſtinguiſhed from what metal, or indeed from what ſubſtance of any kind, the air had been extracted.

Dr Prieſtley made 150 exploſions of a common jar in about a quarter of an ounce meaſure of vitriolic acid air from copper, by which the bulk was diminiſhed about $\frac{1}{3}$, and the remainder ſeemingly not changed, being all abſorbed by water. In the courſe of this proceſs, the air was carefully transferred three times from one veſſel to another; and the laſt veſſel, in which the exploſions were made, was, to all appearance, as black as the firſt; ſo that the air ſeems to be all convertible into this black ſubſtance.

Thinking this diminution of the vitriolic acid air might ariſe from its abſorption by the cement with which the glaſs tubes employed in the laſt experiment were cloſed, he repeated it with the air from quickſilver, in a glaſs ſyphon confined by quickſilver, and the reſult was the ſame.

That this matter comes from the vitriolic acid air only, and not from any combination of the electric matter with it, will appear from the following experiment.

He took the ſimple electric ſpark from a conductor of a moderate ſize, for the ſpace of 5 minutes without interruption, in a quantity of vitriolic acid air,

air, without producing any change in the inſide of the glaſs; when immediately after, making in it only two exploſions of a common jar, each of which might be produced in leſs than a quarter of a minute with the ſame machine in the ſame ſtate, the whole of the inſide of the tube was completely covered with the black matter. Now, had the electric matter formed any union with the air, and this black matter had been the reſult of that combination, all the difference that would have ariſen from the ſimple ſpark or the exploſion, could only have been a more gradual or a more ſudden formation of that matter.

A large phial, about an inch and a half wide, being filled with this air, the exploſion of a very large jar, containing more than 2 feet of coated ſurface, had no effect upon it; from which it ſhould ſeem, that in theſe caſes the force of the ſhock was not able to give the quantity of air ſuch a concuſſion as was neceſſary to decompoſe any part of it.

He had generally made uſe of copper, but afterwards he procured this air from almoſt every ſubſtance from which it could be obtained; the electric exploſion taken in it produced the ſame effect. But as ſome of the experiments were attended with peculiar circumſtances, he briefly mentions them as follows.

When he endeavoured to get vitriolic acid air from lead, putting a quantity of leaden ſhot into a phial containing oil of vitriol, and applying only the uſual degree of heat, a conſiderable quantity of heat was produced; but afterwards, though the heat was increaſed till the acid boiled, no more air could be got. He imagined, therefore, that in this caſe the phlogiſton had in fact been ſupplied by ſomething that had adhered to the ſhot. However, in the air ſo produced, he took the electric exploſion; and in the firſt quantity he tried, a whitiſh matter was produced, almoſt covering the inſide of the tube; but in the ſucceeding experiments, with air produced from the ſame ſhot or from ſomething adhering to it, there was leſs of the whitiſh matter; and at laſt nothing but black matter was produced, as in all the other experiments. Water being admitted to this air, there remained a conſiderable reſiduum, which was very ſlightly inflammable.

Vitriolic acid air is eaſily procured from ſpirit of wine, the mixture becoming black before any air is yielded. The electric exploſion taken in this air alſo produced the black matter.

The experiments made with ether ſeem to throw moſt light upon this ſubject, as this air is as eaſily procured from ether as any other ſubſtance containing phlogiſton. In the air procured by ether the electric exploſion tinged the glaſs very black, more ſo than in any other experiment of the kind; and when water had abſorbed what it could of this air, there was a reſiduum in which a candle burned with a lambent blue flame. But what was moſt remarkable in this experiment was, that beſides the oil of vitriol becoming very black during the proceſs, a black ſubſtance, and of a thick conſiſtence, was formed, which ſwam on the ſurface of the acid.

It is very poſſible, that the analyſis of this ſubſtance may be a means of throwing light upon the nature of the black matter formed by electric exploſions in vitriolic acid air, as they ſeem to reſemble one another very much.

The electric ſpark or exploſion taken in common air, confined by quickſilver in a glaſs tube, covers the inſide of the tube with a black matter, which, when heated, appears to be pure quickſilver. This, therefore, may be the caſe with the black matter into which he ſuppoſed the vitriolic acid air to be converted by the ſame proceſs, though the effect was much more remarkable than in the common air. The exploſion will often produce the diminution of common air in half the time that ſimple ſparks will do it, the machine giving the ſame quantity of fire in the ſame time: alſo, the blackneſs of the tube is much ſooner produced by the ſhocks than by the ſparks. When the tube conſiderably exceeds $\frac{1}{15}$ths of an inch in diameter, it will ſometimes become very black, without any ſenſible diminution of the quantity of air.

## SECT. X. *Of the Methods of meaſuring Electricity both artificial and natural; of condenſing and doubling it, ſo that the ſmalleſt Quantity may be made perceptible; of diſtinguiſhing the two Kinds of Electricity from one another*, &c.

WE have already had occaſion to mention, and in part to explain, the inſtruments for this purpoſe named *electrometers*. When the electricity is very evident, many obvious contrivances may be fallen upon to determine its quality and ſtrength, when compared with that of any other body electrified alſo to a conſiderable degree. But in many caſes the quantity of electricity is ſo ſmall that it does not diſcover itſelf by any of the ordinary electrometers; and in others, though the quantity be very great, yet we are deſtitute of any proper ſtandard which might enable us to compare it with another of apparently the ſame height, or which might determine the degrees of charge which the electrified ſubſtance progreſſively receives.

Deſcrip of vari electro ters.

In the former caſe, Dr Prieſtley recommends a ſingle thread of ſilk as it comes from the worm; which being extremely light and flexible, very readily diſcovers the electric properties of any body, by being firſt attracted and then repelled by it: and, as this ſubſtance at the ſame time has a power of retaining its electricity very ſtrongly, we have thus an opportunity of determining whether the body from which it received the electricity was poſitive or negative. Even this electrometer has not been found to be endowed with all the ſenſibility to be wiſhed for; ſo that others have been contrived which anſwer to a ſtill greater degree of exactneſs. For ordinary purpoſes the following inſtruments are moſt commonly made uſe of.

Pla CLX

Fig. 13. repreſents a ſtand ſupporting the electrometers *D D*, *C C*. *B* is the baſis of it, made of common wood. *A* is a pillar of wax, glaſs, or baked wood. To the top of the pillar, if it be of wax or glaſs, a circular piece of wood is fixed; but if the pillar be of baked wood, that may conſtitute the whole. From this circular piece of wood proceed four arms of glaſs, or baked wood, ſuſpending at their ends four electrometers, two of which *DD* are ſilk threads about eight inches long, ſuſpending each a ſmall downy feather

ds of
aring
ricity,

feather at its end. The other two electrometers *CC* are thoſe with very ſmall balls of cork, or of the pith of alder; and they are conſtructed in the following manner. *a b* is a ſtick of glaſs about ſix inches long, covered with ſealing-wax, and ſhaped at top in a ring: from the lower extremity of this ſtick proceed two fine linen threads (K) *c c* about five inches long, each ſuſpending a cork or pith-ball *d* about $\frac{1}{8}$th of an inch in diameter. When this electrometer is not electrified, the threads *c c* hang parallel to each other, and the cork-balls are in contact; but when electrified, they repel one another, as repreſented in the figure. When it happens to be inconvenient to uſe the inſulating ſtand *A B*, the electrometers may be eaſily ſupported by a glaſs rod or tube.

late
XIV.

Another ſpecies of the above electrometer is repreſented in fig. 14. which conſiſts of a linen thread, having at each end a ſmall cork-ball. This electrometer is ſuſpended by the middle of the thread on any conductor proper for the purpoſe, and ſerves to ſhow the kind and quantity of its electricity.

Fig. 15. repreſents Mr Henly's quadrant electrometer fixed upon a ſmall ſtand, from which it may be occaſionally ſeparated and fixed upon the prime conductor, or in any other place, at pleaſure. This electrometer conſiſts of a perpendicular ſtem formed at the top like a ball, and furniſhed at its lower end with a braſs ferule, by which it may be fixed in one of the holes of the prime conductor, or in its proper ſtand, as occaſion requires. To the upper part of the ſtem or pillar, a graduated ivory ſemicircle is fixed; about the middle of which is a braſs arm, which contains a pin, or the ſmall axis of the index. The index conſiſts of a very ſlender ſtick which reaches from the centre of the graduated ſemicircle to the braſs ferule, and at its lower extremity is faſtened a ſmall cork-ball, nicely turned in a lathe.

When this electrometer is not electrified, the index hangs parallel to the pillar; but when it is electrified, the index recedes more or leſs, according to the quantity of electricity from the ſtem. See *FGDI*, in fig. 14. and *ab* in fig 6. both of which are new and improved ways of applying it; by which the quantity of the ſhocks are regulated in the moſt convenient manner, as will be more particularly explained under *Medical* ELECTRICITY, Sect. XI.

3,
es's
ome-

Fig 16. and 17. repreſent an electrometer nearly ſimilar to that contrived by Mr Brooke. The two inſtruments are ſometimes combined in one, or uſed ſeparately, as in theſe figures. The arms *FHfk*, fig. 17. when in uſe, are to be placed as much as poſſible out of the atmoſphere of a jar, battery, prime conductor, &c. The arm *FH* and the ball *K* are made of copper, and as light as poſſible. The diviſions on the arm *FH* are each of them exactly a grain. They are aſoertained at firſt by placing grain weights on a braſs ball which is within the ball *L* (this ball is an exact counterbalance to the arm *FH* and the ball *K* when the ſmall ſlide on this arm is at the firſt diviſion); and then removing the ſlide till it, together with the ball *K*, counterbalances the ball *L* and the weight laid on it.

*A*, fig. 16. is a dial-plate, divided into 90 equal parts. The index of this plate is carried once round, when the arm *BC* has moved through 90 degrees, or a quarter of a circle. That motion is given to the index by the repulſive power of the charge acting between the ball *D* and the ball *B* *.

Methods of meaſuring Electricity, &c.

The arm *BC* being repelled, ſhows when the charge is increaſing, and the arm *FH* ſhows what this repulſive power is between two balls of this ſize in grains, according to the number the weight reſts at when lifted up by the repulſive power of the charge: at the ſame time the arm *BC* points out the number of degrees to which the ball *B* is repelled; ſo that, by repeated trials, the number of degrees, anſwering to a given number of grains, may be aſcertained, and a table formed from theſe experiments, by which means the electrometer, fig. 16. may be uſed without that of fig. 17.

Mr Brookes thinks, that no glaſs charged (as we call it) with electricity, will bear a greater force than that whoſe repulſive power, between two balls of the ſize he uſed, is equal to 60 grains; that in very few inſtances it will ſtand 60 grains weight; and he thinks it hazardous to go more than 45 grains.

Hence, by knowing the quantity of coated ſurface, and the diameter of the balls, we may be enabled to ſay, ſo much coated ſurface, with a repulſion between balls of ſo many grains, will melt a wire of ſuch a ſize, or kill ſuch an animal, &c.

Mr Brookes thinks, that he is not acquainted with all the advantages of this electrometer; but that it is clear, it ſpeaks a language which may be univerſally underſtood, which no other will do; for though other electrometers will ſhow whether a charge is greater or leſs, by an index being repelled to greater or ſmaller diſtances, or by the charge exploding at different diſtances, yet the power of the charge is by no means aſcertained: but this electrometer ſhows the force of the repulſive power in grains; and the accuracy of the inſtrument is eaſily proved, by placing the weights on the internal ball, and ſeeing that they coincide with the diviſions on the arm *FH*, when the ſlide is removed to them.

Mr Achard has ſhown clearly, that if the ſcale of an electrometer is divided into equal parts (degrees for example), the angle at which the index is held ſuſpended by the electric repulſion will not be a true meaſure of the repulſive force; to eſtimate which truly, he demonſtrates that the arc of the electrometer ſhould be divided according to a ſcale of arcs, the tangents of which are in arithmetical progreſſion.

The electrometer of which this is an imitation was invented by Mr Brookes, and deſcribed in his treatiſe already quoted. An account of it is given in that treatiſe, along with a very full repreſentation of it by plates; but as theſe are ſomewhat difficult to be underſtood, we muſt for further particulars refer to the treatiſe itſelf. On this electrometer, however, we muſt obſerve, that it is conſtructed on the only true principle on which machines for meaſuring the quantity of electricity can be made. The mere attraction of any light body ſhows indeed that the ſubſtance which attracts it is electrified; but this property is by no means calculated to diſcover the comparative ſtrength of it, on account

---

* Phil. Tran. vol. lxxxii. p. 384.

(K) Theſe threads ſhould be wetted in a weak ſolution of ſalt.

count of its continual variation. Thus, if we hold any body within the electrified atmoſphere of another, though it be firſt attracted pretty ſtrongly, yet that attraction will be conſtantly diminiſhing, and at laſt changed into a repulſive power; but the latter, after it has once taken place, continues invariable as long as any degree of electric charge remains.

184
Mr Cavallo's atmoſpherical electrometer.

The electricity of the atmoſphere particularly, has engaged the attention of philoſophers; and by reaſon of its infinite variety, requires the moſt delicate inſtruments to obſerve its minutiæ. Beſides the kite formerly deſcribed, which was an invention of Dr Franklin's, Mr Cavallo has invented ſeveral others. Fig. 61. repreſents a portable atmoſpherical electrometer, the principal part of which is a glaſs tube *CDMN*, cemented at the bottom into the braſs piece *AB*, by which part the inſtrument is to be held when uſed for the atmoſphere; and it alſo ſerves to ſcrew the inſtrument into its braſs caſe *ABO*, fig. 69. The upper part of the tube *CDMN* is ſhaped tapering to a ſmall extremity, which is entirely covered with ſealing-wax; to this tapering part a ſmall tube is cemented; the lower extremity, being alſo covered with ſealing-wax, projects a ſmall way within the tube *CDMN*; into this ſmaller tube a wire is cemented, which with its under extremity touches the flat piece of ivory *H*, faſtened to the tube by means of a cork; the upper extremity of the wire projects about a quarter of an inch above the tube, and ſcrews into the braſs cap *EF*, which cap is open at the bottom, and ſerves to defend the waxed part of the inſtrument from the rain, &c.

*IM* and *KN* are two narrow ſlips of tin-foil, ſtuck to the inſide of the glaſs *CDMN*, and communicating with the braſs bottom *AB*. They ſerve to convey that electricity which, when the balls touch the glaſs, is communicated to it, and being accumulated, might diſturb the free motion of the balls.

To uſe this inſtrument for artificial electricity, electrify the braſs cap by an electrified ſubſtance, and the divergence or convergence of the balls of the electrometer, at the approach of an excited electric, will ſhow the quality of the electricity. The beſt manner to electrify this inſtrument is, to bring excited wax ſo near the cap that one or both of the corks may touch the ſide of the bottle *CDMN*, after which they will ſoon collapſe and appear unelectrified. If now the wax is removed, they will again diverge, and remain electrified poſitively.

When this electrometer is to be uſed to try the electricity of the fogs, air, clouds, &c. the obſerver is to do nothing more than to unſcrew it from its caſe, and hold it by the bottom *AB* to preſent it to the air a little above his head, ſo that he may conveniently ſee the balls *P*, which will immediately diverge if there is any electricity; i. e. whether poſitive or negative may be aſcertained, by bringing an excited piece of ſealing-wax or other electric towards the braſs cap *EF*.

185
M. Sauſſure's improvement on this electrometer.

An improvement of Mr Cavallo's electrometer has been made by M. Sauſſure. The principal circumſtances in which they differ are, 1. The fine wires by which the balls are ſuſpended, ſhould not be long enough to reach the tin-foil which is paſted on the inſide of the glaſs; becauſe the electricity, when ſtrong, will cauſe them to touch this tin-foil twice conſecutively, and thus deprive them in a moment of their electricity. To prevent this defect, and yet give them a ſufficient degree of motion, it is neceſſary to uſe larger glaſſes than thoſe that are generally applied to Mr Cavallo's electrometer; two or three inches diameter will be found to anſwer the purpoſe very well. But as it is neceſſary to carry off the electricity which may be communicated to the inſide of the glaſs, and thus be confounded with that which belongs to thoſe ſubſtances that are under examination; four pieces of tin-foil ſhould be paſted on the inſide of the glaſs; the balls ſhould not be more than $\frac{1}{20}$th of an inch diameter, ſuſpended by ſilver wire, moving freely in holes nicely rounded. The bottom of the electrometer ſhould be of metal; for this renders it more eaſy to deprive them of any acquired electricity, by touching the bottom and top at the ſame time.

186
Serves ſtead o Volta's denſer.

This electrometer may be uſed inſtead of the condenſer of M. Volta, by only placing it on a piece of oiled ſilk, ſomewhat larger than the baſe of the inſtrument: but in this caſe it is the baſe and not the top of the inſtrument, which muſt be brought into contact with the ſubſtance whoſe electricity is to be explored.

187
Aſcert the con ting po of diff ſubſtan

By this inſtrument, it is eaſy to aſcertain the degree of conducting power in any ſubſtance. For example, if it is placed on an imperfect conductor, as dry wood or marble, and if the inſtrument is electrified ſtrongly, and afterwards the top is touched, the electricity will appear to be deſtroyed; but on lifting up the inſtrument by the top, the balls will again open, becauſe the imperfect conductor formed with the baſe a kind of electrophorus, by which the electric fluid was condenſed, and loſt its tenſion, till the perfect conductor was ſeparated from the imperfect one; whereas, if the conductor had been more perfect, it would have been deprived of its electricity immediately on the application of the hand.

18
Or the lectrici

It is eaſy to diſcover alſo, by this inſtrument, the electricity of any ſubſtance, as of cloaths, hair of different animals, &c. For this purpoſe, it muſt be held by the baſe, and the ſubſtance rubbed briſkly (only once) by the ball of the electrometer; the kind of electricity may be aſcertained in the uſual manner. It is proper, however, to obſerve here, that as the top of the electrometer acts in this caſe as an inſulated rubber, the electricity it acquires is always contrary to that of the rubbed body.

18
How t collect great q tity of moſphe cal elec city,

In order to collect a great quantity of electricity from the air, the electrometer is furniſhed with a pointed wire 15 inches or two feet long, which unſcrews in three or four pieces, to render the inſtrument more portable; ſee fig. 62. When it rains or ſnows, the ſmall cover, fig. 63. is to be ſcrewed on the top of the inſtrument, as by this its inſulation is preſerved, notwithſtanding the rain.

19
Or to certain kind o

This inſtrument indicates not only the electricity of fogs, but that alſo of ſerene weather, and enables us to diſcover the kind of electricity which reigns in the atmoſphere; and to a certain degree to form an eſtimate of its quantity, and that under two different points of view, the degree of intenſity, and the diſtance from the earth at which it firſt begins to be ſenſible.

A conductor exhibits ſigns of electricity only when the of the electric fluid is more or leſs condenſed in the air than in the earth. Though the air reſiſts the paſſage of the electric fluid, it is not abſolutely impermeable to it; it ſuffers it to paſs gradually, and generally with more eaſe in proportion as its maſs or thickneſs is leſs. It is therefore intereſting to diſcover at what height it is neceſſary to be elevated, in order to find a ſenſible difference between the electricity of the earth and that of the air. A very ſenſible difference may be generally diſcovered by this inſtrument at the diſtance of four or five feet from the ground; ſometimes it may be ſeen if the inſtrument is placed even on the ground, while at others it muſt be raiſed ſeven or more feet before the balls will open; ſometimes, though ſeldom, this height is not ſufficient. This diſtance is generally greateſt when the electricity is ſtrongeſt, though neceſſarily modified by a variety of circumſtances, ſome of which are known, as the degree of dryneſs or humidity of the air, and others are unkown.

The degree of intenſity, at a given height, may be diſcovered thus: raiſe the electrometer, and judge by the diviſions which are placed on the edge thereof the degree of their divergence. To find the relation between this degree of divergence and the force of the electricity, M. Sauſſure took the following method: As he could not with certainty double or triple a given quantity of electricity; yet as a given force may be reduced one half, a fourth, or eighth, &c. by dividing it between two equal and ſimilar bodies, the electricity contained in one; he took two of his unarmed electrometers, which were as ſimilar as poſſible, and electrified one of them, ſo that the balls ſeparated preciſely 6 lines: he then touched the top thereof by the top of that which was not electrified; in an inſtant the electricity was equally divided between them, as was evident by the divergence of the balls, which was 4 lines in each; conſequently, a diminution of half the denſity had only leſſened the divergence one third. One of theſe electrometers was then deprived of its electricity, and was afterwards brought in contact with the other, as before; the remaining electricity divided itſelf again between them, and the balls fell from 4 to 28 lines, nearly in the ſame proportion as before; in the third operation they fell to 19; in the fourth to one, where he was obliged to ſtop, as there was not now ſufficient force in the fluid to paſs from one electrometer to the other, and diſtribute itſelf uniformly between them. The ſame experiment repeated ſeveral times gave very nearly the ſame reſults. Negative electricity decreaſed alſo in the ſame proportion as the poſitive. The following table may therefore be conſidered as giving a general, though not exact, idea of the increaſe in force, which correſponds to different degrees of divergence in the balls; it is only calculated to every fourth of a line; the force of electricity is always expreſſed by whole numbers, as it would be ridiculous to put a greater degree of axactneſs in the numbers than is to be found in the experiments which form the baſis of the calculation (L).

Thoſe who are deſirous to carry this meaſure of the electric force further, may do it by having ſimilar electrometers conſtructed, but made upon a larger ſcale, and with heavier balls, which would only ſeparate one line, with the degree of electricity that makes the ſmaller ones diverge 6 lines; theſe would conſequently meaſure a force 1024 times greater than that which forms the unity of the preceding table; and thus by degrees we may be enabled to diſcover the ratio of the ſtrongeſt diſcharge of a great battery, or perhaps even of thunder itſelf, to that of a piece of amber, which only attracts a bit of ſtraw or any other light ſubſtance. (M). In

---

(L) M. Sauſſure, in a long note, anticipates the objections that may be made to the foregoing method of eſtimating the force of electricity; but as at the moſt they only ſhow that this ſcience is at preſent in a ſtate of conſiderable imperfection, it will be unneceſſary to take notice of them here.

(M) The conſideration of the repulſive force is not ſufficient to diſcover the abſolute force of an exploſion or electrical diſcharge: for M. Volta has ſhown, that the force of a diſcharge depends principally on the quantity of the electric fluid which paſſes from one body to another. Now the repulſive force of the electrometer only indicates the ratio of this quantity in equal and ſimilar bodies, and which are alſo ſimilarly ſituated. If equal quantities of the electric fluid were imparted to two unequal and ſeparate conductors, the electric fluid being leſs condenſed on the largeſt, would act with the leaſt force on the electrometer; though it is probable, the force of the diſcharge in the two conductors would be equal. The repulſive force ſerves, however, to ſhow what M. Volta calls the *electrical capacity* of a body, the quantity of the electric fluid it actually contains, or is capable of containing. To effect this, and have points of compariſon, we ſhould uſe light metallic balls, of different ſizes, ſuſpended by ſilk thread. One of theſe balls, unelectrified, being brought into contact with the ſubſtance

192 How to obſerve the electricity of the atmoſphere.

In order to obſerve the electricity of the atmoſphere with this inſtrument, we muſt firſt bring the electric fluid contained in the electrometer to the ſame degree of denſity with that at the ſurface of the earth; this is eaſily done by letting the bottom and top touch the ground at the ſame time; then raiſe the point, keeping the bottom ſtill in contact with the ground, from whence it may be lifted up in a vertical poſition till the balls are level with the eye.

193 How to render the ſigns of electricity in the electrometer permanent.

The ſecond circumſtance is to render the divergence of the balls, which is occaſioned by the electricity of the air, permanent. This is effected by touching the top of the electrometer with the finger: but here the acquired electricity becomes contrary to that of the body by which they are electrified. Let us ſuppoſe, for example, that the electrometer is at five feet from the ground, and the balls diverging; touch the top of the electrometer with the finger, and the balls will cloſe; but they will again open if the electrometer is withdrawn from the influence of the electricity of the air, by being brought nearer the ground, or into the houſe. M. Sauſſure only employed this method when the electricity was ſo weak that he could not perceive any until the electrometer was raiſed conſiderably above his eye: as in this caſe he could not perceive the divergence of the balls, he always endeavoured to obtain a permanent electricity in the foregoing manner.

194 How to diſtinguiſh the two electricities.

To know whether the balls ſeparate with poſitive or negative electricity, bring a piece of excited wax gradually near the top of the electrometer; if the balls ſeparate further on the approach of the wax, they are negatively electrified, or of the ſame nature with the electricity of the wax; if on the other hand they come nearer together on the approach of the wax, then the electricity is poſitive, or in a contrary ſtate to that of the wax. If glaſs is uſed, the reſults will be exactly the reverſe of the preceding.

The following example will render the uſe of the foregoing obſervations more familiar. Chooſe an open ſituation free from trees and houſes, ſcrew the conductor on the top of the electrometer, lay hold of it by its baſe, and place it ſo that the baſe and conductor may touch the ground at the ſame time; then elevate it to the height of the eye, and obſerve the quantity of lines, or fourths of a line, that the balls have diverged; now lower it till the balls almoſt touch each other, and obſerve at what diſtance the top of the conductor is from the ground; and this is the height from the ground at which the electricity of the air begins to be ſenſible. If the electricity of the air is ſufficiently ſtrong to make the balls diverge when it ſtands upon the ground, one of the lengths of the electrometer muſt be unſcrewed from it. If the balls however ſtill diverge, the other parts of the conductor ſhould alſo be unſcrewed, and you may mark down, that the electricity is ſenſible at zero, or on the ſurface of the earth. If, on the contrary, the electricity is ſo weak, as not to cauſe the balls to diverge when they are even with the eye, and conſequently when the conductor is two feet higher, or ſeven feet from the ground, you ſhould then raiſe it a foot higher; while it is thus elevated, touch the top with the other hand; when this hand is taken away, lower the electrometer, and if it is electrified you may ſay the electricity is ſenſible at eight feet; if it is not, raiſe it as high as the arm can reach, and repeat the ſame operation; if any electricity is found, write down electricity ſenſible at nine feet; if not, mark 0, or no electricity relative to this inſtrument, and this mode of employing it; for ſigns of electricity may ſtill be obtained, by throwing a metallic ball 50 or 60 feet into the air, which is at the ſame time connected with the electrometer by a metallic thread.

One advantage of this inſtrument is, that it will often exhibit ſigns of electricity when none can be obtained from a conductor of 100 feet in height, becauſe it can more eaſily be preſerved from humidity, &c. which deſtroy the inſulation of the large conductors.

19 Obſer- cal el city.

Aerial electricity varies according to the ſituation; it is generally ſtrongeſt in elevated and inſulated ſituations, not to be obſerved under trees, in ſtreets, in houſes, or any incloſed places; though it is ſometimes to be found pretty ſtrong on quays and bridges. It is alſo not ſo much the abſolute height of the places as their ſituation; thus a projecting angle of a high hill will often exhibit a ſtronger electricity than the plain at the top of the hill, as there are fewer points in the former to deprive the air of its electricity.

The intenſity of the atmoſpheric electricity is varied by a great many circumſtances, ſome of which may be eaſily accounted for, others with more difficulty. When the weather is not ſerene, it is impoſſible to aſſign any rule for their variation, as no regular correſpondence can then be perceived with the different hours of the day, nor with the various modifications of the air. The reaſon is evident; when contrary and variable winds reign at different heights, when clouds are rolling over clouds, theſe winds and clouds, which we cannot perceive by any exterior ſign, influence however the ſtrata of air in which we make our experiments, produce theſe changes of which we only ſee the reſult, without being able to aſſign either the cauſe or its rela-

---

ſubſtance whoſe electricity is to be explored, will diminiſh the tenſion or repulſive force of this ſubſtance; and the quantity diminiſhed by the contact of the ball will give the ratio of the capacity of this ſubſtance with that of the ball. Let us ſuppoſe a Leyden phial uninſulated, but ſo concealed, that only the knob is viſible, and we are therefore ignorant of its ſize, and the ſtrength of the ſhock it will give. Let the top of M. Sauſſure's electrometer be in contact with the knob of the bottle, and the balls of the electrometer ſeparate 6 lines,—from this ſolitary fact, we ſhall gain no information relative to the force of the ſhock; becauſe, if the jar is very large, this degree of tenſion will give a very painful ſenſation; when, if it is very ſmall, with the ſame indicated tenſion, the ſenſation may be almoſt imperceptible. But if we bring a ball of a foot diameter, in contact with the knob of the bottle, and after having thus taken a part of the fluid therefrom, the electrometer is again put in contact with the knob thereof, the remaining quantity of repulſive force will ſhow the relation between its contents and that of the globe of metal, and by this means the intenſity of its charge.

ds of ring icity, relation. Thus, in ſtormy weather, we ſee the electricity ſtrong, then null, and in a moment after ariſe to its former force; one inſtant poſitive, the next negative, without being able to aſſign any reaſon for theſe changes. M. Sauſſure ſays, that he has ſeen theſe changes ſucceed with ſuch rapidity, that he had not time to note them down.

When rain falls without a ſtorm, theſe changes are not ſo ſudden; they are, however, very irregular, particularly with reſpect to the intenſity of force; the quality thereof is more conſtant. Rain or ſnow almoſt uniformly gives poſitive electricity.

In cloudy weather, without rain or ſtorms, the electricity follows generally the ſame laws as in ſerene weather.

Strong winds generally diminiſh its intenſity; they mix together the different ſtrata of the atmoſphere, and make them paſs ſucceſſively towards the ground, and thus diſtribute the electricity uniformly between the earth and the air. M. Sauſſure has obſerved a ſtrong electricity with a ſtrong north wind.

The ſtate of the air in which the electricity is ſtrongeſt, is foggy weather: this is always accompanied with electricity, except when the fog is going to reſolve into rain.

6 iodi- x and ob- le in ectri- f the

The moſt intereſting obſervations, and thoſe which throw the greateſt light upon the various modifications of electricity in our atmoſphere, are thoſe that are made in ſerene weather. In winter (during which moſt of M. Sauſſure's obſervations were made), and in ſerene weather, the electricity was generally weakeſt in an evening, when the dew had fallen, until the moment of the ſun's riſing: its intenſity afterwards augmented by degrees, ſometimes ſooner and ſometimes later; but generally before noon, it attained a certain maximum, from whence it again declined, till the fall of the dew, when it would be ſometimes ſtronger than it had been during the whole day; after which, it would again gradually diminiſh during the whole night; but it is never quite deſtroyed, if the weather is perfectly ſerene.

Atmoſpherical electricity ſeems, therefore, like the ſea, to be ſubject to a flux and reflux, which cauſes it to increaſe and diminiſh twice in 24 hours. The moments of its greateſt force are ſome hours after the riſing and ſetting of the ſun; thoſe when it is weakeſt, precede the riſing and ſetting thereof.

7 uſ- ob- ions s ſub- an rdi- le- of

M. Sauſſure has given an inſtance of this periodic flux in electricity: On the 22d of February 1785, (one of the coldeſt days ever remembered at Geneva), the hygrometer and thermometer were ſuſpended in the open air on a terrace expoſed to the ſouth-weſt; the electrometer, from its ſituation, indicated an electricity equal to what it would have ſhown if it had been placed on an open plain. The height of the barometer was reduced to what it would have been if the mercury had been conſtantly at the temperature of 10 degrees of Reamur's thermometer. The place of obſervation was elevated 60 feet above the level of the lake. The obſervations of the day preceding and following this great cold were marked down by him; becauſe it is pleaſing to have theſe which precede and follow any ſingular phenomena. There was a weak S. W. wind during the whole three days; and it is rather remarkable, that moſt of the great colds, which have been obſerved at Geneva, were preceded by, or at leaſt accompanied with, a little S. W. breeze.

Methods of meaſuring electricity, &c

198 Of the maximum and minimum of the electricity of the atmoſphere on this occaſion.

From the firſt 18 obſervations made during theſe three days, when the ſky was quite ſerene, we learn that the electricity was pretty ſtrong at nine in the morning; that from thence it gradually diminiſhed till towards ſix in the evening, which was its firſt minimum; after which it increaſed again till eight, its ſecond maximum; from whence it again gradually declined till ſix the next morning, which was the time of its ſecond minimum; after which, it again increaſed till ten in the morning, which was the firſt maximum of the following day; as this was cloudy, the electric periods were not ſo regular.

199 Electricity weaker in ſummer than in winter.

The electricity of ſerene weather is much weaker in ſummer than in winter, which renders it more difficult to obſerve theſe gradations in ſummer than in winter; beſides a variety of accidental cauſes, which at the ſame time render them more uncertain. In general, in ſummer, if the ground has been dry for ſome days, and the air is dry alſo, the electricity increaſes from the riſing of the ſun till three or four in the afternoon, when it is ſtrongeſt; it then diminiſhes till the dew begins to fall, which again reanimates it; tho' after this it declines, and is almoſt extinguiſhed during the night.

But the ſerene days that ſucceed rainy weather in ſummer, generally exhibit the ſame diurnal periods or ſtates of electricity, as are to be obſerved in winter.

200 Air always poſitively electrified.

The air is invariably poſitive in ſerene weather, both in winter and ſummer, day and night, in the ſun or in the dew. It would ſeem, therefore, that the electricity of the air is eſſentially poſitive; and that whenever it appears to be negative, in certain rains or in ſtorms, it probably ariſes from ſome clouds, which have been expoſed to the preſſure of the electric fluid contained in the upper part of the atmoſphere, or to more elevated clouds that have diſcharged a part of their fluid upon the earth, or upon other clouds.

In order to find out the cauſe of theſe phænomena, M. Sauſſure inſtituted a ſet of experiments on evaporation, avoiding the uſe of M. Volta's condenſer.

201 Sauſſure's experiments to determine the cauſe of the phenomena of atmoſpherical electricity

To produce a ſtrong evaporation, he threw a maſs of red-hot iron into a ſmall quantity of water, which was contained in a coffee-pot with a large mouth, and ſuſpended by ſilk ſtrings; by this he obtained a ſtrong poſitive electricity; though, according to M. Volta's ſyſtem, it ought to have been negative: the experiment was repeated ſeveral times, varying ſome of the circumſtances, but the reſult was always the ſame.

As it was not eaſy to think ſo able a philoſopher as M. Volta was deceived, it was neceſſary to try the experiment in a manner more analogous to that of M. Volta. A ſmall chafing-diſh was therefore inſulated by ſilk cords, and the coffee-pot, with a ſmall quantity of water, placed on it; one electrometer was connected with the coffee-pot and another with the chafing-diſh; the fire was raiſed by a pair of bellows; when the water had boiled ſtrongly for a few minutes, both electrometers exhibited ſigns of electricity, which, on examination, was found to be negative; proving the truth of M. Volta's experiment.

The evaporation produced by the effervefcence of iron in the vitriolic acid, and by that of chalk in the ſame acid, gave alſo negative electricity.

It was now neceſſary to inquire, why the vapour, excited by the heated iron, produced poſitive electricity; while that from boiling water in any other way produced a negative electricity?

202
Immenſe quantity of electricity extricated from volcanoes, &c.

M. Sauſſure ſuſpected, that the intenſity of heat to which the water is expoſed, by the contact of a body in a ſtate of incandeſcence, was the cauſe of the electricity produced by its evaporation; and that a combination was then formed, by which a new quantity of the electric fluid was produced. This conjecture may at firſt ſight ſeem improbable; but the quantity of electricity produced by this experiment will aſtoniſh thoſe that repeat it: and this quantity is the more ſurpriſing, becauſe, if it is true, according to the ſyſtem of M. Volta, that the waters abſorb, while they are forming a quantity of the electric fluid, there muſt, therefore, be enough developed in this experiment for the formation of the great quantity of vapours produced by the heated iron, and afterwards a ſufficient quantity to electriſy ſtrongly the apparatus, and all theſe vapours.

This experiment ſhows clearly the cauſe of that prodigious quantity of electricity which is unfolded in the eruption of volcanos; as it is probable that the water in theſe, from many circumſtances, acquires a much greater degree of heat than is given to it in our experiments.

203
Poſitive electricity always produced by the combuſtion of iron.

To verify this conjecture, that it was in ſome meaſure the combuſtion of the water or the iron that produced the poſitive electricity, it was proper to try whether, by a regular moderation of the heat of the iron, poſitive electricity would always be obtained. This was eſſayed in the following manner: A large iron crucible, five inches high, four in diameter, and ſix lines thick, was heated red hot, then inſulated; after which, ſmall quantities of water were thrown into it, each projection of the water cooling more and more the crucible; thus deſcending by degrees till there was only ſufficient heat to boil the water; carefully obſerving, and then deſtroying, the electricity produced at each projection. The electricity was always poſitive or null; at the firſt projections it was very ſtrong; it gradually diminiſhed to the twelfth, when it was ſcarce ſenſible, though always with a tendency to be poſitive.

On repeating this experiment, and varying it in different ways, a remarkable circumſtance was obſerved: When a ſmall quantity of water was thrown into the crucible, the moment it was taken from the fire, while it was of a pale red, approaching what is called the *white heat*, no electricity was obtained.

204
Water evaporates more ſlowly on a red hot metal than on one heated to a leſſer degree.

This fact ſeemed to have ſome connection with another mentioned by Muſſchenbroek, that water evaporates more ſlowly on a metal, or any other incandeſcent body, than on the ſame body, heated only a ſmall degree above boiling water. To examine this relation, and to find whether there was any between the periods of evaporation and the production of electricity, M. Sauſſure made a great number of experiments, which are moſt accurately deſcribed in his work; but as the detail would be much too long, we ſhall only preſent the reader with the heads thereof, and a deſcription of the apparatus.

205
Appa
for mak
the exp
ments.

The apparatus conſiſted of a pot of clay, well baked or annealed, 15 lines thick and 4 inches diameter; this was inſulated by a dry glaſs goblet; upon this pot was placed the crucible, or any other heated ſubſtance on which the water was to be thrown, in order to be reduced into vapour; the crucible was contiguous to a wire connected with an electrometer; a meaſure, containing 54 grains weight of diſtilled water, was thrown upon the heated crucible: the time employed in the evaporation thereof was obſerved by a ſecond watch; the electricity produced by this evaporation was noted. When this meaſure of water was reduced into vapour, the electricity of the apparatus is deſtroyed, and a freſh meaſure of water is thrown into the crucible, proceeding in the ſame manner till the crucible is almoſt cold.

206
Experiments
this ap
ratus.

The firſt experiment was with an iron crucible, from which it was found that Muſſchenbroek was not right in ſaying that the evaporation was ſloweſt when the iron was hotteſt; for at the inſtant it was taken from the fire, it required 19 ſeconds to evaporate the water, and took more time till the third projection, when it took 35 ſeconds, though from that period it employed leſs time, or in other words, the evaporation accelerated in proportion as the iron cooled.

With reſpect to the electricity, it was at firſt 0, then poſitive, afterwards negative, then 0, and afterwards poſitive to the end of the experiment. The vapour was not viſible till the 7th projection.

In the ſecond experiment with the ſame crucible, though every endeavour was made uſe of to render them as ſimilar as poſſible, the electricity was conſtantly poſitive.

The third experiment was with a copper crucible: here alſo the electricity was poſitive; and the longeſt time employed in evaporation was not the inſtant of the greateſt heat. It was very curious to ſee the water endeavouring to gather itſelf into a globule, like mercury on glaſs, to be ſometimes immoveable, and then to turn on itſelf horizontally, with great rapidity; ſometimes throwing from ſome of its points a little jet, accompanied with an hiſſing noiſe.

The fourth experiment was with the ſame crucible: the electricity was at firſt negative, then conſtantly poſitive.

The fifth was with a crucible of pure ſilver: a conſiderable time was employed here in evaporating the ſame quantity of water; even in the inſtant of the greateſt heat it took 5 minutes 6 ſeconds; the electricity was weak; three times no electricity was perceived; five times negative electricity was diſcovered.

In a ſixth experiment with the ſame crucible, a poſitive electricity was obtained at the ſecond projection, after which none of any kind was perceived.

The ſeventh with the ſame, gave at firſt a ſtrong negative electricity; the ſecond and third projection gave a weak poſitive electricity.

The eighth was made with a porcelain cup: here the evaporation was ſlower at the ſecond than the firſt projection; but from this it took longer time till it was nds of ring icity,

cold, contrary to what happened with the metals; the electricity was always negative.

The ninth and tenth experiments with the ſame cup produced ſimilar effects.

The eleventh experiment was with ſpirits of wine in a ſilver crucible: there was no electricity produced at the two firſt projections, and what was afterwards obtained was negative.

Twelfth experiment with ether: here the electricity was alſo negative. Theſe two inflammable fluids, in evaporating, followed the ſame laws as water, being diſſipated at firſt moſt rapidly in the greateſt heat, afterwards taking a longer and longer time before they were evaporated to a certain period, then employing leſs time, or evaporating quicker, till the crucible was nearly cold.

Now as china and ſilver always produced negative electricity, while iron and copper have generally given poſitive electricity, we may conclude, that electricity is poſitive with thoſe bodies that are capable of decompoſing water, or of being decompoſed themſelves by their contact with the water; and negative with thoſe which are not at all decompoſed or altered.

e's ure ning ure e-

From hence M. Sauſſure conjectures, that the electric fluid may be looked upon as formed by the union of fire with ſome unknown principle, perhaps a fluid analogous to inflammable air, but exceedingly more ſubtle. This analogy ſeems to him ſufficiently proved by the inflammation of the electric fluid, and by the diminution of the air in which this inflammation is made. Though many doubts have been attempted to be thrown on this inflammation, there ſeems to be one reaſon which forces us to admit it, which is the loſs of a quantity of this fluid at every ſpark; we may diminiſh at pleaſure any quantity of this fluid by taking a number of ſparks from it. From whence alſo it may be inferred, that a conſiderable quantity is deſtroyed every day by thunder.

nen- M. e's

According to this ſyſtem, when the operation, which converts water into vapour, produces at the ſame time a decompoſition, it then generates the electric fluid. A part of this fluid combines itſelf immediately with theſe vapours, and ſerves even to form them. The veſſel in which this operation is performed, will acquire a poſitive electricity, none at all, or a negative, according as the quantity of the fluid generated is ſuperior, equal, or inferior to that which the formation of the vapour conſumes. When no decompoſition accompanies the evaporation, the electricity ought to be conſtantly negative, becauſe there is nothing to replace the quantity of this fluid which is employed in forming the vapour.

If in the foregoing experiments, thoſe ſubſtances which were ſuſceptible of calcination had conſtantly given a poſitive electricity, and thoſe which do not calcine had always given the negative, every thing would have been explained by theſe principles, and they would thence have acquired a greater degree of probability: but the phenomena have not always followed this law. We have ſeen iron and copper ſometimes give a negative electricity, and ſilver the poſitive. The firſt caſe is not difficult to account for; it is well known with what facility iron and copper calcine in a briſk fire; they become covered with a ſcaly cruſt, which is not ſuſceptible of any further alteration with the ſame heat. If the bottom of the crucible acquires this cruſty coating, the drop of water placed thereon will be no longer in contact with a calcinable ſubſtance; there will be no farther decompoſition, no generation of the electric fluid: the vapours, however, which are ſtill formed, will abſorb a part of the fluid naturally contained in the apparatus, and this will therefore be electrified negatively. If ſome of the ſcales ſhould be ſo far detached, that the water may gain ſome points of contact, the quantity thus generated may compenſate for what is abſorbed by the vapours, and thus the electricity will be null. If more are detached, it will ſuperabound and be poſitive. For the ſame reaſons, a large maſs of water, by attacking the iron in a greater number of points, always gives poſitive electricity; and hence, alſo, a ſtrong poſitive electricity is obtained, by throwing a piece of red-hot iron into a maſs of water.

Methods of meaſuring Electricity, &c.

It is not ſo eaſy to explain why ſilver gives ſometimes a poſitive electricity, but by ſuppoſing it to have been mixed with ſome ſubſtances capable of calcination; and this the more, as the white porcelain always gave negative electricity. This ſuppoſition was verified by ſome ſubſequent experiments, in which the ſame ſilver, when purified, always gave a negative electricity.

M. Sauſſure owns himſelf incapable of explaining why heated charcoal always gives negative electricity; unleſs it can be attributed to the promptitude with which ſo rare a ſubſtance loſes its heat by the contact of water.

210
No ſigns of electricity to be obtained from combuſtion.

One fact aſtoniſhed him, namely, that by combuſtion properly ſo called, although it is an evaporation, nay, the higheſt degree of evaporation, he never obtained any ſigns of electricity, though he tried to obtain it in a variety of ways. Probably the current produced by the flame diſperſes and diſſipates the electricity as ſoon as it is formed. The caſe, however, muſt not be looked upon as general, becauſe M. Volta obtained ſigns of electricity from bodies in combuſtion by means of his condenſer.

Another ſingular fact was, his not being able to obtain electricity without ebullition, though he endeavoured to compenſate by the quantity of ſurface for the quantity of vapours that were elevated by boiling water; and indeed, the ſame quantity of water, if extended over too large a ſurface, will not give any electricity.

211
Mr Bennet's electrometer deſcribed.

But of all the inſtruments by which it hath been attempted to meaſure electricity, none have been found to anſwer the purpoſe equally well with that invented by Mr Bennet, of which an account is given in the 77th volume of the Philoſophical Tranſactions, and which is repreſented fig. 64. It conſiſts of two ſlips of leaf gold, *a a*, ſuſpended in a glaſs cylinder *b*. The foot *c* may be made of wood or metal, and the cap *d* of metal; the latter being made flat at top for the convenience of putting any thing upon it that is to be electrified. The cap is about an inch wider than the diameter of the glaſs, and its rim about three quarters of an inch broad, hanging parallel to the glaſs to keep it ſufficiently inſulated, and to turn off the rain. Within this is another circular rim about half as broad as the former, lined with ſilk or velvet, ſo that

it

Methods of meaſuring Electricity, &c.

it may be made to fit the outſide of the glaſs exactly, while the cap may be eaſily taken off to repair any accident happening to the gold-leaf. From the centre of the cap hangs a tin tube ſomewhat longer than the depth of the inner rim, in which a ſmall peg *f* is placed, which may be taken out occaſionally. To this peg, which is rounded at one end and flat at the other, two ſlips of leaf-gold are faſtened with paſte, gum-water, or varniſh. Theſe are about a fifth-part of an inch broad, and two inches long, tapering to a ſharp point. In one ſide of the cap is a ſmall tube *g*, to place wires in: *h h* are two long pieces of tin-foil faſtened with varniſh on oppoſite ſides of the internal ſurface of the glaſs, where the leaf-gold may be expected to ſtrike, and in connection with the foot. The upper end of the glaſs is covered and lined with ſealing-wax as low as the outermoſt rim, to make the inſulation more perfect. An improvement on this electrometer is to make the cylinder pretty long, and to have a ſmall additional tube of gum-lac on the end of it. The ſlips of tin-foil reach almoſt to the edge of the outer rim, and are ſharp pointed at top; widening in the middle, and decreaſing in breadth again as they deſcend.

212 Its extreme ſenſibility.

The ſenſibility of this electrometer is extreme, as appears from the following examples.

1. On putting powdered chalk into a pair of bellows, and blowing it upon the cap, the latter was electrified poſitively when the nozzle of the bellows was about ſix inches from it; but at the diſtance of three feet from the nozzle, the ſame ſtream electrified it negatively. Thus it appears that the electricity may be changed from poſitive to negative from the mere circumſtance of the wider diffuſion of this ſtream of chalk in the air. It may alſo be changed by placing a bunch of fine wire, ſilk, or feathers, in the nozzle of the bellows; and it is likewiſe negative when blown from a pair of bellows without their iron-pipe, ſo that it may come out in a larger ſtream: but this laſt experiment was found to anſwer beſt in wet weather. There is likewiſe a remarkable difference between the experiment in which the electricity is poſitive and that in which it is negative; the former being communicated with ſome degree of permanency to the cap, ſo that the gold-leaf continues for ſome time to diverge; but the latter being only momentary, and the gold-leaf collapſing as ſoon as the cloud of chalk is diſperſed. The reaſon why the former continues is, that the chalk ſticks to the cap.

2. A piece of chalk drawn over a bruſh, or powdered chalk put into the bruſh, and projected upon the cap, electrifies it negatively; but its electricity is not communicated.

3. Powdered chalk blown with the mouth or bellows from a metal plate placed upon the cap, electrifies it permanently poſitive. Or if the chalk is blown from the plate, either inſulated or not, ſo that the powder may paſs over the cap, if not too far off, it is alſo poſitive. Or if a bruſh is placed upon the cap, and a piece of chalk drawn over it, when the hand is withdrawn, the leaf gold gradually opens with poſitive electricity as the cloud of chalk diſperſes.

4. Powdered chalk falling from one plate to another placed upon the inſtrument, electrifies it negatively.

Meth meaſu Electr &c.

Other methods of producing electricity with chalk and other powders have been tried; as projecting chalk from a gooſe wing, chalking the edges of books and clapping the book ſuddenly together, alſo ſifting the powder upon the cap; all which electrified it negatively: but the inſtrument being placed in a duſty road, and the duſt ſtruck up with a ſtick near it, electrified it poſitively. Breaking the *glaſs-tear* upon a book electrified it negatively, but when broken in water it did not electrify it.

Wheat-flour and red-lead are ſtrongly negative in all caſes where the chalk is poſitive. The following powders were like chalk: red ochre and yellow roſin, coal aſhes, powdered crocus metallorum, aurum moſaicum, black-lead, lampblack (which was only ſenſible in the two firſt methods), powdered quick-lime, umber, lapis calaminaris, Spaniſh brown, powdered ſulphur, flowers of ſulphur, iron-filings, ruſt of iron, ſand. Roſin and chalk, ſeparately alike, were changed by mixture; this was often tried in dry weather, but did not ſucceed in damp: white lead alſo ſometimes produced poſitive and ſometimes negative electricity when blown from a plate.

If a metal cup be placed upon the cap with a red-hot coal in it, a ſpoonful of water thrown in electrifies the cap negatively; and if a bent wire be placed in the cap, with a piece of paper faſtened to it to increaſe its ſurface, the poſitive electricity of the aſcending vapour may be tried by introducing the paper into it. Perhaps the electrification of fogs and rain is well illuſtrated by pouring water through an inſulated cullender, containing hot coals, where the aſcending vapour is poſitive and falling drops negative.

21 Confic ably a mente means lighte candle

The ſenſibility of this electrometer may be conſiderably increaſed by placing a candle upon the cap. By this means, a cloud of chalk, which in the other caſe only juſt opens the leaf-gold, will cauſe it to ſtrike the ſides for a long time together; and the electricity, which was not before communicated, now paſſes into the electrometer, cauſing the leaf-gold to repel after it is carried away. Even ſealing-wax by this means communicates its electricity at the diſtance of 12 inches at leaſt, which it would ſcarcely otherwiſe do by rubbing upon the cap.

A cloud of chalk or wheat flower may be made in one room, and the electrometer with its candle be afterwards leiſurely brought from another room, and the cloud will electrify it before it comes very near. The air of a room adjoining to that wherein the electrical machine was uſed, was very ſenſibly electrified, which was perceived by carrying the inſtrument through it with its candle.

21 Its ap tion t lectric kites.

In very clear weather, when no clouds were viſible, the electrometer has been often applied to the inſulated ſtring of kites without metal, and their poſitive electricity cauſed the leaf-gold to ſtrike the ſides; but when a kite was raiſed in cloudy weather with a wire in the ſtring, and when it gave ſparks about a quarter of an inch long, the electricity was ſenſible by the electrometer at the diſtance of ten yards or more from the ſtring; but when placed at the diſtance of ſix feet, the leaf-gold continued to ſtrike the ſides of the electrometer for more than an hour together, with a velocity increaſing and decreaſing with the denſity or diſtance of the unequal clouds which paſſed over.

Sometimes the electricity of an approaching cloud has

ds of
ing
city,

has been ſenſible without a kite, though in a very unfavourable ſituation for it, being in a town ſurrounded with hills, and where buildings encompaſſed the wall on which the electrometer was placed. A thunder-cloud paſſing over, cauſed the leaf-gold to ſtrike the ſides of the glaſs very quick at each flaſh of lightning.

;
ex-
nts,
g
at
ity
e-
ne-

No ſenſible electricity is produced by blowing pure air, projecting water, by ſmoke, flame, or exploſions of gunpowder.

A book was placed upon the cap, and ſtruck with ſilk, linen, woollen, cotton, parchment, and paper, all which produced negative repulſion; but when the other ſide of the book was ſtruck with ſilk, it became poſitive; this ſide, ſtruck at right angles with the former, was again negative; and by continuing the ſtrokes which produced poſitive, it changed to negative for a little while; and, by ſtopping again, became poſitive. No other book would do the ſame, though the ſides were ſcraped unchalked, upon a ſuppoſition that altering the ſurface would produce it. At laſt, one ſide of a book was moiſtened, which changed it; whence it was concluded, that one edge of the book had lain in a damp place; which conjecture was farther confirmed by all the books becoming poſitive in damp weather, and one of them being dried at the fire again became negative.

When the cap is approached with excited ſealing-wax, the leaf-gold may be made to ſtrike the ſides of the glaſs more than twelve times; and as the ſealing-wax recedes, it ſtrikes nearly as often; but if it approaches much quicker than it recedes, the ſecond nnmber will ſometimes be greater.

The quantity of electricity neceſſary to cauſe a repulſion of the leaf-gold is ſo ſmall, that the ſharpeſt point or edges do not draw it off without touching; hence it is unneceſſary to avoid points or edges in the conſtruction of this inſtrument.

xpe-
on
po-
f

To the experiments on blowing powders from a pair of bellows it may be added, that if the powder is blown at about the diſtance of three inches upon a plate which is moiſtened or oiled, its electricity is contrary to that produced by blowing upon a dry plate. This ſhows that the electricity of the ſtreams of powder iſſuing out of the bellows is only contrary to the more expanded part, becauſe it is within the influence of its atmoſphere; for when this is deſtroyed by the adheſion of the powder to the moiſtened plate, it is negative when the bellows are poſitive, as it was before poſitive when the more expanded cloud was negative. The experiments on evaporation of water may be tried with more eaſe and certainty of ſucceſs by heating the ſmall end of a tobacco-pipe, and pouring water into the head; which running down to the heated part, is ſuddenly expanded, and will ſhow its electricity when projected upon the cap of the electrometer more ſenſibly than any other way that has been tried. If the pipe be fixed in a cloven ſtick, and placed in the cap of one electrometer whilſt the ſteam is projected upon another, it produces both electricities at once. Spirit of wine and ether are electrified like water. Oil and vitriolic acid produced ſmoke without any change of electricity. In theſe experiments a long pipe is better than a ſhort one.

Methods of meaſuring electricity, &c.

Beſides theſe inſtruments, there are ſeveral others invented by Mr Cavallo which anſwer the purpoſe of obſerving the electricity of the atmoſphere extremely well, tho' not with ſuch great accuracy as that juſt now deſcribed; and of which he gives the following account.

217
Mr Cavallo's inſtrument for obſerving the electricity of the atmoſphere.

"Fig. 67. repreſents a very ſimple inſtrument for making experiments on the electricity of the atmoſphere; and which, on ſeveral accounts, ſeems to be the moſt proper for that purpoſe. *AB* is a common jointed fiſhing-rod, without the laſt or ſmalleſt joint. From the extremity of this rod proceeds a ſlender glaſs tube *C*, covered with ſealing-wax, and having a cork *D* at its end, from which a pith ball electrometer is ſuſpended. *HGI* is a piece of twine faſtened to the other extremity of the rod, and ſupported at *G* by a ſmall ſtring *FG*. At the end (*I*) of the twine a pin is faſtened; which when puſhed into the cork *D*, renders the electrometer *E* uninſulated. When I would obſerve the electricity of the atmoſphere with this inſtrument, I thruſt the pin (*I*) into the cork *D*; and holding the rod by its lower end *A*, project it out from a window in the upper part of the houſe, into the air, raiſing the end of the rod with the electrometer, ſo as to make an angle of about 50° or 60° with the horizon. In this ſituation I keep the inſtrument for a few ſeconds; and then pulling the twine at *H*, the pin is diſengaged from the cork *D*: which operation cauſes the ſtring to drop in the dotted ſituation *KL*, and leaves the electrometer inſulated, and electrified with an electricity contrary to that of the atmoſphere. This done, I draw the electrometer into the room; and examine the quality of the electricity without obſtruction either from wind or darkneſs. With this inſtrument I have made obſervations on the electricity of the atmoſphere ſeveral times in a day for ſeveral months."

218
His electrometer for rain.

His electrometer for rain is ſhown Plate CLXXVII. fig. 70. and of this he gives the following deſcription. "*ABCI* is a ſtrong glaſs tube about two feet and a half long, having a tin funnel *DE* cemented to its extremity, which funnel defends part of the tube from the rain. The outſide ſurface of the tube from *A* to *B* is covered with ſealing-wax; ſo alſo is the part of it which is covered by the funnel. *FD* is a piece of cane, round which braſs wires are twiſted in different directions, ſo as to catch the rain eaſily, and at the ſame time to make no reſiſtance to the wind. This piece of cane is fixed into the tube; and a ſlender wire proceeding from it goes through the bore of the tube, and communicates with the ſtrong wire *AG*, which is thruſt into a piece of cork faſtened to the end *A* of the tube. The end *G* of the wire *AG* is formed in a ring, from which I ſuſpend a more or leſs ſenſible pith-ball electrometer as occaſion requires. This inſtrument is faſtened to the ſide of the window-frame, where it is ſupported by ſtrong braſs hooks at *CB*; which part of the tube is covered with a ſilk lace, in order to adapt it better to the hooks. The part *FC* is out of the window, with the end *F* elevated a little above the horizon. The remaining part of the inſtrument comes through a hole in one of the lights of the ſaſh within the room, and no more of it touches the ſide of the window than the part *CB*. When it rains, eſpecially in paſſing ſhowers, this inſtrument, ſtanding in the ſituation above deſcribed, is frequently electrified; and, by the diverging of the electrometer, the quantity and quality of the electricity of the rain may be obſerved without any danger of a miſtake. With this inſtrument I have obſerved,

ſerved, that the rain is generally, though not always, electrified negatively; and ſometimes ſo ſtrongly, that I have been able to charge a ſmall coated phial at the wire *A G*. This inſtrument ſhould be fixed in ſuch a manner that it may be eaſily taken off from the window and replaced again as occaſion requires; for it will be neceſſary to clean it very often, particularly when a ſhower of rain is approaching."

210
All theſe inſtruments imperfect.

Notwithſtanding the great accuracy of theſe inſtruments, however, there are ſtill many degrees of electricity too ſmall to be obſerved by any of them. To be able to collect theſe, it is neceſſary to have one capable of retaining the electricity it receives for a conſiderable time, and of allowing it to accumulate till it becomes capable of being meaſured by ſome of the common methods. Upon inſtruments of this kind Mr Cavallo gives the following diſſertation.

220
Mr Cavallo's diſſertation on meaſuring ſmall degrees of electricity.

" Beſides the way of aſcertaining ſmall quantities of electricity by means of very delicate electrometers, two methods have been communicated to the philoſophical world, by which ſuch quantities of electricity may be rendered manifeſt as could not be perceived by other means. The firſt of thoſe methods is an invention of M. Volta, the apparatus for it being called the *condenſer of electricity*, and is deſcribed in the Philoſophical Tranſactions, Vol. LXXII. The ſecond is a contrivance of the above-mentioned Mr Bennet, who calls the apparatus *the doubler of electricity*. A deſcription of it is inſerted in the Philoſophical Tranſactions, Vol. LXXVII.

221
Volta's condenſer.

" M. Volta's condenſer conſiſts of a flat and ſmooth metal plate, furniſhed with an inſulating handle, and a ſemiconducting, or imperfectly inſulating, plane. When one wiſhes to examine a weak electricity with this apparatus, as that of the air in calm and hot weather, which is not generally ſenſible to an electrometer, he muſt place the above-mentioned plate upon the ſemiconducting plane, and a wire, or ſome other conducting ſubſtance, muſt be connected with the metal plate, and muſt be extended in the open air, ſo as to abſorb its electricity; then, after a certain time, the metal plate muſt be ſeparated from the ſemiconducting plane; and being preſented to an electrometer, will electrify it much more than if it had not been placed upon the above mentioned plane.

" The principle on which the action of this apparatus depends is, that the metal plate, whilſt ſtanding contiguous to the ſemiconducting plane, will both abſorb and retain a much greater quantity of electricity than it can either abſorb or retain when ſeparate, its capacity being increaſed in the former and diminiſhed in the latter caſe.

" Whoever conſiders this apparatus, will eaſily find, that its office is not to manifeſt a ſmall quantity of electricity, but to condenſe an expanded quantity of electricity into a ſmall ſpace: hence, if by means of this apparatus one expected to render more manifeſt than it generally is, when communicated immediately to an electrometer, the electricity of a ſmall tourmalin, or of a hair when rubbed, he would find himſelf miſtaken.

222
Mr Bennet's doubler objected to.

" It is Mr Bennet's doubler that was intended to anſwer that end; viz. to multiply, by repeated doubling, a ſmall, and otherwiſe unperceivable, quantity of electricity, till it became ſufficient to affect an electrometer, to give ſparks, &c. The merit of this invention is certainly conſiderable; but the uſe of it is far from preciſe and certain.

" This apparatus conſiſts of three braſs plates, which we ſhall call *A*, *B*, and *C*; each of which is about three or four inches in diameter. The firſt plate *A* is placed upon the gold-leaf electrometer, or it may be ſupported horizontally by any other inſulating ſtand, and its upper part only is thinly varniſhed. The ſecond plate *B* is varniſhed on both ſides, and is furniſhed with an inſulating handle, which is faſtened laterally to the edge of it. The third plate *C* is varniſhed on the under ſide only, and is furniſhed with an inſulating handle, which is perpendicular to its upper ſurface.

" This apparatus is uſed in the following manner. The plate *B* being laid upon the plate *A*, the ſmall quantity of electricity, which is required to be multiplied, is communicated to the under part of the plate *A*, and at the ſame time the upper part of *B* is touched with a finger; then the finger is firſt removed; the plate *B* is afterwards removed from over the plate *A*. The plate *C* is now laid upon *B*, and its upper ſurface is touched, for a ſhort time, with a finger. By this operation it is clear, that if the electricity communicated to the plate *A* is poſitive, the plate *B* muſt have acquired a negative electricity, and the plate *C* muſt have acquired the poſitive, viz. the ſame of the plate *A*. Now the plate *B*, being ſeparated from *C*, is laid as before upon *A*; the edge of *C* is brought into contact with the under part of the plate *A*, and at the ſame time the upper part of *B* is touched with a finger; by which means the plate *B*, being acted upon by the atmoſpheres of both the plates *A* and *C*, will acquire nearly twice as much electricity as it did the firſt time, and of courſe will render the plate *C*, when that is laid upon it, proportionably more electrified than before: thus, by repeating this operation, the electricity may be increaſed to any required degree.

" The varniſh on thoſe ſurfaces of the plates which are to lie contiguous to each other, ſerves to prevent the metal of one touching the metal of the other; for in that caſe, inſtead of one plate cauſing a contrary electricity in the other, the electricity of the firſt would be gradually communicated to the others, and would be diſſipated.

" As ſoon as I underſtood the principle of this contrivance, I haſtened to conſtruct ſuch an apparatus, in order to try ſeveral experiments of a very delicate nature, eſpecially on animal bodies and vegetables, which could not have been attempted before, for want of a method of aſcertaining exceedingly ſmall quantities of electricity; but after a great deal of trouble, and many experiments, I was at laſt forced to conclude, that the doubler of electricity is not an inſtrument to be depended upon, for this principal reaſon, viz. becauſe it multiplies not only the electricity which is willingly communicated to it from the ſubſtance in queſtion; but it multiplies alſo that electricity which in the courſe of the operation is almoſt unavoidably produced by accidental friction; or that quantity of electricity, however ſmall it may be, which adheres to the plates in ſpite of every care and precaution.

" Having found, that with a doubler conſtructed in the above deſcribed manner, after doubling or multiplying

tiplying 20 or 30 times, it always became ſtrongly electrified, though no electricity had been communicated to it before the operation, and though every endeavour of depriving it of any adhering electricity had been practiſed; I naturally attributed that electricity which appeared after repeatedly doubling, to ſome friction given to the varniſh of the plates in the courſe of the operation. In order to avoid entirely this ſource of miſtake, or at leaſt of ſuſpicion, I conſtructed three plates without the leaſt varniſh, and which, of courſe, could not touch each other, but were to ſtand only within about one-eighth of an inch of each other. To effect this, each plate ſtood vertical, and was ſupported by two glaſs ſticks, which were covered with ſealing-wax. Theſe were inſerted into a wonden pedeſtal $7\frac{1}{2}$ inches long, $2\frac{1}{2}$ broad, and $1\frac{1}{4}$th inch thick, being kept faſt by cement both to the pedeſtal and likewiſe to another piece of wood faſtened to the back of the plate. The plate itſelf is of ſtrong tin, and meaſures about eight inches in diameter. The ſtand projects very little before the plate; by which means, when two of thoſe plates are placed upon a table facing each other, the wooden ſtands will prevent their coming into actual contact.

"I need not deſcribe the manner of doubling or of multiplying with thoſe plates; the operation being eſſentially the ſame as when the plates are conſtructed according to Mr Bennet's original plan, excepting that, inſtead of placing them one upon the other, mine are placed facing each other; and in performing the operation they are laid hold of by the wooden ſtand *AB*; ſo that no friction can take place either upon the glaſs legs or upon any varniſh; for theſe plates have no need of being varniſhed. Sometimes, inſtead of touching the plates themſelves with the finger, I have fixed a piece of thin wire to the back of the plate, and have then applied the finger to the extremity of the wire, ſuſpecting that ſome friction and ſome electricity might poſſibly be produced when the finger was applied in full contact to the plate itſelf.

"It is evident, that as the plates do not come ſo near to each other in this as they do in the other conſtruction, the electricity of one of them cannot produce ſo great a quantity of the contrary electricity in the oppoſite plate: hence, in this conſtruction, it will be neceſſary to continue the operation of doubling ſomewhat longer; but this diſadvantage is more than repaid by the certainty of avoiding any friction.

"Having conſtructed thoſe plates, I thought that I might proceed to perform the intended experiments without any further obſtruction: but in this I found myſelf quite miſtaken; for on trying to multiply with thoſe new plates, and when no electricity had been previouſly communicated to any of them, I found, that after doubling 10, 15, or at moſt 20 times, they became ſo full of electricity as to afford even ſparks. All my endeavours to deprive them of electricity proved ineffectual. Neither expoſing them, and eſpecially the glaſs ſticks, to the flame of burning paper, nor breathing upon them repeatedly, nor leaving them untouched for ſeveral days, and even for a whole month, during which time the plates remained connected with the ground by means of good conductors, nor any other precaution I could think of, was found capable of depriving them of every veſtige of electricity; ſo that they might ſhow none after doubling 10, 15, or at moſt 20 times.

"The electricity produced by them was not always of the ſame ſort; for ſometimes it was negative for two or three days together; at other times it was poſitive for two or three days more; and often it changed in every operation. This made me ſuſpect, that poſſibly the beginning of that electricity was derived from my body, and being communicated by the finger to the plate that was firſt touched, was afterwards multiplied. In order to clear this ſuſpicion, I actually tried thoſe plates at different times, viz. before and after having walked a great deal, before and after dinner, &c. noting very accurately the quality of the electricity produced each time; but the effects ſeemed to be quite unconnected with the above mentioned concomitant circumſtances; which independence was further confirmed by obſerving that the electricity produced by the plates was of a fluctuating nature, even when, inſtead of touching the plates with the finger, they had been touched with a wire, which was connected with the ground, and which I managed by means of an inſulating handle.

"At laſt, after a great variety of experiments, which it is unneceſſary to deſcribe, I became fully convinced, that thoſe plates did always retain a ſmall quantity of electricity, perhaps of that ſort with which they had been laſt electrified, and of which it was almoſt impoſſible to deprive them. The various quality of the electricity produced was owing to this, viz. that as one of thoſe plates was poſſeſſed of a ſmall quantity of poſitive electricity, and another was poſſeſſed of the negative electricity, that plate which happened to be the moſt powerful, occaſioned a contrary electricity in the other plate, and finally produced an accumulation of that particular ſort of electricity.

"Thoſe obſervations evidently ſhow, that no preciſe reſult can be obtained from the uſe of thoſe plates; and of courſe, that when conſtructed according to the original plan, they are ſtill more equivocal, becauſe they admit of more ſources of miſtake.

"As thoſe plates, after doubling or multiplying only four or five times, ſhow no ſigns of electricity, none having been communicated to them before, I imagined that they might be uſeful ſo far only, viz. that when a ſmall quantity of electricity is communicated to any of them in the courſe of ſome experiment, one might multiply it with ſafety four or five times, which would even be of advantage in various caſes; but in this alſo my expectations were diſappointed.

"Having obſerved, after many experiments, that, *cæteris paribus*, when I began to multiply from a certain plate, which we ſhall call *A*, the electricity which reſulted was generally poſitive; and when I began with another plate *B*, viz. conſidered this plate *B* as the firſt plate, the reſulting electricity was generally negative; I communicated ſome negative electricity to the plate *A*, with a view of deſtroying its inherent poſitive electricity. This plate *A* being now electrified negatively, but ſo weakly as juſt to affect an electrometer, I began doubling; but after having doubled three or four times, I found, by the help of an electrometer, that the communicated negative electricity in the plate was diminiſhed inſtead of being increaſed; ſo that ſometimes it vaniſhed entirely, though by continuing the operation

tion it often began to increaſe again, after a certain period. This ſhows, that the quantity of electricity, which however ſmall it may be, remains in a manner faſtened to the plates, will help either to increaſe or to diminiſh the accumulation or multiplication of the communicated electricity, according as it happens to be of the ſame or of a different nature.

"After all the above mentioned experiments made with thoſe doubling or multiplying plates, we may come to the following concluſion, viz. that the invention is very ingenious, but their uſe is by no means to be depended upon. It is to be wiſhed that they may be improved ſo as to obviate the weighty objections that have been mentioned; the firſt deſideratum being to conſtruct a ſet of ſuch plates as, when no electricity is communicated, they will produce none after having performed the operation of doubling for a certain number of times.

223 Cavallo's opinion of the methods by which ſmall quantities of electricity can be meaſured.

"Upon the whole, the methods by which ſmall quantities of electricity may be aſcertained with preciſion are, as far as I know, only three. If the abſolute quantity of electricity be ſmall and pretty well condenſed, as that produced by a ſmall tourmalin when heated, or by a hair when rubbed, the only effectual method of manifeſting its preſence, and aſcertaining its quality, is to communicate it immediately to a very delicate electrometer, viz. a very light one, that has no great extent of metallic or of other conducting ſubſtance; becauſe if the ſmall quantity of electricity that is communicated to it be expanded throughout a proportionably great ſurface, its elaſticity, and of courſe its power of ſeparating the corks of an electrometer, will be diminiſhed in the ſame proportion.

"The other caſe is, when one wants to aſcertain the preſence of a conſiderable quantity of electricity, which is diſperſed or expanded into a great ſpace, and is little condenſed, like the conſtant electricity of the atmoſphere in clear weather, or like the electricity which remains in a large Leyden phial after the firſt or ſecond diſcharge.

224 His apparatus for this purpoſe.

"To effect this, I uſe an apparatus, which in principle is nothing more than M. Volta's condenſer; but with certain alterations, which render it leſs efficacious than in the original plan, but at the ſame time render it much leſs ſubject to equivocal reſults. I place two of the above deſcribed tin-plates upon a table, facing each other, and about $\frac{1}{8}$th of an inch aſunder. One of thoſe plates, for inſtance *A*, is connected with the floor by means of a wire, and the other plate *B* is made to communicate, by any convenient means, with the electricity that is required to be collected. In this diſpoſition the plate *B*, on account of the proximity of the other plate, will imbibe more electricity than if it ſtood far from it, the plate *A* in this caſe acting like the ſemiconducting plane of M. Volta's condenſer, though not with quite an equal effect, becauſe the other plate *B* does not touch it; but yet, for the very ſame reaſon, this method is incomparably leſs ſubject to any equivocal reſult. When the plates have remained in the ſaid ſituation for the time that may be judged neceſſary, the communication between the plate *B* and the conducting ſubſtance which conveyed the electricity, muſt be diſcontinued by means of a glaſs ſtick, or other inſulating body; then the plate *A* is removed, and the plate *B* is preſented to an electrometer, in order to aſcertain the quality of the electricity; but if the electrometer be not affected by it, then the plate *B* is brought with its edge into contact with another very ſmall plate, which ſtands upon a ſemiconducting plane, after the manner of M. Volta's condenſer (N); which done, the ſmall plate, being held by its inſulating handle, is removed from the inferior plane, and is preſented to the electrometer: and it frequently happens, that the ſmall plate will affect the electrometer very ſenſibly, and quite ſufficient for the purpoſe; whereas the large plate itſelf ſhowed no clear ſigns of electricity.

"If it be aſked, why I uſe the ſemiconducting plane for this ſmall plate, and not for the large one? the anſwer is, firſt, becauſe the large ſemiconducting plane is incomparably more difficult to be procured than the ſmall one; and, ſecondly, becauſe the ſmall plane may be eaſily deprived of any accidental electricity which may adhere to it; but the large one is more difficultly rendered fit for the purpoſe, eſpecially as the large plate ought in geneaal to remain upon it a much longer time than the ſmall plate is to remain upon its ſemi-conducting plane.

"The third and laſt caſe is, when the electricity to be aſcertained is neither very conſiderable in quantity nor much condenſed; ſuch is the electricity of the hair of certain animals, of the ſurface of chocolate when cooling, &c. In this caſe the beſt method is to apply a metal plate, furniſhed with an inſulating handle, like an electrophorus plate, to the electrified body, and to touch this plate with a finger for a ſhort time whilſt ſtanding in that ſituation; which done, the plate is removed, and is brought near an electrometer; or its electricity may be communicated to the plate of a ſmall condenſer, as directed in the preceding caſe, which will render the electricity more conſpicuous. It is evident, that in this caſe the metal plate will acquire the electricity contrary to that of the ſubſtance in queſtion: but this anſwers the ſame purpoſe; for if the electricity of the plate be found to be poſitive, one muſt conclude, that the electricity of the body in queſtion is negative, and contrariwiſe. In this operation, care muſt be had not to put the metal plate too near, or in full contact with the ſubſtance to be examined, leſt the friction, likely to happen between the plate and the body, ſhould produce ſome electricity, the origin of which might be attributed to other cauſes.

"Having thus far deſcribed the ſureſt methods of aſcertaining the preſence and quality of electricity, when its quantity or degree of condenſation is ſmall, I ſhall now beg leave to add ſome farther remarks on the ſubject of electricity in general, and which have been principally ſuggeſted by what has been mentioned.

"On the hypotheſis of a ſingle electric fluid, it is ſaid, that every ſubſtance in nature, when not electrified

---

(N) This ſmall plate is nearly of the ſize of a ſhilling, and the ſemiconducting plane is of wood covered with copal varniſh.

fied, contains its proper ſhare of electric fluid, which is proportionate to its bulk, or to ſome other of its properties; and it is generally believed, that this equal or proportionate diſtribution of electric fluid takes place with the greateſt part of natural bodies. However, the fact is far from being ſo; and I may venture to aſſert, that, ſtrictly ſpeaking, every ſubſtance is always electrified, *viz.* that every ſubſtance, and even the various parts of the ſame body, contain at all times more or leſs electric fluid than that quantity of it which it ought to contain, in order to be in an electrical equilibrium with the bodies that ſurround it.

“ At firſt ſight it may be thought quite immaterial to know, whether the electric fluid is diſperſed in the juſt proportion among the various ſubſtances which are not looked upon as electrified, or whether it deviates in a ſmall degree from that proportionate diſtribution; but it will hereafter appear, that one of thoſe aſſertions will lead us to the explanation of an intereſting phænomenon in electricity, whereas the other does not admit of it; beſides, what is called a ſmall difference of the proportionate diſtribution, inſomuch as it does not affect our inſtruments, may be ſufficient for ſeveral operations of nature, which it is our intereſt to inveſtigate.

“ If we inquire what phenomena evince this altered diſtribution, or the actually electrified ſtate of all bodies, the preceding obſervations will furniſh ſome very unequivocal ones; eſpecially that of the doubling plates made after my plan, which ſhowed to be electrified even after having remained untouched for a whole month, during which time they had been in communication with the ground; for if each of them had contained an equal ſhare of electric fluid, the electric atmoſphere of one of them could not poſſibly occaſion a contrary electricity in the other, and conſequently no accumulation of that power could have happened.

“ A great number of inſtances are related in books on the ſubject of electricity, and in the Phil. Tranſ. of pieces of glaſs, of ſulphur, of ſealing-wax, &c. having remained electrified ſo far as to affect an electrometer for months after they had been excited, or even touched; but the following experiment will ſhow, in a clearer manner, the great length of time that a quantity of electricity will remain upon a body.

“ Having conſtructed a gold-leaf electrometer in the niceſt manner I could, and which, on account of the non-conducting nature and conſtruction of its upper part, could remain ſenſibly electrified for ſeveral hours together, I communicated ſome electricity to it, which cauſed the ſlips of gold-leaf to diverge with a certain angle; and as the electricity was gradually diſſipated, the divergency diminiſhed in the ſame proportion. Now, whilſt this diminution of divergency was going on, I looked through a ſmall teleſcope, and, by means of a micrometer, meaſured the chords of the angles of divergency, ſetting down the time elapſed between each pair of contiguous obſervations; and as the chord of the angle of divarication is in the direct ſimple proportion of the denſity of the electric fluid (A), I could by this means know how much electric fluid was loſt by the electrometer in a certain time, and of courſe what portion of the electricity firſt communicated to the electrometer ſtill remained in it. Let us make the chord of the angle of divarication on firſt electrifying the electrometer, or rather when firſt obſerved, equal to 16; or let us conceive that quantity of electricity to be diviſible into 16 equal parts.

Method of meaſuring Electricity, &c.

“ I obſerved, that, when the chord of the angle became equal to eight, the time elapſed between this and the firſt obſervation was one minute; when the chord became equal to four, the time elapſed between this point and the preceding obſervation was 3′ 30″; when the chord became equal to two, the time elapſed ſince the preceding obſervation was 17′; and when the chord became equal to one, the time elapſed ſince the preceding obſervation was one hour and a quarter; after which the electrometer remained ſenſibly electrified for a long time.

“ In repeating this experiment, the times elapſed between the correſponding obſervations did not follow ſtrictly the ſame proportion of increaſe; nor did they increaſe regularly in the ſame experiments, which may be attributed in great meaſure to the inaccuracy in obſerving, and to the fluctuating ſtate of the air; but it could be ſafely inferred from all the experiments, that the times required for the diſperſion of the electricity were at leaſt greater than the inverſe duplicate proportion of the denſities of the electricity remaining in the electrometer. And if we imagine, that they continue to diminiſh in the ſame proportion of increaſing time, which is far from being an extravagant ſuppoſition, we ſhall find, by a very eaſy calculation, that about two years after the electrometer would ſtill retain the $\frac{1}{100}$th part of the electricity communicated to it in the beginning of the experiment; and as we do not know how far a quantity of electricity is diviſible, or to what extent it may be expanded, we may conclude with ſaying, that ſtrictly ſpeaking the electrometer would remain electrified for many years.

“ It may be inferred from this, as well as from many other experiments, that the air, or in general any ſubſtance, is a more or leſs perfect conductor of electricity, according as the electricity which is to paſs through it is more or leſs condenſed; ſo that if a given quantity of electric fluid be communicated to a ſmall braſs ball, one may take it away by ſimply touching the ball with a finger; but if the ſame quantity of electric fluid be communicated to a ſurface of about 100 or 1000 ſquare feet, the touching with the finger will hardly take away any part of it.

“ If it be aſked, what power communicates the electricity, or originally diſturbs the equilibrium of the natural quantity of electric fluid in the various bodies of the univerſe? we may anſwer, that the fluctuating electric ſtate of the air, the paſſage of electrified clouds, the evaporation and condenſation of fluids, and the friction ariſing from divers cauſes, are perpetually acting upon the electric fluid of all bodies, ſo as either to increaſe or diminiſh it, and that to a more conſiderable degree than is generally imagined.

“ I ſhall conclude, with briefly propoſing an explanation of the production of electricity by friction, which is dependent upon the above ſtated propoſition,

---

(A) This propoſition was firſt aſcertained by F. Beccaria. See Philoſophical Tranſactions, Vol. LVI.

Methods of meaſuring Electricity, &c.

*viz.* that bodies are always electrified in ſome degree; and likewiſe upon the well known principle of the capacity of bodies for holding electric fluid being increaſed by the proximity of other bodies in certain circumſtances.

"It ſeems to me, that the cylinder of an electrical machine muſt always retain ſome electricity of the poſitive kind, though not equally denſe in every part of its ſurface; therefore, when one part of it is ſet contiguous to the rubber, it muſt induce a negative electricity in the rubber. Now, when, by turning the cylinder, another part of it (which ſuppoſe to have a leſs quantity of poſitive electricity than the preceding) comes quickly againſt the rubber; the rubber being already negative, and not being capable of loſing that electricity very quickly, muſt induce a ſtronger poſitive electricity in the former part which is now oppoſite to it: but this part cannot become more poſitively electrified, unleſs it receives the electric fluid from ſome other body, and therefore ſome quantity of electric fluid paſſes from the loweſt part of the rubber to this part of the glaſs; which additional quantity of electric fluid is retained by it alone only whilſt it remains in contact with the rubber; for after that, its capacity being diminiſhed, the electric fluid endeavours to eſcape from it. Thus we may conceive how every other part of the glaſs acquires the electric fluid, &c. and what is ſaid of the cylinder of an electrical machine may, with proper changes, be applied to any other electric and its rubber."

227 Cavallo's inſtrument for obſerving ſmall quantities of electricity.

An inſtrument for obſerving very ſmall quantities of electricity has likewiſe been invented by the ſame author, and deſcribed in the ſecond part of the volume juſt quoted. The properties of this machine, which from its office may be called *a collector of electricity*, are, *firſt*, that when connected with the atmoſphere, the rain, or in ſhort with any body which produces electricity ſlowly, or which contains that power in a very rarefied manner, it collects the electricity, and afterwards renders both the preſence and quality of it manifeſt, by communicating it to an electrometer. 2*dly*, This collecting power, by increaſing the ſize of the inſtrument, and eſpecially by uſing a ſecond or ſmaller inſtrument of the like ſort to collect the electricity from the former, may be augmented to any degree. 3*dly*, It is conſtructed, managed, and preſerved with eaſe and certainty; and it never gives, nor can it give, an equivocal reſult, as he has proved experimentally, and as will appear by conſidering its conſtruction.

Plate CLXXVIII. exhibits two perſpective views of this collector. Fig. 93. ſhows the inſtrument in the ſtate of collecting the electricity; and fig. 94. ſhows it in the ſtate in which the collected electricity is to be rendered manifeſt. An electrometer is annexed to each. The letters of reference indicate the ſame parts in both figures.

*ABCD* is a flat tin plate, 13 inches long and 8 inches broad; to the two ſhorter ſides of which are ſoldered two tin tubes *AD* and *BC*, which are open at both ends. *DE* and *CF* are two glaſs ſticks covered with ſealing-wax by means of heat, and not by diſſolving the ſealing-wax in ſpirits. They are cemented into the lower apertures of the tin tubes, and alſo in the wooden bottom of the frame or machine at *E* and *F*; ſo that the tin plate *ABCD* is ſupported by thoſe glaſs ſticks in a vertical poſition, and is exceedingly well inſulated. *GHILKM* and *NOPV* are two frames of wood, which being faſtened to the bottom-boards by means of braſs hinges, may be placed ſo as to ſtand in an upright poſition and parallel to the tin-plate, as ſhown in fig. 94. or they may be opened, and laid upon the table which ſupports the inſtrument, as ſhown in fig. 93. The inward ſurfaces of thoſe frames from their middle upwards are covered with gilt paper *XY*; but it would be better to cover them with tin-plates hammered very flat. When the lateral frames ſtand ſtraight up, they do not touch the tin plate; but they ſtand at about one-fifth part of an inch aſunder. They are alſo a little ſhorter than the tin-plate, in order that they might not touch the tin-tubes *AD*, *BC*. In the middle of the upper part of each lateral frame is a ſmall flat piece of wood *S* and *T*, with a braſs hook; the uſe of which is to hold up the frames without the danger of their falling down when not required, and at the ſame time it prevents their coming nearer to the tin-plate than the proper limit. It is evident, that when the inſtrument ſtands as ſhown in fig. 94. the gilt ſurface of the paper *XY*, which covers the inſide of the lateral frames, ſtands contiguous and parallel to the tin-plate.

Method meaſuri Electric &c.

When the inſtrument is to be uſed, it muſt be placed upon a table, a window, or other convenient ſupport; a bottle electrometer is placed near it, and is connected, by means of a wire, with one of the tin tubes *AD*, *BC*; and by another conducting communication the tin-plate muſt be connected with the electrified ſubſtance, the electricity of which is required to be collected on the plate *ABCD*: thus, for inſtance, if it be required to collect the electricity of the rain or of the air, the inſtrument being placed near a window, a long wire muſt be put with one extremity into the aperture *A* or *B* of one of the tin-tubes, and with the other extremity projecting out of the window. If it be required to collect the electricity produced by evaporation, a ſmall tin pan, having a wire or foot of about ſix inches in length, muſt be put upon one of the tin-tubes, ſo that, the wire going into the tube, the pan may ſtand about two or three inches above the inſtrument. A lighted coal is then put into the pan, and a few drops of water poured upon it will produce the deſired effect. Thus far may ſuffice with reſpect to the mechanical deſcription of the inſtrument: the power and uſe of it will be made apparent by the following experiments.

1. Communicate to the tin-plate *ABCD* a quantity of electricity, for inſtance, as much as would very ſenſibly affect a common cork-ball electrometer; then, if the lateral frames *GHM*, *NOP*, ſtand upright, as in fig. 94. the electrometer *W* will ſhow no divergency; but if the frames are opened and let down, as in fig. 93. the balls of the electrometer *W* will immediately repel each other, and by the approach of an excited piece of ſealing-wax, the quality of the electricity may be eaſily aſcertained after the uſual manner. Put up the lateral frames again, and the electricity will apparently vaniſh; let them down, and the electricity will re-appear, and ſo on. If you touch any part of the tin-plate or tin-tubes with your finger, the electricity is thereby entirely removed, and that will be the caſe whether the lateral frames are up or down.

2. Take an extended piece of tin-foil, about four yards ſquare, and, holding it by a ſilk thread, electrify it ſo weakly as not to be capable of affecting an electrometer; then bring it in contact with the tin-plate of the collector, whilſt the lateral frames are up. This done, remove the tin-foil, let down the lateral frames one after the other; and on doing this the electrometer *W* will immediately manifeſt a conſiderable degree of electricity. But if the electrometer were to ſhow no ſenſible degree of electricity, a ſmaller collector, *viz.* one having a tin-plate of about four ſquare inches, muſt be brought into contact with the tin-plate of the large collector, whilſt the lateral frames of the latter only are down; and then the ſmall collector being removed from the large one, its lateral frames are opened, and its tin-plate is preſented to an electrometer, which will thereby be electrified to a much greater degree than the electrometer *W* was by the large collector.

3. Let a common cork-ball electrometer be faſtened to an inſulated conductor, having about two or three ſquare feet of ſurface, and communicate to it ſuch a quantity of electricity as may be ſufficient to let the balls of the electrometer ſtand at about one inch aſunder. In this ſtate bring the conductor in contact with the tin-plate of the collector for a very ſhort time, and it will be found, that the balls of its electrometer will immediately approach and touch each other, ſhowing that the electricity of the conductor is gone to the plate of the collector; and, in fact, if you let down the lateral frames, the balls of the electrometer *W* will immediately repel each other to a very great degree.

It ſeems, therefore, to be clearly ſhown by theſe experiments, that the tin-plate of this inſtrument can collect and retain a vaſt quantity of electricity, when the conducting ſurfaces of the lateral frames are contiguous to it, in compariſon to that quantity which it can either collect or retain when thoſe ſurfaces are removed from its vicinity.

The quantity of electricity which the tin-plate *ABCD* is capable of collecting, principally depends on three circumſtances, *viz.* 1ſt, on the diſtance between the tin-plate and the conducting lateral ſurfaces; the ſmaller that diſtance is, the greater being the collecting power: 2dly, on the ſize of the inſtrument: and, 3dly, on the quantity of electricity poſſeſſed by the body from which it muſt be collected or taken away

The principle upon which the action of this inſtrument depends, is the ſame as that of the electrophorus of M. Volta's condenſer, and of many other electrical experiments; namely, that a body has a much greater capacity for holding electricity when its ſurface is contiguous to a conductor which can eaſily acquire the contrary electricity, than when it ſtands not in that ſituation.

Methods of meaſuring Electricity, &c.

The electrical air thermometer, fig. 34. is an inſtrument deſigned to ſhow the power of electricity by its rarefaction of the air through which the fluid paſſes. But though this inſtrument in theory might be ſuppoſed capable of manifeſting the very leaſt degrees of electricity, the rarefaction of the air by its means is ſo very ſmall, that unleſs the power of electricity be very conſiderable, no expanſion will be perceived. The inſtrument, however, certainly has its uſes, and many curious experiments may be performed with it. *A B* repreſents a glaſs cylinder having a braſs cap, with a wire and knob paſſing through it, and which is cemented on the open part of the glaſs. The under part is inverted into a ſmall diſh *B C*, containing quickſilver or ſome other liquid, which may riſe in the ſmall tube *A H* by any expanſion of the air in the cylinder *A B*. *C D* is an inſulating ſtand, which ſerves to ſuſtain the whole; *E* is an hook by which a communication may be made to the ground; and *F* another for connecting the whole with the prime conductor of an electrical machine. The diſcharges of electricity made by the ſparks between the knobs *G* and *I* expand the air, and force up the fluid into the ſmall tube *A H;* and its riſe there is marked upon a graduated ſcale. This inſtrument will likewiſe anſwer for ſhowing the diminution or increaſe of any kind of air by the electric ſpark, as well as its ſudden expanſion by a ſpark or ſhock of a phial. Mr Morgan has ſhown that the mercury in a common thermometer, if well made, may be raiſed by the electric blaſt.

229
Mr Bennet's doubler of electricity improved by Nicholſon.

In a treatiſe lately publiſhed by the Reverend Mr Abraham Bennet, he gives an account of the machine called the *doubler of electricity*, with ſome improvements upon it by Mr Nicholſon; by which means the machine becomes leſs liable to the objections of Mr Cavallo above-mentioned. In its improved ſtate, it conſiſts of two inſulated and immoveable plates about two inches in diameter, and a moveable plate alſo inſulated, which revolves in a vertical plane parallel to the two immoveable plates, paſſing them alternately.

Plate CLXXVI. Fig. 65.

" The plate *A* is conſtantly inſulated, and receives the communicated electricity. The plate *B* revolves; and when it is oppoſite the plate *A*, the connecting wires at the end of the croſs piece *D* muſt touch the pins of *A* and *C* at *EF*, and a wire proceeding from the plate *B* muſt touch the middle piece *G*, which is ſupported by a braſs, wooden, or other conducting pillar in connection with the earth. In this poſition, if electricity be communicated to the plate *A*, the plate *B* will acquire a contrary ſtate; and paſſing forwards, the wires alſo moving with it by means of the ſame inſulating axis, the plates are again inſulated till the plate *B* is oppoſite to *C*, and then the wire at *H* touches the pin in *C*, connecting it with the earth, and communicating the contrary ſtate of electricity to that of *B*, but of the ſame kind with that of *A*. By moving the handle ſtill further, *B* is again brought oppoſite to *A*; and the connecting wires joining *A* and *C*, they both act upon *B*, which is connected with the earth as before, and nearly double its intenſity, whilſt the electricity of *C* is abſorbed into *A;* becauſe of the increaſed capacity of *A*, whilſt oppoſed to *B*, capable by its connection with the earth of acquiring a contrary ſtate ſufficient to balance the influential atmoſpheres of both plates.

" Thus by continuing to revolve the plate *B*, the proceſs is performed in a very expeditious and accurate manner.

" The ball *I* is made heavier on one ſide than the other, and ſcrewed upon the axis oppoſite to the handle, to counterbalance the plate *B*, which may therefore be ſtopped in any part of its revolution.

" Yet notwithſtanding the convenience and accuracy of this doubler, it always produced ſpontaneous electricity,

city, even after all the reſinous ſubſtances uſed in its conſtruction had been melted over a candle, and after ſtanding a long time with its plates in connection with the earth. I therefore conjectured that this ſpontaneous electricity was not owing to accidental friction, but to the increaſed capacity of approximating parallel plates which might attract and retain their charge tho' neither of them were inſulated. To prove my hypotheſis, I firſt endeavoured more effectually and ſpeedily to deprive the inſtrument of the electricity laſt communicated, and that I might know whether this ſpontaneous charge, ſuppoſed to ariſe from the increaſed capacity of the parallel plates, would be always of the ſame kind.

"To effect this deprivation, I connected the plates *A* and *C* together by a wire hooked at each end upon two ſmall knobs on the backs of the plates, the middle of the ſame wire touching the pillar which ſupports the doubler. Another wire was hooked at one end upon the back of the plate *B*, and at the other end to the braſs ball which counterbalances this plate. Thus all the plates were connected with the earth; and by turning the handle of the doubler, it might be diſcharged of electricity in every part of its revolution.

"After often trying this method of depriving the doubler, I obſerved that its ſpontaneous charge was almoſt always negative. I then touched *A* and *C* with a poſitively charged bottle, and turned the doubler till it produced ſparks for a long time together; and after this ſtrong poſitive charge, I hooked on the wires as above, and revolved the plate *B* about 100 times, which ſo deprived the doubler of its poſitive electricity, that when the wires were taken off, it produced a negative charge at about the ſame number of revolutions which it required before.

"The poſitively charged bottle was again applied; and the wires being hooked upon the plates as before, *B* was revolved only 50 times; yet this was found ſufficient to deprive it of its poſitive charge, and in many experiments 5 or 6 revolutions were ſufficient: but I never thought it ſafe to ſtop at ſo few, and have therefore generally turned the handle 40 or 50 times between every experiment.

"Leſt electricity adhering to the electrometer ſhould obſtruct the above experiments, I did not let it ſtand in contact with the doubler during its revolutions, but touched the plate *A* with the cap of the electrometer, after I ſuppoſed its electricity was become ſufficiently ſenſible: but leſt even this contact ſhould communicate any electricity, I made a cap for my electrometer of ſhell-lac, having a ſmall tin tube in the centre, to which the gold leaf was ſuſpended within the glaſs, and a bent wire was fixed to the top, which might eaſily be joined to the plate *A* of the doubler; and thus the gold-leaf was more perfectly inſulated, and the electricity could not be diffuſed over ſo large a ſurface. The glaſs which inſulates the plates and croſs piece of the doubler was alſo covered with ſhell-lac."

230 Nicholſon's inſtrument for diſtinguiſhing the two electricities.

Fig. 66. ſhows an inſtrument invented by Mr Nicholſon for diſtinguiſhing the two electricities from one another. *A* and *B* are two metallic balls placed at a greater or leſs diſtance from each other by means of the joint at *C*; the two branches *C A* being made of varniſhed glaſs. From one of the balls *B* proceeds a ſhort point towards the other ball *A*. If the two be placed in the courſe or current of the electric matter, ſo that it may paſs through the air from one to the other, its direction will be known. For if the electric matter paſs from *A* to *B*, there will be a certain diſtance of the balls dependent on the ſtrength of electricity, within which the denſe ſparks will paſs from the point; but if its courſe be in the contrary direction, no ſpark will be ſeen, unleſs the balls be almoſt in contact with the point.

23 Obſerv tion, o uſe of electri kite.

We ſhall conclude this ſection with ſome obſervations on the electrical kite; which perhaps may after all be found the only inſtrument that will certainly ſhow the electricity of the atmoſphere upon all occaſions. The uſe of it, however, is very troubleſome, as it obliges the obſerver always to go abroad, which ſometimes muſt be diſagreeable. By means of the apparatus repreſented fig. 72. this inconvenience may be avoided. *A B* repreſents the ſtring of the kite, inſulated by means of the ſilk cord *C*, tied about the foot of a table in the room where the experiments are to be made. This ſtring paſſes out through a window of the room, and ſupports the kite; the electricity being conveyed by means of a ſmall wire to the inſulated conductor *D*, having a quadrant electrometer applied to it, as in the figure. *G* is a glaſs tube about 18 inches long, with a braſs wire and knob proceeding from it; by taking a ſmall ſpark with which from the conductor, the quality of the electricity may be obſerved.

Pla CLX

23 A con ent po electro ter.

Fig. 68. 69. repreſent a pocket electrometer, which may be very conveniently uſed when the atmoſpheric electricity is collected in any quantity. The caſe or handle of this electrometer is formed by a glaſs tube about three inches long and $\frac{1}{10}$ths of an inch in diameter, half of which is covered with ſealing-wax. From one extremity of this tube, *viz.* that without ſealing-wax, a ſmall loop of ſilk proceeds, which ſerves occaſionally to hang the electrometer on a pin, &c. To the other extremity of the tube a cork is adapted, which, being cut tapering on both ends, can fit the mouth of the tube with either end. From one extremity of this cork two linen threads proceed, a little ſhorter than the length of the tube, ſuſpending each a little cone of pith of alder. When this electrometer is to be uſed, that end of the cork which is oppoſite to the threads is puſhed into the mouth of the tube; then the tube forms the inſulated handle of the pith electrometer, as repreſented fig. 69. But when the electrometer is to be carried in the pocket, then the threads are put into the tube, and the cork ſtops it as repreſented fig. 68. The peculiar advantages of this electrometer are, its convenient ſmall ſize, its great ſenſibility, and its continuing longer in good order than any other. Fig. 68. repreſents a caſe to carry the above deſcribed electrometer in. This caſe is like a common toothpike-caſe, except that it hath a piece of amber fixed on one extremity *A*, which may occaſionally ſerve to electriſy the electrometer negatively; and on the other extremity it hath a piece of ivory faſtened upon a piece of amber *B C*. This amber *B C* ſerves only to inſulate the ivory; which when inſulated, and rubbed againſt woollen cloths, acquires a poſitive electricity, and is therefore uſeful to electriſy the electrometer poſitively.

In making experiments with the kite, it is ſometimes neceſſary to act with caution, on account of the

the great quantity of electricity collected by it. Of this we have already given ſome inſtances, to which we ſhall add the following from Mr Bennet; viz. that having on the 5th of July 1788 raiſed a kite with 200 yards of ſtring, when it had been flying about an hour, a dark cloud appeared at a great diſtance, and changed the electricity from poſitive to negative. The electric power increaſed till the cloud became nearly vertical, when ſome large drops of rain fell; and our author attempting to ſecure the ſtring from wet, received ſuch a ſtrong ſhock in his arm, as deprived it for a few ſeconds of ſenſation. The exploſion was heard at the diſtance of about 40 yards, like the loud crack of a whip.

### Sect. XI. *Of the Effects of Electricity on Vegetation.*

It is a very conſiderable time ſince electricians began to make experiments on this ſubject; and it was generally agreed that the electric fluid was favourable to the growth of vegetables. For a long time, however, ſuch reſearches ſeem to have been laid aſide; nor indeed did it ſeem very probable that any quantity of the fluid could be collected artificially ſufficient to be of uſe. But in a late treatiſe the ſubject has been revived by the Abbe Bertholon; who not only ſhows a method of collecting the fluid from the atmoſphere ſo as to be uſeful in ordinary practice, but endeavours to cure by means of this fluid ſome of thoſe diſeaſes to which plants are liable from inſects, and which cannot be removed by any of the ordinary remedies.

“ In the firſt place (ſays the Abbé), there is continually and every where diffuſed in the atmoſphere (particularly in the upper regions) a conſiderable quantity of the electric fluid. On the mountains eſpecially, it is always felt with moſt energy, and ſhows itſelf in greater abundance than on the plains. On the former, if you erect conductors, or lanch electric *paper-kites*, in order to ſeek out and direct this fluid towards the ſurface of the earth, where ſeveral cauſes ſometimes prevent its appearance; you will find it very ſoon ſubjected to your power, deſcend, as if at your command, from heaven itſelf, and creep at your feet to execute your orders. Theſe are facts extremely well aſcertained; but if one doubts of them, he has nothing to do but to erect a ſimilar apparatus or ſet off electric kites to be convinced of the truth. Theſe will immediately and at all times obtain an electricity ſo much the more ſtrong as the height of the apparatus ſhall be the more conſiderable. Being informed, that in England this experiment was tried with the moſt convincing effect, I mention it, as it has hitherto not been publiſhed. Upon a high mountain there were lanched two electric paper-kites, one of which was fixed to the inferior extremity of the other, thus gaining a double advantage in point of height; the conſequence of which was, that the electric effects were incomparably greater than thoſe produced by a ſingle inſtrument. But I ſuppoſe it entirely uſeleſs to inſiſt longer upon a fact ſo well demonſtrated and univerſally admitted.

Effects of Electricity on Vegetation.

“ This principle being granted: in order to remedy the deficiency of electric fluid which has already been proved to be hurtful to vegetation, we muſt erect in the ſpot which we want to fecundate the following new apparatus, which has had all poſſible ſucceſs, and which I ſhall call by the name of the *electro-vegetometer*. This machine is as ſimple in its conſtruction as efficacious in its manner of acting; and I doubt not but it will be adopted by all thoſe who are ſufficiently inſtructed in the great principles of nature.

“ This apparatus is compoſed of a maſt *AB* (Plate CLXXX. fig. 82.), or a long pole thruſt juſt ſo far into the earth as to ſtand firm and be able to reſiſt the winds. That part of the maſt which is to be in the earth muſt be well dried at the fire; and you muſt take care to lay on it a good coat of pitch and tar after taking it from the fire, that the reſinous particles may enter more deeply into the pores of the wood, which will then be dilated, at the ſame time that its humidity will be expelled by the heat. Care muſt likewiſe be taken to throw around that part fixed in the earth a certain quantity of coal-duſt, or rather a thick layer of good cement, and to build beſides a baſe of maſonwork of a thickneſs and depth proportionable to the elevation of the inſtrument, ſo as to keep it durable and ſolid. As to the portion of it above the ground, it will be ſufficient to put upon it ſome coats of oil paint, except one chooſes rather to lay on a coat of bitumen the whole length of the piece.

“ At the top of the maſt there is to be put an iron conſole or ſupport *C*; whoſe pointed extremity you are to fix in the upper end of the maſt, while the other extremity is to terminate in a ring, in order to receive the hollow glaſs-tube which is ſeen at *D*, and in which there is to be glued an iron rod riſing with the point *E*. This rod, thus pointed at its upper extremity, is completely inſulated, by reaſon of its keeping a ſtrong hold of a thick glaſs-tube, which is filled with a quantity of bituminous matter, mixed with charcoal, brick-duſt, and glaſs-powder; all together forming a ſufficiently good and ſtrong cement for the object in view.

To prevent rain wetting the glaſs tube, care muſt be taken to ſolder to the rod *E* a funnel of white-iron; which conſequently is entirely inſulated. From the lower extremity of the rod *E* hangs a chain *G*, which enters into a ſecond glaſs-tube *H*, ſupported by the prop *I*. The lower end of the above-mentioned chain reſts upon a circular piece of iron-wire, which forms a part of the horizontal conductor *KLMN*. In *L* is a breaker with a turning joint or hinge, in order to move to the right or left the iron-rod *LMN*; there is likewiſe another in *Q*, to give ſtill greater effect to the circular movement. *O* and *P* are two ſupports terminating in a fork, where there is fixed a ſilken cord tightly ſtretched, in order to inſulate the horizontal conductor: in *N* are ſeveral very ſharp iron-points.

236
Another form of this inſtrument.

“ In fig. 83. you ſee an apparatus in the main like the former, but with ſome difference in the conſtruction. At the upper extremity of the maſt *ab* there is bored a hole into which enters a wooden cylinder *c*, which has been carefully dried before a great fire, in order to extract its humidity, dilate its pores, and ſaturate it with tar, pitch, or turpentine, applied at repeated intervals. The more heat the wood and bituminous matter receives, the more the ſubſtance penetrates, and the inſulation will be the more complete. It is moreover proper to beſmear the circumference of the little cylinder with a pretty thick coat of bitumen. This preparation being made, we next inſert the cylinder *c*

Effects of Electricity on Vegetation.

into the hole *b* of the maſt; and it is eaſy to join together theſe two wooden pieces in the moſt perfect manner.

"At the upper extremity of the cylinder *c* we ſtrongly attach an iron-rod *g f*; which, inſtead of one, is terminated by ſeveral ſharp points all of gilded iron. In *e* you ſee a branch of iron reſembling the arm of an iron-crow, from whence hangs an iron chain *h i*, at the end of which there is hooked a piece of iron reſembling a maſon's ſquare, and ending in a fork. The piece of iron *l* is a ring with a handle entering a little into the glaſs-tube *m* filled with maſtiche, in the ſame manner as does the iron-rod *n*. The conductor *p o* is to be conſidered as an additional piece to act in that marked *p*. There are likewiſe put iron-ſpikes in *q*: the ſupport *s* reſembles thoſe of *O* and *P* in the former figure. In this new machine you can lengthen or ſhorten the horizontal conductor as you pleaſe; and as the iron-ring *l* turns freely in a circular gorge made in the maſt, the conductor is enabled to deſcribe the entire area of a circle.

237 Effects of theſe inſtruments.

"The conſtruction of this *electro-vegetometer* once well underſtood, it will be eaſy for us to conceive its effects. The electricity which prevails in the aerial regions will ſoon be drawn down by the elevated points of the upper extremity. This effect of the points is proved by the moſt deciſive experiments, and is called by philoſophers the *power of the points*.

"The electric matter brought down by the point *E*, or by thoſe marked *f f f*, will be neceſſarily tranſmitted both by the rod and chain; becauſe the inſulation produced at the upper extremity of the maſt completely prevents its communication with the timber. The electric fluid paſſes from the chain to the horizontal conductor *K M* or *n o*: it then eſcapes by the points at *P* and *q*; becauſe the ſame points that have the power of bringing down the electric fluid, have likewiſe that of puſhing it forward; a thing well known by experience.

238 Method of uſing them.

"The manner of uſing this inſtrument is not more difficult than the knowledge either of its conductor or effects. Suppoſe, for example, we are to place it in the midſt of a kitchen-garden. By making the horizontal conductor turn round ſucceſſively, you will be able to carry the electricity over the whole ſurface of the propoſed ground. The electric fluid thus drawn down, will extend itſelf over all the plants you want to cultivate; and this at a time when there is little or no electricity in the lower regions nigh the ſurface of the earth.

"On the other hand, when it happens that the electric fluid ſhall be in too great abundance in the atmoſphere, in order to take off the effect of the apparatus in *K* fig. 82. and in *n* fig. 83. you have only to hang to it an iron-chain reaching to the ground, or elſe a perpendicular iron-rod, which will have the ſame effect *viz.* that of deſtroying the inſulation, and of inſenſibly tranſmitting the electric fluid in the ſame proportion as it is drawn by the points; ſo that there ſhall never be an overcharge of this fluid in the inſtrument, and its effect ſhall be either ſomething or nothing, according as you add or remove the ſecond chain or the additional rod.

"There will be nothing to fear from the ſpontaneous diſcharge of this apparatus, becauſe it is terminated below by proper points in *P* and *q* of both machines; and it is a certain fact, that a pointed conductor makes no exploſion, and that inſtead of flaſhes there are only luminous ſtreams. However, it will be eaſy to furniſh one, by means of which we may approach the apparatus with perfect ſecurity; it is only neceſſary to hold the hand before it. This has the form of a great C, and is of a height equal to the diſtance that takes place betwixt the horizontal conductor and the ſurface of the earth. This diſcharger near the middle muſt be furniſhed with a glaſs-handle; and at that extremity which is directed towards the conductor, there muſt hang an iron-chain made to trail on the ground. This inſtrument is an excellent ſafeguard. See fig. 84.

Effe Elect on V

23 Grea vanta to be pecte theſe ſtrum

"By means of the electro-vegetometer juſt now deſcribed, one may be able to accumulate at pleaſure this wonderful fluid, however diffuſed in the regions above, and conduct it to the ſurface of the earth, in thoſe ſeaſons when it is either ſcantily ſupplied, or its quantity is inſufficient for vegetation; or although it may be in ſome degree ſufficient, yet can never produce the effects of a multiplied and highly increaſed vegetation. So that by theſe means we ſhall have an excellent vegetable manure or nouriſhment brought down as it were from heaven, and that too at an eaſy expence; for after the conſtruction of this inſtrument, it will coſt you nothing to maintain it: It will be moreover the moſt efficacious you can employ, no other ſubſtance being ſo active, penetrating, or conducive to the germination, growth, multiplication, or reproduction of vegetables. This heavenly manure is that which nature employs over the whole habitable earth; not excepting even theſe regions which are eſteemed barren, but which, however, are often fecundated by thoſe agents which nature knows ſo well to employ to the moſt uſeful purpoſes. Perhaps there was nothing wanting to bring to a completion the uſeful diſcoveries that have been made in electricity, but to ſhow this ſo advantageous an art of employing electricity as a manure; conſequently, that all the effects which we have already mentioned, depend upon electricity alone; and laſtly, that all theſe effects, *viz.* acceleration in the germination, the growth, and production of leaves, flowers, fruit, and their multiplication, &c. will be produced, even at a time when ſecondary cauſes are againſt it: and all this is brought about by the electric fluid, which we have the art of accumulating over certain portions of the earth where we want to raiſe thoſe plants that are moſt calculated for our uſe. By multiplying theſe inſtruments, which are provided at no expence (ſince iron-rods of the thickneſs of one's finger, and even leſs, are ſufficient for the purpoſe), we multiply their beneficial effects, and extend their uſe *ad infinitum*.

"This apparatus having been raiſed with care in the midſt of a garden, the happieſt effects were perceived, *viz.* different plants, herbs, and fruits, in greater forwardneſs than uſual, more multiplied, and of better quality. At the ſame time it was obſervable, that, during the night, the points *P* and *q*, as well as the upper extremities, were often garniſhed with beautiful luminous ſparks. Theſe facts are analogous to an obſervation which I have often made, *viz.* that plants grow beſt and are moſt vigorous near thunder-rods, where their ſituation favours their developement. They like-

Vege rous rods.

likewiſe ſerve to explain why vegetation is ſo vigorous in lofty foreſts, and where the trees raiſe their heads far from the ſurface of the earth, ſo that they ſeek, as it were, the electric fluid at a far greater height than plants leſs elevated; while the ſharp extremities of their leaves, boughs, and branches, ſerve as ſo many points granted them by the munificent hand of nature, to draw down from the atmoſphere that electric fluid, which is ſo powerful an agent in forwarding vegetation, and in promoting the different functions of plants.

“ This electro-vegetometer may be ſet up not only in a kitchen-garden, but in an orchard, in a field of corn, olive-yard, &c. &c. Everywhere the ſame effects are produced, namely, fecundity in the ſoil, quickneſs of vegetation, increaſe of produce, ſuperiority in the quality, &c. This machine is applicable to all kinds of vegetable productions, to all places, and all ſeaſons; and if I am to believe the moſt enlightened and intelligent of my friends, the electro-vegetometer is one of the moſt noble and uſeful diſcoveries that have been made in the preſent century.

“ Beſides the advantages of the electro-vegetometer, of which we have been ſpeaking above, there is ſtill another very important one, namely, that by applying to it a large electrometer or grand conductor, we may thus find out the electricity of the atmoſphere. For this purpoſe we muſt take away the points *HR* (fig. 82. and *r*. fig. 83.) which are ſeen in *Rr*. This machine will likewiſe ſerve the purpoſe of a thunder-rod, if one takes care to thruſt into the earth, to the depth of about 10 or 15 feet, a leaden tube, whoſe upper extremity may riſe a few inches above the ſurface of the ground; and into this tube you are to paſs the long iron chain or perpendicular rod ſet apart for deſtroying the inſulation, and whoſe upper end is to be hooked to a chain in *H*, fig. 82. or in *k*, fig. 83. Theſe two chains are very ſtrong, and are fit for ſerving as an excellent conductor. Or if you chooſe, you may ſubſtitute in their room weſts of white thread, or iron-wires, which will make no difference in the effects of the apparatus. In the figures we have preferred chains, that the diſtinction of the different parts may be the more ſenſibly perceived. With theſe additions the electro-vegetometer will be as good a thunder-rod as any that are ordinarily conſtructed.

Effects of Electricity on Vegetation.

“ It is not only by means of the electricity in the atmoſphere, collected by the above apparatus, that one can ſupply the electric fluid, which is ſo neceſſary to vegetation; but the electricity named *artificial* anſwers the ſame purpoſe. However aſtoniſhing the idea may be, or however impoſſible it may appear to realize it, yet nothing will be found more eaſy upon trial. Let us ſuppoſe that one wants to augment the vegetation of trees in a garden, orchard, &c. without having recourſe to the apparatus deſtined to pump down as it were the electricity from the atmoſphere, it is ſufficient to have a large inſulating ſtool. This may be made in two ways; either by pouring a ſufficient quantity of pitch and melted wax upon the above ſtool, whoſe borders being more raiſed than its middle, will form a kind of frame; or more ſimply, the ſtool (which is likewiſe called the *inſulator*) ſhall only be compoſed of a plate longer than broad, ſupported by four glaſs-pillars, like thoſe uſed for electrical machines. One muſt take care to place above the inſulator a wooden tray full of water, and to cauſe mount upon the ſtool a man carrying a ſmall pump in the form of a ſyringe. If you eſtabliſh a communication between the man and an electrical machine put in motion (which is eaſily done by means of a chain that connects with the conductor of the machine), then the man thus inſulated (as well as every thing upon the ſtool) will be able, by puſhing forward the ſucker, to water the trees, by pouring upon them an electrical ſhower; and thus diffuſing over all the vegetables under its influence a principle of fecundity that exerts itſelf in an extraordinary manner upon the whole vegetable economy: and this method has moreover this advantage, that at all times and in all places it may be practiſed and applied to all plants whatever.

“ Every one knows that the electricity is communicated to the water thus employed; and it would be eaſy to obtain the moſt ample conviction (if any one doubted it), by receiving upon his face or hand this electrical ſhower; he immediately feels ſmall punctures or ſtrokes, which are the effects of the ſparks that iſſue from each drop of water. This is perceived moſt ſenſibly if there is preſented a metal-diſh to this electrical dew; for at the very inſtant of contact, brilliant flaſhes are produced.

“ That the electricity received by the man from the chain may be communicated to the tray, we muſt put a ſmall cake of white-iron, upon the end of which he may place his foot. The tray filled with water is a kind of magazine or reſervoir to ſerve as a continual ſupply to the pump. After watering one tree, you tranſport the ſtool to a ſecond, a third, and ſo on ſucceſſively; which is done in a ſhort time, and requires very little trouble.

“ Inſtead of the chain, it is better to employ a cord or twiſt of pinchbeck or any other metal; by means of which there can be no loſs of the electric matter, as there is in the caſe of the chain by the ring-points. Moreover, this metal cord or thread being capable of being untwiſted and lengthened, there will be no occaſion of tranſporting ſo often the electrical machine. It is almoſt needleſs to add, that this ſtring or metallic chord, which is always inſulated, may reſt upon the ſame kind of ſupports with thoſe which have been exhibited in *O P* and *s* of fig. 82. and 83. This method is ſimple, efficacious, and nowiſe expenſive, and cannot be too much employed.

243
Eaſy method of applying electricity in this manner.

“ If one wants to water either a parterre or common garden-beds and platforms of flowers, or any other plots in which are ſown grain or plants of different ages and kinds, no method is more eaſy and expeditious than the following: Upon a ſmall carriage with two wheels there is placed a framed inſulator in form of a cake of pitch and roſin, as we have mentioned before in fig. 82. The carriage is drawn the whole length of the garden by a man or horſe fixed to it. In proportion as you draw the carriage, the metallic cord winds itſelf upon a bobbin, which turns as uſual. This laſt is inſulated, either becauſe the little apparatus that ſuſtains the bobbin is planted in a maſs of roſin (when you chooſe the axle to be of iron), or elſe becauſe

this

Effects of Electricity on Vegetation.

this moveable axis is a tube of ſolid glaſs. There muſt alſo be a ſupport, which ſerves to prevent the gold-thread or the metallic-cord from trailing on the ground, and thus diſſipating the electricity; and, moreover, it ſerves as an inſulator. To accompliſh this laſt purpoſe, it is neceſſary that the ring into which it paſſes be of glaſs. One may likewiſe employ the inſulators and ſupports marked *OP* and *s*, in fig. 82. and 83. If a gardener, mounted upon an inſulator, holds in one hand a pump full of water, and with the other takes hold of a metallic-cord, in order to tranſmit the electricity which comes from the conductor; in this caſe, the water being electrified, you will have an electrical ſhower; which falling on the whole ſurface of the plants which you want to electrify, will render the vegetation more vigorous and more abundant. A ſecond gardener is to give additional pumps full of water to him who is upon the inſulator, when he ſhall have emptied thoſe he holds; and thus in a little time you will be able to electrify the whole garden. This method takes hardly longer time than the ordinary one; and although it ſhould be a little longer, the great advantages reſulting from it will abundantly recompence the ſmall additional trouble.

"By repeating this operation ſeveral days ſucceſſively, either upon ſeed ſown or plants in a ſtate of growth, you will very ſoon reap the greateſt advantages from it. This operation, equally eaſy with the preceding deſcribed upon the ſubject of watering trees, has been put in practice with the greateſt ſucceſs. Several other methods, anſwering the ſame purpoſe, might be deviſed; but they are all of them pretty ſimilar to that juſt deſcribed.

244
To electrify water kept in reſervoirs, &c.

"I cannot finiſh this article without mentioning another method relative to the preſent object, although it be much leſs efficacious than the preceding ones. It conſiſts in communicating to water kept in baſons, reſervoirs, &c. (for the purpoſe of watering), the electric fluid, by means of a good electrical machine. To this end, one muſt plaſter over with a bituminous cement all the interior ſurface of the baſon deſtined to receive the water that ſerves for irrigation: the nature of this cement anſwering the purpoſe of inſulation, will prevent the electric fluid that communicates with the water from being diſſipated; and the water thus charged with electricity will be the more fitted for vegetation.

"The method juſt now laid down of electrifying water for the purpoſe of watering trees is both eaſy and cheap; the expence of the cement being inconſiderable, as it requires but once to be done, and as it prevents the water from filtrating and being loſt, as well as from hurting the walls themſelves, which would otherwiſe have occaſion to be oftener repaired; conſequently you are ſufficiently indemnified by its utility for all the trouble you take. A machine applied to the extremity of the axle of the electric apparatus might communicate to it a rotatory movement, and ſtill further diminiſh the expence of the operation.

245
Vegetables injured by the electric ſhock.

"If the deficiency of the electric fluid, or rather a ſmall quantity of it, is apt to be hurtful to vegetables, a too great abundance of this matter will likewiſe ſometimes produce pernicious effects. The experiments made by Meſſrs Nairne, Banks, and other learned men of the Royal Society of London, prove ſufficiently this truth. An electric battery, very ſtrong, was diſcharged upon a branch of balſam ſtill holding by its trunk. Some minutes after, there was obſerved a remarkable alteration in the branch, of which the leſs woody parts immediately withered, drooped towards the ground, died next day, and in a ſhort time entirely dried up; at the ſame time that another branch of the ſame plant that had not been put under the electric chain, was not in the ſmalleſt degree affected.

Effect Electi on Ve tion.

"This experiment repeated upon other plants ſhowed the ſame effects; and it was remarked that the attraction, occaſioned by a ſtrong diſcharge of the electricity, produced an alteration different according to the different nature of the plants. Thoſe which are leſs woody, more herbaceous, more aqueous, experience in proportion impreſſions that are ſtronger and much more ſpeedy in their operation.

"A branch of each of the following plants, compoſing an electrical chain, it was obſerved by theſe able philoſophers, that the balſam was affected by the diſcharge of the battery in a few moments after, and periſhed next day. The leaves of a marvel of Peru did not drop till the day following that; and the ſame phenomenon happened to a geranium. Several days elapſed before there was obſerved any fatal effect on the cardinal flower. The branch of a laurel did not ſhow any ſymptoms till after the lapſe of about 15 days, after which it died; but it was a full month before they perceived any ſenſible change on the myrtle; at the ſame time they conſtantly obſerved that the bodies of thoſe plants and branches which had formed no part of the chain, continued to be freſh, vigorous, and covered with leaves in good condition.

24
Blaſti milde poſed owing lightn

"It hardly ever happens that the ſuperabundance of the electric fluid exiſting in a ſmall portion of the atmoſphere where a plant is ſituated, can be ſo great as that which took place by the exploſion of the ſtrong battery of Mr Nairne, directed particularly upon one branch; or if this ſhould happen, it can only be upon a few individual plants in very ſmall number; as when lightning falls upon a tree, breaks it, ſtrips it of its bark, or withers its leaves; or in the caſe of blaſting or mildew in corn, which ſeveral farmers aſcribe to the force of lightning. "This ſentiment (ſays M. du Hamel) has acquired much probability ſince the diſcovery of the great effects of that electricity which is diffuſed ſo abundantly in the atmoſphere when the weather is diſpoſed to be ſtormy." (*Elemens d'Agric.* Tom. I. p. 346.)

"It is not propoſed here to preſcribe the means of remedying the pernicious effects which may be produced upon this occaſion; as there are none of them in circumſtances exactly ſimilar to that of the experiments of the philoſopher juſt now quoted. But although this enormous exceſs of the electric fluid of which we have been ſpeaking, never takes place through any great extent of ſpace, nevertheleſs this exceſs, though even but inconſiderable, may be too great in ſeveral reſpects regarding the vegetable economy; and it is in this caſe that it is proper to ſeek the means of remedying it.

"Let us ſuppoſe that one has ſome plants or ſhrubs, or ects of ctricity Vegeta- n.

or ſome valuable trees or exotics that he wants to preſerve, and is ſenſible that too great a quantity of electricity predominant in the atmoſphere becomes hurtful to them, there are two methods that may ſerve to obviate the evil of which he is apprehenſive. One is, to water plentifully theſe vegetables, ſo that their whole ſurface may be kept ſufficiently wet; the conſequence of which is, that the electricity prevailing in the atmoſphere will be tranſmitted to the earth by the water adhering to the outſide of the plants, as it is well known that water is an excellent conductor of the electric fluid: The other is, to place near theſe trees metallic points, which may be eaſily accompliſhed by ſimple lathes or wooden-poles; along which one muſt faſten by bandages plain iron-wires, ſo as to overtop them by ſome inches. Theſe poles thus prepared, being thruſt into the earth, will then draw down the electric fluid, and tranſmit it to the earth."

247 thods of roying cts by tricity.

Our author now proceeds to conſider of methods of deſtroying the inſects which frequently infeſt and deſtroy vegetables; which, he thinks, may be obtained by means of the electric fluid.

"Experience (ſays he) proves, that in years when vegetation is moſt vigorous and abundant, inſects, if nothing oppoſes them, will then be moſt multiplied; and in fact they are ſometimes ſo to an aſtoniſhing degree. How great miſchief they produce on theſe occaſions, every body knows, and as ardently deſires to find a remedy for the calamity. The damage is indeed ſo conſiderable, that people imagine it is not poſſible by any means to put a ſtop to it; but I am of opinion, it is one of thoſe evils to which electricity may be applied with effect.

248 chief e by ca- illars ing in- ne heart wigs.

"It has been often remarked, that ſeveral ſpecies of worms or caterpillars are found in the heart of ſhoots, twigs, and even the trunks of trees, of ſhrubs, and of plants of different ſorts. There are numbers, for example, in pear and other fruit trees. As ſoon as the animal has got to the inſide of a branch, he forms a gallery according to the length of it: armed with ſtrong ſcaly jaws, he ſoon reduces the woody ſubſtance to powder; and this ſame delicate caterpillar makes the wood, hard as it is, his favourite nouriſhment. Other inſects generally ſhow themſelves in open day: but this one, like a pioneer, marches always in obſcurity within; and we are appriſed of his preſence only by the miſchief he produces, namely, by obſerving the tops of branches to wither, the leaves to fade and incline to the earth, and in fine the whole infected bough to decay and die away. In vain do you ſeek for this frail though terrible animal on the leaves; he enters the ſkin and penetrates the thickeſt bark of the ſurface; he goes even to the heart of the woody ſubſtance; and you can extirpate him only by cutting off the wood; and if this is a remedy, you muſt confeſs that it is at leaſt equal to the miſchief.

"This evil ſo much the more merits attention, that it extends itſelf particularly over a very great number of fruit-trees; in which, for the ſame reaſon, we are as particularly intereſted. Electricity, however, furniſhes us with a remedy of the moſt efficacious ſort to ſtop the progreſs of the evil, by attacking the enemy in his quarters, and deſtroying him in his own mine; which in this event is to become his tomb.

Effects of Electricity on Vegetation.

249 Eaſily killed by an electric ſhock.

"The Leyden phial, by the mere force of its ſhock, which can be augmented gradually, is capable of deſtroying not only rabbits and pigeons, but bulls and oxen, eſpecially when we employ electrical batteries of great ſize, and containing a great number of electrified jars. Of conſequence then it may be employed even with little apparatus to kill a tender and delicate caterpillar, which, in order to ſhelter itſelf from the impreſſions of the air, is obliged to keep perpetually ſhut up in the heart of trees, or in that of twigs, branches, or trunks themſelves.

"In order to ſucceed in killing theſe animals at the time when they begin to ſhow their ravages, which mark likewiſe the place where the caterpillar is concealed, it is ſufficient to make an electric chain with two plain iron-wires, and to place betwixt the two that part of the tree where it is ſuppoſed the inſect reſides. One need not be afraid of taking in even a larger ſpace, for the experiment will ſucceed as well in a great extent as in a ſmall; and beſides, one runs no riſk of miſſing the enemy he wants to combat. Let us ſuppoſe, that one be aſſured from the forementioned ſymptoms, that there is an inſect in the tree; in this caſe you place iron-wires above and below the place where you ſuſpect it to be lodged. Next, you muſt take care to make the one communicate with the exterior ſurface of an ordinary jar charged with electricity, and the other with the interior ſurface, which it is eaſy to do by bending theſe iron-wires ſo as to make them approach the electrical jar; then upon diſcharging this veſſel where the electric fluid ſuperabounds, the exploſion is made to traverſe the part where the animal lodges: the violence of the ſhock makes him die without recovery, and ſo deſtroys the evil in its ſource. If the ravage has not been carried to a high pitch, the tree recovers very ſoon, as I have often obſerved: but whatever be the reſult as to the re-eſtabliſhment in certain circumſtances, the evil proceeds no further; its progreſs ſtops; and it is always a great advantage to have arreſted it in its march.

"Several experiments have convinced me of the ſucceſs of this method. Upon cutting off ſeveral branches on which I diſcharged my jar or Leyden bottle, I conſtantly obſerved the animal dead; and you never fail of killing it when the diſtance betwixt the two extremities of the iron-wires is not too great, and when you take care to approach or remove them ſucceſſively by repeating the ſhock ſeveral times.

"The bottle here employed cannot hurt the vegetable economy, becauſe its dimenſions are not too great, and no batteries are brought in play. The electric ſhock, given in certain bounds, is uſeful to animals; it therefore cannot be noxious to plants in the ſame circumſtances.

250 How to perform the operation on a great number of trees at once.

"This operation is not tedious even when employed upon a great number of trees; but if one wants ſtill further to abridge it, I here give him a method by which the experiment can be made in the ſame inſtant upon all the trees of an orchard, and will not be more tedious than if it were employed upon one tree only. You have only to provide a ſufficient number of iron-wires, and to diſpoſe them as was done for the firſt tree we ſpoke of juſt now, and in the ſame manner; by which means all theſe trees form an electrical

trical chain, and the fluid in the exploſion of the bottle will run over through the whole, ſuppoſing that you have diſcharged the bottle in the ordinary way, and at the ſame time taken care of what is very eſſential, that while the free extremity of the firſt wire touches the exterior ſurface of the electrical jar, the end of the other may communicate with the inſide of the ſame charged phial.

251 How to deſtroy a caterpillar in the root of a tree.

“If the caterpillar be in the root, the operation is pretty much the ſame. By taking away, for an inſtant, a little earth, you eaſily put the affected roots within the chain: but if one is ignorant of the particular ramification of the root which is attacked, without uncovering the tree, you need only inſert in the earth two wires oppoſite in their directions, and then perform the Leyden experiment, which is eaſily done. After having placed theſe two wires north and ſouth, you may repeat the experiment by placing them eaſt and weſt. You can hardly then miſs the inſect, eſpecially if, in order to take in more ſpace, you inſert one of the wires farther than the other: for in this caſe the electric fluid will deſcribe a diagonal, as we have already ſhown in regard to branches.

252 To prevent theſe animals from generating in plants.

“This method ſerves not only to prevent the progreſs of the evil, but in ſome ſenſe to anticipate it. In regard to theſe deſtructive inſects there are epochs as for plants; both of them have marked times for their birth, their developement, their growth, their multiplication, and that relative both to their genera and ſpecies. When the time is come that inſects, caterpillars, and other animals attack plants, one muſt employ, by way of precaution, the method we have juſt now laid down; and by repeating the ſame from day to day for a certain ſpace of time, we will at laſt ſucceed in preſerving trees from the ravages of inſects. The operation is neither tedious nor expenſive; why then not have recourſe to it for thoſe curious and rare trees which come from afar at a great expence, and thoſe valuable other trees that yield us yearly the moſt delicious fruits?

253 Advantages to be expected from this method.

“The method juſt mentioned is the moſt effectual that can be imagined, ſince it purſues the enemy to his moſt concealed corners in the inmoſt texture of the wood, and is capable of killing him in the very heart of trees, under the bark when he is to be found there, in the branches, and in the heart of the roots themſelves: all which we have made appear in the foregoing remarks. I may further add, that there is no other remedy known but by electricity; for how is it poſſible to find out under the bark of a tree one or more inſects that gnaw and deſtroy it? Muſt we not in this caſe ſtrip the mentirely of their bark? and would not, therefore, the remedy be often worſe than the diſeaſe? Beſides, by what means could we penetrate into the heart of the tree? Would not the inſtrument employed to cut and lop it, rather add to the miſchief, eſpecially in the beginning of its progreſs? How again could we rummage to the inſide of the roots? The tree thus uncovered, would it not ſuffer, eſpecially in the great heats, when a perſpiration more abundant muſt render neceſſary a nouriſhment, whoſe quantity ought at all times to be equal at leaſt to the waſte? Thus the celebrated Linnæus, ſtruck with the calamities which fruit-trees in particular ſuffer from inſects and their caterpillars, cried out: “Who ſhall deliver us from this ſcourge?” *Quis poſſit liberare arbores fructiferas a larvis?*”

On this ſubject we cannot help obſerving, that there is ſome reaſon to ſuppoſe that the Abbe has over-rated the power of his remedy with regard to the deſtruction of inſects. There is not the leaſt doubt that an inſect will be deſtroyed by finding a ſhock of electricity through its body; but while this inſect is defended by the vegetable which it has pierced, and in which it lodges, the vegetable will alſo receive a very conſiderable part; and thus the inſect may ſtill eſcape, unleſs the ſhock be augmented to ſuch a degree as to injure the vegetable alſo. His other experiments, it is ſaid, have been confirmed by the obſervations of modern electricians.

## SECT. XII. *Effects of Electricity on Animals; of the Gymnotus, Torpedo, and other Electric Fiſhes; Medical Electricity.*

Soon after the diſcovery of the electrical ſhock, and the method of augmenting the power of electricity, it naturally became an object with philoſophers to inveſtigate the effects of it upon animal bodies. Theſe were quickly found to be entirely ſimilar to ſuch as are produced upon any other conducting ſubſtances, viz. an emiſſion of ſparks, attraction, and repulſion, &c. By degrees it was found, that very ſtrong ſigns of electricity were exhibited by ſome animals, even without the application of any artificial apparatus. The experiment of producing ſparks by ſtroking the back of a cat in froſty weather, readily ſhowed that the electric fluid may exiſt in a very active ſtate in the body of an animal without injuring any of its functions. From animals of the inferior kind a tranſition was made to the human ſpecies; and ſigns of electricity were diſcovered in them where it had not been ſuſpected before. Some people have been remarkable for an extreme luſtre of their eyes; and others have been ſo much electrified naturally, as to give evident ſigns of it when a ſenſible electrometer had been applied to them. Others have manifeſted an extreme ſenſibility of even the ſmalleſt degrees of electricity, inſomuch that they would be affected by a flaſh of lightning, though ſo remote that the thunder could not be heard. All this ſhowed that the ſubtile fluid we treat of bears a very active part in the animal economy, and led to more important reſearches on the ſubject. One of the firſt diſcoveries was, that ſome creatures are ſo ſtrongly electrified naturally as to have it in their power to give a ſtrong ſhock at pleaſure, capable of deſtroying any ſmall animal that comes near them. Of theſe, however, only three, and thoſe of the aquatic kind, have yet been obſerved, viz. the gymnotus electricus, the torpedo, and another called the *ſilurus electricus*.

25 Some mals n rally e trified.

The gymnotus* hath the aſtoniſhing property of giving the electric ſhock to any perſon, or number of perſons, either by the immediate touch with the hand, or by the mediation of any metallic conductor; and a perſon who kept ſome of them told Dr Garden, that they had this property much ſtronger when firſt catched than afterwards.

---

* See article *Gymn*

55 tical erties e gym- s.

wards. "The perſon (ſays he) who is to receive the ſhock, muſt take the fiſh with both hands, at ſome conſiderable diſtance aſunder, ſo as to form the communication, otherwiſe he will not receive it, at leaſt I never ſaw any one ſhocked from taking hold of it with one hand only; though ſome have aſſured me, that they were ſhocked by laying one hand on it. I myſelf have taken hold of the largeſt with one hand often without ever receiving a ſhock; but I never touched it with both hands, at a little diſtance aſunder, without feeling a ſmart ſhock. I have often remarked, that when it is taken hold of with one hand, and the other is put into the water over its body without touching it, the perſon received a ſmart ſhock; and I have obſerved the ſame effect follow when a number joined hands, the perſon at one extremity of the circle taking hold of or touching the fiſh, and the perſon at the other extremity putting his hand into the water over the body of the fiſh. The ſhock was communicated through the whole circle as ſmartly as if both the extreme perſons had touched the fiſh. In this it ſeems to differ widely from the torpedo, or elſe we are much miſinformed of the manner in which the benumbing effect of that fiſh is communicated. The ſhock which the gymnotus gives ſeems to be wholly electrical; and all the phenomena or properties of it exactly reſemble thoſe of the electric *aura* of our atmoſphere when collected, as far as they are diſcoverable from the ſeveral trials made on this fiſh. This ſtroke is communicated by the ſame conductors, and intercepted by the interpoſition of the ſame original electrics, or electrics *per ſe* as they uſed to be called. The keeper of this fiſh informs me, that he catched them in Surinam river, a great way up, beyond where the ſalt-water reaches; and that they are a freſh-water fiſh only. He ſays, that they are eaten, and by ſome people eſteemed a great delicacy. They live on fiſh, worms, or any animal-food if it is cut ſmall ſo that they can ſwallow it. When ſmall fiſhes are thrown into the water, they firſt give them a ſhock, which kills or ſo ſtupifies them, that they can ſwallow them eaſily and without any trouble. If one of theſe ſmall fiſhes, after it is ſhocked, and to all appearance dead, be taken out of the veſſel where the electrical fiſh is, and put into freſh water, it will ſoon revive again. If a larger fiſh than they can ſwallow be thrown into the water, at a time that they are hungry, they give him ſome ſmart ſhocks till he is apparently dead, and then they try to ſwallow or ſuck him in; but, after ſeveral attempts, finding he is too large, they quit him. Upon the moſt careful inſpection of ſuch fiſh, I could never ſee any mark of teeth, or the leaſt wound or ſcratch on them. When the electrical fiſh are hungry, they are pretty keen after their food; but they are ſoon ſatiſfied, not being able to contain much at one time. An electrical fiſh of three feet and upwards in length cannot ſwallow a ſmall fiſh above three or at moſt three inches and a half long. I am told, that ſome of theſe have been ſeen in Surinam river upwards of 22 feet long, whoſe ſtroke or ſhock proved inſtant death to any perſon that unluckily received it."

256 ne very ge ones nd in inam r.

Several other accounts of this fiſh have been publiſhed by different perſons, but none of them ſo full and diſtinct as the above. They all agree that the electric virtue of the fiſh is very ſtrong. Mr Fermin, in his natural hiſtory of Surinam, publiſhed in 1765, tells us, that one cannot touch it with the hands, or even with a ſtick, without feeling a horrible numbneſs in the arms up to the ſhoulders; and he farther relates, that, making 14 perſons graſp each other by the hands, while he graſped the hand of the laſt with one of his, and with the other touched the eel with a ſtick, the whole number felt ſo violent a ſhock, that he could not prevail on them to repeat the experiment. V. Vanderlott, in two letters from Rio Eſſequebo, dated in 1761, makes two ſpecies, the black and the reddiſh; though he acknowledges, that, excepting the difference of colour and degree of ſtrength, they are not materially different. In moſt experiments with theſe animals, he remarked a ſurpriſing reſemblance between them and an electrical apparatus: nay, he obſerved, that the ſhock could be given to the finger of a perſon held at ſome diſtance from the bubble of air formed by the fiſh when he comes to the ſurface of the water to breathe; and he concluded, that at ſuch times the electrical matter was diſcharged from his lungs. He mentions another characterizing circumſtance, which is, that though metals in general were conductors of its electric property, yet ſome were found to be ſenſibly better than others for that purpoſe. Of this property Dr Prieſtley takes notice, and ſays, that a gold ring is preferable to any thing elſe. The ſame is likewiſe obſerved by Linnæus. Dr Prieſtley adds, that the ſenſation is ſtrongeſt when the fiſh is in motion, and is tranſmitted to a great diſtance; ſo that if perſons in a ſhip happen to dip their fingers or feet in the ſea, when the fiſh is ſwimming at the diſtance of 15 feet from them, they are affected by it. He alſo tells us, that the gymnotus itſelf, notwithſtanding all its electric powers, is killed by the lobſter.

257 Remarkable difference of the conducting power of metals with regard to this ſhock.

258 Of the torpedo.

The ſurpriſing property of the torpedo* in giving a violent ſhock to the perſon who takes it in his hands, or who treads upon it, was long an object of wonder. For ſome time it was in general reckoned to be entirely fabulous; but at laſt the matter of fact being aſcertained beyond a doubt, philoſophers endeavoured to find out the cauſe. M. Reaumur reſolved it into the action of a vaſt number of minute muſcles, which by their accumulated force gave a ſudden and violent ſtroke to the perſon who touched it. But ſolutions of this kind were quite unſatiſfactory, becauſe the ſtroke was found to be communicated through water, iron, wood, &c. When the phenomena of electricity began to be better known, it was then ſuſpected that the ſhock of the torpedo was occaſioned by a certain action of the electric fluid; but as not the leaſt ſpark of fire, or noiſe, could ever be perceived, this too ſeemed inſufficient. Of late, however, Mr Walſh has with indefatigable pains, not only explained this ſurpriſing phenomenon on the known principles of electricity, but given a demonſtration of his being in the right, by conſtructing an artificial torpedo, by which a ſhock reſembling that of the natural one can be given.

259 Artificial one made by Mr Walſh.

The electric organs of the torpedo conſiſt of two ſets of very ſmall cylinders lying under the ſkin, one of which is electrified poſitively and the other negatively,

---

* For its natural hiſtory, ſee the article *Raja*, of which the torpedo is a ſpecies.

Effects on Animals.

tively, ſeemingly at the pleaſure of the fiſh. When a communication is made between the ſet of cylinders poſitively electrified and thoſe which are negatively ſo, a diſcharge and ſhock enſue, like what happens in the caſe of the Leyden phial. The only difficulty now is to account for the total abſence of a ſpark (which in the caſe of the torpedo never exiſts even in the ſmalleſt degree), and the impoſſibility of conducting the ſhock through the ſmalleſt interval of air. But this alſo is explained in a ſatisfactory manner by Mr Walſh, and ſhown to be nothing elſe than what every day takes place in our electrical experiments. It is well known, that a ſmall charge of electricity, if put into a little phial, will occaſion a bright ſpark and loud noiſe when diſcharged: but if the ſame charge is put into a phial much larger, the ſpark and noiſe will be leſs in proportion; neither will the ſpark break through near ſuch a ſpace of air in the latter caſe as in the former; though the ſhock would in both caſes be the ſame to a perſon who received it through his body. If, inſtead of a large phial, we ſuppoſe the charge to be diffuſed all over a large battery, the ſhock would ſtill be the ſame, and yet the ſpark and noiſe attending it would be almoſt imperceptible. The caſe is juſt the ſame with the torpedo. Each of the electric organs is a battery compoſed of innumerable ſmall cylinders, which diſcharging themſelves all at once produce a formidable ſhock; but by reaſon of the ſmallneſs of the charge of each, the ſpark is imperceptible, and cannot break through the leaſt ſpace of air. The truth of this was exemplified in Mr Walſh's artificial torpedo, which though it would give a very conſiderable ſhock through a conductor totally uninterrupted, yet on the leaſt breach therein, even for the breadth of a hair, no ſhock was felt.

260 Why no ſpark is diſcovered in the ſhock given by the torpedo.

In every other reſpect the electricity of the torpedo agrees with that exhibited by the common electrical machines. An inſulated perſon cannot receive a ſhock by touching one of the electric organs of the fiſh; but a violent ſtroke is given to the perſon, whether inſulated or not, who lays one hand on the poſitive and the other on the negative organ. The fiſh, as is reaſonable to imagine, ſeems to have this electric property in its own power; and appears ſenſible of his giving the ſhock, which is accompanied by a kind of winking of his eyes.

261 Of the ſilurus electricus.

The third fiſh which is known to have the power of giving the ſhock, is found in the rivers of Africa, but we have a very imperfect account of its properties (o). This animal belongs to the order called in Willoughby's ſyſtem *ſilurus*; hence it is commonly called *ſilurus electricus*. Some of thoſe fiſhes have been ſeen even above 20 inches long. The body of the ſilurus electricus is oblong, ſmooth, and without ſcales; being rather large, and flattened towards its anterior part. The eyes are of a middle ſize, and are covered by the ſkin which envelopes the whole head. Each jaw is armed with a great number of ſmall teeth. About the mouth it has ſix filamentous appendices, viz. four from the under lip and two from the upper; the two external ones, or farthermoſt from the mouth on the under lip, are the longeſt. The colour of the body is greyiſh, and towards the tail it has ſome blackiſh ſpots. The electric organ ſeems to be towards the tail, where the ſkin is thicker than on the reſt of the body; and a whitiſh fibrous ſubſtance, which is probably the electric organ, has been diſtinguiſhed under it. It is ſaid that the ſilurus electricus has the property of giving a ſhock or benumbing ſenſation like the torpedo, and that this ſhock is communicated through ſubſtances that are conductors of electricity; but no other particular about it is known with any conſiderable degree of certainty.

An inquiſitive mind will immediately aſk, for what purpoſe has nature furniſhed thoſe animals with ſo ſingular a property? But the preſent knowledge of the ſubject ſeems to furniſh no other anſwer, except that they are endowed with the power of giving the ſhock for the ſake of ſecuring their prey, by which they muſt ſubſiſt, and perhaps of repelling larger animals which might otherwiſe annoy them.

The ancients conſidered the ſhocks given by the torpedo as capable of curing various diſorders; and a modern philoſopher will hardly heſitate to believe their aſſertions, after that electricity has been found to be a remedy for many diſeaſes.

Beſides theſe animals which manifeſt their electric power evidently by giving a ſtrong ſhock, there are others in which the fluid ſeems to act by the emiſſion of light. This indeed has not been proved by actual experiment, tho' it would certainly be well worth while to try whether by inſulating a number of them, any more evident ſigns of electricity could be obtained. Theſe creatures are of the inſect tribe; ſome of them furniſhed with wings, as the ſhining flies in the warm countries; while others, as the glow-worm, crawl perpetually on the earth. It is moſt probable alſo, that the ſparkling of ſea-water is owing to the electricity of the inſects which occaſion it. Be this as it will, however, from the inſtances already adduced, it is certain that the electric fluid pervades at all times the whole body of every animal; whence, by exciting or diminiſhing its action, it is reaſonable to ſuppoſe that many important changes might be made in the human body, and hence the foundation of *Medical Electricity*.

Though the effects of this fluid as a remedy for diſeaſes fall particularly to be mentioned under the article MEDICINE, we cannot help here taking notice, that a very ſtrange uncertainty remains concerning what we ſhould imagine to be its firſt and moſt obvious effects; namely, whether ſimple electrification has any effect in quickening and augmenting the pulſe? This was ſaid to be the caſe by the firſt electricians, but denied by their ſucceſſors; and even when the great machine at Haarlem is made uſe of, it ſtill remains doubtful whether there be any effect of this kind or not.

The ſhock of the Leyden phial having been found effectual in removing ſome complaints, the uſe of it was introduced into the common practice of medicine; and is ſtill continued, though a more gentle method of uſing the fluid is now generally preferred. The apparatus for the medical electrician, beſides the machine already deſcribed, conſiſts of the following parts. 1. An

infu-

---

(o) Meſſrs Adanſon and Forſkal make a ſhort mention of it, and M. Brouſſonet deſcribes it under the French name of *le Trembleur* in the Hiſt. de l'Academie Royale des Sciences for the year 1782.

inſulating ſtool with glaſs feet, or, what is much better, an arm chair, well rounded at the edges of the wooden parts, and fixed on a large ſtool with glaſs feet, which ſhould be at leaſt nine or ten inches in length; for the longer the feet are, the better will the inſulation be. The inſide part of the back of the chair ſhould move on an hinge, that it may occaſionally be let down to the ſtool, and ſo the back of the patient be electrified more conveniently; the arms of the chair ſhould be made longer than ordinary. 2. A Leyden bottle with a diſcharging electrometer. 3. A pair of directors of conſiderable ſize, with glaſs handles and wooden points. 4. A large metallic ball of braſs or copper, with a metallic handle to receive the ſparks. The ball ſhould be unſcrewed, and the wire long and ſharp pointed to receive the ſtream of electric fire. 5. A few glaſs tubes of different bores, ſome of them with capillary points. 6. Several yards of braſs wire or chain; or, which is much better, ſeveral lengths of wires with loops at the end; the part of the wire between theſe being covered with ſome non-conducting ſubſtance, as a ſilk ribbon, &c.

V.

The directors are repreſented by fig. 29. the handles being of glaſs, one of them having a ball on its end repreſented by *A*; the other is without the ball, having its wire bent for the conveniency of conducting the electric ſtream on the eye, &c. Either of the balls may be unſcrewed from the wires, and the wooden point *B* ſcrewed in its place, or the pointed end of the braſs wire uſed. The glaſs handles ſhould be held as far from the braſs work as poſſible. To convey the electric fluid to the ear or throat, glaſs tubes with ſliding braſs wires through them ſhould be made uſe of, ſuch as are repreſented in fig. 30.

Fig. 31, 32. repreſent the electric forceps, which is thought by ſome electricians to be more convenient for giving the ſhock than the directors. Fig. 33. is the medical jar, with an electrometer, that regulates the ſtrength of the ſhock, and enables the operator to give a ſucceſſion of them of nearly equal force. On the upper part of a bent piece of glaſs *C* is cemented a braſs ſocket *D*, which is faſtened to a ſpring tube *E*; a wire *F* moves in this tube, ſo that the ball *G* may be ſet at any required diſtance from the ball *H*. The end *I* of the bent piece of glaſs is alſo cemented to a ſpring tube, which ſlides upon the wire *K*, communicating with the inſide of the jar.

ock ti- rt ody

To uſe this medical jar, the ball *H* muſt be placed in contact with the conductor of the electrical machine, or at leaſt be connected with it by a wire; after which it is to be charged in the uſual manner. If a wire proceeds from the ball *L* to the outſide coating, the jar will be immediately diſcharged, as the accumulation of the electric fluid is ſufficiently powerful to paſs through the ſpace of air between the two balls: hence a ſhock may be communicated to the arm by means of the wires and directors as in the figure, and it will be ſtronger in proportion as the diſtance of the ball *G* from *H* is augmented. This electrometer acts in the manner of the common diſcharging rod, and therefore has received the name of the *diſcharging electrometer*.

III.

In fig. 6. we have a repreſentation of Mr Lane's electrometer applied to the machine for medical electricity. *G*, the lower part of which is incloſed in the pillar *F*, is made of wood baked and boiled in linſeed-oil, and bored cylindrically for two-thirds of its length. The braſs work is fixed to the pillar by the ſcrew *H*, and is moveable in the groove *I*, ſo that it may be raiſed higher or lower as the height of the jar *D* requires. A ſteel ſcrew *L* paſſes through the braſs work, having its threads about $\frac{1}{12}$th of an inch diſtant from one another. To the end of this, and oppoſite to *K*, is fixed a hemiſpherical and well poliſhed piece of braſs; and a braſs ball *M*, likewiſe well poliſhed, is fixed to the prime conductor. To this ſcrew is annexed a circular plate *O*, divided into 12 equal parts; and in every revolution of this ſcrew pointing to the diviſions of the ſcale *N*, each of which are equal to one turn of the ſcrew. The uſe of this electrometer is to diſcharge the jar *D*, or any battery connected with the prime conductor, when the machine is not applied to medical purpoſes. If a perſon holds a wire faſtened to the ſcrew *H* in one hand, and another wire (fixed to *E* by a loop of braſs) paſſing from the frame of the machine to a tin-plate on which the jar *D* ſtands, or the hook *E* connected with it, he will perceive no ſhock when *K* and *M* are in contact; and the degree of exploſion, as well as the quantity of electricity accumulated in the jar, will be regulated by the diſtance of *K* and *M* from each other.

The improved way of applying the diſcharging electrometer to the conductor, is found to be much more convenient and ready than any other; as it has alſo the advantage of being uſeful to a jar or battery of any ſize. See fig. 6. where *a A* repreſents the electrometer as applied to the conductor; *c d* the improved medical jar ſuſpended at a ſmall diſtance from it. A ſmall glaſs tube *e f* is fixed in this jar, a part of the lower end of which is coated. Two wires paſs through the braſs ball *C* on the top of this tube; one of which is connected with the bottom of the jar, and the other goes only to the internal coating of the ſmall tube. The wires are moveable at pleaſure, and the jar is ſuſpended from the conductor by a braſs ring; and a chain or wire muſt be fixed to the hook *d* at the bottom. From a bare inſpection of the figure, it appears that the arm will receive the ſhock by the diſcharge of the jar *a c d*: for, by turning the cylinder round, the jar ſoon becomes charged either with one or both wires in it; and directly as the charge becomes ſufficiently ſtrong to paſs thro' the air, it will explode, and the fluid paſs to the end of *b* next to it, going through the wire to the wriſt, and from thence up to the other chain at the ſhoulder. By reverſing the poſitions or the connections of the two wires, the progreſs of the ſhocks will be reverſed, *viz.* from the ſhoulder to the wriſt. If the ſhort wire alone be left in the jar *c d*, and the diſcharging ball of the electrometer *a b c* be placed from a quarter of an inch to a whole one from the conductor, a moſt delicate ſmall ſhock may be given, and repeated any number of times at pleaſure. This is called the *electrical vibrating ſhock*.

Plate CLXXV.

Fig. 31. *g* repreſents the bottle director. It is hollow, and coated like a common jar, acting as ſuch, and in ſome caſes is looked upon as convenient. With this, as with the common director, it is proper to preſs the ends againſt the part where the ſhock is to be applied.

P CLXXVI.
266 Pocket electrical apparatus.

Fig 56. repreſents a ſmall pocket electrical apparatus, which may ſometimes be of uſe for medical purpoſes as well as others. It is packed up in a very ſmall ſize, being only five inches long, two broad, and one deep. It is capable of a tolerable ſtrong charge or accumulation of electricity, and will give a ſmall ſhock to one, two, three, or a greater number of perſons.

*A* is the Leyden phial or jar that holds the charge; *B* is the diſcharger to diſcharge the jar when required without electrifying the perſon that holds it; *C* is a ſilk ribbon prepared by a coating of varniſh, ſo as to be excited, and communicate its electricity to the jar; *D* are two hair, &c. ſkin rubbers, which are to be placed on the firſt and middle fingers of the left hand, and ſerve to excite the ribbon *C*.

*To charge the jar.* Place the two finger-caps *D* on the firſt and middle finger of the left hand; hold the jar *A* at the ſame time at the joining of the red and black *E* on the outſide between the thumb and firſt finger of the ſame hand; then take the ribbon in your right hand, and ſteadily and gently draw it upwards between the two rubbers *D*, on the two fingers, taking care at the ſame time the braſs ball of the jar is kept nearly cloſe to the ribbon while it is paſſing through the fingers. By repeating this operation 12 or 14 times the electrical fire will paſs into the jar, which will become charged; and by placing the diſcharger *C* againſt it, as in the plate, you will ſee a ſenſible ſpark paſs from the ball of the jar to that of the diſcharger. If the apparatus is dry and in good order, you will hear the crackling of the fire when the ribbon is paſſing through the fingers, and the jar will diſcharge at ſome diſtance.

*To electrify a perſon.* You muſt deſire him to take the jar in one hand, and with the other touch the knob of it: or, if diverſion is intended, deſire the perſon to ſmell at the knob *A* of it, in expectation of ſmelling the ſcent of a roſe or a pink: this laſt mode has occaſioned it to be ſometimes called the *magic ſmelling bottle.*

The following are the principal methods by which electricity may be applied to the human body with a medical view.

267 Various methods of applying electricity.

1. *By merely placing the patient in an inſulated chair, and connecting him with the prime conductor.*—When the machine is in action, he will thus be filled with the electric fluid, which will be continually diſſipated from the points and edges of his clothes: and though the effects of this are probably too ſlow to be rendered very advantageous, yet a ſedentary perſon might perhaps derive ſome benefit from ſitting in an inſulated chair, having before him an inſulated table, the chair to be connected with the ball of a large charged jar or battery; by which means a ſmall quantity of the fluid will be continually paſſing through thoſe innumerable capillary veſſels, on the right ſtate of which our health ſo much depends.

2. *By throwing the fluid upon, or extracting it from a patient, by means of a wooden point.*—This may be effected in a twofold manner: 1*ſt*, By inſulating the patient, and connecting him either with the cuſhion or the poſitive prime conductor, the operator preſenting the point. 2*d*, Let the patient ſtand upon the ground, and the wire of the director be connected either with the poſitive or negative parts of the machine. The ſenſation produced by the fluid when acting in this manner is mild and pleaſing, reſembling the ſoft breezes of a gentle wind; generating a genial warmth, and promoting the ſecretion and diſſipation of tumors, inflammations, &c.

3. *By the electric friction.*—Cover the part to be rubbed with woollen cloth or flannel. The patient may be ſeated in an inſulated chair, and rubbed with the ball of a director that is in contact with the conductor; or he may be connected with the conductor, and rubbed with a braſs ball which communicates with the ground. The friction thus produced is evidently more penetrating, more active, and more powerful, than that which is communicated by the fleſh bruſh; and there is very little fear of being thought too ſanguine. This, when uſed but for a few minutes, will be found more efficacious than the other after ſeveral hours application.—Electricity applies here with peculiar propriety to ſpaſm, pleuriſy, and ſome ſtages of the palſy; and in every caſe anſwers the end of bliſtering where the diſcharge is not wanted, being the moſt ſafe and powerful ſtimulant we know.

4. *By taking ſtrong ſparks from the patient.* Here, as in every other caſe, the operator may connect the ball of the director with the poſitive or negative conductor, or he may connect the patient with either of theſe and the ball with the ground. Now it is clear from what has been already laid down, that if the director be connected with the poſitive conductor, the fluid is thrown upon the patient, if with the cuſhion the fluid is extracted from him. Let the patient be inſulated, and the action is in ſome meaſure reverſed; if he is joined to the negative conductor or cuſhion, he will receive a ſpark from a perſon ſtanding on the floor; but if he communicates with the poſitive conductor, he will give the ſpark to the perſon on the ground.

5. *By cauſing a current of the electric fluid to paſs from one part of the body, and thus confining and concentrating its operation without communicating the ſhock.* Place the patient in an inſulated chair, and touch one part of the body with a director, joined to a poſitive conductor; then with a braſs-ball communicating with the ground touch another part; and when the machine is in action the fluid will paſs through the required part from the conductor to the ball; the force of the ſtream will be different according to the ſtrength of the machine, &c. Or connect one director with the cuſhion and the other with the poſitive conductor, and apply theſe to the part through which the fluid is to paſs, and when the machine is in action the electricity will paſs from one ball to the other. It is not neceſſary to inſulate the patient in this caſe.

6. *By the ſhock.* Which may be given to any part of the human body, by introducing that part of the body into the circuit which is made between the outſide and inſide of the bottle. This is conveniently effected, by connecting one director by a piece of wire with the electrometer and the other with the outſide of the bottle; then hold the directors by their glaſs-handles, and apply the balls of them to the extremity of the parts through which the ſhocks are to be paſſed. The force of the ſhock, as we have already obſerved, is augmented or diminiſhed by increaſing or leſſening the diſtance between

between the two balls, which muſt be regulated by the operator to the ſtrength and ſenſibility of the patient. Inſtead of the common bottle, we may have a ſmall one with a glaſs tube proceeding from it, through which proceeds a wire and hook to hang it upon the machine, with a longer one from the outſide coating, and which is to be carried by means of a director to the patient. When this is uſed as a common bottle, both wires are to be left there, and the ſhock is communicated by two directors, one connected with the bottom, the other with the top. The operator will often find himſelf embarraſſed in giving ſmall ſhocks, the fluid paſſing from the conductor to the ball of the electrometer, inſtead of going through the circuits he deſires: when this happens, which may be known by the chattering noiſe of the ſpark, the reſiſtance formed to the diſcharge is ſo great, that the fluid cannot force its way through the circuit: to remedy this, paſs two metallic pins through the cloathing, ſo that they may be in contact with the ſkin, which will leſſen the reſiſtance and conduct the fluid.

7. *By a ſenſation between a ſhock and the ſpark, which does not communicate that diſagreeable feeling attending the common ſhock.* This is effected by taking out the long wire from the ſmall medical bottle, and leaving the ſhorter one which is connected with the tube in its place, the directors to be connected and uſed as before. The effect of this ſpecies of ſhock, if it may be called one, is to produce a great vibration in the muſcular fibres, without inducing that pungent ſenſation which the ſhock effects. It is therefore applicable to ſome ſtages of palſy and rheumatiſm; it may alſo ſerve as an artificial means of exerciſe.

8. *By the bottle-director.* Inſulate the patient, and place one of the balls in contact with him; by which means this director is charged. Now if a wire is conveyed from the bottom of this to the top of another director, the bottle-director will be diſcharged whenever the other ball *h* is brought in contact with the patient; ſo that by bringing it down with rapidity, any number of ſmall ſhocks may be procured in a minute: or connect the inſulated patient with the top or inſide of a large charged jar, and then this apparatus uſed in the foregoing manner will diſcharge from the large jar at each ſpark its own contents, and by repetition diſcharge the whole jar: thus a number of ſhocks may be given without continually turning the machine or employing an aſſiſtant.

9. *By paſſing the whole fluid contained in the Leyden phial through a diſeaſed part without giving the ſhock.* Connect a director, by means of a wire, with the ball of a Leyden jar; charge the jar either completely or partially, and then apply the ball or point of the conductor to the part intended to be electrified, and the fluid which was condenſed in the phial will be thrown on the part in a denſe ſlow ſtream, attended with a pungent ſenſation which produces a conſiderable degree of warmth. If a wire that communicates with the ground is placed oppoſite to the end of the director, the paſſage of the fluid will be rendered more rapid, and the ſenſation ſtronger. Or inſulate the patient, connect him with the top of a jar, charge this, and then apply a metal wire or piece of wood to the part thro' which you mean to make the fluid paſs. It is obvious, that in this caſe the circuit between the inſide and the outſide of the jar is not completed, therefore the ſhock will not be felt. The condenſed fluid paſſes in a denſe ſlow ſtream through the required part, while the outſide acquires a ſufficient quantity from ſubſtances near it to reſtore the equilibrium.

It is in all caſes moſt adviſable to begin with the more gentle operations, and proceed gradually to increaſe the force as the ſtrength and conſtitution of the patient or the nature of the diſorder requires. The ſtream from a wooden point, a wooden ball, or braſs point, may be firſt uſed; ſparks, if neceſſary, may then be taken, or ſmall ſhocks given.

In rheumatic caſes the electric friction is generally uſed. If the pains are local, ſmall ſhocks may be given. To relieve the toothache, very ſmall ſhocks may be paſſed through the tooth; or, cover the part affected with flannel, and rub it with a director communicating with the machine.

In inflammations and other diſorders of the eyes, the fluid ſhould be thrown from a wooden point: the ſenſation here produced is that of a gentle cooling wind; but, at the ſame time, it generates a genial warmth in the part affected.

In palſies, the electric friction and ſmall ſhocks are adminiſtered. Streams of the fluid ſhould always be made to paſs through the affected part.

The only treatiſe we have yet had from the faculty on the ſubject of medical electricity is a pamphlet, intitled, Conſiderations on the Efficacy of Electricity in removing Female Obſtructions, by Mr Birch; and if its merits were to be confined to this diſeaſe alone (in which it may be reckoned a ſpecific), it would be intitled to the attention of practitioners; but we have reaſon to expect much more from it, ſince the prejudices of the faculty ſeem removed, and the practice is becoming more general every day.

## SECT. XIII. *Of the Uſes of the Electric Fluid in the Syſtem of Nature at large.*

268
Electricity concerned in the production of clouds, rain, hail, ſnow, &c.

THESE are ſo many and ſo various, that it may be ſaid without much exaggeration, that whether we look to the heaven above or to the earth beneath, we can ſcarce perceive any thing that is not acted upon, and in a manner perfectly ſubjected to the operations of this wonderful fluid. If we attend to the common phenomena of our atmoſphere, experiments ſhow that electricity is connected with every one of them. If we evaporate water by means of heat, it appears from the experiments of M. Sauſſure, related n° 201. *et ſeq.* that a ſtrong electricity is produced. If vapour is condenſed into rain, a quantity of electricity is alſo produced; and if water is frozen into ice, if it deſcends in hail or ſnow, electricity appears to be equally concerned. When clouds emit their electricity in great quantities, they inſtantly diſſolve in rain; which is more or leſs heavy according to the quantity of electricity diſcharged, as in thunder-ſtorms; and when this quantity is exceſſive, a vaſt many diſcharges are frequently made before the rain can deſcend. Hence it is reaſonable to conclude, that though heat may be the cauſe of the firſt riſe of vapour, it is the electric fluid which unites it with the air in ſuch a manner as to be perfectly diſſolved and become tranſparent in it (p). This is confirmed by an obſervation related under the article Cloud; namely, that ſmall clouds floating in the atmoſphere will frequently be ſeen to attract one another, and ſo meet together; after which, if they have been of nearly an equal ſize, both will almoſt inſtantly vaniſh. Tranſparency itſelf, as we have ſeen in many inſtances through the courſe of this treatiſe, depends on the vibratory motion of the electric fluid; and when we are aſſured that it depends on this in ſeveral caſes, we may conclude from analogy that it does ſo in all. In the caſe of vapour diſſolved in the atmoſphere, therefore, as long as this particular motion continues through it, the vapour remains diſſolved and tranſparent; but when the electricity comes to be diſpoſed to aſſume the other motion, of which it is exceedingly ſuſceptible, *viz.* that of running in a ſtream from one place to another, the vibratory motion ceaſes, the vapour formerly diſſolved loſes its tranſparency, and appears in the form in which it was originally raiſed by heat, *viz.* that of an opaque ſmoke or miſt. As this miſt muſt always be electrified (for it is in the diſpoſition of the fluid to fly to a diſtant place that electricity conſiſts), the fluid then begins to exert its power of attraction, and the miſt collects in bodies larger or ſmaller according to the quantity of motion with which the electric matter is affected: and thus we ſee how by means of this diſpoſition of the fluid, cloudy weather, rain, or the moſt violent thunder-ſtorms, may be produced.

269
It regulates the heat of the different climates.

On looking farther into the operations of nature, we find the electric fluid acting in a ſtill higher capacity, and regulating the temperature of the different climates throughout the world. Under the article Chemistry, n°99. it has been ſhown, that what is heat in ſummer becomes electric fluid in winter; and under the article Cold, it has been ſhown that cold as well as heat is a poſitive ſubſtance. In the preſent treatiſe it has been proved at length, that the electric fluid and the light of the ſun are the ſame; the former being in truth no other than the ſolar light abſorbed by the earth, entangled among its particles, becoming ſubject to new laws, and acting in many caſes as if it were a diſtinct fluid. Hence it becomes a proper antagoniſt to the light itſelf: for as the latter is only the fluid of electricity moving in a vibratory manner, and what we call electricity is the ſame fluid either in a comparatively ſtagnant ſituation, or diſpoſed to run with violence from one place to another; it is plain that the motion of the light muſt be oppoſed by the fluid tho' ſtagnant, and much more if it be moving in any oppoſite manner. But the action of light when augmented is heat: the power which oppoſes it therefore, *i. e.* the electric fluid moving in an oppoſite direction, as explained under Chemistry, n° 102. is *cold* itſelf; and hence the ſtrong electric appearances in the atmoſphere in cold countries, or in cold weather even in our own country. Hence alſo the electricity of the ſerene ſky is weaker in ſummer than in winter; and combuſtion, which is a very ſtrong vibratory action of the electric matter, produces no electricity, the one action being inconſiſtent with the other. The electric fluid therefore regulates the light and heat of the ſun throughout the whole world, and is itſelf regulated by them; ſo that neither heat nor cold can ultimately predominate any where.

Deſcending from the atmoſphere into the earth itſelf, we find the electric matter no leſs concerned there than in the atmoſphere. It has been already obſerved, that its vibratory motion probably gives tranſparency to all bodies. Sometimes this motion is augmented to a great degree, as in the waters of the ocean, which become unuſually clear before tempeſts and hurricanes. Its action in producing earthquakes is explained at large under the article Earthquake, as well as in ſetting fire to volcanoes under the article Volcano. Like other fluids, its action ſeems to gain a great increaſe of power when it runs for a conſiderable way along any conductor. This may be eaſily conceived from the conſideration, that the ſubſtance along which it runs is every where preſſed by a fluid of the ſame kind, which continually accelerates its motions, and at laſt gives them an intenſity capable of acting as the moſt vehement fire. The fact has been long obſerved, and is confirmed by the experiments of Mr Wilſon in the Pantheon as well as by thoſe of later electricians. In the former, the ſpark taken from a vaſt conductor of 155 feet in length, was ſo ſtrong that it reſembled the diſcharge of a large jar, or rather a ſmall battery; and was ſo very pungent, that few who had tried it once would venture on a ſecond experiment. The lateſt experiments were made with a number of tin conductors joined to each others ends: in which ſituation it was found that the ſpark taken from them was much ſtronger than when they were laid at each others ſides, though the ſurface was in both caſes exactly the ſame. Hence we ſee, that if by any means the electric fluid ſhall meet with an unuſually good conductor for a conſiderable way through the earth, the extremity of that conducting part may be heated, ſet on fire, or violent exploſions iſſue from it; and the ſame thing will take place in the atmoſphere. Upon this principle then may we account for natural hot-baths; exploſions ſuddenly iſſuing from the earth, by which people have ſometimes been killed; clouds and whirlwinds charged with an enormous quantity of electricity, and far beyond what in the ordinary way they could contain, &c.

Thus, to the action of the electric fluid we are in an eſpecial manner to aſcribe the temperature of the air throughout the whole globe; all the phenomena of rain, ſnow, hail, lightning, tempeſts, and in all probability the currents of the air itſelf named *winds*. Certain it is at leaſt, that every electrified ſubſtance has an atmoſphere round it reſembling a gentle blaſt of

---

(p) In this there appears ſome inaccuracy of expreſſion: but as it is ſomewhat difficult to find terms at once ſufficiently accurate and intelligible, we ſhall hear obſerve, that by the word *heat* we mean the electric or univerſal fluid moving in a certain manner, *viz.* from a centre to a circumference; by *cold*, the ſame fluid preſſing from a circumference to a centre; by the *electric fluid* ſimply, the ſame either comparatively ſtagnant, or moving in any other way than thoſe juſt mentioned.

A. Bell Prin. Wal. Sculptor fecit.

in the
n of
e.

of cool air; and it is alſo very remarkable, that the electric fluid itſelf cannot be blown away from any ſubſtance, even by the moſt violent blaſt of air we can imagine. An undoubted evidence of this is, that if you ſet up a ſmall ball or pointed body upon the conductor of a ſtrong machine, ſo that a ſtream of electric light may iſſue from it, it will not be in your power to turn this flame aſide in the ſmalleſt degree by the moſt violent blaſt of a bellows. On the contrary, if any body is preſented to it which has a tendency to attract, the flame will move acroſs the blaſt of air directly contrary to it, or in the ſame direction with it, in the very ſame manner as if no ſuch thing was preſent. As the electric fluid therefore acts independent of the air, and cannot have its motions controlled by it, it is highly probable that all the motions of the atmoſphere are controlled by this fluid alone: and indeed if we allow it to be the proper antagoniſt to the light of the ſun itſelf, we muſt readily allow it alſo to be the regulator of every other power on this earth.

72
bably
uſe of
ation

Its effects on vegetation have been treated of in the laſt ſection, though we cannot certainly ſay that it is the original cauſe of this proceſs. It ſeems, however, to be the true cauſe of CRYSTALLIZATION; which, as remarked under that article, probably is only an incipient or imperfect vegetation. The moſt convincing proof of this is from the experiments of Mr Lichtenberg with a large electrophorus; in which the knob of an electrified phial being drawn over the ſurface of the electric plate, finely powdered roſin afterwards ſifted upon the place aſſumed the figure of ſtars and other beautiful ramifications, indicating not only an inclination to arrange itſelf in the ſame regular order with the cryſtals of ſalts, but to run out into branches like thoſe of vegetables.

73
us fi-
made
mears
var-
d plate
ſs.

Theſe experiments have been repeated to great advantage by the Reverend Mr Bennet, according to whoſe method the figures repreſented in Plate CLXXIX were made. The apparatus uſed for making them conſiſted only of a common Leyden phial, and a plate of glaſs 15 inches ſquare covered on one ſide with a varniſh of gum lac diſſolved in ſpirit of wine (Q), and ſeveral times laid over. The other ſide is covered with tin-foil laid on with common paſte. When it is to be uſed, the glaſs-plate is put upon a metallic ſtand with the tin-foiled ſide laid undermoſt; the phial is to be charged, and the knob drawn over the varniſhed ſide. Thus any kind of figure may be drawn or letters made as repreſented in the plate; and from every figure beautiful ramifications will proceed, longer or ſhorter according to the ſtrength of the charge. On ſome occaſions, however, the charge may be too ſtrong, particularly where we wiſh to repreſent letters, ſo that the whole will be blended into one confuſed maſs. The round figures are formed by placing metallic rings or plates upon the electrical plate; and then giving them a ſpark from the electrified bottle, or ſending a ſhock through them. The figures may be rendered permanent by blowing off the looſe chalk, and clapping on a piece of black-ſized paper upon them; or if they are wanted of another colour, they may eaſily be obtained by means of lake, vermilion, roſe-pink, or any of the ordinary colours ground very fine. The eaſieſt way of applying them ſeems to be by a barber's puff-bellows.

Uſes in the Syſtem of Nature

This tendency of the electrical fluid to produce ramifications in its paſſage through other ſubſtances, is likewiſe evident from the figure of the poſitive flaſhes deſcribed by Mr Nicholſon, and repreſented Plate CLXXVIII. It may indeed be objected, that in both caſes the fluid has to make its way thro' non-conducting ſubſtances, where it meets with a conſiderable reſiſtance; ſo that the caſe cannot be applicable to vegetation, where a ready conductor is always found in the moiſture with which the earth abounds. But if we conſider that the earth, and every thing contained in it, is already ſaturated with electric matter, it muſt readily appear that no new quantity can be forced into it without meeting with a conſiderable reſiſtance; and therefore it will branch out and divaricate in the very ſame manner when paſſing through the earth, that it does when artificially ſent through the air, or made to diffuſe itſelf on the ſurface of an electric ſubſtance. If in the earth it meets with ſuch particles as ſerve to facilitate its paſſage, theſe will be arranged according to the direction of the fluid itſelf; and thus theſe particles being conſolidated by other powers, or by electricity itſelf acting in a different manner, may be ſuppoſed to aſſume the figures of branched roots; while the continual accumulation of new matter augments them in bulk, and is what we call the *growth* of the plant, or its drawing nouriſhment from the ground. It is not indeed pretended that we can explain the manner in which plants grow; the utmoſt we can do is to attain ſome ſlight and general idea of the cauſe, and how by the action of that cauſe, directing itſelf according to the laws given it by the Author of nature, the effects may be produced. This is ſufficient to ſatisfy the curioſity natural to the human mind: a farther knowledge would not only be entirely uſeleſs, but in all probability is inconſiſtent with the limited ſtate of our faculties at preſent. What is here ſaid concerning vegetation, may be applied equally to the formation and growth of animal bodies; but this ſubject is ſtill more obſcure and difficult: it has been ſuppoſed by many, however, that the nervous fluid is the ſame with that of electricity; for which many probable reaſons might be aſſigned, though the ſubtilty and inviſibility of both muſt for ever prevent us from obtaining any direct proof on this ſubject.

274
Is the cauſe of magnetiſm, and probably of attraction of every kind.

When we conſider the reſt of the terreſtrial phenomena, we find the ſame fluid concerned in every one of them, or rather acting as their only cauſe. There is not in nature a more ſurpriſing phenomenon than that of the magnet; and this, by repeated experiments, has been proved to depend on electricity. Magnetical needles have often been endowed with their virtue by means of artificial electricity, and iron has been known to receive it from lightning; whence we may reaſonably conclude, that the power of the magnet at all times depends upon the ſecret operation of the electric fluid. By extending its power to the production of attractive and repulſive forces in all caſes, and which from many na-

---

(Q) Two ounces of ſhell-lac powdered and mixed with ſix ounces of ſpirit of wine anſwers very well for this purpoſe. The glaſs muſt be warmed, and the varniſh ſpread upon it with a camel's hair pencil. Care muſt be taken, however, not to lay it on too thick, otherwiſe the effect will not follow.

natural phenomena is extremely probable, we ſhall ſtill give it a higher rank in the ſyſtem of nature. We ſhall now find it guiding the planets in their courſes through the heavens, giving ſtability and coheſion not only to terreſtrial ſubſtances, but to the globe of earth itſelf, and to all other bodies in the univerſe.

275 Count Treſſan's ſyſtem of natural philoſophy.

A ſyſtem of natural philoſophy on this principle was begun in the year 1747, and lately publiſhed by the Count de Treſſan. In this the electric fluid is conſidered as the firſt principle of motion in the univerſe, and the immediate agent by which the ſyſtem of nature is governed. According to him, the fixed ſtars themſelves are no other than as many foci of action communicating electricity to their ſurrounding planets, which have electric atmoſpheres of different extents. He ſhows the operation of the fluid in all the different phenomena of earth, air, water, fire, &c. deſcending even to the moſt minute, as well as conſidering the moſt grand and ſublime, exhibitions of nature. That the electric fluid is capable of imitating many of theſe phenomena, is certain; as for example, thoſe of earthquakes, water-ſpouts, tides, &c. of which an account is given under their proper articles. By means of the ſame fluid alſo we may imitate the planetary motions; and for this ſeveral contrivances have been fallen upon: the principal are as follow.

276 Methods of imitating the planetary motions.

1. From the prime conductor of an electric machine ſuſpend ſix concentric hoops of metal at different diſtances from one another, in ſuch a manner as to repreſent in ſome meaſure the proportional diſtances of the planets. Under theſe, and at the diſtance of about half an inch, place a metallic plate, and upon this plate, within each of the hoops, a glaſs-bubble blown very thin and light. On electrifying the hoops, the bubbles will be immediately attracted by them, and will continue to move round the hoops as long as the electrification continues. If the electricity is very ſtrong, the bubbles will frequently be driven off, run hither and thither on the plate, making a variety of ſurpriſing motions round their axis; after which they will return to the hoop, and circulate as before; and if the room is darkened, they will all appear beautifully illuminated with electric light.

2. Provide a ball of cork about three quarters of an inch in diameter, hollowed out in the internal part by cutting it in two hemiſpheres, ſcooping out the inſide, and then joining them together with paſte. Having attached this to a ſilk thread between three and four feet in length, ſuſpend it in ſuch a manner that it may juſt touch the knob of an electric jar, the outſide of which communicates with the ground. On the firſt contact it will be repelled to a conſiderable diſtance, and after making ſeveral vibrations will remain ſtationary; but if a candle is placed at ſome diſtance behind it, ſo that the ball may be between it and the bottle, the ball will inſtantly begin to move, and will turn round the knob of the jar, moving in a kind of ellipſis as long as there is any electricity in the bottle. This experiment is very ſtriking, tho' the motions are far from being regular; but it is remarkable that they always affect the elliptical rather than the circular form.

3. Cut a piece of India paper in the ſhape of an iſoſceles triangle, whoſe ſides are about two inches long, and two-tenths of an inch in breadth; then erect a braſs ball of two or three inches diameter on a braſs wire one-ſixth of an inch in thickneſs, and two feet ſix inches long, on the prime conductor: electrify the conductor, and then bring the obtuſe end of the piece of paper within the atmoſphere of the ball; let it go, and it will revolve round the ball, turning often round its own axis at the ſame time.

27 Object from a Mr M ſwered

We ſhall not here enter into any ſpeculations concerning the way in which it might be ſuppoſed poſſible to produce the planetary motions by means of the efflux of the ſun's light, and the return of the electric fluid towards him. Before we can make excurſions into theſe celeſtial ſpaces, it is abſolutely neceſſary to remove an objection derived from Mr Morgan's experiment, that the electric fluid cannot pervade a perfect vacuum; and from which he concludes, that the electric fluid cannot paſs beyond the limits of our atmoſphere. On this experiment, however, we muſt obſerve, that though it were really proved in a much more deciſive manner than is done by this experiment, that the fluid cannot be *artificially* driven through a vacuum, this would not prove that it cannot naturally paſs through it, unleſs we ſhould ſuppoſe the powers of nature and of art to be equal to one another. But that even the powers of art, in Mr Morgan's experiment, have not a fair chance of ſucceſs, is evident from an inſpection of fig. 80. Here he endeavours to force the electric fluid through a long courſe of perfect vacuum, and finds the power of his machine inſufficient for the purpoſe. Yet one of Mr Morgan's own experiments might have led him to vary this one in ſuch a manner as would perhaps have ſhown the poſſibility of tranſmitting the fluid through the moſt perfect vacuum that can be made. He informs us, that a ſpark, which in the open air cannot exceed one quarter of an inch diameter, will appear to fill the whole of an exhauſted receiver four inches wide and eight inches long; tho' in the latter caſe it will be exceſſively faint in compariſon with what it would have been in the atmoſphere: yet, in order to prove that the faintneſs of the electric light *in vacuo* depends on the enlarged ſpace through which it is diffuſed, we have only to introduce two pointed wires into the vacuum, ſo that the fluid may paſs from the point of the one to the point of the other; and when the diſtance between them is not more than the tenth of an inch, in this caſe we ſhall find the ſpark as bright as in the open air.

The inference to be derived from this experiment is obvious. Had Mr Morgan, inſtead of attempting to cauſe the fluid paſs through the whole length of the vacuum, put two wires in the inſide at a ſmall diſtance from each other, as deſcribed in the experiment juſt now mentioned, it is very probable that the fluid would have made its way through that ſmall diſtance. It muſt be acknowledged indeed, that, conſidering the very great difficulty of making this experiment at any rate, we could ſcarce expect that this additional trouble could be taken: but without this, or ſomething equivalent, his concluſion cannot by any means be allowed to be juſt; nor, even if it had been tried, would it have determined the queſtion in his favour.

The great difficulty in this experiment is to give a reaſon why in a certain degree of exhauſtion the vacuum ſhould be ſo eaſily penetrated by the fluid, and in another ſhould make ſuch reſiſtance; but the following conſiderations will probably throw ſome light on this.

the
of

this ſubject. 1. In all caſes where the fluid is obliged to pervade the ſubſtance of any medium whatever, it moves with difficulty. Thus, if a vaſt quantity of electricity is ſent through a ſmall wire, the reſiſtance it meets with is ſo great that the wire is diſperſed with violence; and if the battery is large, it cannot be totally diſcharged, as was the caſe with Dr Van Marum's battery, mentioned n° 150. Again, if the ſpark be taken in water, a moſt violent exploſion takes place; and yet both metals and water are good conductors of electricity. 2. In all caſes where we ſet the electric fluid in motion, the utmoſt we can do is to give it a tendency to circulate; and unleſs we allow it to do ſo, no electricity will be produced. Thus, if we extricate the fluid from the earth by means of an electrical machine, diſcharge it upon a conductor, and form a communication between that and another part of the earth, the circulation will go on very readily, and the fluid will eaſily return to the place from whence it came. If the communication betwixt the earth and conductor be cut off by an electric, the circulation will nevertheleſs go on; the fluid will evaporate in the air, and from thence reach the earth by channels inviſible to us. The effect will be the ſame in all caſes where its motion in a certain direction is ſtopped: but what we call *ſtopping* it, is only rendering its paſſage more difficult in one particular place than in another; for as to any abſolute ſtop or impediment, ſuch as could reſiſt the whole force of the fluid, as Mr Morgan ſuppoſes, there is not the leaſt probability that it exiſts in nature. The whole that can be inferred from Mr Morgan's experiment therefore is, that the electric fluid will more readily evaporate and paſs ſilently thro' the air than through a complete vacuum. The queſtion, however, ſtill recurs: Since this fluid paſſes very readily through rarefied air, why does it heſitate after a certain degree of rarefaction, and at laſt ſtop altogether when the air is totally exhauſted? To this it may be replied, that when air is heated it becomes leſs electric than when cold, and by an increaſe of heat becomes at laſt an excellent conductor. On the other hand, by an increaſe of cold its electric properties become proportionably greater, and conſequently the difficulty with which the fluid gets through it increaſes in proportion. Under the article *ELASTIC Vapours*, it is ſhown that the true principle of elaſticity is *heat*; and under the article CHEMISTRY, n° 99. it is ſhown, that heat and electricity are convertible into one another. In proportion as the air is rarefied, therefore, it abſorbs heat, and conſequently becomes a better conductor; but when it is totally exhauſted, nothing remains but the fluid of electricity itſelf; the ſame indeed with that of heat, but deprived of motion, and conſequently capable of making a much greater reſiſtance. Now the ſtrongeſt ſpark that can be drawn from any of our machines perhaps does not equal $\frac{1}{100}$th of an inch in diameter, as appears from the holes made by them in paper or cards when pierced, as directed in Sect. VIII. But when a perfect vacuum is made, this ſmall ſpark is obliged to act upon a cylinder of electric matter perhaps 6000 or 7000 times greater in diameter than itſelf, each point of which reſiſts with the whole force the exploſion itſelf has; and what is worſe, the whole of this muſt be put in motion before any diſcharge can be made. The reſiſtance therefore is ſo violent, that the fluid rather paſſes through the air as already explained: nevertheleſs, if it were poſſible to make a perfect vacuum of no greater diameter than that of the electric ſpark, there is no reaſon to ſuppoſe that it would not be penetrated by it; and of this Mr Morgan's experiments with the two wires above mentioned ſeems to be a confirmation.

Uſes in the Syſtem of Nature.

On the whole, it is evident, that we cannot from this or indeed any other experiment argue againſt the poſſibility of the paſſage of the electric fluid from any part of the creation to another. *We* cannot force it, it is true, becauſe it is diſpoſed by its own natural laws to reſiſt our efforts; but where it is diſpoſed by theſe laws to yield in one place, there will undoubtedly be a current of it thither from ſome other, which we would find ourſelves equally unable to ſtop by all the machines that ever have been or will be invented. There is as yet therefore not the leaſt proof that the electric fluid does not pervade the moſt diſtant regions of ſpace, and there perform all thoſe great operations which have been aſcribed to unknown and inexplicable powers. For a further account of the operations of this fluid in producing the phenomena of nature, ſee the articles ATMOSPHERE, *AURORA Borealis*, EARTHQUAKE, HAIL, HURRICANE, LIGHTNING, METEOR, RAIN, SNOW, &c.

# INDEX.

rides
uary.

ELECTRIDES, anciently iſlands in the Adriatic ſea, which received their name from the quantity of amber *(electrum)* which they produced. They were at the mouth of the Po, according to Apollonius of Rhodes, but ſome hiſtorians doubt of their exiſtence.

ELECTROMETER. See Electricity, n° 27.

ELECTROPHORUS. *Ibid.* n° 16.

ELECTRUM, in natural hiſtory. See Amber.

ELECTUARY, in pharmacy, a form of medicine compoſed of powders and other ingredients, incorporated with ſome conſerve, honey, or ſyrup; to be divided into doſes, like boluſes, when taken.

Voſſius obſerves, that all the remedies preſcribed for the ſick, as well as the confections taken by way of regale. were called by the Greeks εκλειγματα, and εκλεικτα, of the verb λειχω, "I lick;" whence, ſays he, was formed the Latin *electarium*, and afterwards *electuarium*. This conjecture he ſupports from the laws of Sicily, where it is ordained, that *electuaries*, ſyrups, and other remedies, be prepared after the legal manner. The Bollandiſts, who relate this etymology, ſeem to confirm it. For the compoſition and different ſorts of electuaries, ſee Pharmacy.

Eleemoſyna, Eleemoſynarius.

ELEEMOSYNA *Carucarum*, or *pro Aratris*, or *Aratri.* in our ancient cuſtoms, a penny which king Ethelred ordered to be paid for every plough in England towards the ſupport of the poor. Sometimes it is alſo called *eleemoſyna regis*, becauſe firſt appointed by the king.

ELEEMOSYNARIUS, in our our old writers, is uſed for the almoner or peculiar officer who received the eleemoſynary rents and gifts, and diſtributed them

to

to pious and charitable uſes. There was ſuch an officer in all religious houſes. The biſhops alſo uſed to have their almoners, as now the king has.

ELEGANCE, (from *eligo* "I chooſe,") denotes a manner of doing or ſaying things politely, agreeably, and with choice. With choice, ſo as to riſe above the common manners; politely, ſo as to ſtrike people of delicate taſte; and agreeably, ſo as to diffuſe a reliſh which gratifies every body.

ELEGANCE, in oratory and compoſition, an ornament of politeneſs and agreeableneſs ſhown in any diſcourſe, with ſuch a choice of rich and happy expreſſions, as to riſe politely above the common manners, ſo as to ſtrike people of a delicate taſte.

It is obſerved, that elegance, though irregular, is preferable to regularity without elegance: that is, by being ſo ſcrupulous of grammatical conſtruction, we loſe certain licences wherein the elegance of language conſiſts.

ELEGIAC, in ancient poetry, any thing belonging to elegy. See ELEGY.

ELEGIT, in law, a writ of execution, which lies for a perſon who has recovered debt or damages; or upon a recognizance in any court, againſt a defendant that is not able to ſatisfy the ſame in his goods.

ELEGY, a mournful and plaintive kind of poem. See the article POETRY.

ELEMENTS, in phyſics, the firſt principles of which all bodies in the ſyſtem of nature are compoſed.

Theſe are ſuppoſed to be few in number, unchangeable, and by their combinations to produce that extenſive variety of objects to be met with in the works of nature.

That there is in reality ſome foundation for this doctrine of elementary bodies is plain; for there are ſome principles evidently exempted from every change or decay, and which can be mixed or changed into different forms of matter. A perſon who ſurveys the works of nature in an inattentive manner, may perhaps form a contrary opinion, when he conſiders the numerous tribes of foſſils, plants, and animals, with the wonderful variety that appears among them in almoſt every inſtance. He may from thence be induced to conclude, that nature employs a vaſt variety of materials in producing ſuch prodigious diverſity. But let him inquire into the origin of this apparent diverſity, and he will find that theſe bodies which ſeem the moſt different from each other are at bottom nearly the ſame. Thus the blood, chyle, milk, urine, &c. as well as the various ſolid parts of animals, are all compoſed of one particular ſubſtance; graſs, for inſtance, by the aſſiſtance of air and water, and even ſometimes of very inſipid kinds of graſs. The ſame ſimplicity preſents itſelf in the original compoſition of the nouriſhment of vegetables, notwithſtanding the variety among them with reſpect to hardneſs, ſoftneſs, elaſticity, taſte, odour, and medical qualities. They chiefly depend, for theſe, upon water and the light of the ſun; and the ſame ſimplicity muſt take place in animals that are fed on vegetables. The analyſis of animal ſubſtances confirm this hypotheſis; for they can all be reduced into a few principles, which are the ſame in all, and only differ with regard to the proportions in which they are combined. With regard to animals, the caſe appears to be the ſame: and the more we are acquainted with them, the more reaſon we have to believe that the variety in their origin is very ſmall.

Notwithſtanding the infinite variety of natural productions, therefore, it appears, that the materials employed in their production are but few; that theſe are uniformly and certainly the ſame, totally exempted from any change or decay; and that the conſtant and gradual change of one body into another is produced by the various ſeparations and combinations of the original and elementary parts, which is plain from the regularity and uniformity of nature at all times. There is a change of forms and combinations through which it paſſes, and this has been the caſe from the earlieſt accounts of time; the productions of nature have always been of the ſame kind, and ſucceeded one another in the ſame order. If we examine an oak, for inſtance, we find it compoſed of the ſame matter with that of any other that has exiſted from the earlieſt ages. This regularity and uniformity in the courſe of nature ſhows that the elementary parts of bodies are permanent and unchangeable; for if theſe elementary particles which conſtituted an oak ſome thouſand years ago, had been undergoing any gradual decay, the oaks of the preſent times would have been found conſiderably different from thoſe that exiſted long ago; but as no difference has been obſerved, it would ſeem that the ultimate elements of bodies have always continued the ſame.

Reflections of this kind have ſuggeſted an idea of ſeveral principal elements of which all other bodies are compoſed, which by their various combinations furniſhed all the variety of natural bodies. Democritus, and other great philoſophers of antiquity, fixed the number to four, which have retained the name of elements ever ſince. Theſe are, fire, air, earth, and water; each of which they imagined was naturally diſpoſed to hold its own place in the univerſe. Thus, the earth, as heavieſt, naturally tended towards the centre, and occupied the lower parts; the water, as approaching next to it in gravity, was ſpread chiefly on the outſide of the earth; the air, being more ſubtle and rare, occupied the middle place; while the fire, being ſtill more ſubtile and active, receded to the greateſt diſtance of all, and was ſuppoſed to compoſe the planets and ſtars. This ſyſtem was extended to all the productions of nature. Meteors were produced from a combination of fire and air; animals were conſidered as compoſed of earth and water; and thoſe that were warm had likewiſe a proportion of the element of fire. Thus they went on, explaining ſome of the moſt ſtriking qualities of the ſeveral productions of nature from the different proportions of the four elements they contained.

But though this ſyſtem appears not at all deſtitute of beauty and propriety, and on this account has been in ſome meaſure received even to the preſent time, we find reaſon to doubt whether theſe four ſubſtances be really elementary bodies; nor do they anſwer our purpoſe in forming a ſyſtem, as we know too little of the intimate ſtructure and texture of them to enable us to explain other bodies by them.

Any other attempts that have been made to aſſign the number of elementary bodies have been much leſs fortunate. The chemiſts, with Paracelſus at their head, pretend to ſpeak of four elementary bodies, ſalt, ſulphur, earth, and mercury: but when we attempt to form an idea of what they mean, we find it very perplexed; and that the expreſſions concerning them are enveloped in ſo much obſcurity, that they cannot be comprehended; and the theory is built entirely upon experiments made on metallic ſubſtances.

Under the article Chemistry, n° 26. we have ſhown, that the elements, whatever they are, muſt neceſſarily be inviſible or imperceptible by any of our ſenſes. An inquiry into their number or properties therefore muſt be attended with very little ſucceſs; and all the knowledge we can have upon the ſubject muſt be drawn from a view of their combinations, and reaſoning analogically from the tranſmutations we obſerve to take place in nature. The modern diſcoveries in aerology have enabled us to proceed farther in this way than what it was poſſible for the ancient philoſophers to do. We now find that all the different kinds of air are compoſed of that inviſible and ſubtile fluid named *heat*, united in a certain way with ſome other ſubſtance: by which union the compound acquires the properties of gravitation, expanſion, rarefaction, &c. for pure heat, unleſs when united with ſome terreſtrial ſubſtance, neither gravitates nor expands. This is evident from the phenomena of the burning-glaſs, where the light concentrated in the focus will neither heat the air nor water, unleſs it meets with ſomething with which it can form a permanent union. Heat therefore is juſtly to be conſidered as one of the original elements; being always capable of uniting with bodies, and of being extricated from them unchanged; while the ſame bodies are by their union with it changed into various forms; water, for inſtance, into ice or vapour, both of which return into their original ſtate by the abſtraction or addition of heat in a certain degree. Hence it becomes almoſt natural to conclude, that there are only two elements in the univerſe: and this opinion we find adopted by ſeveral philoſophers, particularly the Count de Treſſan in his Eſſay on the Electric Fluid. According to this doctrine, two primitive material ſubſtances ſeem to exiſt in nature; one that inceſſantly acts, and to which it is eſſential to be in motion; the other abſolutely paſſive, and whoſe nature it is to be inert, and move entirely as directed by the former. Should this doctrine be adopted, little difficulty would occur in determining the active matter to be that univerſal fluid which in its various modifications of light, heat, and electricity, has ſuch a ſhare in the operations of nature. But in fixing on the paſſive element we are greatly embarraſſed; nor are the diſcoveries in aerology or any other ſcience as yet able to remove the difficulty entirely. In our experiments on this and ſome other parts of chemiſtry, we find three things that ſeem to be unchangeable, viz. earth; phlogiſton; and that inviſible, though terreſtrial and gravitating principle called by the antiphlogiſtians the *oxygenous* or acidifying principle, and by the phlogiſtians the baſis of dephlogiſticated air. In our experiments on the firſt, we find that earth, though vitrified by the moſt intenſe fire, may be recovered in its proper form; and ſome very pure earths, particularly magneſia alba, cannot be changed even in the focus of the moſt powerful mirror. In like manner we may diſſipate charcoal *in vacuo* by the ſolar rays, and the compound is inflammable air: we may decompoſe this compound by a metallic calx, and we have our charcoal again unchanged, for all metals contain charcoal in ſubſtance. Let us try to deſtroy it by common fire, and we have it then in the fixed air produced, from which it may be recovered unchanged by means of the electric ſpark. With the baſis of dephlogiſticated air the caſe is ſtill more difficult; for we cannot by any means procure a ſight of it by itſelf. We may combine it with heat, and we have dephlogiſticated air; to the compound we may add charcoal, and we have fixed air; by decompoſing the former by burning iron in it, we have the metal greatly increaſed in weight by ſome unknown ſubſtance; and if we attempt to ſeparate the latter, we have water, or ſome kind of vapour, which ſtill conceals it from our view.

In ſome experiments made by Mr Watt, and of which an account is given under the article Acid, n° 12. we find that nitrous acid might be phlogiſticated by the pureſt earth or metallic calx; whence it is not unreaſonable to ſuppoſe that phlogiſton may be only a certain modification of earth, and not an element diſtinct from it: but with regard to the baſis of dephlogiſticated air, no experiment has ever ſhown that it can either be procured by itſelf, or changed into any other ſubſtance; ſo that it appears to have the nature of an element as much as light or heat. Though we ſhould therefore be inclined to divide the whole matter of the univerſe into two claſſes, the one active and the other acted upon, we muſt allow that the paſſive matter even on this earth is not preciſely of the ſame kind: much leſs are we to extend our ſpeculations in this reſpect to the celeſtial regions; for who can determine whether the ſubſtance of the moon is the ſame with that of our earth, or that the elements of Jupiter are the ſame with thoſe of Saturn? There is even a difficulty with regard to the diviſion which ſeems ſo well eſtabliſhed, *viz.* of matter in general into active and paſſive; for no perſon can prove, that the matter which is active in one caſe may not be paſſive in another, and occaſionally reſume its activity. Something like this certainly happens in the caſe of the electric fluid, which is modified into heat or light, according to different circumſtances; and we cannot know but it is the very ſame ſubſtance that conſtitutes the moſt ſolid bodies. This opinion at leaſt did not ſeem abſurd to Sir Iſaac Newton, who propoſed it as a query, Whether groſs bodies and light were not convertible into one another? The end of our inquiries on this ſubject therefore muſt be, That the univerſe may be compoſed of many elements, or of one element; and of the nature of theſe elements, or of the ſingle one, we know nothing.

**Element**, in a figurative ſenſe, is uſed for the principles and foundations of any art or ſcience; as Euclid's Elements, &c.

**Elements**, in aſtronomy, are thoſe principles deduced from aſtronomical obſervations and calculations, and thoſe fundamental numbers which are employed in the conſtruction of tables of the planetary motions. Thus, the elements of the theory of the ſun, or rather of the earth, are his mean motion and eccentricity, and the motion of the aphelia. The elements of the theory of the moon are its mean motion; that of its node and apogee, its eccentricity, the inclination of its orbit to the plane of the ecliptic, &c.

ELEMI, or Elemy, in the materia medica. See Amyris.

ELENCHUS, in antiquity, a kind of ear-rings ſet with large pearls.

Elenchus, in logic, by the Latins called *argumentum* and *inquiſitio*, is a vicious or fallacious argument, which deceives under the appearance of a truth; the ſame with what is otherwiſe called *ſophiſm*.

ELEPHANT, in zoology. See Elephas.

*American Elephant*: An animal only known in a foſſile ſtate, and that but partially, from the teeth, ſome of the jaw-bones, the thigh-bones, and vertebræ, found with many others five or ſix feet beneath the ſurface on the banks of the Ohio. But theſe bones differ in ſeveral reſpects from thoſe of the elephant; for which, ſee *Foſſil Bones*. As yet the living animal has evaded our ſearch. Mr Pennant thinks it "more than probable, that it ſtill exiſts in ſome of thoſe remote parts of the vaſt new continent unpenetrated yet by Europeans. Providence maintains and continues every created ſpecies; and we have as much aſſurance that no race of animals will any more ceaſe while the earth remains, than *ſeed-time and harveſt*, *cold and heat*, *ſummer and winter*, *day or night*. See Mammuth.

*Elephant-Beetle*. See Scarabæus.

*Knights of the Elephant*, an order of knighthood in Denmark, conferred upon none but perſons of the firſt quality and merit. It is alſo called the *order of St Mary*. Its inſtitution is ſaid to have been owing to a gentleman among the Daniſh croiſes having killed an elephant, in an expedition againſt the Saracens, in 1184; in memory of which, king Canutus inſtituted this order, the badge of which is a towered elephant, with an image of the holy virgin encircled with rays, and hung on a watered ſky-coloured ribbon, like the George in England.

ELEPHANTA, a ſmall, but very remarkable iſland about five miles from the caſtle of Bombay in the Eaſt Indies. Of this we have the following deſcription in Mr Groſe's Voyage to the Eaſt Indies. "It can at moſt be but about three miles in compaſs, and conſiſts of almoſt all hill: at the foot of which, as you land, you ſee, juſt above the ſhore, on your right, an elephant, coarſely cut out in ſtone, of the natural bigneſs, and at ſome little diſtance not impoſſible to be taken for a real elephant, from the ſtone being naturally of the colour of that beaſt. It ſtands on a platform of ſtones of the ſame colour. On the back of this elephant was placed, ſtanding, another young one, appearing to have been all of the ſame ſtone, but has been long broken down. Of the meaning, or hiſtory, of this image, there is no tradition old enough to give any account. Returning then to the foot of the hill, you aſcend an eaſy ſlant, which about half way up the hill brings you to the opening or portal of a large cavern hewn out of a ſolid rock, into a magnificent temple: for ſuch ſurely it may be termed, conſidering the immenſe workmanſhip of ſuch an excavation; and ſeems to me a far more bold attempt than that of the pyramids of Egypt. There is a fair entrance into this ſubterraneous temple, which is an oblong ſquare, in length about 80 or 90 feet, by 40 broad. The roof is nothing but the rock cut flat at top, and in which I could not diſcern any thing that did not ſhow it to be all of one piece. It is about 10 feet high, and ſupported towards the middle, at equidiſtance from the ſides and from one another, with two regular rows of pillars of a ſingular order. They are very maſſive, ſhort in proportion to their thickneſs, and their capital bears ſome reſemblance to a round cuſhion preſſed by the ſuperincumbent mountain, with which they are alſo of one piece. At the further end of this temple are three gigantic figures; the face of one of them is at leaſt five feet in length, and of a proportionable breadth But theſe repreſentations have no reference or connection, either to any known hiſtory or the mythology of the Gentoos. They had continued in a tolerable ſtate of preſervation and wholeneſs, conſidering the remoteneſs of their antiquity, until the arrival of the Portugueſe, who made themſelves maſters of the place; and in the blind fury of their bigotry, not ſuffering any idols but their own, they muſt have even been at ſome pains to maim and deface them, as they now remain, conſidering the hardneſs of the ſtone. It is ſaid they even brought field-pieces to the demolition of images, which ſo greatly deſerved to be ſpared for the unequalled curioſity of them. Of this Queen Catherine of Portugal was, it ſeems, ſo ſenſible, that ſhe could not conceive that any traveller would return from that ſide of India without viſiting the wonders of this cavern; of which too the ſight appeared to me to exceed all the deſcriptions I had heard of them. About two-thirds of the way up this temple, on each ſide, and fronting each other, are two doors or outlets into ſmaller grots or excavations, and freely open to the air. Near and about the door-way, on the right-hand, are ſeveral mutilated images, ſingle and in groupes. In one of the laſt, I remarked a kind of reſemblance to the ſtory of Solomon dividing the child, there ſtanding a figure with a drawn ſword, holding in one hand an infant with the head downwards, which it appears in act to cleave through the middle. The outlet of the other on the left hand is into an area of about 20 feet in length and 12 in breadth; at the upper end of which, as you turn to the right, preſents itſelf a colonade covered at top, of 10 or 12 feet deep, and in length anſwering to the breadth of the area: this joins to an apartment of the moſt regular architecture, an oblong ſquare, with a door in perfect ſymmetry; and the whole executed in quite a contrary taſte and manner from any of the oldeſt or beſt Gentoo buildings any where extant. I took particular notice of ſome paintings round the cornices, not for any thing curious in the deſign, but for the beauty and freſhneſs of the colouring, which muſt have laſted ſome thouſands of years, on ſuppoſing it, as there is all reaſon to ſuppoſe it, cotemporary with the building itſelf. The floor of the apartment is generally full of water, its pavement or ground-work not permitting it to be drawn off or to be ſoaked up. For it is to be obſerved, that even the cavern itſelf is not viſitable after the rains until the ground of it has had time to dry into a competent hardneſs."

ELEPHANTIASIS, called alſo the *lepra of the Arabians*, in medicine, a chronical diſeaſe, one of the two ſpecies of leproſy which affects the whole body, where even the bones as well as the ſkin are covered with ſpots and tumors, which being red at laſt turn black. See Medicine-*Index*.

ELEPHANTINE, or Elephantis (anc. geog.), an iſland in the Nile to the ſouth of Syene; with a cognominal town, where the navigation on the Nile ends, becauſe

becauſe juſt below the leſs cataract. And here to the weſt of the Nile ſtood the laſt Roman garriſon (Notitia Imperii).

ELEPHANTINE, in Roman antiquity, an appellation given to the books wherein were regiſtered the tranſactions of the ſenate and magiſtrates of Rome, of the emperors or generals of armies, and even of the provincial magiſtrates; the births and claſſes of the people, and other things relating to the cenſus.

They are ſuppoſed to have been ſo called, as being made of leaves of ivory or elephants tuſks.

ELEPHANTOMACHI. See ETHIOPIA.

ELEPHANTOPUS, in botany: A genus of the polygamia ſegregatæ order, belonging to the ſyngeneſia claſs of plants; and in the natural method ranking under the 49th order, *Compoſitæ* The calyculus is quadriflorus, with hermaphrodite florets ligulated or plane; the receptacle is naked; the pappus briſtly.

ELEPHAS, the ELEPHANT, in zoology, a genus of quadrupeds belonging to the order of bruta. The characters are theſe: The elephant has no foreteeth in either jaw, and the dog-teeth are very long: the proboſcis or trunk is long, and capable of laying hold of any thing; and the body is ſomewhat naked.

The elephant is the largeſt of all land-animals. From the front to the origin of the tail he is generally about 16 feet long, from the end of the trunk 25 feet, and about 14 feet high. The circumference of the neck is 17 feet, and the circumference of the body at the groſſeſt part 25 feet 10 inches; the tail is about 6 feet long, and $2\frac{1}{2}$ in circumference. The circumference of the legs is about 6 feet. Theſe are the largeſt dimenſions. But the animal differs in ſize in different countries; in ſome not exceeding 7 feet in height. The eyes are ſmall in proportion to the ſize of the animal. The muzzle is very different from that of any other quadruped; it is nothing but the origin of a long trunk which hangs between the two large tuſks; the mouth appears behind the trunk, which ſerves in place of an upper lip, and the under lip terminates in a point. The feet are ſhort, round, clumſy, and only diſtinguiſhable by the toes. The trunk is, properly ſpeaking, the noſe extended, and terminated by a couple of noſtrils. But, beſides ſerving as an organ of ſmell, the trunk performs all the functions of a ſtrong and dexterous arm. The trunk of an elephant is about 8 feet long, $5\frac{1}{2}$ feet in circumference near the mouth, and one foot and a half near the extremity: it is a pipe of an irregular conical figure, and widened at the end: the ſuperior ſide of the trunk is convex, and furrowed tranſverſely, and the inferior ſide is flat, and has two longitudinal rows of ſmall protuberances reſembling the tentacula of the ſilk-worm and moſt other caterpillars. The upper part of the trunk correſponds with the extremity of the noſe in other quadrupeds, and anſwers the ſame intention; the inferior part ſerves as an upper lip, including the noſtrils at the ſame time. For the trunk is a continued canal, divided into two cavities by a longitudinal partition: theſe cavities aſcend along the forepart of the upper jaw, where they make a turn inward, and deſcend into the palate, and then terminate in two ſeparate orifices; they have likewiſe each a ſeparate orifice at the end of the trunk. At the place where theſe cavities make a turn, and before they enter into the bones of the head, there is a moveable cartilaginous plate ſituated in ſuch a manner as enables the animal to ſhut the canal, and to prevent the water with which it occaſionally fills the trunk from entering into the paſſage of the noſe where the organs ſerving for the ſenſation of ſmell are placed. The elephant can move the trunk in all directions; he can extend or ſhorten it at pleaſure, without altering the diameters of the two canals within. By this means reſpiration is not interrupted, whatever be the ſituation of the trunk; and the water is allowed to remain till the animal chooſes to throw it out by an exſpiration. Each canal is lined with a ſmooth ſtrong membrane, and the ſurface of the trunk is covered with another ſtrong membrane or ſkin. The ſubſtance contained between the exterior and interior membranes, is a compoſition of longitudinal and tranſverſe muſcles, which ſerve to extend and contract the length of the trunk. At the extremity of the trunk there is a concave protuberance, in the bottom of which are the two paſſages of the noſtrils. The inferior part of the protuberance is thicker than the ſides, and the ſuperior part is ſtretched out like a finger about five inches long; which, together with the edges of the whole extremity of the trunk, takes on different figures according to the neceſſities of the animal. It is by this organ that the animal lays hold of food or other ſubſtances; which he manages with as much dexterity as a man does his hand, taking up grains of corn, or the ſmalleſt piles of graſs, and conveying them to his mouth. When he drinks, he thruſts his trunk into the water, and fills it by drawing in his breath and exhauſting the air: when the trunk is thus filled with water, he can either throw it out to a great diſtance, or drink it by putting the end of the trunk in his mouth.

The two large tuſks, which ſome call the *horns* of the elephant, are of a yellowiſh colour, and extremely hard. The bony ſubſtance of which they are compoſed is known by the name of IVORY, and much uſed in different branches of manufacture.

The ears are very large, and reſemble thoſe of an ape. The ſkin of the elephant has but few hairs on it, and placed at great diſtances from each other. It is full of wrinkles, like thoſe on the palm of a man's hand, beſides many chapped and greaſy ridges. The female has two dugs, one on each ſide of the breaſt.

M. Buffon ſuppoſed the ancients to have been "deceived, when they tell us, that the elephants copulate like other quadrupeds, the female only lowering her crupper for the more eaſy reception of the male. The ſituation of the parts ſeems to render this mode of junction impoſſible. The female elephant has not like other quadrupeds the orifice of the vagina adjacent to the anus; for it is ſituated nearly in the middle of the belly, about two and a half or three feet diſtant from the anus. On the other hand, the male organ is by no means proportioned to the magnitude of his body, nor to ſo long an interval, which in the ſituation ſuppoſed would preclude the practicability of his approach. Naturaliſts as well as travellers agree in affirming, that the male organ of the elephant exceeds not either in length or diameter that of a horſe. It is, therefore, impoſſible that he ſhould attain his end in the ordinary poſition of quadrupeds. The female muſt neceſſarily lie on her back. De Feynes and Tavernier poſitively aſſert, and the ſituation of the parts confirms their evidence, that theſe animals cannot intermix in any other manner. They require, therefore, more time and conveniency for this operation than other quadrupeds; and it is perhaps for this reaſon that they never copulate but when they enjoy full liberty, and have every neceſſary article at their command. The female muſt not only conſent, but ſolicit the male, by a poſition which ſhe never aſſumes unleſs when ſhe thinks herſelf in perfect retirement." The fact, however, has been controverted by others. Dr Sparrman informs us, that in order if poſſible to determine the queſtion, he let ſlip no opportunity of interrogating on the ſubject every elephant-hunter he met with at the Cape; who all agreed in replying that they were moſt inclined to the common opinion, if they had not been differently informed by two of their companions, Jacob Kok and Marcus Potgieter, who had actually ſeen elephants copulate. "I met (ſays our author) only with the former of theſe hunters, who told me he had likewiſe himſelf been of opinion that the female was obliged to lie on her back on this occaſion; till at length, being out along with Potgieter hunting of elephants, he had occaſion to think otherwiſe. On a certain ſpot they came to, they could reckon about eight elephants, which, on account of the ſmall ſize of their tuſks, they took for females, excepting two large ones; which making ſeveral circles round one of theſe that they took for females (the only one perhaps in rut) frequently, in all probability by way of careſſing her, ſtruck her with their trunks, till at length ſhe threw herſelf down upon her knees, and keeping the ſpine of her back in a ſtiff and extended poſition, brought her hind-feet quite cloſe to her fore-feet, or ſomewhat beyond them; ſo that ſhe almoſt as it were ſtood upon her head. In this forced poſture they ſaw her wait a long while together for the careſſes of the males, who, in fact, likewiſe endeavoured to perform the matrimonial rites, but from jealouſy hindered each other whenever either of them began to mount. After two hours had thus elapſed, the patience of our hunters began to tire; and the rather, becauſe on account of the uneven and ſtoney nature of the ground, which, however, had no wood upon it, and of a river being between them, they could not dare to advance and fire at theſe animals. I will not diſſemble, that though I have not the leaſt occaſion to doubt the veracity of my informer, and though what he told me is by no means impoſſible, I yet find great difficulty in this matter. But on the other hand, the ſame may be ſaid of M. Buffon's or the common opinion; firſt, as they have not been able to confirm it by the teſtimony of any eye-witneſs, nor even by any inſtance of this kind in other quadrupeds properly ſo called; that is, in ſuch animals as have ſome degree of affinity with elephants; ſecondly, as the female's lying on her back can hardly be more convenient for the male, eſpecially as the vagina, according to what I am told, goes from the fore-part backwards; thirdly, it is beſides well known, that the older elephants, on account of the unwieldineſs of their bodies, chiefly ſtand when they ſleep, in order to avoid the trouble and difficulty of lying down and getting up again. Tavernier, indeed, in his third volume, informs us, that the tame females when in rut make themſelves a kind of bed, and lay themſelves in it on their backs, at the ſame time inviting the male elephant by a peculiar cry, &c. but as the author did not ſee this himſelf, and that beſides it is entirely contrary to the modeſty and diſlike to copulation for which the female elephants have always been remarked, I cannot do otherwiſe than leave M. Tavernier's relation and different opinions touching the ſubject to the teſt of future experience."

Mr J. C. Wolf, however, in his Voyage to Ceylon lately publiſhed, confirms the common opinion, and gives an account of the operation in queſtion as if he had more than once ſeen it performed. "The male (he informs us) makes a pit or hollow in the ground, and aſſiſts his conſort to lay herſelf on her back; and in caſe he finds her perfectly compliant and agreeable, very complaiſantly helps her up again after the buſineſs is finiſhed (for ſhe cannot poſſibly riſe of herſelf), by throwing his trunk round her neck: but if ſhe at firſt ſtood ſhilly-ſhally, and gave herſelf prudiſh airs, he then even lets her lie, and goes about his buſineſs." But concerning the credit due to this author, the public ſeem not to be agreed. On the other hand, M. Buffon, in his Supplement, has retracted his former opinion, upon the authority of M. Bles (ſecretary during 12 years to the Dutch government in Ceylon); who deſcribes the copulation of theſe animals in the ſame manner as Farmer Kok does in the extract above given from Dr Sparrman. "Having perceived (ſays M. Bles) that the Count de Buffon, in his excellent work, is deceived with regard to the copulation of the elephants, I know, that in ſeveral parts of Aſia and Africa theſe animals, eſpecially during the ſeaſon of love, remain almoſt in the moſt inacceſſible places of the foreſts; but in the iſland of Ceylon, where I lived 12 years, the land being every where inhabited, they cannot ſo eaſily conceal themſelves; and having often examined them, I perceived that the female organ is ſituated nearly under the middle of the belly, which would lead us to think, with M. Buffon, that the males cannot cover the females in the manner of other quadrupeds. However, there is only a ſlight difference of ſituation. When they inclined to copulate, I perceived that the female bowed down her head and neck, and leaned her two fore-legs, which were alſo bended, upon the root of a tree, as if ſhe meant to proſtrate herſelf on the ground; and the two hind-legs remained erect, which gave the male an opportunity of embracing her as other quadrupeds do. I can likewiſe affirm, that the females go with young about nine months. Moreover, the elephants never copulate unleſs when in a ſtate of freedom. In the ſeaſon of love, the males are ſtrongly chained for four or five weeks, during which time they diſcharge vaſt quantities of ſemen, and are ſo furious, that their cornacks or governors cannot come near them without danger. The approach of the rutting ſeaſon is eaſily known; for ſome days before it happens, an oily liquor flows from a ſmall hole on each ſide of the head. The domeſtic female on theſe occaſions ſometimes makes her eſcape, and joins the wild males in the woods. Some days afterward, her cornack goes in queſt of her, and calls her by her name till ſhe comes. She ſubmits to him with complacence, and allows herſelf to be conducted home, and ſhut up in the ſtable. It was from caſes of this kind that it was diſcovered that the females bring forth about the end of nine months."—The firſt remark, with regard to the mode of copulating, M. Buffon thinks unqueſtionable, ſince M. Marcel Bles aſſures us that he has ſeen the elephants perform the operation. But as to the time of geſtation, which he limits to nine months, we ought to ſupend our judgment, becauſe all travellers affirm that the female elephant is believed to go with young no leſs than two years.

Elephants, even in a ſavage ſtate, are peaceable and gentle creatures. They never uſe their weapons but in defence of themſelves or companions. Their ſocial diſpoſitions are ſo ſtrong, that they are ſeldom found alone, but march always in large troops: the oldeſt and moſt experienced lead the van; the younger, or lame ones, keep in the middle; and thoſe of a ſecond rate, as to age, walk in the rear. The females carry their young on their tuſks, embracing them at the ſame time with their trunk. They ſeldom march in this regular order but when they reckon the journey dangerous, ſuch as an expedition to cultivated lands, where they expect to meet with reſiſtance. On other occaſions they are leſs cautious; ſome of them falling behind or ſeparating from the reſt, but ſeldom ſo far as to be without the reach of aſſiſtance by alarming and aſſembling their companions. It is dangerous to offer them the leaſt injury; for they run ſtraight upon the offender; and although the weight of their body be great, their ſteps are ſo large, that they eaſily outrun the ſwifteſt man, whom they either pierce with their tuſks, or ſeize with their trunk, dart him in the air like a ſtone, and then trample him under their feet. But they never attack any perſon unleſs when provoked. However, as they are extremely ſenſible and delicate with regard to injuries, it is always prudent to keep out of their way. Travellers who frequent theſe countries kindle large fires, and beat drums during the night, in order to prevent their approach. After being once attacked by men, or falling into any ambuſh, they are ſaid never to forget the injury, but ſearch for every opportunity of getting revenge. As they are endowed perhaps with a more exquiſite ſenſation of ſmell than any other animal, owing to the great extent of their noſe, they can ſcent a man at a very great diſtance, and trace him by his footſteps.

Elephants are peculiarly fond of the banks of rivers, deep valleys, and marſhy grounds, eſpecially when well ſhaded with trees. They delight in drawing up water into their trunks, even when they do not drink it, and amuſe themſelves in daſhing the water around. They cannot endure cold, and are equally averſe to an exceſs of heat: in order to avoid the ſcorching heat of the ſun, they retire to the thickeſt and moſt ſhady parts of the foreſt. The bulk of their bodies is ſo enormous, that they do not chooſe to go into deep waters ſo frequently as ſome other quadrupeds; although the length of their trunk, which they raiſe ſtraight up, and by which they reſpire, is a great advantage in ſwimming.

The ordinary food of elephants is roots, herbs, leaves, the tender branches of trees, fruits, and grains: but they abhor fleſh or fiſh. When any of them diſcovers a fine paſture, he immediately calls and invites his companions to come and eat with him. As they devour a large quantity of food in a ſhort time, they are always ſhifting their paſture; when they meet with cultivated grounds, they make a prodigious deſolation, and deſtroy more plants by their feet than they uſe for nouriſhment: which laſt is very conſiderable, amounting to 150 pounds of herbage every day: by this means, as they conſtantly graze in large troops, they lay waſte whole fields in an hour. The Indians and negroes employ every art to prevent them from viſiting their cultivated lands, making great noiſes, and burning large fires round their fields. However, theſe precautions are not always ſufficient to prevent the elephants from viſiting them. They chaſe away the domeſtic animals, put the men to flight, and ſometimes even throw down their timber huts. Elephants are hardly ſuſceptible of fear: the only things which can ſurpriſe them or ſtop their courſe are artificial fires, ſuch as ſquibs, crackers, &c. the effects of which are ſo ſudden and ſo quickly repeated, that the elephants frequently turn back; and when one runs, all the reſt inſtantly follow his example.

Although the ſocial diſpoſition in the elephant be exceeding ſtrong; yet whenever the females come in ſeaſon, it immediately gives place to the ſtronger and more intereſting paſſion of love. They obſerve the greateſt delicacy in their amours, abhorring nothing ſo much as to be ſeen by their companions. The troop divide themſelves into couples, ſteal off into the moſt ſecret places of the foreſt, and then give way to all the impulſes of nature, which are lively and laſting in proportion to the long period of abſtinence; for, according to all accounts, except that of M. Bles already noticed (A), the female goes with young two years, and it is only once in three years that the ſeaſon of love returns. They bring forth but one at a time; which, as ſoon as it comes into the world, is as large as a wild boar, and is furniſhed with teeth: however, the large tuſks do not make their appearance till ſome time after, and at the age of ſix months they are ſeveral inches long. Elephants of this age are as large as an ox when in a natural ſtate.

The manner of taking and taming elephants, therefore, merits our attention. In foreſts and ſuch places as are frequented by elephants, the Indians chooſe a ſpot and incloſe it with ſtrong palliſades; they uſe the largeſt trees as the principal ſtakes, to which are fixed ſmaller ones in a tranſverſe direction. Theſe croſs trees are fixed ſo as to allow a man to paſs eaſily through. There is likewiſe a large port left for the elephant, over which is ſuſpended a ſtrong barrier, which is let down as ſoon as he enters. In order to decoy him into the incloſure, the hunters take along with them a tame female in ſeaſon, and travel about till they come ſo near as that the cry of the female can reach a male, whom they previouſly obſerve in the foreſt; then the guide of the female makes her give the cry peculiar to the ſeaſon of love: the male inſtantly replies, and ſets out in queſt of her. The guide then makes the female proceed towards the artificial incloſure, repeating her cries from time to time as ſhe goes along. She enters into

---

(A) Mr Bles's information is adopted by Mr Pennant: That they go only nine months with young, he ſays, is gueſſed by the caſual eſcape of the tame females, when in rut, into the woods; where they couple with the wild; are ſoon diſcovered and brought back, and obſerved to bring forth in about nine months from the time.

Elephas.

into the incloſure, the male follows her, and the Indians immediately ſhut the port behind him. He no ſooner diſcovers the hunters, and that he is incloſed, than his paſſion for the ſex is converted into rage and fury. The hunters entangle him with ſtrong ropes; they fetter his legs and trunk; they bring two or three tame elephants in order to pacify and reconcile him to his condition. In a word, they reduce him to obedience in a few days, by a proper application of torture and careſſes. There are many other methods of catching elephants. Inſtead of making large incloſures with palliſades, like the kings of Siam, and other monarchs, the poor Indians content themſelves with a very ſimple apparatus: they dig deep pits in the roads frequented by elephants, covering them over with branches of trees, turf, &c. When an elephant falls into one of theſe pits, he is unable to get out again.

The elephant, when tamed, is the moſt friendly and obedient of all animals: he is entirely attached to the perſon who feeds and takes care of him. In a ſhort time he underſtands ſigns, and the ſound of his maſter's voice. He diſtinguiſhes the language of paſſion, of command, of ſatisfaction; and acts accordingly. He receives his orders with attention, and executes them with prudence and alacrity, but without precipitation. He eaſily learns to bow his knees and lower his body, for the convenience of thoſe who mount him. He careſſes his friends with his trunk. He lifts burdens with his trunk, and aſſiſts thoſe who are loading him in laying them on his back. He delights in ſhining harneſs and trappings. When yoked in a cart or waggon, he pulls equally and cheerfully, unleſs he be abuſed by injudicious chaſtiſements. His guide is generally mounted on his neck, with a ſmall rod of iron ſharp at the point in his hand; he directs his motion by pricking him on the ears and head; but, for the moſt part, a word is ſufficient.

A tame elephant will do more labour than ſix horſes; but then he requires a proportional quantity of food. They are the principal beaſts of burden in many parts of Africa and the Eaſt Indies. They carry ſacks and bundles of all kinds on their neck, back, and tuſks. They never loſe or damage any thing committed to their care: they will ſtand on the edge of a river, take bundles off their necks and tuſks, lay them carefully in a boat wherever they are deſired, and try with their trunk whether they are properly ſituated; if they be loaded with caſks, they go in queſt of ſtones to prop them and prevent them from rolling.

The elephant is not only the moſt tractable, but the moſt intelligent, of animals; ſenſible of benefits, reſentful of injuries, and endowed even with a ſenſe of glory.—In India, they were once employed in the launching of ſhips: one was directed to force a very large veſſel into the water; the work proved ſuperior to his ſtrength: his maſter, with a ſarcaſtic tone, bid the keeper take away this lazy beaſt and bring another: the poor animal inſtantly repeated his efforts, fractured his ſkull, and died on the ſpot. In Delli, an elephant paſſing along the ſtreets, put his trunk into a taylor's ſhop, where ſeveral people were at work: one of them pricked the end with his needle: the beaſt paſſed on; but in the next dirty puddle filled his trunk with water, returned to the ſhop, and ſpurting every drop among the people who had offended him, ſpoilt their work.

Ludolph. com in hiſt. Æthiop. p. 147.

Ibid.

An elephant in Adſmeer, which often paſſed thro' the bazar or market, as he went by a certain herbwoman, always received from her a mouthful of greens: at length he was ſeized with one of his periodical fits of rage, broke his fetters, and, running through the market, put the crowd to flight; among others, this woman, who in haſte forgot a little child ſhe had brought with her. The animal recollecting the ſpot where his benefactreſs was wont to ſit, took up the infant gently in his trunk, and placed it in ſafety on a ſtall before a neighbouring houſe. Another, in his madneſs, killed his *cornac* or governor: the wife ſeeing the misfortune, took her two children and flung them before the elephant, ſaying, "Now you have deſtroyed their father, you may as well put an end to their lives and mine." It inſtantly ſtopped. relented, took the greateſt of the children, placed him on its neck, adopted him for his *cornac*, and never afterwards would permit any body elſe to mount it.

Buffon, p. 78.

A ſoldier at Pondicherry, who was accuſtomed, whenever he received the portion that came to his ſhare, to carry a certain quantity of it to one of theſe animals, having one day drank rather too freely, and finding himſelf purſued by the guards, who were going to take him to priſon, took refuge under the elephant's body and fell aſleep. In vain did the guard try to force him from this aſylum, as the elephant protected him with his trunk. The next morning the ſoldier, recovering from his drunken fit, ſhuddered with horror to find himſelf ſtretched under the belly of this huge animal. The elephant, which without doubt perceived the man's embarraſſment, careſſed him with his trunk, in order to inſpire him with courage and make him underſtand that he might now depart in ſafety.

Mem. p ſervir a l'Hiſt. nimau par M ſieurs de l'Acad Sciences, Part II.

A painter was deſirous of drawing the elephant which was kept in the menagerie at Verſailles in an uncommon attitude, which was that of holding his trunk raiſed up in the air with his mouth open. The painter's boy, in order to keep the animal in this poſture, threw fruit into his mouth; but as the lad frequently deceived him, and made an offer only of throwing him the fruit, he grew angry; and. as if he had known that the painter's intention of drawing him was the cauſe of the affront that was offered him, inſtead of revenging himſelf on the lad, he turned his reſentment on the maſter, and taking up a quantity of water in his trunk, threw it on the paper on which the painter was drawing, and ſpoiled it.

Voyage la Caill p. 160.

At the Cape of Good Hope, it is cuſtomary to kill thoſe animals, for the ſake of their teeth, by the chaſe. Three horſemen, well mounted and armed with lances, attack the elephant alternately, each relieving the other as they ſee their companion preſſed, till the beaſt is ſubdued. Three Dutchmen (brothers), who had made large fortunes by this buſineſs, determined to retire to Europe, and enjoy the fruits of their labours; but reſolved, before they went, to have a laſt chaſe by way of amuſement: they met with their game, and began the attack in the uſual manner; but unfortunately one of their horſes fell down and flung its rider: the enraged animal inſtantly ſeized the unhappy man with its trunk, flung him up to a vaſt height in the air, and received

ceived him on one of its tuſks; then turning towards the two other brethren, as if it were with an aſpect of revenge and inſult, held out to them the impaled wretch writhing on the bloody tooth.

From the earlieſt accounts in hiſtory, the eaſtern nations have employed elephants in war; Alexander the Great was the firſt European who ever mounted an elephant. He carried a number of them into Greece, which Pyrrhus employed ſome years after againſt the Romans at the battle of Tarentum. Both the Greeks and Romans ſoon learnt to get the better of thoſe monſtrous animals: they opened their ranks and allowed them to paſs through; neither did they attempt to hurt them, but threw darts, &c. at their guides. Now that fire-arms are the principal inſtruments of war, elephants, who are terrified at the noiſe and flame, inſtead of being uſeful, would only tend to embarraſs and confuſe an army. However, in Cochin and other parts of Malabar, as alſo in Tonquin, Siam, and Pegu, where fire-arms are little underſtood, they are ſtill uſed in battle. The guide ſits aſtride upon the neck, and the combatants ſit or ſtand upon the other parts of the body. They are alſo extremely ſerviceable in fording of rivers, and carrying over the baggage on their backs. After the keepers have loaded them with ſeveral hundred weight, they faſten ropes to them; of which the ſoldiers taking hold, either ſwim or are drawn acroſs the river. In time of action, they now and then fix an heavy iron chain to the end of their trunks, which they whirl round with ſuch agility, as to make it impoſſible for an enemy to approach them at that time. Another uſe they ſtill have for this creature in war, is to force open the gates of a city or garriſon which is cloſely beſieged. This he does by ſetting his backſide againſt them, riggling backwards and forwards with his whole weight, till he has burſt the bars, and forced an entrance: to prevent which, moſt of the garriſons in this country have large ſpikes ſtuck in their gates, that project to a conſiderable diſtance. However, after all, thoſe prodigious animals are kept more for ſhow and grandeur than for uſe, and their keeping is attended with a very great expence, for they devour vaſt quantities of proviſion; and you muſt ſometimes regale them with a plentiful repaſt of cinnamon, of which they are exceſſively fond. It is ſaid to be no uncommon thing with a Nabob, if he has a mind to ruin a private gentleman, to make him a preſent of an elephant, which he is ever afterwards obliged to maintain at a greater expence than he can afford: by parting with it, he would certainly fall under the diſpleaſure of the grandee, beſides forfeiting all the honour which his countrymen think is conferred upon him by ſo reſpectable a preſent.

When the elephant is properly managed, he lives very long even in a ſtate of ſlavery and labour. That ſome have lived in this ſtate 130 years, is pretty well authenticated. In a natural ſtate, they often exceed 200 years, and propagate their ſpecies till they are 120: It is 30 years before they come to their full growth.

The elephant inhabits India, and ſome of its greater iſlands, Cochin China, and ſome of the provinces of China. It abounds in the ſouthern parts of Africa, from the river Senegal to the Cape; and from thence as high as Ethiopia on the other ſide. They are found in the greateſt numbers in the interior parts, where there are vaſt foreſts, near the ſides of rivers. The wild elephants of Ceylon live in troops or families diſtinct and ſeparate from all others, and ſeem to avoid the ſtrange herds with particular care. When a family removes from place to place, the largeſt-tuſked males put themſelves at the head; and if they meet with a large river, are the firſt to paſs it. On arriving on the oppoſite bank, they try whether the landing-place is ſafe: in caſe it is, they give a ſignal of a note from the trunk, as if it were the ſound of a trumpet, on which the remaining part of the old elephants ſwim over; the little elephants follow, holding one another by locking their trunks together; and the reſt of the old ones bring up the rear. In the woods are often ſeen a ſolitary male elephant, wandering like an outlaw baniſhed from the herd and all the race. Theſe are as if in a ſtate of deſperation, and very dangerous. A ſingle man will put to flight whole herds of ſocial elephants: this alone fears not his preſence, but will ſtand firm, putting his power to defiance. Elephants are not at preſent domeſticated in Africa, but only in the more civilized parts of Aſia. They are much more numerous in Africa. In ſome parts they ſwarm ſo, that the negroes are obliged to make their habitations under ground for fear of them. They are killed and eaten by the natives, and the trunk is ſaid to be a delicious morſel. All the teeth are brought from Africa: they are frequently picked up in the woods; ſo that it is uncertain whether they are ſhed teeth, or thoſe of dead animals. The African teeth which come from Moſambique are ten feet long; thoſe of Malabar only three or four; the largeſt in Aſia are thoſe of Cochin China, which even exceed the ſize of the elephants of Moſambique. The ſkin is thick, and, when dreſſed, proof againſt a muſket ball. The fleſh, the gall, the ſkin, and the bones, are ſaid to be uſed medicinally by the Chineſe. See Plate CLXXX.

ELEVATION, the ſame with ALTITUDE or height.

*Elevation of the Hoſt*, in the church of Rome, that part of the maſs where the prieſt raiſes the hoſt above his head for the people to adore.

ELEVATOR, in anatomy, the name of ſeveral muſcles, ſo called from their ſerving to raiſe the parts of the body to which they belong.

ELEVATORY, in ſurgery, an inſtrument for raiſing depreſſed or fractured parts of the ſkull, to be applied after the integuments and perioſteum are removed. See SURGERY.

ELEVE, a term purely French, though of late uſed alſo in our language. Literally it ſignifies a diſciple or ſcholar bred up under any one, being formed from the Italian *allievo*, an "apprentice" or "novice."

It was firſt uſed by the French writers in ſpeaking of painters; ſuch a painter was an eleve of Da Vinci, of Raphael, &c. From painting it came to be applied to ſuch as ſtudied or learned any other art under a maſter. In the Royal Academy of Sciences, there were 20 eleves: and in that of inſcriptions, 10 eleves. The eleves are to act in concert with the penſionaries. See ACADEMY.

The denomination *eleve*, however, has been ſince ſuppreſſed, and that of *adjoint* ſubſtituted in its room; becauſe every body did not know the ſenſe affixed to it by the academy: and now the penſionary academiſts have not, as formerly, each of them an eleve; but the eleves

eleves are become adjoints, or aſſociates of the academy.

ELEVENTH, or chord of the eleventh. See INTERVAL.

ELEUSINIA, in Grecian antiquity, a feſtival kept in honour of Ceres, every fourth year by ſome ſtates, but by others every fifth. The Athenians celebrated it at Eleuſis, a town of Attica; whence the name.

Ceres, ſays an Athenian orator (Iſocrates), wandering in queſt of her daughter Proſerpine, came into Attica, where ſome good offices were done her, which it is unlawful for thoſe who are not initiated to hear. In return ſhe conferred two unparalleled benefits; to wit, the knowledge of agriculture, by which the human race is raiſed above the brute creation; and the myſteries, from which the partakers derive ſweeter hopes than other men enjoy, both as to the preſent life and to eternity. It was the popular opinion, that the Eleuſinian goddeſſes ſuggeſted prudent counſel to their votaries, and influenced their conduct; that theſe were reſpected in the infernal regions, and had precedence in the aſſemblies of the bleſſed; while the unhallowed were in utter darkneſs, wallowing in mire, or labouring to fill a leaky veſſel. The Athenians were ſolicitous to ſecure theſe advantages to their children, by having them initiated as ſoon as was allowed.

Ceres was ſuppoſed to be particularly partial to Eleuſis and its vicinity. *There* were the memorials of her preſence and of her bounty; the well-named *Callichorus*, by which ſhe had reſted, in the reign of Erectheus; the ſtone on which ſhe ſat, named *the ſorrowful;* the Rharian plain, where barley was firſt ſown; and the threſhing-floor and altar of Triptolemus, a herdſman whom ſhe inſtructed in the culture of that grain, the uſe of which ſucceeded to acorns. Her myſteries continued to poſſeſs a pre-eminence in holineſs, and to be accounted as much ſuperior to all other religious feſtivals as the gods were to the heroes. Even the garments worn at the ſolemnity were ſuppoſed to partake of their efficacy, and to be endued with ſignal virtues. It was uſual to retain them until they were periſhing; and then to dedicate them in the temple, or to reſerve them for the purpoſe of enwrapping new-born children.

The myſtic temple, as it was called, provided by Pericles for the ſolemnity, created ſuch awe by its ſanctity as could be equalled only by the effect of its beauty and magnitude, which excited aſtoniſhment in every beholder. The profane or uninitiated were forbidden to enter it on any pretence. Two young Acarnanians happened inadvertently to mix with the croud at the ſeaſon of the myſteries, and to go in; but the queſtion ſuggeſted by their ignorance preſently betrayed them, and their intruſion was puniſhed with death. The chief prieſt, hierophant, or myſtagogue, was taken from the Eumolpidæ, a holy family flouriſhing at Athens, and deſcended from Eumolpus, a ſhepherd and favourite of Ceres. He was enjoined celibacy, and wore a ſtole or long garment, his hair, and a wreath of myrtle. The grand requiſites in his character were ſtrength and melody of voice, ſolemnity of deportment, magnificence, and great decorum. Under him, beſides many of inferior ſtation, was the daduchus or torch-bearer, who had likewiſe his hair, with a fillet; the prieſt, who officiated at the altar; and the hiero-ceryx or ſacred herald; all very important perſonages. The latter was of a family which claimed the god Mercury and Aglauros the daughter of Cecrops for its anceſtors.

The ſecrecy in which the myſteries were enveloped, ſerved to enhance the idea of their conſequence, and to increaſe the deſire of participation. It was ſo particular, that no perſon was allowed even to name the hierophant by whom he had been initiated. Public abhorrence and deteſtation awaited the babbler, and the law directed he ſhould die.

The Athenians ſuffered none to be initiated into theſe myſteries but ſuch as were members of their city. This regulation, which compelled Hercules, Caſtor, and Pollux, to become citizens of Athens, was ſtrictly obſerved in the firſt ages of the inſtitution, but afterwards all perſons, barbarians excepted, were freely initiated.

The feſtivals were divided into great and leſs myſteries. The leſs were inſtituted from the following circumſtance. Hercules paſſed near Eleuſis while the Athenians were celebrating the myſteries, and deſired to be initiated. As this could not be done, becauſe he was a ſtranger, and as Eumolpus was unwilling to diſpleaſe him on account of his great power, and the ſervices which he had done to the Athenians, another feſtival was inſtituted without violating the laws. It was called μικρα, and Hercules was ſolemnly admitted to the celebration and initiated. Theſe leſs myſteries were obſerved at Agræ near the Iliſſus. The greater were celebrated at Eleuſis, from which place Ceres has been called *Eleuſinia*. In later times the ſmaller feſtivals were preparatory to the greater, and no perſon could be initiated at Eleuſis without a previous purification at Agræ. This purification they performed by keeping themſelves pure, chaſte, and unpolluted, during nine days; after which they came and offered ſacrifices and prayers, wearing garlands of flowers, called ισμερα or ιμηρα, and having under their feet Διος κωδιον, *Jupiter's ſkin*, which was the ſkin of a victim offered to that god. The perſon who aſſiſted was called υδρανος from υδωρ *water*, which was uſed at the purification, and they themſelves were called μυσται, *the initiated.*

A year after the initiation at the leſs myſteries they ſacrificed a ſow to Ceres, and were admitted in the greater, and the ſecrets of the feſtivals were ſolemnly revealed to them, from which they were called εφοροι and εποπται, *inſpectators.*

This feſtival was obſerved in the month Boedromion or September, and continued nine days from the 15th till the 23d. During that time it was unlawful to arreſt any man or preſent any petition, on pain of forfeiting a thouſand drachmas, or according to others on pain of death. It was alſo unlawful for thoſe who were initiated to ſit upon the cover of a well, to eat beans, mullets, or weazels. If any woman rode to Eleuſis in a chariot, ſhe was obliged by an edict of Lycurgus to pay 6,000 drachmas. The deſign of this law was to deſtroy all diſtinction between the richer and poorer ſort of citizens. When the ſeaſon approached, the myſtæ or perſons who had been initiated only in the leſſer myſteries, repaired to Eleuſis to be inſtructed in the ceremonial. The ſervice for the opening of the temple, with morning ſacrifice, was performed

formed. The ritual was then produced from the ſanctuary. It was enveloped in ſymbolical figures of animals, which ſuggeſted words compendiouſly, in letters with ligatures, implicated, the tops huddled together, or diſpoſed circularly like a wheel; the whole utterly inexplicable to the profane. The caſe, which was called *Petroma*, conſiſted of two ſtones exactly fitted. The myſterious record was replaced after the reading, and cloſed up until a future feſtival. The principal rite was nocturnal, and confined to the temple and its environs. The myſtæ waited without, with impatience and apprehenſion. Lamentations and ſtrange noiſes were heard. It thundered. Flaſhes of light and of fire rendered the deep ſucceeding darkneſs more terrible. They were beaten, and perceived not the hand. They beheld frightful apparitions, monſters, and phantoms of a canine form. They were filled with terror, became perplexed and unable to ſtir. The ſcene then ſuddenly changed to brilliant and agreeable. The propylæa or veſtibules of the temple were opened, the curtains withdrawn, the hidden things diſplayed. They were introduced by the hierophant and daduchus, and the former ſhowed them the myſteries. The ſplendor of illumination, the glory of the temple and of the images, the ſinging and dancing which accompanied the exhibition, all contributed to ſooth the mind after its late agitation, and to render the wondering devotee tranquil and ſelf-fatisfied. After this inſpection, or, as it was called, the *autopſia*, they retired, and others advanced. The ſucceeding days were employed in purification, in ſacrifice, in pompous proceſſions, and ſpectacles, at which they aſſiſted, wearing myrtle-crowns. The ſecond day was called αλαδε μυσται, *to the ſea, you that are initiated*; becauſe they were commanded to purify themſelves by bathing in the ſea. On the third day ſacrifices, and chiefly a mullet, were offered; as alſo barley from a field of Eleuſis. Theſe oblations were called Θυα, and held ſo ſacred that the prieſts themſelves were not, as in other ſacrifices, permitted to partake of them. On the fourth day they made a ſolemn proceſſion, in which the καλαθιον, *holy baſket of Ceres* was carried about in a conſecrated cart, while on every ſide the people ſhouted χαιρε Δημητερ, *Hail, Ceres!* After theſe followed women, called κιστοφοροι, who *carried baſkets*, in which was ſeſamin, carded wool, grains of ſalt, a ſerpent, pomegranates, reeds, ivy boughs, certain cakes, &c. The fifth was called Ἡ των λαμπαδων ημερα, *the torch day*; becauſe on the following night the people ran about with torches in their hands. It was uſual to dedicate torches to Ceres, and contend which ſhould offer the biggeſt, in commemoration of the travels of the goddeſs, and of her lighting a torch in the flames of mount Ætna. The ſixth day was called Ιακχος, from Iacchus, the ſon of Jupiter and Ceres, who accompanied his mother in her ſearch after Proſerpine with a torch in his hand. From that circumſtance his ſtatue had a torch in his hand, and was carried in ſolemn proceſſion from the Geramicus to Eleuſis. The ſtatue with thoſe that accompanied it, called Ιακχαγωγοι, was crowned with myrtle. In the way nothing was heard but ſinging and the noiſe of brazen kettles as the votaries danced along. The way through which they iſſued from the city was called Ιερα οδος *the ſacred way*, the reſting place Ιερα συκη, from a *fig-tree* which grew in the neighbourhood. They alſo ſtopped on a bridge over the Cephiſus, where they derided thoſe that paſſed by. After they had paſſed this bridge, they entered Eleuſis by a place called μυστικη εισοδος, *the myſtical entrance*. On the ſeventh day were ſports, in which the victors were rewarded with a meaſure of barley, as that grain had been firſt ſown in Eleuſis. The eighth day was called Επιδαυριων ημερ, becauſe once Æſculapius at his return from Epidaurus to Athens was initiated by the repetition of the leſs myſteries. It became cuſtomary, therefore, to celebrate them a ſecond time upon this, that ſuch as had not hitherto been initiated might be lawfully admitted. The ninth and laſt day of the feſtival was called Πλημοχοαι *earthen veſſels*, becauſe it was uſual to fill two ſuch veſſels with wine; one of which being placed towards the eaſt, and the other towards the weſt; which, after the repetition of ſome myſtical words, were both thrown down, and the wine being ſpilt on the ground was offered as a libation.

The ſtory of Ceres and Proſerpine, the foundation of the Eleuſinian myſteries, was partly local. It was both verbally delivered, and repreſented in allegorical ſhow. Proſerpine was gathering flowers when ſhe was ſtolen by Pluto. Hence the proceſſion of the holy baſket, which was placed on a car dragged along by oxen, and followed by a train of females, ſome carrying the myſtic cheſts, ſhouting, *Hail, Ceres!* At night a proceſſion was made with lighted torches, to commemorate the goddeſs ſearching for her daughter. A meaſure of barley, the grain which, it was believed, ſhe had given, was the reward of the victors in the gymnic exerciſes; and the tranſaction at the temple had a reference to the legend. A knowledge of theſe things and places, from which the profane were excluded, was the amount of initiation; and the mode of it, which had been deviſed by craft, was ſkilfully adapted to the reigning ſuperſtitions. The operation was forcible, and the effect in proportion. The prieſthood flouriſhed as piety increaſed. The diſpenſation was corrupt, but its tendency not malignant. It produced ſanctity of manners and an attention to the ſocial duties; deſire to be as diſtinguiſhed by what was deemed virtue as by ſilence.

Some have ſuppoſed the principal rites at this feſtival to have been obſcene and abominable, and that from thence proceeded all the myſterious ſecrecy. They were carried from Eleuſis to Rome in the reign of Adrian, where they were obſerved with the ſame ceremonies as before, though perhaps with more freedom and licentiouſneſs. They laſted about 1800 years, and were at laſt aboliſhed by Theodoſius the Great.

ELEUSIS, (anc. geog.) a town in Attica between Megara and the Piræus, celebrated for the feſtivals of Ceres. See the preceding article.—Thoſe rites were finally extinguiſhed in Greece upon the invaſion of Alaric the Goth. Eleuſis, on the overthrow of its goddeſs and the ceſſation of its gainful traffic, probably became ſoon an obſcure place, without character or riches. For ſome ages, however, it was not entirely forſaken, as is evident from the vaſt conſumption of the ancient materials, and from the preſent remains, of which the following account is given by Dr Chandler †. "The port was ſmall and of a circular form. The

† *Travels in Greece*, p. 189.

Eleuſinia. ſtones of one pier are ſeen above water, and the correſponding ſide may be traced. About half a mile from the ſhore is a long hill, which divides the plain. In the ſide next the ſea are traces of a theatre, and on the top are ciſterns cut in the rock. In the way to it, ſome maſſes of wall and rubbiſh, partly ancient, are ſtanding; with ruined churches; and beyond, a long broken aqueduct croſſes to the mountains. The Chriſtian pirates had infeſted the place ſo much, that in 1676 it was abandoned. It is now a ſmall village at the eaſtern extremity of the rocky brow, on which was once a caſtle; and is inhabited by a few Albanian families, employed in the culture of the plain, and ſuperintended by a Turk, who reſides in an old ſquare tower. The proprietor was Achmet Aga, the primate or principal perſon of Athens.

"The myſtic temple at Eleuſis was planned by Ictinus, the architect of the Parthenon. Pericles was overſeer of the building. It was of the Doric order; the cell ſo large as to admit the company of a theatre. The columns on the pavement within, and their capitals, were raiſed by Coræbus. Metagenes of Xypete added the architraves and the pillars above them, which ſuſtained the roof. Another completed the edifice. This was a temple *in antis*, or without exterior columns, which would have occupied the room required for the victims. The aſpect was changed to *Proſtylos* under Demetrius the Phalerean; Philo a famous architect erecting a portico, which gave dignity to the fabric, and rendered the entrance more commodious. The ſite was beneath the brow, at the eaſt end, and encompaſſed by the fortreſs. Some marbles, which are uncommonly maſſive, and ſome pieces of the columns, remain on the ſpot. The breadth of the cell is about 150 feet; the length, including the pronaos and portico, is 216 feet; the diameter of the columns, which are fluted 6 inches from the bottom of the ſhafts, is 6 feet and more than 6 inches. The temple was a decaſtyle or had 10 columns in the front, which was to the eaſt. The peribolus or incloſure, which ſurrounded it on the north-eaſt and on the ſouth ſide, meaſures 387 feet in length from north to ſouth, and 328 feet in breadth from eaſt to weſt. On the weſt ſide it joined the angles of the weſt end of the temple in a ſtraight line. Between the weſt wall of the incloſure and temple and the wall of the citadel was a paſſage of 42 feet 6 inches wide, which led to the ſummit of a high rock at the north-weſt angle of the incloſure, on which are viſible the traces of a temple *in antis*, in length 74 feet 6 inches from north to ſouth, and in breadth from the eaſt to the wall of the citadel, to which it joined on the weſt, 54 feet. It was perhaps that ſacred to Triptolemus. This ſpot commands a very extenſive view of the plain and bay. About three-fourths of the cottages are within the precincts of the myſtic temple, and the ſquare tower ſtands on the ruined wall of the incloſure.

"At a ſmall diſtance from the north end of the incloſure is a heap of marble, conſiſting of fragments of the Doric and Ionic orders; remains, it is likely, of the temples of Diana Propylea and of Neptune, and of the Propyleum or gateway. Wheler ſaw ſome large ſtones carved with wheat-ears and bundles of poppy. Near it is the buſt of a coloſſal ſtatue of excellent workmanſhip, maimed, and the face diſfigured; the breadth at the ſhoulders, as meaſured by Pococke, 5 feet and an half; and the baſket on the head above 2 feet deep. It probably repreſented Proſerpine. In the heap are two or three inſcribed pedeſtals; and on one are a couple of torches, croſſed. We ſaw another fixed in the ſtone ſtairs, which lead up the ſquare tower on the outſide. It belonged to the ſtatue of a lady, who was hierophant or prieſteſs of Proſerpine, and had covered the altar of the goddeſs with ſilver. A well in the village was perhaps that called Callichorus, where the women of Eleuſis were accuſtomed to dance in honour of Ceres. A tradition prevails, that if the broken ſtatue be removed, the fertility of the land will ceaſe. Achmet Aga was fully poſſeſſed with this ſuperſtition, and declined permitting us to dig or meaſure there, until I had overcome his ſcruples by a preſent of a handſome ſnuff-box containing ſeveral zechins or pieces of gold."

ELEUTHERIA, a feſtival celebrated at Platæa in honour of Jupiter *Eleutherius*, or "the aſſertor of liberty," by delegates from almoſt all the cities of Greece. Its inſtitution originated in this: After the victory obtained by the Grecians under Pauſanias over Mardonius the Perſian general in the country of Platæa, an altar and ſtatue were erected to Jupiter Eleutherius, who had freed the Greeks from the tyranny of the barbarians. It was further agreed upon in a general aſſembly, by the advice of Ariſtides the Athenian, that deputies ſhould be ſent every fifth year, from the different cities of Greece, to celebrate Eleutheria, feſtivals of liberty. The Platæans celebrated alſo an anniverſary feſtival in memory of thoſe who had loſt their lives in that famous battle. The celebration was thus: At break of day a proceſſion was made with a trumpeter at the head, ſounding a ſignal for battle. After him followed chariots loaded with myrrh, garlands, and a black bull, and certain free young men, as no ſigns of ſervility were to appear during the ſolemnity, becauſe they in whoſe honour the feſtival was inſtituted had died in the defence of their country. They carried libations of wine and milk in large-eared veſſels, with jars of oil, and precious ointments. Laſt of all appeared the chief magiſtrate, who, though not permitted at other times to touch iron, or wear garments of any colour but white, yet appeared clad in purple, and taking a water-pot out of the city chamber, proceeded through the middle of the town, with a ſword in his hand, towards the ſepulchres. There he drew water from a neighbouring ſpring, and waſhed and anointed the monuments, after which he ſacrificed a bull upon a pile of wood, invoking Jupiter and infernal Mercury, and inviting to the entertainment the ſouls of thoſe happy heroes who had periſhed in the defence of their country. After this he filled a bowl with wine, ſaying, I drink to thoſe who loſt their lives in the defence of the liberties of Greece. There was alſo a feſtival of the ſame name obſerved by the Samians in honour of the god of love. Slaves alſo, when they obtained their liberty, kept a holiday, which they called *Eleutheria*.

ELF, a term now almoſt obſolete, formerly uſed to denote a fairy or hobgoblin; an imaginary being, the creature of ignorance, ſuperſtition, and craft. See FAIRY.

*Elf-Arrows*, in natural hiſtory, a name given to the flints anciently faſhioned into arrow-heads, and ſtill found foſſile in Scotland, America, and ſeveral other parts of the world: they are believed by the vulgar to be ſhot by fairies, and that cattle are ſometimes killed by them.

ELGIN, the capital of the county of Moray in Scotland, and formerly a biſhop's ſee, is ſituated on the river Loſey about ſix miles north from the Spey, in W. Long. 2. 25. N. Lat. 57. 40. Mr Pennant ſays, it is a good town, and has many of the houſes built over piazzas; but, excepting its great cattle-fairs, has little trade. It is principally remarkable for its eccleſiaſtical antiquities. The cathedral, now in ruins, has been formerly a very magnificent pile. The weſt door is very elegant and richly ornamented. The choir is very beautiful, and has a fine and light gallery running round it; and at the eaſt end are two rows of narrow windows in an excellent Gothic taſte. The chapter-houſe is an octagon; the roof ſupported by a fine ſingle column with neat carvings of coats of arms round the capital. There is ſtill a great tower on each ſide of this cathedral; but that in the centre, with the ſpire and whole roof, are fallen in; and form moſt awful fragments, mixed with the battered monuments of knights and prelates. Boethius ſays, that Duncan, who was killed by Macbeth at Inverneſs, lies buried here. The place is alſo crowded with a number of modern tomb-ſtones.—The cathedral was founded by Andrew de Moray, in 1224, on a piece of land granted by Alexander II.; and his remains were depoſited in the choir, under a tomb of blue marble, in 1244. The great tower was built principally by John Innes biſhop of this ſee, as appears by the inſcription cut on one of the great pillars: "Hic Jacet in Xto, pater et dominus, Dominus *Johannes de Innes* hujus eccleſiæ Epiſcopus;—qui hoc notabile opus incepit et per ſeptennium ædificavit." Elgin is a royal borough; and gives title of earl to the family of Bruce.

ELIAS, the prophet, memorable for having eſcaped the common cataſtrophe of mankind; being taken up alive into heaven, in a fiery chariot, about 895 B. C. See *the Bible*.

ELICHMAN (John), a native of Sileſia in the 17th century, who practiſed phyſic at Leyden, and was remarkable for underſtanding 16 languages. He ſupported an opinion, that the German and Perſian languages were derived from the ſame origin. His Latin tranſlation of the Tablet of Cebes, with the Arabic verſion and the Greek, was printed at Leyden in 1640, under the care of Salmaſius, who prefixed thereto a very ample preface.

ELIQUATION, in chemiſtry, an operation by which a more fuſible ſubſtance is ſeparated from one that is leſs ſo, by means of a heat ſufficiently intenſe to melt the former, but not the latter. Thus an allay of copper and lead may be ſeparated by a heat capable of melting the latter, but not the former.

ELIS. See ELEA.

ELIS, (anc. geog.), the capital of the diſtrict of that name in Peloponneſus, ſituated on the Peneus, which ran through it. It was the country of Phædo the philoſopher, ſcholar of Socrates, and friend of Plato; who inſcribes with his name the dialogue on the immortality of the ſoul. Pyrrho alſo was of this city, at the head of the ſect called after him *Pyrrhoniſts*.

The city of Elis owed its origin to an union of ſmall towns after the Perſian war. It was not encompaſſed immediately with a wall; for it had the care of the temple at Olympia, and its territory was ſolemnly conſecrated to Jupiter. To invade or not protect it was deemed impiety; and armies, if marching through, delivered up their weapons, which, on their quitting it, were reſtored. Amid warring ſtates the city enjoyed repoſe, was reſorted to by ſtrangers, and flouriſhed. The region round about it was called *cœle* or *hollow*, from the inequalities. The country was reckoned fertile, and particularly fit for the raiſing of flax. This, which grew no where elſe in Greece, equalled the produce of Judæa in fineneſs, but was not ſo yellow. Elis was a ſchool, as it were, for Olympia, which was diſtant 37 miles. The athletic exerciſes were performed there, before the more ſolemn trial, in a gymnaſium, by which the Peneus ran. The hellanodics or præfects of the games paired the rival combatants by lot, in an area called *Plethrium* or *The Acre*. Within the wall grew lofty plane-trees; and in the court, which was called the *Xyſtus*, were ſeparate courſes marked for the foot-races. A ſmaller court was called the *Quadrangle*. The præfects, when choſen, reſided for 10 months in a building erected for their uſe, to be inſtructed in the duties of their office. They attended before ſun-riſe to preſide at the races; and again at noon, the time appointed for the pentathlum or five ſports. The horſes were trained in the agora or market-place, which was called the *Hippodrome*. In the gymnaſium were altars and a cenotaph of Achilles. The women, beſides other rites, beat their boſoms in honour of this hero, on a fixed day toward ſunſet. There alſo was the town-hall, in which extemporary harangues were ſpoken and compoſitions recited. It was hung round with bucklers for ornaments. A way led from it to the baths through the Street of Silence; and another to the market-place, which was planned with ſtreets between porticoes of the Doric order adorned with altars and images. Among the temples one had a circular periſtyle or colonnade; but the image had been removed and the roof was fallen in the time of Pauſanias. The theatre was ancient, as was alſo a temple of Bacchus, one of the deities principally adored at Elis. Minerva had a temple in the citadel, with an image of ivory and gold made (it was ſaid) by Phidias. At the gate leading to Olympia was the monument of a perſon, who was buried, as an oracle had commanded, neither within nor without the city. The ſtructures of Elis, Dr Chandler obſerves, ſeem to have been raiſed with materials far leſs elegant and durable than the produce of the Ionian and Attic quarries. The ruins are of brick, and not conſiderable, conſiſting of pieces of ordinary wall, and an octagon building with niches, which, it is ſuppoſed, was the temple with a circular periſtyle. Theſe ſtand detached from each other, ranging in a vale ſouthward from the wide bed of the river Peneus; which, by the margin, has ſeveral large ſtones, perhaps reliques of the gymnaſium. The citadel was on a hill, which has on the top ſome remnants of wall.

ELISHA the prophet, famous for the miracles he performed, died about 830 B. C. See *the Bible*.

ELISION, in grammar, the cutting off or ſuppreſſing a vowel at the end of a word, for the ſake of ſound or meaſure, the next word beginning with a vowel.

Eliſions are pretty frequently met with in Engliſh poetry, but more frequently in the Latin, French, &c. They chiefly conſiſt in ſuppreſſions of the *a*, *e*, and *i*, though an eliſion ſuppreſſes any of the other vowels.

ELIXATION, in pharmacy, the extracting the virtues of ingredients by boiling or ſtewing.

ELIXIR, in medicine, a compound tincture extracted from many efficacious ingredients. Hence the difference between a tincture and an elixir ſeems to be this, that a tincture is drawn from one ingredient, ſometimes with an addition of another to open it and to diſpoſe it to yield to the menſtruum; whereas an elixir is a tincture extracted from ſeveral ingredients at the ſame time.

ELIZABETH, queen of England, daughter of Harry VIII. and Anna Boleyn, was born at Greenwich, September 7th, 1533. According to the humour of the times, ſhe was early inſtructed in the learned languages, firſt by Grindal, who died when ſhe was about 17, and afterwards by the celebrated Roger Aſcham. She acquired likewiſe conſiderable knowledge of the Italian, Spaniſh, and French languages. Dr Grindal was alſo her preceptor in divinity, which ſhe is ſaid to have ſtudied with uncommon application and induſtry. That Elizabeth became a Proteſtant, and her ſiſter Mary a Papiſt, was the effect of that cauſe which determines the religion of all mankind; namely, the opinion of thoſeby whom they were educated: and this difference of opinion, in their tutors, is not at all ſurpriſing, when we recollect, that their father Harry was of both religions, or of neither.

But the ſtudies of Elizabeth were not confined merely to languages and theology: ſhe was alſo inſtructed in the political hiſtory of the ancients; and was ſo well ſkilled in muſic, as to ſing and play "artfully and ſweetly."

After the ſhort reign of her brother Edward, our heroine being then about 20 years of age, her *firebrand* ſiſter acceding to the crown, Elizabeth experienced a conſiderable degree of perſecution, ſo as to be not a little apprehenſive of a violent death. She was accuſed of nobody knows what; impriſoned; and, we are told, inhumanly treated. At laſt, by the interceſſion of king Philip of Spain, ſhe was ſet at liberty; which ſhe continued to enjoy till, on the death of her *pious* ſiſter, ſhe, on the 17th of November 1558, aſcended the throne of England. Her political hiſtory as a queen, is univerſally known and admired *: but her attention to the government of her kingdom did not totally ſuſpend her purſuit of learning. Aſcham, in his *Schoolmaſter*, tells us, that, about the year 1563, five years after her acceſſion, ſhe being then at Windſor, beſides her perfect readineſs in Latin, Italian, French, and Spaniſh, ſhe read more Greek in one day than ſome prebendaries of that church did read Latin in a whole week, (p. 21.)—She employed Sir John Forteſcue to read to her, Thucydides, Xenophon, Polybius, Euripides, Æſchines, and Sophocles. (*Ballard*, p. 219.)—That the Latin language was familiar to her, is evident from her ſpeech to the univerſity of Oxford, when ſhe was near ſixty; alſo from her ſpirited anſwer to the Poliſh ambaſſador in the year 1598. And that ſhe was alſo ſkilled in the art of poetry appears, not only from the ſeveral ſcraps which have been preſerved, but likewiſe from the teſtimony of a cotemporary writer, Puttenham, in his *Art of Engl. Poetry* (a very ſcarce book). Theſe are his words:—"But, laſt in recital, "and firſt in degree, is the queen, whoſe learned, de-"licate, noble muſe, eaſily ſurmounteth all the reſt, "for ſenſe, ſweetneſs, or ſubtilty, be it in ode, ele-"gy, epigram, or any other kind of poem," &c. In this author are to be found only a ſpecimen of 16 verſes of her Engliſh poetry. "But," ſays Mr Walpole, "a greater inſtance of her genius, and that too in "Latin, was her extempore reply to an inſolent pro-"hibition delivered to her from Philip II. by his am-"baſſador, in this tetraſtic.

Te veto ne pergas bello defendere Belgas:
Quæ Dracus eripuit, nunc reſtituantur oportet:
Quas pater evertit, jubeo te condere cellas:
Religio papæ fac reſtituatur ad unguem.

"She inſtantly anſwered him, with as much ſpirit "as ſhe uſed to return his invaſions,"

Ad Græcas, bone rex, fient mandata kalendas.

Being earneſtly preſſed by a Romiſh prieſt, during his perſecution, to declare her opinion concerning the real preſence of Chriſt's body in the wafer, ſhe anſwered,

Chriſt was the word that ſpake it;
He took the bread, and brake it;
And what that word did make it,
That I believe, and take it.

*Fuller's Holy State.*

She gave the characters of four knights of Notttinghamſhire in the following diſtich:

Gervaſe the gentle, Stanhope the ſtout,
Markham the lion, and Sutton the lout.

*Walp. Cat.*

Coming into a grammar-ſchool, ſhe characteriſed three claſſic authors in this hexameter:

Perſius a crab-ſtaff; bawdy Martial; Ovid a fine wag.

*Full. Worth. of Warw.* 126.

Sir Walter Raleigh having wrote on a window,

Fain would I climb, yet fear I to fall;

She immediately wrote under it,

If thy heart fail thee, climb not at all.

*Worth. of Devonſh.* 261.

Doubtleſs, ſhe was a woman of ſingular capacity and extraordinary acquirements: and, if we could forget the ſtory of the Scottiſh Mary, and of her favourite Eſſex, together with the burning of a few Anabaptiſts; in ſhort, could we forbear to contemplate her character through the medium of religion and morality, we might pronounce her the moſt illuſtrious of illuſtrious women. See further, the articles England, Mary, and Scotland. She died in her palace at Richmond, the 24th of March 1602, aged 70, having reigned 44 years; and was interred in the chapel of Henry VII. in Weſtminſter Abbey. Her ſucceſſor James erected a magnificent monument to her memory.—She wrote, 1. The Mirrour, or Glaſs of the Sinful Soul. This was tranſlated out of French verſe into

* See (Hiſtory of) *England.*

Engliſh proſe, when ſhe was eleven years old. It was dedicated to queen Catherine Parr. Probably it was never printed; but the dedication and preface are preſerved in the *Sylloge epiſtolarum*, in Hearne's edition of *Livii Foro-Julienſis*, p. 161. 2. Prayers and Meditations, &c. Dedicated to her father, dated at Hatfield, 1545. Manuſcript, in the royal library. 3. A Dialogue out of Xenophon, in Greek, between Hiero a King, yet ſome time a private perſon, and Simonides a Poet, as touching the life of the Prince and Private Man. Firſt printed, from a manuſcript in her majeſty's own hand writing, in the Gentleman's Magazine for 1743. 4. Two orations of Iſocrates, tranſlated into Latin. 5. Latin Oration at Cambridge. Preſerved in the king's library: alſo in Hollinſhed's Chron. p. 1206; and in Fuller's Hiſt. of Cambr. p. 138. 6. Latin Oration at Oxford. See Wood's Hiſt. and Antiq. of Oxf. lib i. p. 289. alſo in Dr Jebb's Append. to his Life of Mary Queen of Scots. 7. A Comment on Plato. 8. *Boethius de conſolatione philoſophiæ*, tranſlated into Engliſh anno 1593. 9. *Salluſt de bello Jugurthino*, tranſlated into Engliſh anno 1590. 10. A play of Euripides, tranſlated into Latin, (Cat. of Royal Auth.) 11. A Prayer for the uſe of her fleet in the great expedition in 1596. 12. Part of Horace's Art of Poetry, tranſlated into Engliſh anno 1598. 13. *Plutarch de curioſitate*, tranſlated into Engliſh. 14. Letters on various occaſions to different perſons; ſeveral ſpeeches to her parliament; and a number of other pieces.

ELIZABETH PETROWNA. (daughter of Peter the Great), the laſt empreſs of Ruſſia, diſtinguiſhed herſelf by her ſignal clemency. She made a vow, that no perſon ſhould be put to death in her reign, and ſhe ſtrictly obſerved it. The example has been followed, and confirmed by law. under the preſent auguſt ſovereign of Ruſſia, Catharine II. Elizabeth died in 1762, in the 21ſt year of her reign and 52d of her age.

ELK, in zoology. See CERVUS.

ELL, *(ulna,)* a meaſure, which obtains, under different denominations, in moſt countries, whereby cloths, ſtuffs, linens, ſilks, &c. are uſually meaſured; anſwering nearly to the yard of England, the canna of Italy, the vara of Spain, the palm of Sicily, &c.

Servius will have the ell to be the ſpace contained between the two hands when ſtretched forth; but Suetonius makes it only the cubit.

The ells moſt frequently uſed with us are the Engliſh and Flemiſh; the former containing three feet nine inches, or one yard and a quarter; the latter only 27 inches, or three quarters of a yard; ſo that the ell Engliſh is to the Flemiſh ell as five to three. In Scotland, the ell contains $37\frac{2}{10}$ Engliſh inches.

M. Ricard, in his Treatiſe of Commmerce, reduces the ells thus: 100 ells of Amſterdam are equal to $98\frac{3}{4}$ of Brabant, Antwerp, and Bruſſels; to $58\frac{1}{2}$ of England and France; to 120 of Hamburgh, Francfort, Leipſic, and Cologne; 125 of Breſlaw; 110 of Bergen and Drontheim; and 117 of Stockholm.

Elliot.

ELLIOT, (the Right Honourable George Auguſtus, Lord Heathfield), was the youngeſt ſon of the late Sir Gilbert Elliot, Baronet, of Stobbs (A) in Roxburghſhire; and was born about the year 1718. He received the firſt rudiments of his education under a private tutor; and at an early time of life was ſent to the univerſity of Leyden, where he made conſiderable progreſs in claſſical learning, and ſpoke with fluency and elegance the German and French languages. Being deſigned for a military life, he was ſent from thence to the celebrated *Ecole Royale du Genie Militaire*, conducted by the great Vauban, at La Fere in Picardy; where he laid the foundation of what he ſo conſpicuouſly exhibited at the defence of Gibraltar. He completed his military courſe on the continent by a tour, for the purpoſe of ſeeing in practice what he had ſtudied in theory. Pruſſia was the model for diſcipline, and he continued ſome time as a volunteer in that ſervice.

Mr Elliot returned in the 17th year of his age to his native country, Scotland; and was the ſame year, 1735, introduced by his father Sir Gilbert to Lieutenant-Colonel Peers of the 23d regiment of foot, then lying at Edinburgh, as a youth anxious to bear arms for his king and country. He was accordingly entered as a volunteer in that regiment, where he continued for a year or more. From the 23d regiment he went into the engineer corps at Woolwich, and made great progreſs in that ſtudy, until his uncle Colonel Elliot brought him in his adjutant of the ſecond troop of horſe grenadiers. With theſe troops he went upon ſervice to Germany, and was with them in a variety of actions. At the battle of Dettingen he was wounded. In this regiment he bought the rank of captain and major, and afterwards purchaſed the lieutenant-colonelcy from Colonel Brewerton, who ſucceeded to his uncle. On arriving at this rank, he reſigned his commiſſion as an engineer, which he had enjoyed along with his other rank, and in which ſervice he had been actively employed very much to the advantage of his country. He received the inſtructions of the famous engineer Bellidor, and made himſelf completely maſter of the ſcience of gunnery. Had he not ſo diſintereſtedly reſigned his rank in the engineer department, he would long before his death, by regular progreſſion, have been at the head of that corps. Soon after this he was appointed aid-de-camp to George II. and was diſtinguiſhed for his military ſkill and diſcipline. In the year 1759, he quitted the ſecond troop of horſe grenadier guards, being ſelected to raiſe, form, and diſcipline,

---

(A) The ancient and honourable family of Elliot of Stobbs, as well as the collateral branch of Elliot of Minto in the ſame county, and of Elliot of Port-Elliot in Cornwall, are originally from Normandy. Their anceſtor, Mr Aliott, came over with William the Conqueror, and held a diſtinguiſhed rank in his army. There is a traditionary anecdote in the family relating to an honourable diſtinction in their coat, which, as it correſponds with hiſtory, bears the probability of truth. When William ſet foot on Engliſh land, he ſlipped and fell on the earth. He ſprung up, and exclaimed that it was a happy omen—he had embraced the country of which he was to become the lord. Upon this Aliott drew his ſword, and ſwore by the honour of a ſoldier, that he would maintain, at the hazard of his blood, the right of his lord to the ſovereignty of the earth which he had embraced. On the event of conqueſt, King William added to the arms of Aliott, which was a baton *or*, on a field *azure*, an arm and ſword as a creſt, with the motto, *Per ſaxa, per ignes, fortiter et recte.*

Elliot. diſcipline, the firſt regiment of light horſe, called after him *Elliot's*. As ſoon as they were raiſed and formed, he was appointed to the command of the cavalry in the expedition on the coaſts of France, with the rank of brigadier general. After this he paſſed into Germany, where he was employed on the ſtaff, and greatly diſtinguiſhed himſelf in a variety of movements; where his regiment diſplayed a ſtrictneſs of diſcipline, an activity and enterpriſe, which gained them ſignal honour: and indeed they have been the pattern regiment, both in regard to diſcipline and appointment, to the many light dragoon troops that have been ſince raiſed in our ſervice. From Germany he was recalled for the purpoſe of being employed as ſecond in command in the memorable expedition againſt the Havannah; the circumſtances of which conqueſt are well known.

On the peace his gallant regiment was reviewed by the king, when they preſented to his majeſty the ſtandards which they had taken from the enemy. Gratified with their fine diſcipline and high character, the king aſked General Elliot what mark of his favour he could beſtow on his regiment equal to their merit? He anſwered, that his regiment would be proud if his majeſty ſhould think, that, by their ſervices, they were intitled to the diſtinction of *Royals*. It was accordingly made a royal regiment, with this flattering title, "The 15th, or *King*'s Royal Regiment of Light Dragoons." At the ſame time the king expreſſed a deſire to confer ſome honour on the general himſelf; but the latter declared, that the honour and ſatisfaction of his Majeſty's approbation of his ſervices was his beſt reward.

During the peace he was not idle. His great talents in the various branches of the military art gave him ample employment. In the year 1775, he was appointed to ſucceed General A'Court as commander in chief of the forces in Ireland; but did not continue long in this ſtation, not even long enough to unpack all his trunks: for finding that interferences were made by petty authority derogatory of his own, he reſiſted the practice with becoming ſpirit; and not chooſing to diſturb the government of the ſiſter kingdom on a matter perſonal to himſelf, he ſolicited to be recalled. He accordingly was ſo, and appointed to the command of Gibraltar in a fortunate hour for the ſafety of that important fortreſs. The ſyſtem of his life, as well as his education, peculiarly qualified him for this truſt. He was perhaps the moſt abſtemious man of the age; neither indulging himſelf in animal food nor wine. He never ſlept more than four hours at a time; ſo that he was up later and earlier than moſt other men. He ſo inured himſelf to habits of hardineſs, that the things which are difficult and painful to other men, were to him his daily practice, and rendered pleaſant by uſe. It could not be eaſy to ſtarve ſuch a man into a ſurrender, nor poſſible to ſurpriſe him. The example of the commander in chief in a beſieged garriſon had a moſt perſuaſive efficacy in forming the manners of the ſoldiery. Like him his brave followers came to regulate their lives by the moſt ſtrict rules of diſcipline before there aroſe a neceſſity for ſo doing; and ſevere exerciſe, with ſhort diet, became habitual to them by their own choice. The military ſyſtem of diſcipline which he introduced, and the preparations which he made for his defence, were contrived with ſo much judgment, and executed with ſo much addreſs, that he was able with a handful of men to preſerve his poſt againſt an attack, the conſtancy of which, even without the vigour, had been ſufficient to exhauſt any common ſet of men. Collected within himſelf, he in no inſtance deſtroyed, by premature attacks, the labours which would coſt the enemy time, patience, and expence to complete; he deliberately obſerved their approaches, and ſeized on the proper moment, with the keeneſt perſpection, in which to make his attack with ſucceſs. He never ſpent his ammunition in uſeleſs parade or in unimportant attacks He never relaxed from his diſcipline by the appearance of ſecurity, nor hazarded the lives of his garriſon by wild experiments. By a cool and temperate demeanour, he maintained his ſtation for three years of conſtant inveſtment, in which all the powers of Spain were employed. All the eyes of Europe were on this garriſon; and his conduct has juſtly exalted him to the moſt elevated rank in the military annals of the day. On his return to England, the gratitude of the Britiſh ſenate was as forward as the public voice in giving him that diſtinguiſhed mark his merit deſerved. Both houſes of parliament voted an unanimous addreſs of thanks to the general. The king conferred on him the honour of Knight of the Bath, with a penſion during his own and a ſecond life of his own appointment; and on June 14. 1787, his majeſty advanced him to the peerage by the title of *Lord Heathfield Baron Gibraltar*, permitting him to take, in addition to his family arms, the arms of the fortreſs he had ſo bravely defended, to perpetuate to futurity his noble conduct.

His lordſhip died on the 6th of July 1790, at his chateau at Aix-la-Chapelle, of a ſecond ſtroke of the palſy, after having for ſome weeks preceding enjoyed tolerable good health and an unuſual flow of ſpirits. His death happened two days before he was to have ſet out for Leghorn in his way to Gibraltar; of which place he was once more appointed to the defence, in the view of an approaching war.—He married Ann, daughter of Sir Francis Drake of Devonſhire; and had by her (who died in 1769) Francis-Auguſtus, now Lord Heathfield, lieutenant-colonel of the 6th regiment of horſe.

ELLIPOMACROSTYLA, in natural hiſtory, the name of a genus of cryſtals. The word is derived from the Greek, *ελλιπης imperfect*, *μακρος long*, and *στυλος a column;* and expreſſes an imperfect cryſtal with a long column. The perfect figure of cryſtal being a column terminated by a pyramid at each end; thoſe which want this character are eſteemed imperfect: and accordingly the bodies of this genus are defined to be imperfect cryſtals with ſingle pyramids; one end of their column being affixed to ſome ſolid body, and compoſed of thin and ſlender hexangular columns, terminated by hexangular pyramids.

ELLIPOPACHYSTYLA, in natural hiſtory, the name of a genus of cryſtals. The word is derived from the Greek, *ελλιπης imperfect*, *παχυς thick*, and *στυλος a column;* and expreſſes a cryſtal of the imperfect kind with a thick column. The bodies of this genus are cryſtals compoſed of an hexangular column, conſiderably thick and ſhort, affixed irregularly at one end to ſome ſolid body, and terminated at the other by an hexangular pyramid.

ELLIPSIS, in geometry, a curve line returning into itſelf, and produced from the ſection of a cone by a plane cutting both its ſides, but not parallel to the baſe. See *Conic Sections*.

Ellipsis, in grammar, a figure of ſyntax, wherein one or more words are not expreſſed; and from this deficiency it has got the name *ellipſis*.

ELLIPTIC, or Elliptical, ſomething belonging to an ellipſis.

ELLIPOMACHROSTYLA, in natural hiſtory, a genus of imperfect cryſtals, with ſingle pyramids; one end of their column being affixed to ſome ſolid body. They are dodecahedral, with hexangular columns and hexangular pyramids.

Of theſe cryſtals authors enumerate a great many ſpecies; among which are the whitiſh pellucid ſprig cryſtal, a bright brown kind, a dull brown kind, and a bright yellow kind; all which are farther diſtinguiſhed according to the different lengths of their pyramids.

ELLIPOPACRYSTYLA, in natural hiſtory a genus of imperfect cryſtals, compoſed of 12 planes, in an hexangular column, terminated by an hexangular pyramid at one end, and irregularly affixed to ſome other body at the other, with ſhorter columns.

There are two ſpecies of theſe cryſtals; one ſhort, bright, and colourleſs, found in great plenty in New Spain and other parts of America; the other, a ſhort, dull, and duſky brown one, found in Germany, and ſometimes in England.

ELLISIA, in botany: A genus of the monogynia order, belonging to the pentandria claſs of plants; and in the natural method ranking under the 28th order, *Luridæ*. The corolla is monopetalous and funnelſhaped; the berry carnous and bilocular; there are two ſeeds muricated or ſet with ſmall raiſed points, the one higher than the other.

ELM, in botany. See Ulmus.

ELMACINUS (George), author of a *Hiſtory of the Saracens*, was born in Egypt towards the middle of the 13th century. His hiſtory comes down from Mahomet to the year of the Hegira 512, anſwering to the year of our Lord 1134; in which he ſets down year by year, in a very conciſe manner, whatever regards the Saracen empire, intermixed with ſome paſſages relating to the eaſtern Chriſtians. His abilities muſt have been conſiderable; ſince, though he profeſſed Chriſtianity, he held an office of truſt near the perſons of the Mahometan princes. He was ſon to Yaſer Al Amid, ſecretary to the council of war under the ſultans of Egypt for 45 years; and in 1238, when his father died, ſucceeded him in his place. His hiſtory of the Saracens was tranſlated from Arabic into Latin by Erpinius; and printed in theſe two languages in folio, at Leyden, in 1625. Erpinius died before the publication; but Golius took care of it, and added a preface. It was dedicated by Erpinius's widow to Dr Andrews, biſhop of Wincheſter.

ELOCUTION. See Oratory, Part III.

ELOGY, a praiſe or panegyric beſtowed on any perſon or thing, in conſideration of its merit. The beauty of elogy conſiſts in an expreſſive brevity. Elogiums ſhould not have ſo much as one epithet, properly ſo called, nor two words ſynonymous: they ſhould ſtrictly adhere to truth; for extravagant and improbable elogies rather leſſen the character of the perſon or thing they would extol.

ELOHI, Eloi, or *Elohim*, in ſcripture, one of the names of God. But it is to be obſerved, that angels, princes, great men, judges, and even falſe gods, are ſometimes called by this name. The ſequel of the diſcourſe is what aſſiſts us in judging rightly concerning the true meaning of this word. It is the ſame as *Eloha*. One is the ſingular, the other the plural. Nevertheleſs *Elohim* is often conſtructed in the ſingular number, particularly when the true God is ſpoken of; but when falſe gods are ſpoke of, it is conſtrued rather in the plural.

ELOINED, in law, ſignifies reſtrained or hindered from doing ſomething: thus it is ſaid, that if thoſe within age be eloined, ſo that they cannot ſue perſonally, their next friend ſhall ſue for them.

ELONGATION, in aſtronomy, the digreſſion or receſs of a planet from the ſun, with reſpect to an eye placed on our earth. The term is chiefly uſed in ſpeaking of Venus and Mercury, the arch of a great circle intercepted between either of theſe planets and the ſun being called the *elongation* of that planet from the ſun.

Elongation, in ſurgery, is an imperfect luxation, occaſioned by the ſtretching or lengthening of the ligaments of any part.

ELOPEMENT, in law, is where a married woman departs from her huſband, and cohabits with an adulterer; in which caſe the huſband is not obliged to allow her any alimony out of his eſtate, nor is he chargeable for neceſſaries for her of any kind. However, the bare advertiſing a wife in the gazette, or other public paper, is not a legal notice to perſons in general not to truſt her; though a perſonal notice given by the huſband to particular perſons is ſaid to be good.—An action lies, and large damages may be recovered, againſt a perſon for carrying away and detaining another man's wife.

ELOQUENCE, the art of ſpeaking well, ſo as to affect and perſuade. See Oratory.

ELSHEIMER (Adam), a celebrated painter, born at Francfort on the Maine, 1574. He was firſt a diſciple of Philip Uffenbach a German; but his deſire of improvement carrying him to Rome, he ſoon became a moſt excellent artiſt in landſcapes, hiſtory, and night-pieces, with ſmall figures. His works are but few; and the great pains he beſtowed in finiſhing them raiſed their prices ſo high, that they are hardly any where to be found but in the cabinets of princes. He was of a melancholy turn, and ſunk under the embarraſſments of his circumſtances in 1610. James Erneſt Thomas of Landau was his diſciple; and imitated his ſtyle ſo nicely, that their performances are not eaſily diſtinguiſhed.

ELSIMBURG, a port-town of Sweden, in the province of Gothland, and territory of Schonen, ſeated on the ſide of the Sound, over againſt Elſinore. It was formerly a fortreſs belonging to the Danes; but all the fortifications were demoliſhed in 1679, and there is only one tower of a caſtle which remains undemoliſhed. It now belongs to Sweden. E. Long. 13. 20. N. Lat. 56. 2.

**ELSINORE**, or Elſinoor, a port-town of Denmark, ſeated on the Sound, in the iſle of Zealand. E. Long. 13. 23. N. Lat. 56. 0.—It was a ſmall village, containing a few fiſhermens huts, until 1445, when it was made a ſtaple town by Eric of Pomerania; who conferred upon the new ſettlers conſiderable immunities, and built a caſtle for their defence. From that period it gradually increaſed in ſize and wealth, and is now the moſt commercial place in Denmark next to Copenhagen. It contains about 5000 inhabitants, amongſt whom are a conſiderable number of foreign merchants, and the conſuls of the principal nations trading to the Baltic. The paſſage of the Sound is guarded by the fortreſs of Cronborg, which is ſituated upon the edge of a peninſular promontory, the neareſt point of land from the oppoſite coaſt of Sweden. It is ſtrongly fortified towards the ſhore by ditches, baſtions, and regular entrenchments; and towards the ſea by ſeveral batteries, mounted with 60 cannon, the largeſt whereof are 48 pounders. Every veſſel, as it paſſes, lowers her top-ſails, and pays a toll at Elſinore. It is generally aſſerted, that this fortreſs guards the Sound; and that all the ſhips muſt, on account of the ſhoal waters and currents, ſteer ſo near the batteries as to be expoſed to their fire in caſe of refuſal. This, however, is a miſtaken notion. On account indeed of the numerous and oppoſite currents in the Sound, the ſafeſt paſſage lies near the fortreſs; but the water in any part is of ſufficient depth for veſſels to keep at a diſtance from the batteries, and the largeſt ſhips can even ſail cloſe to the coaſt of Sweden. The conſtant diſcharge, however, of the toll, is not ſo much owing to the ſtrength of the fortreſs as to a compliance with the public law of Europe Many diſputes have ariſen concerning the right by which the crown of Denmark impoſes ſuch a duty. The kings of Sweden, in particular, claiming an equal title to the free paſſage of the Strait, were for ſome time exempted by treaty from paying it; but in 1720, Frederic I. agreed that all Swediſh veſſels ſhould for the future be ſubject to the uſual impoſts. All veſſels, beſide a ſmall duty, are rated at 1¼ *per cent.* of their cargoes, except the Engliſh, French, Dutch, and Swediſh, which pay only one *per cent.* and in return, the crown takes the charge of conſtructing light-houſes, and erecting ſignals to mark the ſhoals and rocks. from the Categate to the entrance into the Baltic. The tolls of the Sound, and of the two Belts, ſupply an annual revenue of above L.100,000.

**ELVAS**, a large town, and one of the beſt and moſt important in Portugal, ſeated in the province of Alentejo, a few miles from the frontiers of Eſtramadura in Spain. It is built on a mountain, and is ſtrongly fortified with works of free-ſtone. The ſtreets of the town are handſome, and the houſes neat; and there is a ciſtern ſo large, that it will hold water enough to ſupply the whole town ſix months. The water is conveyed to it by a magnificent aqueduct, three miles in length, ſuſtained in ſome places by four or five high arches, one upon another. It was bombarded by the French and Spaniards in 1706, but without effect. It has generally a garriſon of 1000 men. The king founded an academy here, in 1733, for young gentlemen. W. Long. 7. 28. N. Lat. 38. 39

**ELUDING**, the act of evading or rendering a thing vain and of no effect; a dexterous getting clear, or eſcaping out of an affair, difficulty, embarraſſment, or the like. We ſay, to *elude* a propoſition, &c. The deſign of chicanery is, to *elude* the force of the laws: this doctor has not reſolved the difficulty, but *eluded* it. Alexander, ſays the hiſtorian, in cutting the Gordian knot, either *eluded* the oracle or fulfilled it: *Ille nequicquam luctatus cum latentibus nodis, Nihil, inquit, intereſt, quomodo ſolvatur; gladioque ruptis omnibus loris, oraculi ſortem vel* eludit, *vel implevit.*

**ELVELA**, in botany: A genus of the natural order of fungi, belonging to the cryptogamia claſs of plants. The fungus is turbinated, or like an inverted cone.

**ELUL**, in ancient chronology, the 12th month of the Jewiſh civil year, and the ſixth of the eccleſiaſtical: it conſiſted of only 29 days, and anſwered pretty nearly to our Auguſt.

**ELUTRIATION**, in chemiſtry, an operation performed by waſhing ſolid ſubſtances with water, ſtirring them well together, and haſtily pouring off the liquid, while the lighter part remains ſuſpended in it, that it may thereby be ſeparated from the heavier part. By this operation metallic ores are ſeparated from earth, ſtones, and other unmetallic particles adhering to them.

**ELY**, a city and biſhop's ſee of Cambridgeſhire, ſituated about 12 miles north of Cambridge. E. Long. 15. 0. N. Lat. 52. 24. It is a county of itſelf, including the territory around; and has a judge who determines all cauſes civil and criminal within its limits. The church hath undergone various alterations ſince it was firſt eſtabliſhed by Etheldra, the wife of Egfride, king of Northumberland, who founded a religious houſe here, and planted it with virgins, and became the firſt abbeſs of it herſelf. The Danes entirely ruined this eſtabliſhment; then Ethelwald, the 27th biſhop of Wincheſter, rebuilt the monaſtery, and filled it with monks; to whom king Edgar, and many ſucceeding monarchs, beſtowed many privileges, and great grants of land; ſo that this abbey became in proceſs of time the beſt of any in England. Richard, the 11th abbot, wiſhing to free himſelf of the biſhop of Lincoln, within whoſe dioceſe his monaſtery was ſituated, and not liking ſo powerful a ſuperior, he made great intereſt with king Henry I. to get Ely erected into a biſhoprick; and ſpared neither purſe nor prayers to bring this about. He even brought the biſhop of Lincoln to conſent to it, by giving him and his ſucceſſors the manors of Bugden, Biggleſwade, and Spalding, which belonged to the abbey, in lieu of his juriſdiction; but he lived not to taſte the ſweets of his induſtry and ambition, he dying before his abbey was erected into a ſee. His ſucceſſor was the firſt biſhop of Ely: but the great privileges the biſhop enjoyed were almoſt wholly taken away, or much reſtricted, by the act of parliament, 27th Henry VIII. regarding the reſtoring to the crown the ancient royalties: So, inſtead of being palatine of the iſle of Ely, the biſhop and his temporal ſteward were by that act declared to be from thenceforth juſtices of the peace in the ſaid iſland. This dioceſe contains all Cambridgeſhire, and the iſle of Ely, excepting Iſelham, which belongs to the ſee of Rocheſter, and 15 other pariſhes, that are in the dioceſe of Norwich; but it has a pariſh in Norfolk,

folk, viz. Emneth. The number of pariſhes in this dioceſe are 141, whereof 75 are impropriate. It hath but one archdeacon, viz. of Ely. It is valued in the king's books at L.2134 : 18 : 5. The clergy's tenth, amounting to the ſum of L.384 : 14 : 9¼. The biſhopric is computed to be worth annually L.4000. The church is dedicated to St Ethelred. The building, as it now appears, has been the work of ſeveral of its biſhops. The weſt parts were rebuilt by biſhop Ridal; the choir and lanthern were begun by biſhop Norwold, and finiſhed by biſhop Frodſham. This ſee hath given two ſaints and two cardinals to the church of Rome; and to the Engliſh nation nine lord chancellors, ſeven lord treaſurers, one lord privy-ſeal, one chancellor of the exchequer, one chancellor to the univerſity of Oxford, two maſters of the rolls, and three almoners. To this cathedral belong a biſhop, a dean, an archdeacon, eight prebendaries, with vicars, lay-clerks, choriſters, a ſchoolmaſter, uſher, and 28 king's ſcholars.

ELYMAIS, the capital city of the land of Elam, or the ancient Perſia. We are told (1 Mac. vi. 1.) that Antiochus Epiphanes, having underſtood that there were very great treaſures lodged in a temple at Elymais, determined to go and plunder it: but the citizens getting intelligence of his deſign, made an inſurrection, forced him out of the city, and obliged him to fly. The author of the ſecond book of Maccabees (ix. 2.) calls this city *Perſepolis*, in all probability becauſe formerly it was the capital of Perſia: for it is known from other accounts, that Perſepolis and Elymais were two very different cities, the latter ſituated upon the Eulæus, the former upon the Araxis.

ELYMUS, in botany: A genus of the digynia order, belonging to the triandria claſs of plants; and in the natural method ranking under the fourth order, *Gramina*. The calyx is lateral, bivalved, aggregate, and multiflorous.

ELYOT (Sir Thomas), a gentleman of eminent learning in the 16th century, was educated at Oxford, travelled into foreign countries, and upon his return was introduced to court. His learning recommended him to Henry VIII. who conferred the honour of knighthood on him, and employed him in ſeveral embaſſies; particularly in 1532, to Rome, about the divorce of queen Catharine, and afterwards to Charles V. about 1536. He wrote. *The Caſtle of Health*, *The Governor*, *Banquet of Sapience*, *Of the Education of Children*, *De rebus memorabilibus Angliæ*, and other books; and was highly eſteemed by all his learned cotemporaries.

ELYSIUM, (Ελυσιος,) in the ancient theology, or rather mythology, a place in the *inferi* or lower world, furniſhed with fields, meads, agreeable woods, groves, ſhades, rivers, &c. whither the ſouls of good people were ſuppoſed to go after this life.

Orpheus, Hercules, and Æneas, are ſuppoſed to have deſcended into Elyſium in their life-time, and to have returned again; (Virg. lib. vi. ver. 638, &c.) Tibullus (lib. i. eleg. 3.) gives us fine deſcriptions of the Elyſian fields.

Virgil oppoſes Elyſium to Tartarus; which was the place where the wicked underwent their puniſhment.

> *Hic locus eſt, partes ubi ſe via findit in ambas:*
> *Dextera, quæ Ditis magni ſub mœnia tendit:*
> *Hac iter* Elyſium *nobis: at læva malorum*
> *Exercet pœnas, & ad impia Tartara mittit.*

He aſſigns Elyſium to thoſe who died for their country, to thoſe of pure lives, to truly inſpired poets, to the inventors of arts, and to all who have done good to mankind.

Some authors take the fable of Elyſium to have been borrowed from the Phœnicians; as imagining the name *Elyſium* formed from the Phœnician עלז *alaz*, or עלץ *alats*, or עלס *alas*, "to rejoice," or "to be in joy;" the letter *a* being only changed into *e*, as we find done in many other names; as in *Enakim* for *Anakim*, &c. On which footing, Elyſian fields ſhould ſignify the ſame thing as a place of pleaſure; or,

> ——*Locos lætos, & amœna virecta*
> *Fortunatorum nemorum, ſedeſque beatas.* Virg.

Others derive the word from the Greek λυω *ſolvo*, "I deliver, I let looſe or diſengage;" becauſe here mens ſouls are freed or diſincumbered from the fetters of the body. Beroaldus, and Hornius (Hiſt. Philoſoph. lib. iii. cap. 2.) take the place to have derived its name from Eliza, one of the firſt perſons who came into Greece after the deluge, and the author and father of the Ætolians.

The Elyſian fields were, according to ſome, in the Fortunate Iſlands on the coaſt of Africa; in the Atlantic. Others place them in the iſland of Leuce; and according to the authority of Virgil, they were ſituated in Italy. According to Lucian, they were near the moon; or in the centre of the earth, if we believe Plutarch. Olaus Wormius contends that it was in Sweden the Elyſian fields were placed.

ELZEVIRS, celebrated printers at Amſterdam and Leyden, who greatly adorned the republic of letters by many beautiful editions of the beſt authors of antiquity. They fell ſomewhat below the Stephenſes in point of learning, as well as in their editions of Greek and Hebrew authors; but as to the choice of good books, they ſeem to have equalled, and in the neatneſs and elegance of their ſmall characters, greatly to have exceeded them. Their Virgil, Terence, and Greek Teſtament, have been reckoned their maſterpieces; and are indeed ſo very fine, that they juſtly gained them the reputation of being the beſt printers in Europe. There were five of theſe Elzevirs, namely, Lewis, Bonaventure, Abraham, Lewis, and Daniel. Lewis began to be famous at Leyden in 1595, and was remarkable for being the firſt who obſerved the diſtinction between the *v* conſonant and *u* vowel, which had been recommended by Ramus and other writers long before, but never regarded. Daniel died in 1680 or 1681; and though he left children who carried on the buſineſs, paſſes nevertheleſs for the laſt of his family who excelled in it. The Elzevirs have printed ſeveral catalogues of their editions; but the laſt, publiſhed by Daniel, is conſiderably enlarged, and abounds with new books. It was printed at Amſterdam, 1674, in 12mo, and divided into ſeven volumes.

EMANATION, the act of flowing or proceeding from ſome ſource or origin. Such is the emanation of light from the ſun; or that of effluvia from odorous, &c. bodies; of wiſdom from God, &c.—The word is formed of the Latin *e* "out of," and *manare* "to flow or ſtream."

EMANATION is alſo uſed for the thing that proceeds, as well as the act of proceeding. The power given a judge is an emanation from the regal power; the reaſonable ſoul is an emanation from the Divinity.

EMANCIPATION, in the Roman law, the ſetting free a ſon from the ſubjection of his father; ſo that whatever moveables he acquires belong in property to him, and not to his father, as before emancipation.

Emancipation puts the ſon in a capacity of managing his own affairs, and of marrying without his father's conſent, though a minor. Emancipation differs from manumiſſion, as the latter was the act of a maſter in favour of a ſlave, whereas the former was that of a father in favour of his ſon.

There were two kinds of emancipation: the one tacit, which was by the ſon's being promoted to ſome dignity, by his coming of age, or by his marrying, in all which caſes he became his own maſter of courſe. The other, expreſs; where the father declared before a judge, that he emancipated his ſon. In performing this, the father was firſt to ſell his ſon imaginarily to another, whom they called *pater fiduciarius*, father in truſt; of whom being bought back again by the natural father, he manumitted him before the judge by a verbal declaration.

Emancipation ſtill obtains in France with regard to minors or pupils, who are hereby ſet at liberty to manage their own effects, without the advice or direction of their parents or tutors.

EMARGINATED, among botaniſts. See BOTANY, p. 444, n° 181.

EMASCULATION, the act of caſtrating or depriving a male of thoſe parts which characteriſe his ſex. See CASTRATION, and EUNUCH.

EMAUS, EMMAUS, or *Ammaus*, (anc. geog.), a village, 60 ſtadia to the north-weſt of Jeruſalem, or about ſeven miles: it afterwards became a town, and a Roman colony, *Nicopolis*, (Jerome). Reland has another *Emmaus* towards Lydda, 22 miles from Jeruſalem, (Itinerary); a third, near Tiberias.

EMBALMING, is the opening a dead body, taking out the inteſtines, and filling the place with odoriferous and deficcative drugs and ſpices, to prevent its putrifying. The Egyptians excelled all other nations in the art of preſerving bodies from corruption; for ſome that they have embalmed upwards of 2000 years ago, remain whole to this day, and are often brought into other countries as great curioſities. Their manner of embalming was thus: they ſcooped the brains with an iron ſcoop out at the noſtrils, and threw in medicaments to fill up the vacuum: they alſo took out the entrails, and having filled the body with myrrh, caſſia, and other ſpices, except frankincenſe, proper to dry up the humours, they pickled it in nitre, where it lay ſoaking for 70 days. The body was then wrapped up in bandages of fine linen and gums, to make it ſtick like glue; and ſo was delivered to the kindred of the deceaſed, entire in all its features, the very hairs of the eye-lids being preſerved. They uſed to keep the bodies of their anceſtors, thus embalmed, in little houſes magnificently adorned, and took great pleaſure in beholding them, alive as it were, without any change in their ſize, features, or complexion. The Egyptians alſo embalmed birds, &c. The prices for embalming were different; the higheſt was a talent, the next 29 minæ, and ſo decreaſing to a very ſmall matter: but they who had not wherewithal to anſwer this expence, contented themſelves with infuſing, by means of a ſyringe, through the fundament, a certain liquor extracted from the cedar; and, leaving it there, wrapped up the body in ſalt of nitre: the oil thus preyed upon the inteſtines, ſo that when they took it out, the inteſtines came away with it, dried, and not in the leaſt putrified: the body being encloſed in nitre, grew dry, and nothing remained beſides the ſkin glued upon the bones.

The method of embalming uſed by the modern Egyptians, according to Maillet, is to waſh the body ſeveral times with roſe-water, which, he elſewhere obſerves, is more fragrant in that country than with us; they afterwards perfume it with incenſe, aloes, and a quantity of other odours, of which they are by no means ſparing; and then they bury the body in a winding ſheet, made partly of ſilk and partly of cotton, and moiſtened, as is ſuppoſed, with ſome ſweet-ſcented water or liquid perfume, though Maillet uſes only the term *moiſtened*; this they cover with another cloth of unmixed cotton, to which they add one of the richeſt ſuits of clothes of the deceaſed. The expence, he ſays, on theſe occaſions, is very great, though nothing like what the genuine embalming coſt in former times.

EMBARCADERO, in commerce, a Spaniſh term, much uſed along the coaſts of America, particularly thoſe on the ſide of the South Sea. It ſignifies a place which ſerves ſome other conſiderable city farther within land, for a port or place of ſhipping, *i. e.* of embarking and diſembarking commodities. Thus Calao is the embarcadero of Lima, the capital of Peru; and Arica the embarcadero of Potoſi. There are ſome embarcaderos 40, 50, and even 60 leagues off the city, which they ſerve in that capacity.

EMBARGO, in commerce, an arreſt on ſhips or merchandiſe, by public authority; or a prohibition of ſtate, commonly on foreign ſhips, in time of war, to prevent their going out of port, ſometimes to prevent their coming in, and ſometimes both, for a limited time.

The king may lay embargoes on ſhips, or employ thoſe of his ſubjects, in time of danger, for the ſervice and defence of the nation: but they muſt not be for the private advantage of a particular trader or company; and therefore a warrant to ſtay a ſingle ſhip is no legal embargo. No inference can be made from embargoes which are only in war-time; and are a prohibition by advice of council, and not at proſecution of parties. If goods be laden on board, and after an embargo or reſtraint from the prince or ſtate comes forth, and then the maſter of the ſhip breaks ground, or endeavours to ſail, if any damage accrues, he muſt be reſponſible for the ſame; the reaſon is, becauſe his freight is due, and muſt be paid, even tho' the goods be ſeized as contraband.

EMBARRASS, (*Embarraſſment*), a French term, though now naturalized; denoting a difficulty or obſtacle which perplexes or confounds a perſon, &c.

EMBASSADOR. See AMBASSADOR.

EMBASSY, the office or function of an AMBASSADOR.

EMBDEN, a port-town and city of Germany, capital of a county of the ſame name, now in poſſeſſion of the king of Pruſſia; it is ſituated at the mouth of the river Ens. E. Long. 6. 45. N. Lat. 53. 50.

EMBER-WEEKS, are thoſe wherein the *ember* or *embring days* fall.

In the laws of king Alfred, and thoſe of Canute, thoſe days are called *ymbren*, that is, circular days, from whence the word was probably corrupted into *ember-days*: by the canoniſts they are called *quatuor anni tempora*, the four cardinal ſeaſons, on which the circle of the year turns: and hence Henſhaw takes the word to have been formed, viz. by corruption from *temper* of *tempora*.

The ember-days are, the Wedneſday, Friday, and Saturday, after Quadrageſima Sunday, after Whitſunday, after Holy-rood day in September, and after St Lucia's day in December: which four times anſwer well enough to the four quarters of the year, Spring, Summer, Autumn, and Winter.

Mr Somner thinks they were originally faſts, inſtituted to beg God's bleſſing on the fruits of the earth. Agreeably to which, Skinner ſuppoſes the word *ember* taken from the aſhes, *embers*, then ſtrewed on the head.

Theſe ember-weeks are now chiefly taken notice of, on account of the ordination of prieſts and deacons; becauſe the canon appoints the Sundays next ſucceeding the ember-weeks, for the ſolemn times of ordination: Though the biſhops, if they pleaſe, may ordain on any Sunday or holiday.

EMBERIZA, in ornithology, a genus of birds belonging to the order of paſſeres. The bill is conical, and the mandibles recede from each other towards the baſe; the inferior mandible has the ſides narrowed inwards, but the upper one is ſtill narrower. The moſt remarkable ſpecies are,

1. The nivalis, or great pyed mountain-finch of Ray, and the ſnow-bird of Edwards, has white wings, but the outer edge of the prime-feathers are black; the tail is black, with three white feathers on each ſide. Theſe birds are called in Scotland *ſnow-flakes*, from their appearance in hard weather and in deep ſnows. They arrive in that ſeaſon among the Cheviot-hills and in the Highlands in amazing flocks. A few breed in the Highlands, on the ſummit of the higheſt hills, in the ſame places with the *ptarmigans*; but the greateſt numbers migrate from the extreme north. They appear in the Shetland iſlands; then in the Orkneys; and multitudes of them often fall, wearied with their flight, on veſſels in the Pentland Frith. Their appearance is a certain fore-runner of hard weather, and ſtorms of ſnow, being driven by the cold from their common retreats. Their progreſs ſouthward is probably thus; Spitzbergen and Greenland, Hudſon's Bay, the Lapland Alps, Scandinavia, Iceland, the Ferroe Iſles, Shetland, Orkneys, Scotland, and the Chivot-hills. They viſit at that ſeaſon all parts of the northern hemiſphere, Pruſſia, Auſtria, and Siberia. They arrive lean, and return fat. In Auſtria, they are caught and fed with millet, and, like the ortolan, grow exceſſively fat. In their flights, they keep very cloſe to each other, mingle moſt confuſedly together, and fling themſelves collectively into the form of a ball; at which inſtant the fowler makes great havock among them.

2. The miliaris, or grey emberiza, is of a greyiſh colour, ſpotted with black in the belly, and the orbits are reddiſh. It is the bunting of Engliſh authors, and a bird of Europe.

3. The hortulana, or ortolan, has black wings; the firſt three feathers on the tail are white on the edges, only the two lateral are black outwardly. The orbits of the eyes are naked and yellow; the head is greeniſh, and yellow towards the inferior mandible. It feeds principally upon the panick-graſs; grows very fat; and is reckoned a delicate morſel by certain epicures, eſpecially when fattened artificially. Theſe birds are found in ſeveral parts of Europe, but are not met with in Britain; are common in France and Italy, and ſome parts of Germany and Sweden, migrating from one to the other in ſpring and autumn; and in their paſſage are caught in numbers, in order to fatten for the table. This ſpecies will ſometimes ſing very prettily, and has been kept for that purpoſe. The ſong is not unlike that of the yellow-hammer, but finer and ſweeter. In ſome parts it makes the neſt in a low hedge; in others, on the ground. It is careleſsly conſtructed, not unlike that of the lark. The female lays four or five greyiſh eggs, and in general has two broods in a year.

The manner of fattening theſe birds for the table is as follows. They are taken and placed in a chamber lightened by lanthorns; ſo that, not knowing the viciſſitudes of day and night, they are not agitated by the change. Are fed with oats and millet; and grow ſo fat, that they would certainly die if not killed in a critical minute. They are a mere lump of fat; of a moſt exquiſite taſte, but apt ſoon to ſatiate. Theſe birds receive both their Greek and Latin name from their food, the millet. Ariſtotle calls them *cynchromi*; and the Latins, *miliariæ*. The latter kept and fattened them in their *ornithones*, or fowl-yards, as the Italians do at preſent; which the ancients conſtructed with the utmoſt magnificence, as well as conveniency.

4. The citrinella, or yellow-hammer, has a blackiſh tail, only the two outward ſide-feathers are marked on the inner edge with a ſharp white ſpot. It is a bird of Europe, and comes about houſes in winter: it builds its neſt on the ground on meadows.

5. The ſchœniclas, or reed-ſparrow, has a black head, a blackiſh-grey body, and a white ſpot on the quill-feathers. It inhabits marſhy places, moſt commonly among reeds, from which it takes its name. Its neſt is worthy of notice for the artful contrivance of it, being faſtened to four reeds, and ſuſpended by them like a hammock, about three feet above the water; the cavity of the neſt is deep, but narrow; and the materials are buſhes, fine bents, and hairs. It lays four or five eggs of a bluiſh white, marked with irregular purpliſh veins, eſpecially on the larger end. It is a bird much admired for its ſong; and, like the nightingale, it ſings in the night.

6. The oryzivora, or rice-bunting, with the head and whole under ſide of the body black; hind part of the

neck in ſome pale yellow, and in others white; coverts of the wings, and primaries, black, the laſt edged with white; part of the ſcapulars, leſſer coverts of the wings, and rump, white; back black, edged with dull yellow; tail of the ſame colours, and each feather ſharply pointed; the legs are red. The head, upper part of the neck, and back, of the female, is yellowiſh brown, ſpotted with black; the under part, of a dull yellow; the ſides thinly ſtreaked with black.

Theſe birds inhabit in vaſt numbers the iſland of Cuba, where they commit great ravages among the early crops of rice, which precede thoſe of Carolina. As ſoon as the crops of that province are to their palate, they quit Cuba, and paſs over the ſea, in numerous flights, directly north; and are very often heard in their paſſage by ſailors frequenting that courſe. Their appearance is in September, while the rice is yet milky; and commit ſuch devaſtations, that 40 acres of that grain have been totally ruined by them in a ſmall time. They arrive very lean: but ſoon grow ſo fat, as to fly with difficulty; and, when ſhot, often burſt with the fall. They continue in Carolina not much above three weeks, and retire by the time the rice begins to harden; going on to other parts, and ſtaying in each only ſo long as the rice continues green. They come into Rhode Iſland and New York at the end of April, or the ſecond week in May, frequenting the borders of fields, and live on inſects, &c. till the maize is fit for their palate; when they begin by pecking holes in the ſides of the huſks, and after ſatiating themſelves go on to another; which leaves room for the rain to get in, and effectually ſpoils the plants. They continue there during the ſummer, and breed; returning, as autumn approaches, to the ſouthward. The males and females do not arrive together; the females come firſt.—They are eſteemed to be the moſt delicate birds of thoſe parts; and the male is ſaid to have a fine note. This ſpecies is known in the country by the names of *bob lincoln* and *conquedle*; likewiſe called by ſome the *white-backed maize thief*.

There are above 50 other ſpecies; two of which, *viz.* the black-throated bunting a native of America, and the cinereous bunting an inhabitant of Canada, are figured on Plate CLXXXII. as ſpecimens of the genus.

EMBLEM, a kind of painted ænigma, which, repreſenting ſome obvious hiſtory, with reflections underneath, inſtructs us in ſome moral truth or other matter of knowledge. See Devise, Ænigma, &c.

Such is that very ſignificant image of Scævola holding his hand in the fire; with the words, *Agere et pati fortiter Romanum eſt*, "To do and ſuffer courageouſly is Roman."

The word is pure Greek, formed of the verb ἐμβαλλειν, "to caſt in, to inſert." Suetonius relates, that Tiberius made the word be eraſed out of the decree of the Roman ſenate, becauſe borrowed from another language.

The emblem is ſomewhat plainer and more obvious than the ænigma.—Gale defines emblem an ingenious picture, repreſenting one thing to the eye, and another to the underſtanding.

The Greeks alſo gave the name Emblems, ἐμβληματα, to inlayed or Moſaic works, and even to all kinds of ornaments of vaſes, moveables, garments, &c. And the Latins uſed *emblema* in the ſame ſenſe. Accordingly, Cicero reproaching Verres with the ſtatues and fine wrought works he had plundered from the Sicilians, calls the ornaments fixed thereto (and which on occaſion might be ſeparated from them) *emblemata*. Add, that Latin authors frequently compare the figures and ornaments of diſcourſe to theſe *emblemata*. Thus, an ancient Latin poet praiſing an orator, ſays, that all his words were ranged like the pieces in Moſaic:

> *Quam lepide* λεξεις *compoſtæ, ut teſſerulæ omnes,*
> *Arte pavimenti, atque* emblemate *vermiculato.*

With us, emblem ordinarily ſignifies no more than a painting, baſſo-relievo, or other repreſentation, intended to hold forth ſome moral or political inſtruction.

What diſtinguiſhes an emblem from a deviſe is, that the words of an emblem have a full complete ſenſe of themſelves; nay, all the ſenſe and ſignification which they have together with the figure. But there is a yet further difference between emblem and deviſe: for a deviſe is a ſymbol appropriated to ſome perſon, or that expreſſes ſomething which concerns him particularly; whereas an emblem is a ſymbol that regards all the world alike.

Theſe differences will be more apparent, from comparing the emblem above quoted, with the deviſe of a candle lighted, and the words *Juvando conſumor*, "I waſte myſelf in doing good." See Devise.

EMBOLISMUS, Εμβολισμος, in chronology, ſignifies "intercalation." The word is formed of ἐμβαλλειν, "to inſert."

As the Greeks made uſe of the lunar year, which is only 354 days, in order to bring it to the ſolar, which is 365 days, they had every two or three years an emboliſm, i. e. they added a 13th lunar month every two or three years, which additional month they called *embolimæus*, ἐμβολιμαιος, becauſe inſerted, or intercalated.

EMBOSSING, or Imbossing, in architecture and ſculpture, the forming or faſhioning works in relievo, whether cut with a chiſel or otherwiſe.

Emboſſing is a kind of ſculpture, wherein the figures ſtick out from the plane whereon it is cut: and according as the figures are more or leſs prominent, they are ſaid to be in alto, mezzo, or baſſo, relievo; or high, mean, or low, relief. See Enchasing.

EMBOTHRIUM, in botany: A genus of the monogynia order, belonging to the tetrandria claſs of plants. There is no calyx; the corolla conſiſts of four linear oblique petals; the ſtamina are four very ſhort filaments; the antheræ are pretty large, oblong, and ſeated within the cavity of the petal. The pericarpium is a round unilocular follicle, ſharpened at both ends; the ſeeds are four or five in number, egg-ſhaped, and compreſſed.

EMBRASURE, in architecture, the enlargement made of the aperture of a door or window, on the inſide of the wall; its uſe being to give the greater play for the opening of the door or caſement, or to admit the more light.

EMBROCATION, in ſurgery and pharmacy, an external kind of remedy, which conſiſts in an irrigation of the part affected, with ſome proper liquor, as oils, ſpirits, &c. by means of a woollen or linen cloth, or a ſpunge, dipped in the ſame.

EMBROIDERY, a work in gold, or ſilver, or ſilk thread, wrought by the needle upon cloth, ſtuffs, or muſlin, into various figures. In embroidering ſtuffs, the work is performed in a kind of loom; becauſe the more the piece is ſtretched, the eaſier it is worked. As to muſlin, they ſpread it upon a pattern ready deſigned; and ſometimes, before it is ſtretched upon the pattern, it is ſtarched, to make it more eaſy to handle. Embroidery on the loom is leſs tedious than the other, in which, while they work flowers, all the threads of the muſlin, both lengthwiſe and breadthwiſe, muſt be continually counted; but, on the other hand, this laſt is much richer in points, and ſuſceptible of greater variety. Cloths too much milled are ſcarce ſuſceptible of this ornament, and in effect we ſeldom ſee them embroidered. The thinneſt muſlins are left for this purpoſe; and they are embroidered to the greateſt perfection in Saxony: in other parts of Europe, however, they embroider very prettily, and eſpecially in France.

There are ſeveral kinds of embroidery: as, 1. Embroidery on the ſtamp; where the figures are raiſed and rounded, having cotton or parchment put under them to ſupport them. 2. Low embroidery; where the gold and ſilver lie low upon the ſketch, and are ſtitched with ſilk of the ſame colour. 3. Guimped embroidery: this is performed either in gold or ſilver; they firſt make a ſketch upon the cloth, then put on cut vellum, and afterwards ſow on the gold and ſilver with ſilk thread: in this kind of embroidery they often put gold and ſilver cord, tinſel, and ſpangles. 4. Embroidery on both ſides; that which appears on both ſides of the ſtuff. 5. Plain embroidery; where the figures are flat and even, without cords, ſpangles, or other ornaments.

By ſtat. 22. Geo. II. c. 36. no foreign embroidery, or gold and ſilver brocade, ſhall be imported, upon pain of being forfeited and burnt, and penalty of 100l. for each piece. No perſon ſhall ſell, or expoſe to ſale, any foreign embroidery, gold or ſilver thread, lace, fringe, brocade, or make up the ſame into any garment, on pain of having it forfeited and burnt, and penalty of 100l. All ſuch embroidery, &c. may be ſeized and burnt; and the mercer, &c. in whoſe cuſtody it was found, ſhall forfeit 100l.

EMBRUN, or AMBRUN, a city of Dauphiny, in France, near the confines of Piedmont. E. Long. 6. 6. N. Lat. 44. 35.

EMBRYO, in phyſiology, the firſt rudiments of an animal in the womb, before the ſeveral members are diſtinctly formed; after which period it is denominated a *fetus*. See GENERATION, and FETUS.

EMERALD, a genus of precious ſtones belonging to the order of ſiliceous earths. The word is derived, according to ſome, from the French *eſmaraude*, and that from the Latin *ſmaragdus*, ſignifying the ſame thing; by others it is ſaid to be derived from the Italian *ſmeraldo*, or the Arabian *zomorrad*. According to Cronſtedt the emerald is the ſofteſt of all the precious ſtones, though other naturaliſts place it the next after the diamond in this reſpect. It is perhaps the moſt beautiful of all the gems, and, according to Wallerius, when heated in the fire, changes its colour to a deep blue, and becomes phoſphoreſcent; but recovers its green colour when cold. When pulveriſed it has a white appearance, and, with borax, melts to a very thin and colourleſs glaſs. It becomes electric by being rubbed, and ſome have the property of the tourmalin, viz. of being electrified by heat, and in that ſtate attracting aſhes or other light ſubſtances; though the emeralds are leſs powerful than the tourmalin, and after having attracted the aſhes, they retain them without any ſigns of repulſion.

Pliny mentions twelve different kinds of theſe precious ſtones; though it appears, from the vaſt ſize of ſome of them, that they muſt have been only certain kinds of green ſpar, or other green ſtone, which at that time went under the name of *emerald* among the ancients. The true emerald is found only in very ſmall cryſtals, from the ſize $\frac{1}{16}$th of an inch in diameter to that of a walnut. Theophraſtus, however, mentions one four cubits long and three broad; likewiſe an obeliſk compoſed of only four emeralds, the whole length being 40 cubits, and the breadth from four to two.

Engeſtroom informs us, that the emeralds, in their rough or native ſtate, conſiſt of hexagonal columns moſtly truncated at both ends; and that he had ſome in his poſſeſſion, which in a gentle heat became colourleſs; but in a ſtrong heat white and opaque, without any mark of fuſion. Brunick diſtinguiſhes them into two claſſes. 1. The pale green emerald, which comes from the eaſt and from Peru, the figure being that of an hexagonal truncated priſm, and the baſis a vein of white quartz. 2. The dark green emerald, which is alſo columnar, but very dark-coloured, ſtriped longitudinally, and has little tranſparency. The points are generally broken off longitudinally, though Davila mentions one reſembling a blunt triangular pyramid; and in the Imperial cabinet at Vienna, there is one with a five-ſided pyramid. Theſe are the emeralds which become electrical by heat; though all of them do not; and thoſe which do ſo cannot be known but by actual experiment. The fineſt ſpecimen of the former kind of emeralds is to be ſeen in the treaſure of the holy chapel of Loretto, containing upwards of 100 of theſe precious ſtones great and ſmall. A fellow to this was made by art, and both were preſents to the king of Sicily, deſigned to repreſent two mount Calvaries.

Emeralds are diſtinguiſhed by the jewellers into two kinds, the oriental and occidental. The true oriental emerald is very ſcarce, and at preſent only found in the kingdom of Cambay. So great indeed is the ſcarcity of them, that an opinion prevailed that there are no oriental emeralds. This opinion is adopted, among others, by Mr Bruce; who informs us, that he made an excurſion to the iſland of emeralds in the Red Sea, and endeavours to ſhow that there never were any emeralds but what came from America, and that thoſe ſaid to have been found in the Eaſt Indies were imported from that continent. It is probable indeed, that in former times any kind of cryſtal tinged of a green colour might be called an *emerald*, and hence the green cochle ſpar brought from Egypt may have obtained the name of *mother of emeralds*; but of late ſome emeralds have been brought from Cambay into Italy which greatly excelled thoſe of America. The beſt emeralds of the weſtern continent come from Peru, and are called *oriental* by the jewellers: ſome are found in Europe, principally in the duchy of Sileſia in Germany.

*Rough* EMERALDS.—Thoſe of the firſt and coarſeſt ſort, called *plaſmes*, for grinding, are worth 27 ſhillings ſterling the marc, or 8 ounces. The demi-morillons, 8l. ſterl. per marc. Good morillons, which are only little pieces,

pieces, but of fine colour, from 13l. to 15l. per marc. Emeralds, larger than morillons, and called *of the third colour* or *ſort*, are valued at from 50l. to 60l. the marc. Emeralds, called *of the ſecond ſort*, which are in larger and finer pieces than the preceding, are worth from 65l. to 75l. per marc. Laſtly, thoſe of the firſt colour, otherwiſe called *negres cartes*, are worth from 110l. to 115l.

*Emeralds ready cut, or poliſhed and not cut, being of good ſtone, and a fine colour, are worth,*

*To counterfeit Emeralds:* Take of natural cryſtal, four ounces; of red-lead, four ounces; verdegris, forty-eight grains; crocus martis, prepared with vinegar, eight grains: let the whole be finely pulverized and ſifted; put this into a crucible, leaving one inch empty: lute it well, and put it into a potter's furnace, and let it ſtand there as long as they do their pots. When cold, break the crucible; and you will find a matter of a fine emerald colour, which, after it is cut and ſet in gold, will ſurpaſs in beauty an oriental emerald.

EMERSION, in phyſics, the riſing of any ſolid above the ſurface of a fluid ſpecifically heavier than itſelf, into which it had been violently immerged or thruſt.

It is one of the known laws of hydroſtatics, that a lighter ſolid being forced down into a heavier fluid, immediately endeavours to emerge; and that with a force or moment equal to the exceſs of weight of a quantity of the fluid above that of an equal bulk of the ſolid. Thus, if a ſolid be immerged in a fluid of double its ſpecific gravity, it will emerge again till half its bulk or body be above the ſurface of the fluid.

Emersion, in aſtronomy, is when the ſun, moon, or other planet, begins to re-appear, after its having been eclipſed, or hid by the interpoſition of the moon, earth, or other body.

The difference of longitude is ſometimes found by obſerving the immerſions and emerſions of the firſt of Jupiter's ſatellites. The immerſions are obſerved from the time of Jupiter's being in conjunction with the ſun to his oppoſition; and the emerſion, from the oppoſition to the conjunction; which two intervals are uſually ſix months a-piece, and divide the year between them. But when Jupiter is in conjunction with the ſun, and 15 days before and afterwards, there is nothing to be obſerved; the planet, with his ſatellites, being then loſt in the light of the ſun.

Emersion is alſo uſed when a ſtar, before hid by the ſun, as being too near him, begins to re-appear, and to get out of his rays.

EMERSON (William), a late eminent mathematician, was born in June 1701, at Hurworth, a village about three miles ſouth of Darlington; at leaſt it is certain that he reſided here from his childhood. His father Dudley Emerſon was a tolerable proficient in mathematics; and without his books and inſtructions, perhaps his own genius (moſt eminently fitted for mathematical diſquiſitions) would have never been unfolded. He was inſtructed in the learned languages by a young clergyman, then curate of Hurworth, who was boarded at his father's houſe. In the earlier part of his life he attempted to teach a few ſcholars: but whether from his conciſe method (for he was not happy in explaining his ideas), or the warmth of his natural temper, he made no progreſs in his ſchool: he therefore ſoon left it off; and ſatisfied with a moderate competence left him by his parents, he devoted himſelf to a ſtudious retirement. Towards the cloſe of the year 1781 (being ſenſible of his approaching diſſolution), he diſpoſed of the whole of his mathematical library to a bookſeller at York; and on May 20th 1782, he died of a lingering and painful diſorder at his native village, aged near 81 years.

Mr Emerſon in his perſon was rather ſhort, but ſtrong and well-made, with an open countenance and ruddy complexion. He was exceedingly ſingular in his dreſs. He had but one coat, which he always wore open before, except the lower button; no waiſtcoat; his ſhirt quite the reverſe of one in common uſe, no opening before, but buttoned cloſe at the collar behind; a kind of flaxen wig which had not a crooked hair in it, and probably had never been tortured with a comb from the time of its being made. He always walked up to London when he had any thing to publiſh, reviſing ſheet by ſheet himſelf:—Truſting no eyes but his own, was always a favourite maxim with him. He never advanced any mathematical propoſition that he had not firſt tried in practice, conſtantly making all the different parts himſelf on a ſmall ſcale, ſo that his houſe was filled with all kinds of mechanical inſtruments together or disjointed. He would frequently ſtand up to his middle in water while fiſhing, a diverſion he was remarkably fond of. He uſed to ſtudy inceſſantly for ſome time, and then for relaxation take a ramble to any pot-alehouſe where he could get any body to drink with and talk to. The duke of Mancheſter was highly pleaſed with his company, and uſed often to come to him in the fields and accompany him home, but could never perſuade him to get into a carriage. On theſe occaſions he would ſometimes exclaim, "Damn your whim-wham! I had rather walk." He was a married man; and his wife uſed to ſpin on an old-faſhioned wheel, whereof a very accurate drawing is given in his mechanics. He was deeply ſkilled in the ſcience of muſic, the theory of ſounds, and the various ſcales both ancient and modern, but was a very poor performer.

The following is a liſt of Mr Emerſon's works. 1. The Doctrine of Fluxions. 2. The Projection of the Sphere, orthographic, ſtereographic, and gnomonical. 3. The Elements of Trigonometry. 4. The Principles of Mechanics. 5. A Treatiſe of Navigation on the Sea. 6. A Treatiſe of Algebra, in two books. 7. The Arithmetic of Infinites, and the differential Method, illuſtrated by Examples. 8. Mechanics; or the Doctrine of Motion. 9. The Elements of Optics, in four books. 10. A Syſtem of Aſtronomy. 11. The

11. The Laws of Centripetal and Centrifugal Force. 12. The Mathematical Principles of Geography. 13. Tracts, 8vo. 14. Cyclomatheſis; or an eaſy Introduction to the ſeveral Branches of the Mathematics. 15. A ſhort Comment on Sir Iſaac Newton's Principia; to which is added, A Defence of Sir Iſaac againſt the Objections that have been made to ſeveral Parts of his Works. 16. A Miſcellaneous Treatiſe, containing ſeveral Mathematical Subjects, 8vo. 1776.

EMERY, in natural hiſtory, a rich iron-ore found in large maſſes of no determinate ſhape or ſize, extremely hard, and very heavy. It is uſually of a duſky browniſh red on the ſurface; but when broken, is of a fine bright iron-grey, but not without ſome tinge of redneſs; and is ſpangled all over with ſhining ſpecks, which are ſmall flakes of a foliaceous talk, highly impregnated with iron. It is alſo ſometimes very red, and then uſually contains veins of gold. It makes no effervеſcence with any of the acid menſtruums; and is found in the iſland of Guernſey, in Tuſcany, and many parts of Germany.

*Com.* 7. Dr Lewis is of opinion, that ſome kinds of emery may contain the metal called *platina*, and on this ſubject has the following curious obſervations. ‘ Alonſo Barba mentions a ſubſtance called *chumpi;* which is a hard ſtone of the emery kind, participating of iron, of a grey colour ſhining a little, very hard to work, becauſe it reſiſts the fire much, found in Potoſi, Chocaya, and other places, along with blackiſh and reddiſh ores that yield gold. If platina is really found in large maſſes, either generally or only now and then, one might reaſonably expect thoſe maſſes to be ſuch as are here deſcribed.

“ Of the ſame kind perhaps alſo is the mineral mentioned by ſeveral authors under the name of Spaniſh emery, *ſmiris Hiſpanica*, which ſhould ſeem, from the accounts given of it, to be no other than platina or its matrix. The *ſmiris* is ſaid to be found in the gold mines, and its exportation prohibited; to contain films or veins of native gold; to be in great requeſt among the alchemiſts; to have been ſometimes uſed for the adulteration of gold; to ſtand, equally with the noble metal, cupellation, quartation, antimony, and the regal cement; and to be ſeparable from it by amalgamation with mercury, which throws out the *ſmiris* and retains the gold; properties ſtrongly characteriſtic of platina, and which do not belong to any known ſubſtance beſides. This debaſement of gold *per extractum ſmiridis Hiſpanici* is mentioned by Becher in his *Minera arenaria*, and ſeveral times hinted at in his *Phyſica ſubterranea*. Both Becher and Stahl indeed call the ſubſtance which the gold receives from the emery an earth, whereas platina is undoubtedly a metal; but this does not at all invalidate our ſuppoſition, for they give the name of earth alſo to the ſubſtance which copper receives from calamine in being made into braſs, which is now known to be metallic.

“ From theſe obſervations I have been led to ſuſpect, that the European emeries likewiſe might poſſibly participate of platina. If this was certain, it would account ſatisfactorily for the uſe which ſome of the alchemiſts are ſaid to have made of emeries and other ferrugineous ores; and we ſhould no longer doubt, or wonder, that by treating gold with theſe kinds of minerals, they obtained a permanent augmentation; that this augmentation, though it reſiſted lead, antimony, aquafortis, and the regal cement, was ſeparable, as Becher owns it was, by quickſilver; and that, when it exceeded certain limits, it rendered the gold pale and brittle.

“ If emery contains platina, I imagined it might be diſcoverable by boiling the powdered mineral in melted lead, and afterwards working off the lead upon a teſt or cupel. The experiment was made with eight ounces of the fineſt powder of common emery, and the ſame quantity of lead; which were covered with black flux to prevent the ſcorification of the lead, and urged with a ſtrong fire for two or three hours. The lead became hard, rigid, of a dark colour, and a granulated texture, as if it had really imbibed ſome platina from the emery; but in cupellation it worked almoſt entirely off, leaving only a bead about the ſize of a ſmall pin's head, which was probably no other than ſilver contained in the lead.

“ I repeated the experiment with ſome variation, thinking to obtain a more perfect reſolution of the emery by vitrifying it with the lead. Two ounces of fine emery and ſix ounces of minium were well mixed together, and urged with a ſtrong fire, in a cloſe crucible, for an hour: they melted into an uniform dark browniſh glaſs. The glaſs was powdered, mixed with four ounces of fixt alkaline ſalt and ſome powdered charcoal, and put into a freſh crucible, with ſome common ſalt on the ſurface: The fire was pretty ſtrongly excited; but the fuſion was not ſo perfect as could be wiſhed, and only about two ounces of lead were found revived. This lead had ſuffered nearly the ſame change as that in the foregoing experiment; and, like it, gave no appearance of platina on being cupelled.

“ It ſeems to follow from theſe experiments, that the emery employed in them contained no platina; but as it is not to be ſuppoſed that all emeries are of one compoſition, other ſorts may deſerve to be ſubmitted to the ſame trials. As gold is contained in ſome parcels of common minerals, and by no means in all the individuals of any one ſpecies; platina may poſſibly in like manner be found in ſome European ores, though there is not the leaſt footſtep of it in other parcels of the ſame kind of ore.”

EMETICS, medicines that induce vomiting.

EMIMS, ancient inhabitants of the land of Canaan beyond Jordan, who were defeated by Chedorlaomer and his allies, Gen. xiv. 5. Moſes tells us, that they were beaten in Shaveh Kirjathaim, which was in the country of Sihon conquered from the Moabites, Joſh. xiii. 19—21. The Emims were a warlike people, of a gigantic ſtature, great and many, and tall as the Anakims.

EMINENCE, in geography, a little hillock or aſcent above the level of the adjoining champaign.

Eminence is alſo a title of honour given to cardinals. The decree of the pope, whereby it was appointed that the cardinals ſhould be addreſſed under the quality of *eminence*, bears date the 10th of January 1630. They then laid aſide the titles of *illuſtriſſimi*, and *reverendiſſimi*, which they had borne before.

The grand maſter of Malta is likewiſe addreſſed under the quality of *eminence*. The popes John VIII. and Gregory VII. gave the ſame title to the kings of France. The emperors have likewiſe borne it.

*Eminentiſſimus*, the ſuperlative of *eminent*, has of late been attributed to the cardinals.

EMIR, a title of dignity among the Turks, ſignifying a prince.

This title was firſt given to the caliphs; but when they aſſumed the title of Sultans, that of emir remained to their children; as that of Cæſar among the Romans. At length the title came to be attributed to all who were judged to deſcend from Mahomet by his daughter Fatimah, and who wear the green turban inſtead of the white. The Turks make an obſervation, that the emirs, before their fortieth year, are men of the greateſt gravity, learning, and wiſdom; but after this, if they are not great fools, they diſcover ſome ſigns of levity and ſtupidity. This is interpreted by the Turks as a ſort of divine impulſe in token of their birth and ſanctity. The Turks alſo call the vizirs, baſhaws, or governors of provinces, by this name.

EMISSARY, in a political ſenſe, a perſon employed by another to ſound the opinions of people, ſpread certain reports, or act as a ſpy over other people's actions.

*Emissary-Veſſels*, in anatomy, the ſame with thoſe more commonly called Excretory.

EMISSION, in medicine, a term uſed chiefly to denote the ejaculation of the ſemen or ſeed in the act of coition. See Coition, and Generation.

EMMANUEL, or Immanuel, a Hebrew word which ſignifies, 'God with us.' Iſaiah (viii. 14.), in that celebrated prophecy, wherein he declares to Ahaz the birth of the Meſſiah, who was to be born of a virgin, ſays, This child ſhall be called, and really be, Emmanuel, that is, *God with us*. The ſame prophet (viii. 8.) repeats the ſame thing, while he is ſpeaking of the enemy's army, which, like a torrent, was to overflow Judea. 'The ſtretching out of his wings ſhall fill the breadth of thy land, O Emmanuel.' The evangeliſt Matthew (i. 23.) informs us, that this prophecy was accompliſhed in the birth of Chriſt, born of the virgin Mary, in whom the two natures divine and human were united, and ſo in this ſenſe he was really Emmanuel, or 'God with us.'

EMMERICK, a rich fortified town of Germany, in the circle of Weſtphalia, and duchy of Cleves. It carries on a good trade with the Dutch, and both Proteſtants and Catholics have the free exerciſe of their religion. The ſtreets are neat and regular, and the houſes tolerably built. It was taken by the French in 1672, and delivered to the elector of Brandenburgh in 1673, under whoſe juriſdiction it now is. It is ſeated near the Rhine. E. Long. 5. 29. N. Lat. 52. 5.

EMMIUS (Ubbo), born at Gretha in Eaſt Frieſland in 1547, was a very learned profeſſor, and choſen rector of the college of Norden in 1579. This ſeminary flouriſhed exceedingly under his care; and declined as viſibly after he was ejected, in 1587, for refuſing to ſubſcribe the Confeſſion of Augſburg. The year after, he was made rector of the college of Leer; and when the city of Groningen confederated with the United Provinces, the magiſtrates appointed him rector of that college: which employment he filled with the higheſt repute near 20 years; until, the college being erected into an univerſity, he was the firſt rector, and one of the chief ornaments of it by his lectures, till his infirmities prevented his public appearance. His wiſdom was equal to his learning; ſo that the governor of Frieſland and Groningen often conſulted him, and ſeldom failed to follow his advice. He wrote *Vetus Græcia illuſtrata*, 3 vols; *Decades Rerum Freſicarum*; and many other valuable works. He died in 1625.

EMMENAGOGUES, Εμμηναγωγα, in medicine, ſuch remedies as promote the menſtrual diſcharge. They are thus called from εν "in," μην "month," αγω *duco*, "I lead," becauſe their natural periods of flowing are once a-month.

EMOLLIENTS, in medicine and pharmacy, are ſuch remedies as ſheath and ſoften the aſperity of the humours, and relax and ſupple the ſolids at the ſame time.

EMOLUMENT, is properly applied to the profits ariſing daily from an office or employ. The word is formed of the Latin *emolumentum*, which according to ſome, primarily ſignifies the profits redounding to the miller from his mill; of *molo, molere*, "to grind."—The patent, or other inſtrument, whereby a perſon is preferred to an office, gives him a right to enjoy all the dues, honours, profits, and emoluments belonging thereto.—*Emolument* is alſo uſed, in a ſomewhat greater latitude, for profit or advantage in the general.

EMOTION and Passion, in the human mind, are thus diſtinguiſhed by a celebrated writer*. An internal motion or agitation of the mind, when it paſſeth away without deſire, is denominated *an emotion*: when deſire follows, the motion or agitation is denominated *a paſſion*. A fine face, for example, raiſeth in me a pleaſant feeling: if that feeling vaniſh without producing any effect, it is in proper language an *emotion*; but if the feeling, by reiterated views of the object, becomes ſufficiently ſtrong to occaſion deſire, it loſes its name of emotion, and acquires that of *paſſion*. The ſame holds in all the other paſſions. The painful feeling raiſed in a ſpectator by a ſlight injury done to a ſtranger, being accompanied with no deſire of revenge, is termed an emotion; but that injury raiſeth in the ſtranger a ſtronger emotion, which being accompanied with deſire of revenge, is a paſſion. External expreſſions of diſtreſs produce in the ſpectator a painful feeling, which being ſometimes ſo ſlight as to paſs away without any effect, is an emotion; but if the feeling be ſo ſtrong as to prompt deſire of affording relief, it is a paſſion, and is termed *pity*. Envy is emulation in exceſs: if the exaltation of a competitor be barely diſagreeable, the painful feeling is an emotion; if it produce deſire to depreſs him, it is a paſſion. See Passion.

EMOUY, or Hia-men, an iſland and port of China, under the juriſdiction of the province of Fo-kien.

The port is properly but an anchoring-place for ſhips, incloſed on one ſide by the iſland from which it takes its name, and on the other by the main-land: but it is ſo extenſive, that it can contain ſeveral thouſands of veſſels; and the depth of its water is ſo great, that the largeſt ſhips may lie cloſe to the ſhore without danger.

In the beginning of the preſent century it was much frequented by European veſſels; but few viſit it at preſent, as all the trade is carried on at Canton. The emperor keeps here a garriſon of 6 or 7000 men, commanded by a Chineſe general. In entering this road,

* *Elem Critici* vol. i.

road, a large rock muſt be doubled which ſtands at the mouth of it, and divides it almoſt as the Mingant divides the harbour of Breſt. This rock is viſible, and riſes ſeveral feet above the ſurface of the water.

The iſland of Emouy is particularly celebrated on account of the magnificence of its principal pagod, conſecrated to the deity Fo. This temple is ſituated in a plain, terminated on one ſide by the ſea, and on the other by a lofty mountain. Before it the ſea, flowing through different channels, forms a large ſheet of water which is bordered with turf of the moſt beautiful verdure. The front of this edifice is 180 feet in length, and its gate is adorned with figures in relief, which are the uſual ornaments of the Chineſe architecture. On entering, you find a vaſt portico, with an altar in the middle, on which is placed a gigantic ſtatue of gilt braſs, repreſenting the god Fo, ſitting croſs-legged. Four other ſtatues are placed at the corners of this portico, which are 18 feet high, although they repreſent people ſitting. Each of theſe ſtatues is formed from a ſingle block of ſtone. They bear in their hands different ſymbols which mark their attributes, as formerly in Athens and Rome the trident and caduceus diſtinguiſhed Neptune and Mercury. One holds a ſerpent in its arms, which is twiſted round its body in ſeveral folds; the ſecond has a bent bow and a quiver; the two others preſent, one a kind of battle-axe, and the other a guitar, or ſome inſtrument of the ſame kind.

After croſſing this portico, you enter a ſquare outer court, paved with large gray ſtones, the leaſt of which is ten feet in length and four in breadth. At the four ſides of this court ariſe four pavilions, which terminate in domes, and have a communication with one another by means of a gallery which runs quite round it. One of theſe contains a bell ten feet in diameter; the wooden-work which ſupports this heavy maſs cannot be ſufficiently admired. In the other is kept a drum of an enormous ſize, which the bonzes uſe to proclaim the days of new and full moon. It muſt be obſerved, that the clappers of the Chineſe bells are on the outſide, and made of wood in the form of a mallet. The two other pavilions contain the ornaments of the temple, and often ſerve to lodge travellers, whom the bonzes are obliged to receive. In the middle of this court is a large tower, which ſtands by itſelf, and terminates alſo in a dome, to which you aſcend by a beautiful ſtone ſtair-caſe that winds round it. This dome contains a temple remarkably neat; the ceiling is ornamented with moſaic work, and the walls are covered with ſtone figures in relief, repreſenting animals and monſters. The pillars which ſupport the roof of this edifice are of wood varniſhed; and on feſtivals are ornamented with ſmall flags of different colours. The pavement of the temple is formed of little ſhells, and its different compartments preſent birds, butterflies, flowers, &c.

The bonzes continually burn incenſe upon the altar, and keep the lamps lighted, which hang from the ceiling of the temple. At one extremity of the altar ſtands a brazen urn, which when ſtruck ſends forth a mournful ſound: on the oppoſite ſide is a hollow machine of wood, of an oval form, uſed for the ſame purpoſe, which is to accompany with its ſound their voices when they ſing in praiſe of the tutelary idol of the pagod. The god Pouſſa is placed on the middle of this altar, on a flower of gilt braſs, which ſerves as a baſe, and holds a young child in his arms; ſeveral idols, which are no doubt ſubaltern deities, are ranged around him, and ſhow by their attitudes their reſpect and veneration.

The bonzes have traced out on the walls of this temple ſeveral hierogliphical characters in praiſe of Pouſſa; there is alſo to be ſeen an hiſtorical or allegorical painting in freſco, which repreſents a burning lake, in which ſeveral men appear to be ſwimming, ſome carried by monſters, others ſurrounded by dragons and winged ſerpents. In the middle of the gulph riſes a ſteep rock, on the top of which the god is ſeated, holding in his arms a child, who ſeems to call out to thoſe who are in the flames of the lake; but an old man, with hanging ears and horns on his head, prevents them from climbing to the ſummit of the rock, and threatens to drive them back with a large club. The bonzes are at a loſs what anſwer to give, when any queſtions are aſked them concerning this painting. Behind the altar is a kind of library, containing books which treat of the worſhip of idols.

On deſcending from this dome you croſs the court, and enter a kind of gallery, the walls of which are lined with boards; it contains 24 ſtatues of gilt braſs, repreſenting the ſame number of philoſophers, ancient diſciples of Confucius. At the end of this gallery you find a large hall, which is the refectory of the bonzes; and after having traverſed a ſpacious apartment, you at length enter the temple of Fo, to which there is an aſcent by a large ſtone ſtair-caſe. It is ornamented with vaſes full of artificial flowers (a work in which the Chineſe excel); and here alſo are found the ſame kind of muſical inſtruments as thoſe mentioned before. The ſtatue of the god is not to be ſeen but through a piece of black gauze, which forms a kind of veil or curtain before the altar. The reſt of the pagod conſiſts of ſeveral large chambers, exceedingly neat, but badly diſpoſed; the gardens and pleaſure grounds are on the declivity of the mountain; and a number of delightful grottos are cut out in the rock, which afford an agreeable ſhelter from the exceſſive heat of the ſun.

There are ſeveral other pagods in the iſle of Emouy; among which is one called *The Pagod of the Ten Thouſand Stones*, becauſe it is built on the brow of a mountain where there is a like number of little rocks, under which the bonzes have formed grottos and very pleaſant covered ſeats. A certain rural ſimplicity reigns here, which captivates and delights.

Strangers are received by theſe bonzes with great politeneſs, and may freely enter their temples; but they muſt not attempt to gratify their curioſity fully, nor to enter thoſe apartments into which they are not introduced, eſpecially if they are accompanied by ſuſpicious perſons; for the bonzes, who are forbid under pain of ſevere puniſhment to have any intercourſe with women, and who often keep them in private, might, from fear of being diſcovered, revenge themſelves for too impertinent a curioſity.

EMPALEMENT, an ancient kind of puniſhment, which conſiſted in thruſting a ſtake up the fundament. The word comes from the French *empaler*, or the Italian *impalare*; or rather, they are all alike derived from the Latin *palus* "a ſtake," and the prepoſition *in*, "in or into." We find mention of empaling in Juvenal. It was frequently practiſed in the time of Nero, and continues to be ſo in Turkey.

*Empalement of a Flower*, the ſame with Calyx.

EMPANELLING. See Impanelling.

EMPARLANCE. See Imparlance.

EMPEDOCLES, a celebrated philoſopher and poet, was born at Agrigentum, a city in Sicily. He followed the Pythagorean philoſophy, and admitted the metemſychoſis. He conſtantly appeared with a crown of gold on his head; to maintain, by this outward pomp, the reputation he had acquired of being a very extraordinary man. Yet Ariſtotle ſays, that he was a great lover of liberty, extremely averſe to ſtate and command, and that he even refuſed a kingdom that was offered him. His principal work was a Treatiſe in verſe on the Nature and Principles of Things. Ariſtotle, Lucretius, and all the ancients, make the moſt magnificent elogiums on his poetry and eloquence.

He taught rhetoric; and often alleviated the anxieties of his mind, as well as the pains of his body, with muſic. It is reported, that his curioſity to viſit the flames of the crater of Ætna proved fatal to him. Some maintain that he wiſhed it to be believed that he was a god; and that his death might be unknown, he threw himſelf into the crater and periſhed in the flames. His expectations, however, were fruſtrated; and the volcano by throwing up one of his ſandals diſcovered to the world that Empedocles had periſhed by fire. Others report that he lived to an extreme old age; and that he was drowned in the ſea about 440 years before the Chriſtian era.

EMPEROR *(imperator)*, among the ancient Romans, ſignified a general of an army, who, for ſome extraordinary ſucceſs, had been complimented with this appellation. Thus Auguſtus, having obtained no leſs than twenty famous victories, was as often ſaluted with the title *emperor*; and Titus was denominated *emperor* by his army after the reduction of Jeruſalem.

Afterwards, it came to denominate an abſolute monarch or ſupreme commander of an empire. In this ſenſe Julius Cæſar was called *emperor*: the ſame title deſcended with the dignity to Octavius, Auguſtus, Tiberius, and Caligula; and afterwards it became elective.

In ſtrictneſs, the title *emperor* does not, and cannot, add any thing to the rights of ſovereignty: its effect is only to give precedence and pre-eminence above other ſovereigns; and as ſuch, it raiſes thoſe inveſted with it to the ſummit of all human greatneſs.

It is diſputed, whether or not emperors have the power of diſpoſing of the regal title. It is true, they have ſometimes taken upon them to erect kingdoms; and thus it is that Bohemia and Poland are ſaid to have been raiſed to the dignity: thus alſo, the emperor Charles the Bald, in the year 877, gave Provence to Boſon, putting the diadem on his head, and decreeing him to be called "king," *ut more priſcorum imperatorum regibus videretur dominari.* Add, that the emperor Leopold erected the ducal Pruſſia into a kingdom in favour of the elector of Brandenburg; and though ſeveral of the kings of Europe refuſed for ſome time to acknowledge him in that capacity, yet by the treaty of Utrecht in 1712 they all came in.

In the Eaſt, the title and quality of emperor are more frequent than they are among us; thus, the ſovereign princes of China, Japan, Mogul, Perſia, &c. are all emperors of China, Japan, &c. In the year 1723, the czar of Muſcovy aſſumed the title of *emperor of all Ruſſia*, and procured himſelf to be recognized as ſuch by moſt of the princes and ſtates of Europe.

In the Weſt, the title has been a long time reſtrained to the emperors of Germany. The firſt who bore it was Charlemagne, who had the title of emperor conferred on him by Pope Leo III. though he had all the power before. The imperial prerogatives were formerly much more extenſive than they are at preſent. At the cloſe of the Saxon race, A. D. 1024, they exerciſed the right of conferring all the eccleſiaſtical benefices in Germany; of receiving the revenues of them during a vacancy; of ſucceeding to the effects of inteſtate eccleſiaſtics; of confirming or annulling the elections of the popes; of aſſembling councils, and of appointing them to decide concerning the affairs of the church; of conferring the title of king on their vaſſals; of granting vacant fiefs; of receiving the revenues of the empire; of governing Italy as its proper ſovereigns; of erecting free cities, and eſtabliſhing fairs in them; of aſſembling the diets of the empire, and fixing the time of their duration; of coining money, and conferring the ſame privilege on the ſtates of the empire; and of adminiſtering both high and low juſtice within the territories of the different ſtates: but in the year 1437, they were reduced to the right of conferring all dignities and titles, except the privilege of being a ſtate of the empire; of *preces primariæ*, or of appointing once during their reign a dignitary in each chapter or religious houſe; of granting diſpenſations with reſpect to the age of majority; of erecting cities, and conferring the privilege of coining money; of calling the meetings of the diet, and preſiding in them.

To which ſome have added, 1. That all the princes and ſtates of Germany are obliged to do them homage, and ſwear fidelity to them. 2. That they, or their generals, have a right to command the forces of all the princes of the empire, when united together. 3. That they receive a kind of tribute from all the princes and ſtates of the empire, for carrying on a war which concerns the whole empire, which is called the *Roman month*. For the reſt, there is not a foot of land or territory annexed to his title: but ever ſince the reign of Charles IV. the emperors have depended entirely on their hereditary dominions as the only ſource of their power, and even of their ſubſiſtence. See Diet and Electors.

The kings of France were anciently alſo called emperors, at the time when they reigned with their ſons, whom they aſſociated to the crown. Thus Hugh Capet, having aſſociated his ſon Robert, took the title of emperor, and Robert that of king; under which titles they are mentioned in the Hiſtory of the Council of Rheims, by Gerbert, &c. King Robert is alſo called emperor of the French by Helgau of Fleury. Louis le Gros, upon aſſociating his ſon, did the ſame. In the Firſt Regiſter of the King's Charters, fol. 166, are found letters of Louis le Gros, dated in 1116, in favour of Raymond biſhop of Maguelonne, wherein he ſtyles himſelf, *Ludovicus, Dei ordinante providentia,*

*Fran-*

*Francorum imperator auguſtus.* The kings of England had likewiſe anciently the title of emperors, as appears from a charter of king Edgar: *Ego Edgarus Anglorum baſileus, omniumque regum inſularum oceani quæ Britanniam circumjacent, &c. imperator & dominus.*

EMPETRUM, BERRY-BEARING HEATH: A genus of the triandria order, belonging to the monœcia claſs of plants. In the natural method this genus is ranked by Linnæus under the 54th order, *Miſcellaneæ;* and likewiſe among thoſe of which the order is doubtful. The male calyx is tripartite; the corolla tripetalous; the ſtamina long; the female calyx is tripartite; the corolla tripetalous; the ſtyles nine; the berry nine-ſeeded. There are two ſpecies; one of which, viz. the nigrum, which bears the crow-crake berries, is a native of Britain. It grows wild on boggy heaths and mountains. Children ſometimes eat the berries; but, when taken in too great quantity, they are apt to occaſion a headach. Grouſe feed upon them. When boiled with alum, they afford a dark purple dye. Goats are not fond of it. Cows, ſheep, and horſes refuſe it.

EMPHASIS, in rhetoric, a particular ſtreſs of the voice and action, laid on ſuch parts or words of the oration as the orator wants to inforce upon his audience. See DECLAMATION; ORATORY, Part IV.; and READING.

EMPHYSEMA, in ſurgery, a windy tumor, generally occaſioned by a fracture of the ribs, and formed by the air inſinuating itſelf, by a ſmall wound, between the ſkin and muſcles, into the ſubſtance of the cellular or adipoſe membrane, ſpreading itſelf afterwards up to the neck, head, belly, and other parts, much after the manner in which butchers blow up their veal.

EMPIRE *(imperium)*, in political geography, a large extent of land, under the juriſdiction or government of an emperor. See EMPEROR.

In ancient hiſtory we read of four great monarchies or empires, viz. that of the Babylonians, Chaldeans, and Aſſyrians; that of the Medes and Perſians; that of the Greeks; and that of the Romans. The firſt ſubſiſted from the time of Nimrod, who founded it in the year of the world 1800, according to the computation of Uſher, to Sardanapalus their laſt king in 3257, and conſequently laſted above 1450 years. The empire of the Medes commenced under Arbace, in the year of the world 3257, and was united to that of the Babylonians and Perſians under Cyrus, in the 3468, and it cloſed with the death of Darius Codomannus in 3674. The Grecian empire laſted only during the reign of Alexander the Great, beginning in the year of the world 3674, and terminating with the death of this conqueror in 3681, his conqueſts being divided among his captains. The Roman empire commenced with Julius Cæſar, when he was made perpetual dictator, in the year of the city 708, and of the world 3956, 48 years after Chriſt. The ſeat of the empire was removed to Byzantium by Conſtantine, in the year of our Lord 334; the eaſt and weſt were then united under the title of the Roman empire, till the Romans proclaimed Charlemagne emperor, A. D. 800. From this epocha the eaſt and weſt formed two ſeparate empires; that of the eaſt, governed by Greek emperors, commenced A. D. 802: and being gradually weakened, terminated under Conſtantine Palæologus in 1453. The weſtern empire was afterwards known by the appellation of the empire or German empire.

Antiquaries diſtinguiſh between the medals of the *upper*, and *lower* or *bas, empire.*—The curious only value thoſe of the upper empire, which commences with Cæſar or Auguſtus, and ends in the year of Chriſt 260. The lower empire comprehends near 1200 years, reckoning down to the deſtruction of Conſtantinople in 1453.—They uſually diſtinguiſh two ages, or periods, of the lower empire: the firſt beginning where the upper ends, viz. with Aurelian, and ending with Anaſtaſius, including 200 years; the ſecond beginning with Anaſtaſius, and ending with the Palæologi, which includes 1000 years.

*EMPIRE*, or *The empire*, uſed abſolutely and without any addition, ſignifies the empire of Germany; called alſo, in juridical acts and laws, The holy Roman empire. It had its beginning with the ninth century; Charlemagne being created firſt emperor by Pope Leo III. who put the crown on his head in St Peter's church on Chriſtmas-day in the year 800.

Authors are at a loſs under what form of government to range the empire. Some of them maintain it to be a monarchical ſtate, becauſe all the members thereof are obliged to aſk the inveſtiture of their ſtates of the emperor, and to take an oath of fidelity to him. Others conſider it as a republic, or ariſtocratic ſtate, becauſe the emperor cannot reſolve or determine any thing without the concurring ſuffrages of the princes. It is added, that if they require inveſtiture from, and ſwear fealty to him, it is only as head of the republic, and in the name of the republic, and not in his own; juſt as at Venice every thing is tranſacted in name of the doge. Others will have the empire to be a monarcho-ariſtocratic ſtate, *i. e.* a mixture of monarchy and ariſtocracy; becauſe, though the emperor in many caſes ſeems to act ſovereignly, yet his decrees and reſolves have no force, in caſe the ſtate refuſe to confirm them. Laſtly, it has been called an ariſto-democratic ſtate, becauſe the diet, wherein the ſovereignty is lodged, is compoſed of princes and the deputies of the cities; and is divided into three orders or bodies, called *colleges*, viz. the college of electors, the college of princes, and the college of cities.

We ſay, diet of the empire, circles of the empire, fiefs of the empire, princes of the empire, eſtates of the empire, members of the empire, capitulations of the empire. See DIET, CIRCLE, PRINCE, CAPITULATION, &c.

The ſtates or eſtates of the empire are of two kinds, mediate and immediate. The immediate ſtates are thoſe who hold immediately of the empire: Whereof, again, there are two kinds; the firſt, ſuch as have ſeats and voices in the imperial diet; the ſecond, ſuch as have none. The mediate ſtates are thoſe who hold of the immediate.

The ſtates which now compoſe the empire are, The princes of the empire, the counts of the empire, the free barons of the empire, the prelates of the empire, the princeſſes or abbeſſes of the empire, the nobles of the empire, and the imperial cities.

EMPIRIC, an appellation given to thoſe phyſicians who conduct themſelves wholly by their own experience, without ſtudying phyſic in a regular way.

Some even uſe the term, in a ſtill worſe ſenſe, for a quack who preſcribes at random, without being at all acquainted with the principles of the art.

EMPIS, in zoology, a genus of inſects belonging to the order Diptera; of which the characters are theſe: The proboſcis is of an horny ſubſtance, bivalve, reflexed under the head and breaſt, and longer than the thorax. See a ſpecimen on Plate CLXXXII.

EMPLASTER. See PLASTER.

EMPORIÆ, a double city of the Hither Spain, near the Pyrenees; ſeparated by a wall; one part occupied by the Greeks of Phocæa, whence originally are the Maſſilienſes; the other, by native Spaniards, to whom was added by Auguſtus a Roman colony. Now Ampurias, in Catalonia. E. Long. 2. 50. N. Lat. 42. 15.

EMPORIUM, in medicine, is often uſed for the common ſenſory in the brain. See BRAIN.

EMPORIUM, (anc. geog.), two cities near Placentia; one well fortified, and guarded by a ſtrong garriſon, at which Hannibal met a repulſe: the other, Hannibal took and plundered. Now thought to be Ponte Nura, in the duchy of Placentia.

EMPRESS, the ſpouſe of an emperor, or a woman who governs an empire. See EMPEROR.

EMPROSTHOTONOS, a ſpecies of convulſion, wherein the head bends forward.

EMPYÆMA, in medicine, a diſorder wherein purulent matter is contained in the thorax or breaſt, after an inflammation and ſuppuration of the lungs and pleura. See MEDICINE-*Index*.

EMPYREAL AIR. So Dr Higgens denominates that which Dr Prieſtley calls *dephlogiſticated* air, and other philoſophers *vital* or *pure* air.

EMPYREUM, a term uſed by divines for the higheſt heaven, where the bleſſed enjoy the beatific viſion. The word is formed of εν and πυρ *fire*, becauſe of its ſplendor.

EMPYREUMA, in chemiſtry, ſignifies a very diſagreeable ſmell produced from burnt oils. It is often perceived in diſtillations of animal as well as vegetable ſubſtances when they are expoſed to a quick fire.

EMRODS. See HEMORRHOIDS.

EMULATION, a generous ardor kindled by the praiſe-worthy examples of others, which impels us to imitate, to rival, and, if poſſible, to excel them. This paſſion involves in it eſteem of the perſon whoſe attainments or conduct we emulate, of the qualities and actions in which we emulate him, and a deſire of reſemblance, together with a joy ſpringing from the hope of ſucceſs. The word comes originally from the Greek αμιλλα, *diſpute, conteſt*; whence the Latin, *æmulus*, and thence our *emulation*.

Plato obſerves of emulation, that it is the daughter of envy; if ſo, there is a great difference between the mother and the offſpring; the one is a virtue and the other a vice. Emulation admires great actions, and ſtrives to imitate them; envy refuſes them the praiſes that are their due; emulation is generous, and only thinks of ſurpaſſing a rival; envy is low, and only ſeeks to leſſen him. Perhaps, therefore, it would be more juſt to ſuppoſe emulation the daughter of admiration: admiration, however, is a principal ingredient in the compoſition of it.

EMULGENT, or RENAL, ARTERIES, thoſe which ſupply the kidneys with blood; being ſometimes ſingle, ſometimes double, on each ſide. See ANATOMY, nº 23.

EMULSION, a ſoft liquid remedy, of a colour and conſiſtence reſembling milk. See PHARMACY.

EMUNCTORY, in anatomy, a general term for all thoſe parts which ſerve to carry off the excrementitious parts of the blood and other humours of the body. Such more eſpecially are the kidneys, bladder, and moſt of the glands.

ENALLAGE, in grammar, is when one word is ſubſtituted for another of the ſame part of ſpeech: A ſubſtantive for an adjective; as *exercitus victor*, for *victorioſus*; *ſcelus*, for *ſceleſtus*: A primitive for a derivative; as *Dardana arma*, for *Dardania*: An active for a paſſive; as *nox humida cœlo præcipitat*, for *precipitatur*, &c.

ENAMEL, in general, is a vitrified matter betwixt the parts of which is diſperſed ſome unvitrified matter: hence enamel ought to have all the properties of glaſs except tranſparency.

Enamels have for their baſis a pure cryſtal glaſs or frit, ground up with a fine calx of lead and tin prepared for the purpoſe, with the addition uſually of white ſalt of tartar. Theſe ingredients baked together are the matter of all enamels, which are made by adding colours of this or that kind in powder to this matter, and melting or incorporating them together in a furnace.

For white enamel, Neri *(De Arte Vitriar.)* directs only mangane ſe to be added to the matter which conſtitutes the baſis. For azure, zaffer mixed with calx of braſs. For green, calx of braſs with ſcales of iron, or with crocus martis. For black, zaffer with mangane ſe or with crocus martis; or mangane ſe with tartar. For red, mangane ſe, or calx of copper and red tartar. For purple, mangane ſe with calx of braſs. For yellow, tartar and mangane ſe. And for violet-coloured enamel, mangane ſe with thrice-calcined braſs.

In making theſe enamels, the following general cautions are neceſſary to be obſerved. 1. That the pots muſt be glazed with white glaſs, and muſt be ſuch as will bear the fire. 2. That the matter of enamels muſt be very nicely mixed with the colours. 3. When the enamel is good, and the colour well incorporated, it muſt be taken from the fire with a pair of tongs. 4. The general way of making the coloured enamel is this: Powder, ſift, and grind, all the colours very nicely, and firſt mix them with one another, and then with the common matter of enamels: then ſet them in pots in a furnace; and when they are well mixed and incorporated, caſt them into water; and when dry, ſet them in a furnace again to melt; and when melted, take a proof of it. If too deep-coloured, add more of the common matter of enamels; and if too pale, add more of the colours.

Enamels are uſed either in counterfeiting or imitating precious ſtones, in painting in enamel; or by enamellers, jewellers, and goldſmiths, in gold, ſilver, and other metals. The two firſt kinds are uſually prepared by the workmen themſelves, who are employed in theſe arts. That uſed by jewellers, &c. is brought to us chiefly from Venice or Holland, in little cakes of different ſizes, commonly about four inches diameter, having the mark of the maker ſtuck upon it with a puncheon. It pays 1 s. $7\frac{41}{100}$d. the pound on importation,

tation, and draws back 1 s. $5\frac{70}{100}$d. at the rate of 4 s. per pound.

ENAMELLING, the art of laying enamel upon metals, as gold, ſilver, copper, &c. and of melting it at the fire, or of making divers curious works in it at a lamp. It ſignifies alſo to paint in enamel.

*The method of painting in* ENAMEL. This is performed on plates of gold or ſilver, and moſt commonly of copper, enamelled with the white enamel; whereon they paint with colours which are melted in the fire, where they take a brightneſs and luſtre like that of glaſs. This painting is the moſt prized of all for its peculiar brightneſs and vivacity, which is very permanent, the force of its colours not being effaced or ſullied with time as in other painting, and continuing always as freſh as when it came out of the workmens hands. It is uſual in miniature; it being the more difficult the larger it is, by reaſon of certain accidents it is liable to in the operation. Enamelling ſhould only be practiſed on plates of gold, the other metals being leſs pure: copper, for inſtance, ſcales with the application, and yields fumes; and ſilver turns the yellow white. Nor muſt the plate be made flat; for in ſuch caſe, the enamel cracks; to avoid which, they uſually forge them a little round or oval, and not too thick. The plate being well and evenly forged, they uſually begin the operation by laying on a couch of white enamel (as we obſerved above) on both ſides, which prevents the metal from ſwelling and bliſtering; and this firſt layer ſerves for the ground of all the other colours. The plate being thus prepared, they begin at firſt by drawing out exactly the ſubject to be painted with red vitriol, mixed with oil of ſpike, marking all parts of the deſign very lightly with a ſmall pencil. After this, the colours (which are to be before ground with water in a mortar of agate extremely fine, and mixed with oil of ſpike ſomewhat thick) are to be laid on, obſerving the mixtures and colours that agree to the different parts of the ſubject; for which it is neceſſary to underſtand painting in miniature. But here the workman muſt be very cautious of the good or bad qualities of the oil of ſpike he employs to mix his colours with, for it is very ſubject to adulterations.

Great care muſt likewiſe be taken, that the leaſt duſt imaginable come not to your colours while you are either painting or grinding them; for the leaſt ſpeck, when it is worked up with it, and when the work comes to be put into the reverberatory to be red hot, will leave a hole, and ſo deface the work.

When the colours are all laid, the painting muſt be gently dried over a ſlow fire to evaporate the oil, and the colours afterwards melted to incorporate them with the enamel, making the plate red-hot in a fire like what the enamellers uſe. Afterwards that part of the painting muſt be paſſed over again which the fire hath any thing effaced, ſtrengthening the ſhades and colours, and committing it again to the fire, obſerving the ſame method as before, which is to be repeated till the work be finiſhed.

*Method of* ENAMELLING *by the Lamp.* Moſt enamelled works are wrought at the fire of a lamp, in which, inſtead of oil, they put melted horſe-greaſe, which they call *caballine oil.* The lamp, which is of copper, or white iron, conſiſts of two pieces; in one of which is a kind of oval plate, ſix inches long, and two high, in which they put the oil and the cotton. The other part, called the *box*, in which the lamp is incloſed, ſerves only to receive the oil which boils over by the force of the fire. This lamp, or, where ſeveral artiſts work together, two or three more lamps are placed on a table of proper height. Under the table, about the middle of its height, is a double pair of organ-bellows, which one of the workmen moves up and down with his foot to quicken the flame of the lamps, which are by this means excited to an incredible degree of vehemence. Grooves made with a gauge in the upper part of the table, and covered with parchment, convey the wind of the bellows to a pipe of glaſs before each lamp; and that the enamellers may not be incommoded with the heat of the lamp, every pipe is covered at ſix inches diſtance with a little tin plate, fixed into the table by a wooden handle. When the works do not require a long blaſt, they only uſe a glaſs-pipe, into which they blow with their mouth.

It is incredible to what a degree of fineneſs and delicacy the threads of enamel may be drawn at the lamp. Thoſe which are uſed in making falſe tufts of feathers are ſo fine, that they may be wound on the reel like ſilk or thread. The fictitious jets of all colours, uſed in embroideries, are alſo made of enamel; and that with ſo much art, that every ſmall piece hath its hole to paſs the thread through wherewith it is ſewed. Theſe holes are made by blowing them into long pieces; which they afterwards cut with a proper tool.

It is ſeldom that the Venetian or Dutch enamels are uſed alone: they commonly melt them in an iron-ladle, with an equal part of glaſs or cryſtal; and when the two matters are in perfect fuſion, they draw it out into threads of different ſizes, according to the nature of the work. They take it out of the ladle while liquid, with two pieces of broken tobacco-pipes, which they extend from each other at arm's length. If the thread is required ſtill longer, then another workman holds one end, and continues to draw it out, while the firſt holds the enamel to the flame. Thoſe threads, when cold, are cut into what lengths the workman thinks fit, but commonly from 10 to 12 inches; and as they are all round, if they are required to be flat, they muſt be drawn through a pair of pinchers while yet hot. They have alſo another iron inſtrument in form of pinchers, to draw out the enamel by the lamp when it is to be worked and diſpoſed in figures. Laſtly, they have glaſs-tubes of various ſizes, ſerving to blow the enamel into various figures, and preſerve the neceſſary vacancies therein; as alſo to ſpare the ſtuff, and form the contours. When the enameller is at work, he ſits before the lamp with his foot on the ſtep that moves on the bellows; and holding in his left hand the work to be enamelled, or the braſs or iron-wires the figures are to be formed on, he directs with his right the enamel thread, which he holds to the flame with a management and patience equally ſurpriſing. There are few things they cannot make or repreſent with enamel; and ſome figures are as well finiſhed, as if done by the moſt ſkilful carvers.

ENARTHROSIS, in anatomy, a ſpecies of DIARTHROSIS.

ENCÆNIA, the name of three ſeveral feaſts celebrated by the Jews in memory of the dedication, or rather purification, of the temple, by Judas Maccabæus, Solomon, and Zorobabel. This term is likewiſe uſed in church-hiſtory for the dedication of Chriſtian churches.

ENCAMPMENT, the pitching of a CAMP.

ENCANTHIS, in ſurgery, a tubercle ariſing either from the caruncula lachrymalis, or from the adjacent red ſkin; ſometimes ſo large, as to obſtruct not only the puncta lachrymalia, but alſo part of the ſight or pupil itſelf. See SURGERY.

ENCAUSTIC and ENCAUSTUM, the ſame with enamelling and enamel. See ENAMELLING and ENAMEL.

*Encaustic Painting*, a method of painting made uſe of by the ancients, in which wax was employed to give a gloſs to their colours, and to preſerve them from the injuries of the air.

This ancient art, after having been long loſt, was reſtored by Count Caylus, a member of the Academy of Inſcriptions in France; and the method of painting in wax was announced to the Academy of Painting and Belles Lettres in the year 1753; though M. Bachelier, the author of a treatiſe *De l'Hiſtoire & du Secret de la Peinture en Cire*, had actually painted a picture in wax in 1749; and he was the firſt who communicated to the public the method of performing the operation of inuſtion, which is the principal characteriſtic of the encauſtic painting. The Count kept his method a ſecret for ſome time, contenting himſelf with exhibiting a picture at the Louvre in 1754, repreſenting the head of Minerva, painted in the manner of the ancients, which excited the curioſity of the public, and was very much admired. In the interval of ſuſpence, ſeveral attempts were made to recover the ancient method of painting. The firſt ſcheme adopted was that of melting wax and oil of turpentine together, and uſing this compoſition as a vehicle for mixing and laying on the colours. But this method did not explain Pliny's meaning, as the wax is not burnt in this way of managing it. In another attempt, which was much more agreeable to the hiſtorian's deſcription of encauſtic painting, the wax was melted with ſtrong lixivium of ſalt of tartar, and with this the colours were ground. When the picture was finiſhed, it was gradually preſented to the fire, ſo as to melt the wax; which was thus diffuſed through all the particles of the colours, ſo that they were fixed to the ground, and ſecured from the acceſs of air or moiſture. But the method of count Caylus is much more ſimple: the cloth or wood, which he deſigned for the baſis of his picture, is waxed over, by only rubbing it ſimply with a piece of bees-wax; the wood or cloth, ſtretched on a frame, being held horizontally over, or perpendicularly before a fire, at ſuch a diſtance, that the wax might gradually melt, whilſt it is rubbed on, diffuſe itſelf, penetrate the body, and fill the interſtices of the texture of the cloth, which, when cool, is fit to paint upon; but as water-colours, or thoſe that are mixed up with common water, will not adhere to the wax, the whole picture is to be firſt rubbed over with Spaniſh chalk or white, and then the colours are applied to it; when the picture is dry, it is put near the fire, whereby the wax melts, and abſorbs all the colours.

Mr J. H. Muntz, in a treatiſe on this ſubject, has propoſed ſeveral improvements in the art of encauſtic painting. When the painting is on cloth, he directs it to be prepared by ſtretching it on a frame, and rubbing one ſide ſeveral times over with a piece of bees-wax, or virgin wax, till it is covered with a coat of wax of conſiderable thickneſs. In fine linen, this is the only operation neceſſary previous to painting; but coarſe cloth muſt be rubbed gently on the unwaxed ſide with a pumice ſtone, to take of all thoſe knots which would prevent the free and accurate working of the pencil. Then the ſubject is to be painted on the unwaxed ſide with colours prepared and tempered with water; and when the picture is finiſhed, it muſt be brought near the fire, that the wax may melt and fix the colours. This method, however, can only be applied to cloth or paper, through the ſubſtance of which the wax may paſs; but in wood, ſtone, metals, or plaſter, the former method of Count Caylus muſt be obſerved.

Mr Muntz has alſo diſcovered a method of forming grounds for painting with crayons, and fixing theſe, as well as water-colours, employed with the pencil. On the unwaxed ſide of a linen cloth, ſtretched and waxed as before, lay an even and thick coat of the colour proper for the ground; having prepared this colour by mixing ſome proper pigment with an equal quantity of chalk, and tempering them with water. When the colour is dry, bring the picture to the fire that the wax may melt, paſs through the cloth, and fix the ground. An additional quantity of wax may be applied to the back of the picture, if that which was firſt rubbed on ſhould not be ſufficient for the body of colour; but as this muſt be laid on without heat, the wax ſhould be diſſolved in oil of turpentine, and applied with a bruſh, and the canvas be again expoſed to the fire, that the freſh ſupply of wax may paſs through the cloth, and be abſorbed by the colour; and thus a firm and good body will be formed for working on with the crayons. If cloth and paper are joined together, the cloth muſt be firſt fixed to the ſtraining frame, and then the paper muſt be paſted to it with a compoſition of paſte made with wheaten flour, or ſtarch and water, and about a twelfth part of its weight of common turpentine. The turpentine muſt be added to the paſte when it is almoſt ſufficiently boiled, and the compoſition well ſtirred, and left to ſimmer over the fire for five or ſix minutes; let wax be diſſolved in oil of turpentine to the conſiſtence of a thin paſte; and when the cloth and paper are dry, let them be held near a fire; and with a bruſh lay a coat of the wax and turpentine on both ſides the joined cloth and paper, in ſuch a degree of thickneſs, that both ſurfaces may ſhine throughout without any appearance of dull ſpots. Then expoſe the cloth to the fire or to the ſun; by which means the oil will evaporate, and the wax become ſolid, and be fit to receive any compoſition of colour for a ground, which is to be laid on as above directed in the caſe of cloth without paper.

Almoſt all the colours that are uſed in oil-painting may be alſo applied in the encauſtic method. Mr Muntz objects, indeed, to brown, light pink, and unburnt *terra di Sienna;* becauſe theſe, on account of their gummy or ſtony texture, will not admit ſuch a coheſion with the wax as will properly fix them; but other colours which cannot be admitted in oil-painting, as red lead, red orpiment, cryſtals of verdegris, and red precipitate of mercury, may be uſed here. The crayons uſed in encauſtic painting are the ſame with thoſe uſed in the common way of crayon painting, excepting thoſe that in their compoſition are too tenacious; and the method of uſing them is the ſame in both caſes.

The encauſtic painting has many peculiar advantages: though the colours have not the natural varniſh or ſhining which they acquire with oil, they have all the ſtrength of paintings in oil, and all the airineſs of water-colours, without partaking of the apparent character or defects of either; they may be looked at in any light and in any ſituation, without any falſe glare: the colours are firm, and will bear waſhing; and a picture, after having been ſmoaked, and then expoſed to the dew, becomes as clean as if it had been but juſt painted. It may alſo be retouched at pleaſure without any detriment to the colours; for the new colours will unite with the old ones, without ſpots, as is the caſe in common ſize painting; nor is it neceſſary to rub the places to be retouched with oil as in oil pictures; it is not liable to crack, and eaſily repaired, if it ſhould chance to ſuffer any injury. The duration of this painting is alſo a very material advantage; the colours are not liable to fade and change; no damp can affect them, nor any corroſive ſubſtance injure them; nor can the colour fall off in ſhivers from the canvas. However, notwithſtanding all theſe and other advantages enumerated by the abbe Mazeas and Mr Muntz, this art has not yet been much practiſed. Many of theſe properties belong to a much higher ſpecies of encauſtic painting afterwards diſcovered in England, the colours of which are fixed by a very intenſe heat; nor are the colours or grounds on which they are laid liable to be diſſolved or corroded by any chemical menſtruum, nor, like the glaſſy colours of enamel, to run out of the drawing on the fire. What this method conſiſts in will appear from the following account communicated in a letter from Mr Joſiah Colebrooke to the earl of Macclesfield preſident of the Royal Society in 1759.

"The art of painting with burnt wax (ſays he) has long been loſt to the world. The uſe of it to painters in the infancy of the art of painting, was of the utmoſt conſequence. Drying oil being unknown, they had nothing to preſerve their colours entire from the injury of damps and the heat of the ſun: a varniſh of ſome ſort was therefore neceſſary; but they being unacquainted with diſtilled ſpirits, could not, as we now do, diſſolve gums to make a tranſparent coat for their pictures: this invention therefore of burnt wax ſupplied that defect to them; and with this manner of painting, the chambers and other rooms in their houſes were furniſhed: this Pliny calls *encauſtum*, and we *encauſtic painting*.

"The following experiments which I have the honour to lay before your Lordſhip and the Society, were occaſioned by the extract of a letter from the abbe Mazeas, tranſlated by Dr Parſons, and publiſhed in the ſecond part of the XLIXth volume of the Philoſophical Tranſactions, n° 100. concerning the ancient method of painting with burnt wax, revived by count Caylus.

"The count's method was, 1. To rub the cloth or board deſigned for the picture ſimply over with bees-wax. 2. To lay on the colours mixed with common water; but as the colours will not adhere to the wax, the whole picture was firſt rubbed over with (A) Spaniſh chalk, and then the colours are uſed. 3. When the picture is dry, it is put near the fire, whereby the wax melts, and abſorbs all the colours.

"Exp. I. A piece of oak-board was rubbed over with bees-wax, firſt againſt the grain of the wood, and then with the grain, to fill up all the pores that remained after it had been planed, and afterwards was rubbed over with as much dry Spaniſh white as could be made to ſtick on it. This, on being painted (the colours mixed with water only), ſo clogged the pencil, and mixed ſo unequally with the ground, that it was impoſſible to make even an outline, but what was ſo much thicker in one part than another, that it would not bear ſo much as the name of painting; neither had it any appearance of a picture. However, to purſue the experiment, this was put at a diſtance from the fire, on the hearth, and the wax melted by ſlow degrees: but the Spaniſh white (though laid as ſmooth as ſo ſoft a body would admit, before the colour was laid on), on melting the wax into it, was not ſufficient to hide the grain of the wood, nor ſhow the colours by a proper whiteneſs of the ground; the wax, in rubbing on the board, was unavoidably thicker in ſome parts than in others, and the Spaniſh white the ſame: on this I ſuſpected there muſt be ſome miſtake in the Spaniſh white, and made the inquiry mentioned (in the note A).

"To obviate the inequality of the ground in the firſt experiment;

"Exp. 2. A piece of old wainſcot (oak board) $\frac{1}{4}$th of an inch thick; which, having been part of an old drawer, was not likely to ſhrink on being brought near the fire: this was ſmoothed with a fiſh-ſkin, made quite warm before the fire; and then, with a bruſh dipped in white wax, melted in an earthen pipkin, ſmeared all over, and applied to the fire again, that the wax might be equally thick on all parts of the board, a ground was laid (on the waxed board), with levigated chalk mixed with gum-water, (*viz.* gum Arabic diſſolved in water): when it was dry, I painted it with a kind of landſcape; and purſuing the method laid down by count Caylus, brought it gradually to the fire. I fixed the picture on a fire-ſcreen, which would preſerve the heat, and communicate it to the back part of the board. This was placed firſt at the diſtance of three feet from the fire, and brought forwards by ſlow degrees, till it came

---

(A) "Spaniſh chalk is called by Dr Parſons, in a note, *Spaniſh white* This is a better kind of whitening than the common, and was the only white that had the name of *Spaniſh* annexed to it that I could procure, though I inquired for it at moſt if not all the colour-ſhops in town.

"My friend M. da Coſta ſhowed me a piece of Spaniſh chalk in his collection, which ſeemed more like a CIMOLIA (tobacco-pipe clay), and was the reaſon of my uſing that in one of the experiments.

within one foot of the fire, which made the wax ſwell and bloat up the picture; but as the chalk did not abſorb the wax, the picture fell from the board and left it quite bare.

“ Exp. 3. I mixed three parts white wax, and one part white reſin, hoping the tenacity of the reſin might preſerve the picture. This was laid on a board heated with a bruſh, as in the former; and the ground was chalk, prepared as before. This was placed horizontally on an iron box, charged with an hot heater, ſhifting it from time to time, that the wax and reſin might penetrate the chalk; and hoping from this poſition, that the ground, bloated by melting the wax, would ſubſide into its proper place; but this, like the other, came from the board, and would not at all adhere.

“ Exp. 4. Prepared chalk four drams, white wax, white reſin, of each a dram, burnt alabaſter half a dram, were all powdered together and ſifted, mixed with ſpirit of molaſſes inſtead of water, and put for a ground on a board ſmeared with wax and reſin, as in Exp. 3. This was alſo placed horizontally on a box-iron as the former: the picture bliſtered, and was cracked all over: and though removed from the box-iron to an oven moderately heated (in the ſame horizontal poſition), it would not ſubſide, nor become ſmooth When it was cold, I took an iron ſpatula made warm, and moved it gently over the ſurface of the picture, as if I were to ſpread a plaſter. (This thought occurred. from the board being prepared with wax and reſin, and the ground having the ſame materials in its compoſition, the force of the ſpatula might make them unite). This ſucceeded ſo well, as to reduce the ſurface to a tolerable degree of ſmoothneſs; but as the ground was broke off in many places, I repaired it with flake white, mixed up with the yolk of an egg and milk, and repainted it with molaſſes ſpirit (inſtead of water), and then put it into an oven with a moderate degree of heat. In this I found the colours fixed, but darker than when it was at firſt painted: and it would bear being waſhed with water, not rubbed with a wet cloth.

“ Exp. 5. A board (that had been uſed in a former experiment) was ſmeared with wax and reſin, of each equal parts; was wetted with molaſſes ſpirit, to make whitening (or Spaniſh white) mixed with gum-water adhere. This, when dry, was ſcraped with a knife, to make it equally thick in all places. It was put into a warm oven, to make the varniſh incorporate partly with the whitening before it was painted; and it had only a ſmall degree of heat: water only was uſed to mix the colours. This was again put into an oven with a greater degree of heat; but it flaked off from the board: whether it might be owing to the board's having had a ſecond coat of varniſh (the firſt having been ſcraped and melted off), and that the unctuous parts of the wax had ſo entered its pores, that it would not retain a ſecond varniſh, I cannot tell.

“ Exp. 6. Having miſcarried in theſe trials, I took a new board, planed ſmooth, but not poliſhed either with a fiſh-ſkin or ruſhes: I warmed it, and ſmeared it with wax only; then took *cimolia* (tobacco-pipe clay) diveſted of its ſand, by being diſſolved in water and poured off, leaving the coarſe heavy parts behind. After this was dried and powdered, I mixed it with a ſmall quantity of the yolk of an egg and cow's milk, and made a ground with this on the waxed board: this I was induced to try, by knowing that the yolk of an egg will diſſolve almoſt all unctuous ſubſtances, and make them incorporate with water; and I apprehended, that a ground, thus prepared, would adhere ſo much the more firmly to the board than the former had done, as to prevent its flaking off. The milk, I thought, might anſwer two purpoſes; firſt, by uniting the ground with the wax; and ſecondly, by anſwering the end of ſize or gum-water, and prevent the colours from ſinking too deep into the ground, or running one into another. When the ground was near dry, I ſmoothed it with a pallet knife, and waſhed with milk and egg where I had occaſion to make it ſmooth and even: when dry I painted it, mixing the colours with common water; this, on being placed horizontally in an oven only warm enough to melt the wax, flaked from the board; but held ſo much better together than any of the former, that I paſted part of it on paper.

“ Exp. 7. Flake-white (or the pureſt ſort of white-lead) mixed with egg and milk, crumbled to pieces in the oven, put on the waxed board, as in the laſt experiment.

“ The bad ſucceſs which had attended all the former experiments, led me to conſider of what uſe the wax was in this kind of painting: and it occurred to me, that it was only as a varniſh to preſerve the colours from fading.

“ In order to try this:

“ Exp. 8. I took what the brick-layers call *fine ſtuff*, or *putty* (B): to this I added a ſmall quantity of burnt alabaſter, to make it dry: this it ſoon did in the open air; but before I put on any colours, I dried it gently by the fire, leſt the colours ſhould run. When it was painted, I warmed it gradually by the fire (to prevent the ground from cracking) till it was very hot. I then took white wax three parts, white reſin one part, melted them in an earthen pipkin, and with a bruſh ſpread them all over the painted board, and kept it cloſe to the fire in a perpendicular ſituation, that what wax and reſin the plaſter would not abſorb might drop off. When it was cold, I found the colours were not altered, either from the heat of the fire, or paſſing the bruſh over them. I then rubbed it with a ſoft linen cloth, and thereby procured a kind of gloſs, which I afterwards increaſed by rubbing it with an hard bruſh; which was ſo far from ſcratching or leaving any marks on the picture, that it became more ſmooth and poliſhed by it.

“ After I had made all the foregoing experiments, in converſation with my honoured and learned friend Dr Kidby, a fellow of this ſociety, I ſaid I had been trying to find out what the encauſtic painting of the ancients was Upon which he told me, that there was a paſſage in Vitruvius *de Architectura*, relative to that kind of painting; and was ſo good as to tranſcribe it for me from the 7th book, chap. 9. *De minii temperatura.* Vitruvius's words are: *At ſi quis ſubtilior fuerit, & voluerit expolitionem miniaceam ſuum colorem retinere,*

---

(B) Putty is lime ſlaked, and, while warm, diſſolved in water, and ſtrained through a ſieve.

*retinere, cum paries expolitus & aridus fuerit, tunc ceram Punicam liqueſactam igni, paulo oleo temperatam, ſeta inducat, deinde poſtea carbonibus in ferreo vaſe compoſitis, eam ceram apprime cum pariete, caleſaciendo ſudore cogat, fiatque ut peræquetur, deinde cum candela linteiſque puris ſubigat, uti ſigna marmorea nuda curantur. Hæc autem* καυσις *Græce dicitur. Ita obſtans ceræ Punicæ lorica non patitur, nec lunæ ſplendorem, nec ſolis radios lambendo eripere ex his politionibus colorem.*

" Which I thus tranſlate : ' But if any one is more wary, and would have the poliſhing [painting] with vermilion hold its colour, when the wall is painted and dry, let him take Carthaginian [Barbary] wax, melted with a little oil, and rub it on the wall with an hair-pencil; and afterwards let him put live coals into an iron veſſel [chaffing-diſh], and hold it cloſe to the wax, when the wall, by being heated, begins to ſweat; then let it be made ſmooth : afterwards let him rub it with a (c) candle and (d) clean linen rags, in the ſame manner as they do the naked marble ſtatues. This the Greeks call καυσις. The coat of Carthaginian wax (thus put on) is ſo ſtrong, that it neither ſuffers the moon by night, nor the ſun-beams by day, to deſtroy the colour.'

" Being ſatisfied, from this paſſage in Vitruvius, that the manner of uſing wax in Exp. 8. was right, I was now to find if the wax-varniſh, thus burnt into the picture, would bear waſhing. But here I was a little diſappointed ; for rubbing one corner with a wet linen cloth, ſome of the colour came off; but waſhing it with a ſoft hair-pencil dipped in water, and letting it dry without wiping, the colour ſtood very well.

" A board painted, as in Exp. 8. was hung in the moſt ſmoky part of a chimney for a day, and expoſed to the open air in a very foggy night. In the morning the board was ſeemingly wet through, and the water ran off the picture. This was ſuffered to dry without wiping ; and the picture had not ſuffered at all from the ſmoke or the dew, either in the ground or the colours; but when dry, by rubbing it, firſt with a ſoft cloth, and afterwards with a bruſh, it recovered its former gloſs.

" Suſpecting that ſome tallow might have been mixed with the white wax I had uſed, which might cauſe the colours to come off on being rubbed with a wet cloth, I took yellow wax which had been melted from the honeycomb in a private family, and conſequently not at all adulterated: to three parts of this I added one part reſin, and melted them together.

" Exp. 9. Spaniſh-white, mixed with fiſh-glue, was put for a ground on a board, and painted with water-colours only. The board was made warm ; and then the wax and reſin were put on with a bruſh, and kept cloſe to the fire till the picture had imbibed all the varniſh, and looked dry. When it was cold, I rubbed it firſt with a linen cloth, and then poliſhed it with an hard bruſh.

" In theſe experiments I found great difficulties with regard to colours. Many water-colours being made from the juices of plants, have ſome degree of an acid in them ; and theſe, when painted on an alkaline ground, as chalk, whitening, *cimolia*, and plaſter, are totally changed in their colours, and from green become brown ; which contributes much to make the experiments tedious. I would therefore adviſe the uſe of mineral or metallic colours for this ſort of painting, as moſt likely to preſerve their colour: for although I neutralized Spaniſh white, by fermenting it with vinegar, and afterwards waſhed it very well with water, it did not ſucceed to my wiſh.

" Theſe experiments, and this paſſage from Vitruvius, will in ſome meaſure explain the obſcurity of part of that paſſage in Pliny which Dr Parſons, in his learned comment on the encauſtic painting with wax, ſeems to deſpair of.

" *Ceris pingere*, was one ſpecies of encauſtic painting. Ενκαυστον, *inuſtum*, may be tranſlated, " forced in by the means of fire, burnt in:" for whatever is forced in by the help of fire can be rendered into Latin by no other ſignificant word that I know of but *inuſtum*. If this is allowed me, and I think I have the authority of Vitruvius (a writer in the Auguſtine age) for it, who ſeems to have wrote from his own knowledge, and not like Pliny, who copied from others much more than he knew himſelf, the difficulty with regard to this kind of painting is ſolved, and the encauſtic with burnt wax recovered to the public.

" What he means by the next kind he mentions, *in ebore ceſtro id eſt viriculo*, I will not attempt to explain at preſent.

" The ſhip-painting is more eaſily accounted for: the practice being in part continued to this time ; and is what is corruptly called *breaming*, for brenning or burning.

" This is done by reeds ſet on fire, and held under the ſide of a ſhip till it is quite hot; then reſin, tallow, tar, and brimſtone, melted together, and put on with an hair bruſh while the planks remain hot, make ſuch a kind of paint as Pliny deſcribes : which, he ſays, *nec ſole, nec ſale, ventiſque corrumpitur*. As they were ignorant of the uſe of oil-painting, they mixed that colour with the wax, &c. which they intended for each particular part of the ſhip, and put it on in the manner above deſcribed.

" In the pictures painted for theſe experiments, and now laid before your lordſhip and the ſociety, I hope neither the deſign of the landſcape, nor the execution of it, will be ſo much taken into conſideration as the varniſh (which was the thing wanted in this inquiry): and I think that will evince, that the encauſtic painting

---

(c) The account of the method of poliſhing [painting] walls coloured with vermilion, gave me great ſatisfaction, as it proved the method I had taken in experiment 8. (which I had tried before I ſaw or knew of this paſſage in Vitruvius) was right. The uſe of the candle, as I apprehend, was to melt the wax on the walls where by accident the bruſh had put on too much, or afford wax where the bruſh had not put on enough, or had left any part bare.

(d) The rubbing the wall with a linen cloth, while warm, will do very well, where there is only one colour to be preſerved ; but where there are many, as in a landſcape, it will be apt to take off ſome, or render the colouring rather faint ; which I found by wiping the wax off from a painting while it was hot.

ing with burnt wax is fully reſtored by theſe experiments; and though not a new invention, yet having been loſt for ſo many ages, and now applied further, and to other purpoſes, than it was by Vitruvius (who confined it to vermilion only), may alſo amount to a new diſcovery, the uſe of which may be a means of preſerving many curious drawings to poſterity: for this kind of painting may be on paper, cloth, or any other ſubſtance that will admit a ground to be laid on it. The proceſs is very ſimple, and is not attended with the diſagreeable ſmell unavoidable in oil-painting, nor with ſome inconveniences inſeparable from that art; and as there is no ſubſtance we know more durable than wax, it hath the greateſt probability of being laſting."

Still, however, there ſeem to have been ſome defects or inconveniences attending theſe and other ſubſequent attempts: for we find the ancient or ſome ſimilar method of painting in wax remaining a deſideratum upwards of 25 years after the publication of the preceding experiments; when in 1787 a method was communicated to the Society of Arts by Miſs Greenland, for which ſhe was rewarded with a prize. The ground of her information ſhe received at Florence, through the acquaintance of an amateur of painting, who procured her the ſatiſfaction of ſeeing ſome paintings in the ancient Grecian ſtyle, executed by Signora Parenti, a profeſſor at that place, who had been inſtructed by a Jeſuit at Pavia, the perſon who made the fartheſt diſcoveries in that art. Miſs Greenland's friend knowing ſhe was fond of painting, informed her what were the materials the paintreſs uſed, but could not tell her the proportions of the compoſition; however, from her anxiety to ſucceed in ſuch an acquiſition, ſhe made various experiments, and at laſt obtained ſuch a ſufficient knowledge of the quantities of the different ingredients as to begin and finiſh a picture, which ſhe afterwards preſented to the Society for their inſpection.

Her method is as follows: "Take an ounce of white wax, and the ſame weight of gum maſtich powdered. Put the wax in a glazed earthen veſſel over a very ſlow fire; and when it is quite diſſolved ſtrew in the maſtich, a little at a time. ſtirring the wax continually until the whole quantity of gum is perfectly melted and incorporated: then throw the paſte into cold water; and when it is hard, take it out of the water, wipe it dry, and beat it in one of Mr Wedgwood's mortars, obſerving to pound it at firſt in a linen cloth to abſorb ſome drops of water that will remain in the paſte, and would prevent the poſſibility of reducing it to a powder, which muſt be ſo fine as to paſs through a thick gauze. It ſhould be pounded in a cold place and but a little while at a time, as after long beating the friction will in a degree ſoften the wax and gum, and inſtead of their becoming a powder they will return to a paſte.

"Make ſome ſtrong gum-arabic water; and when you paint, take a little of the powder, ſome colour, and mix them together with the gum-water Light colours require but a ſmall quantity of the powder, but more of it muſt be put in proportion to the body and darkneſs of the colours; and to black there ſhould be almoſt as much of the powder as colour.

"Having mixed the colours, and no more than can be uſed before they grow dry, paint with fair water, as is practiſed in painting with water-colours, a ground on the wood being firſt painted of ſome proper colour prepared in the ſame manner as is deſcribed for the picture; walnut-tree and oak are the ſorts of wood commonly made uſe of in Italy for this purpoſe. The painting ſhould be very highly finiſhed; otherwiſe, when varniſhed, the tints will not appear united.

"When the painting is quite dry, with rather a hard bruſh, paſſing it one way, varniſh it with white wax, which is put into an earthen veſſel, and kept melted over a very ſlow fire till the picture is varniſhed, taking great care the wax does not boil. Afterwards hold the picture before a fire, near enough to melt the wax, but not make it run; and when the varniſh is entirely cold and hard, rub it gently with a linen cloth. Should the varniſh bliſter, warm the picture again very ſlowly, and the bubbles will ſubſide. When the picture is dirty, it need only be waſhed with cold water."

The opinion given by the Society upon the above is: The method made uſe of by Miſs Greenland provides againſt all inconveniences; and the brilliancy of the colours in the picture painted by her, and exhibited to the Society, fully juſtifies the opinion, that the art of painting in wax, as above deſcribed, highly merited the reward of a gold pallet voted to her on this occaſion.

ENCEINTE, in fortification, is the wall or rampart which ſurrounds a place, ſometimes compoſed of baſtions or curtains, either faced or lined with brick or ſtone, or only made of earth. The enceinte is ſometimes only flanked by round or ſquare towers, which is called a *Roman wall*.

ENCEPHALI, in medicine, worms generated in the head, where they cauſe ſo great a pain as ſometimes to occaſion diſtraction

The encephali are very rare; but there are ſome diſeaſes wherein they ſwarm; from whence we are told peſtilential fevers have wholly ariſen. Upon the diſſection of one who died of this fever, a little, ſhort, red worm was found in the head, which malmſey wine, wherein horſe-radiſh had been boiled, could alone deſtroy. This medicine was afterwards tried on the ſick, moſt of whom it cured.

The like worms have alſo been taken out by trepanning, and the patient cured. Thoſe worms that generate in the noſe, ears, and teeth, are alſo called *encephali*.

ENCHANTER, a perſon ſuppoſed to practiſe enchantment or faſcination. See FASCINATION, WITCHCRAFT, &c.

*ENCHANTER's Nightſhade*, in botany. See CIRCÆA.

ENCHASING, INCHASING, or *Chaſing*, the art of enriching and beautifying gold, ſilver, and other metal-work, by ſome deſign or figures repreſented thereon in low relievo.

Enchaſing is practiſed only on hollow thin works, as watch-caſes, cane-heads, tweezer-caſes, or the like. It is performed by punching or driving out the metal, to form a figure, from withinſide, ſo as to ſtand out prominent from the plane or ſurface of the metal. In order to this, they provide a number of fine ſteel blocks or puncheons of divers ſizes; and the deſign being drawn on the ſurface of the metal, they apply the inſide upon the heads or tops of theſe blocks, directly under the lines or parts of the figures; then, with a fine hammer, ſtriking on the metal, ſuſtained by the block, the metal yields, and the block makes an indenture or cavity on the inſide, correſponding to which there is a prominence on the outſide, which is to ſtand for that part of the figure.

Thus the workman proceeds to chaſe and finiſh all the parts by the ſucceſſive application of the block and hammer to the ſeveral parts of the deſign. And it is wonderful to conſider with what beauty and juſtneſs, by this ſimple piece of mechaniſm the artiſts in this kind will repreſent foliages, groteſques, animals, hiſtories, &c.

ENCLITICA, in grammar, particles which are ſo cloſely united with other words as to ſeem part of them, as in *virumque*, &c.—There are three enclitic particles in Latin, viz. *que*, *ne*, *ve*.

ENCRATITES, in church-hiſtory, heretics who appeared towards the end of the ſecond century: they were called *Encratites*, or *Continentes*, becauſe they gloried in abſtaining from marriage and the uſe of wine and animal-food.

ENCURECK, in natural hiſtory, a venomous inſect found in Perſia, and ſaid to be a kind of tarantula. According to Olearius as quoted by Mr Boyle, it neither ſtings nor bites; but lets fall its venom like a drop of water, which cauſes inſufferable pain in the part for a time, and afterwards ſo profound a ſleep, that nothing can awake the patient except cruſhing one of the creatures on the part affected. It is nevertheleſs ſaid, that the ſheep eat theſe inſects without damage.

ENCYCLOPÆDIA, a term nearly ſynonymous with CYCLOPÆDIA; but adopted in preference to it in denominating the preſent work, as being more definite and of better authority. According to an obſervation of the late learned printer Mr Bower, the prepoſition EN makes the meaning of the word more preciſe: For *Cyclopædia* may denote "the inſtruction OF a circle," as *Cyropædia* is "the inſtruction OF Cyrus," whereas in *Encyclopædia* the prepoſition determines the word to be from the dative of *cyclus*, "inſtruction IN a circle." And Voſſius in his book *De vitiis ſermonis*, has obſerved, "That *Cyclopædia* is uſed by ſome authors, but *Encyclopædia* by the beſt."

ENDEMIC, or ENDEMICAL, DISEASES, thoſe to which the inhabitants of particular countries are ſubject more than others, on account of the air, water, ſituation, and manner of living.

ENDIVE, in botany. See CICHORIUM.

ENDLESS, ſomething without an end: thus authors mention endleſs rolls, the endleſs ſcrew, &c.

ENDOR, (anc. geog.), a town of Galilee, four miles to the ſouth of mount Tabor; in the tribe of Manaſſeh, where the Pythoneſs was conſulted by Saul: at this day, ſays Jerome, a large village.

ENDORSE, in heraldry, an ordinary, containing the eighth part of a pale, which Leigh ſays is only uſed when a pale is between two of them.

ENDORSED, in heraldry, is ſaid of things borne back to back, more uſually called ADOSSE.

ENDORSEMENT, in law and commerce. See INDORSEMENT.

ENDOWMENT, in law, denotes the ſettling a dower on a woman: though ſometimes it is uſed figuratively, for ſettling a proviſion upon a parſon, on the building of a church; or the ſevering a ſufficient portion of tithes for a vicar, when the benefice is appropriated.

ENDYMION, (fab. hiſt.), a ſhepherd, ſon of Æthlius and Calyce. It is ſaid that he required of Jupiter to grant to him to be always young, and to ſleep as much as he would; whence came the proverb of *Endymionis ſomnum dormire*, to expreſs a long ſleep. Diana ſaw him naked as he ſlept on mount Latmos; and was ſo ſtruck with his beauty, that ſhe came down from heaven every night to enjoy his company. Endymion married Chromia daughter of Itonus; by whom he had three ſons Pæon, Epeus, and Æolus, and a daughter called *Eurydice*. The fable of Endymion's amours with Diana, or the moon, aroſe from his knowledge of aſtronomy; and as he paſſed the night on ſome high mountain to obſerve the heavenly bodies, it came to be reported that he was courted by the moon. Some ſuppoſe that there were two of that name; the ſon of a king of Elis, and the ſhepherd or aſtronomer of Caria. The people of Heraclea maintained that Endymion died on mount Latmos, and the Eleans pretended to ſhow his tomb at Olympia in Peloponneſus.

ENEMY, in law, an alien or foreigner, who publicly invades the kingdom.

ENERGUMENS, in church-hiſtory, perſons ſuppoſed to be poſſeſſed by the devil, concerning whom there were many regulations among the primitive Chriſtians. They were denied baptiſm and the euchariſt; at leaſt, this was the practice of ſome churches: and though they were under the care of exorciſts, yet it was thought a becoming act of charity, to let them have the public prayers of the church, at which they were permitted to be preſent. See EXORCISM.

ENERGY, a term of Greek origin, ſignifying the power, virtue, or efficacy of a thing. It is alſo uſed, figuratively, to denote emphaſis of ſpeech.

ENERVATING, the act of deſtroying the force, uſe, or office, of the nerves, either by cutting them, by weakening them with debauchery, or by ſome other violence.

Exceſs of wine, and other ſtrong, hot, ſpirituous liquors, enervate or weaken the nerves. When they would render a horſe uſeleſs, they enervate him, or cut his nerves.

ENFANS PERDUS, the ſame with forlorn-hope. See FORLORN.

ENFILADE, in the art of war, is uſed in ſpeaking of trenches, or other places, which may be ſcoured by the enemy's ſhot along their whole length. In conducting the approaches at a ſiege, care muſt be taken that the trenches be not enfiladed from any work of the place.

ENFINE', formerly ANTINOE; a city of Egypt, built by Adrian in honour of his favourite Antinous. It is ſituated towards the middle of the Said, or Upper Egypt, and ſtill contains ſeveral ſtately monuments of antiquity. In ancient times this city was very magnificent. It was about half a league in circumference, having two principal ſtreets 45 feet wide, interſecting each other at right angles, and running thro' its whole length. The others were more narrow, but equally ſtraight; the two largeſt having gates at each end, part of which ſtill remain. According to the Nubian geographer, it was called the city of the Magi, becauſe Pharaoh is ſaid to have cauſed the magicians come from thence to his court. Near it were the ruins of Abydus, where there was an oracle of the god Beſa, one of the moſt ancient in Egypt, and which was ſtill famous in the time of Conſtantius; and hence ſome have derived the appellation juſt mentioned, the neighbouring people coming in crowds to conſult the oracle.

The ruins of the gates are the moſt beautiful pieces of architecture to be met with in this place. The handſomeſt has three vaulted entries; the middle one being 40 feet in height, 22 wide, and 20 thick; the other two ſmaller. Each of the facades of this edifice is ornamented with four pilaſters in bas relief, with Corinthian capitals, the acanthus leaves of which have a conſiderable projection. It was ſurrounded by eight Corinthian columns, of which only one now remains, but the pedeſtals of the reſt are ſtill entire. Beſides theſe, there are heaps of rubbiſh in different parts of the town, apparently the remains of ancient temples or palaces. All theſe ſeem to have been bordered by a colonnade, forming a portico on each ſide, where the inhabitants might walk ſecure from the heat of the ſun. One of the ſquares was ornamented with four large Corinthian pillars, three of which are deſtroyed all but the baſes. The fourth is quite entire, about 50 feet high, and the ſhaft compoſed of ſeveral ſtones. The pedeſtal has a Greek inſcription, pretty much defaced, dedicating it to the emperor Alexander Severus, to whom the ſenate of ALEXANDRIA had already dedicated the famous column mentioned under that article. Theſe four other columns were therefore probably raiſed in honour of that emperor after his victories over the Perſians; for the foliage of the oak, with which the firſt ſtone of the ſhaft is decorated, was a ſign of victory among the Romans. Towards the end of the fourth century the city was peopled by Chriſtians; and Palladius aſſures us, that there were at that place 12 convents of virgins, and ſeveral others inhabited by monks. In the environs there are ſtill ſeveral coptic monaſteries poſſeſſed by monks equally miſerable and ignorant. The Nubian Geographer informs us, that the city was ſurrounded by a well cultivated country, abounding in fruits and harveſts; but theſe have now given place to ſands and barren deſarts. The ruins of Abydus above mentioned are ſtill to be ſeen near this place.

ENFRANCHISEMENT, in law, the incorporating a perſon into any ſociety or body politic.

ENGASTRIMYTHI, in Pagan theology, the Pythians, or prieſteſſes of Apollo, who delivered oracles from within, without any action of the mouth or lips.

The ancient philoſophers, &c. are divided upon the ſubject of the engaſtrimythi. Hippocrates mentions it as a diſeaſe. Others will have it a kind of divination. Others attribute it to the operation or poſſeſſion of an evil ſpirit. And others to art and mechaniſm. M. Scottus maintains that the engaſtrimythi of the ancients were poets, who, when the prieſts could not ſpeak, ſupplied the defect by explaining in verſe what Apollo dictated in the cavity of the baſon on the ſacred tripod.

ENGENDERING, a term ſometimes uſed for the act of producing or forming any thing: thus meteors are ſaid to be engendered in the middle region of the atmoſphere, and worms in the belly.

ENGINE, in mechanics, is a compound machine, made of one or more mechanical powers, as levers, pullies, ſcrews, &c. in order to raiſe, caſt, or ſuſtain any weight, or produce any effect which could not be eaſily effected otherwiſe. The word is formed of the French *engin*, from the Latin *ingenium* "wit;" by reaſon of the ingenuity required in the contrivance of engines to augment the effect of moving powers.

*ENGINE for extinguiſhing Fires.* See HYDROSTATICS, n° 33.

*Pile ENGINE*, one contrived for driving piles. See *PILE-Engine.*

*Steam-ENGINE*, a machine to raiſe water by fire, or rather by the force of water turned into ſteam. See *STEAM-Engine.*

ENGINEER, in the military art, an able expert man, who, by a perfect knowledge in mathematics, delineates upon paper, or marks upon the ground, all ſorts of forts, and other works proper for offence and defence. He ſhould underſtand the art of fortification, ſo as to be able, not only to diſcover the defects of a place, but to find a remedy proper for them; as alſo how to make an attack upon, as well as to defend, the place. Engineers are extremely neceſſary for theſe purpoſes: wherefore it is requiſite, that beſides being ingenious, they ſhould be brave in proportion. When at a ſiege the engineers have narrowly ſurveyed the place, they are to make their report to the general, by acquainting him which part they judge the weakeſt, and where approaches may be made with moſt ſucceſs. Their buſineſs is alſo to delineate the lines of circumvallation and contravallation, taking all the advantages of the ground; to mark out the trenches, places of arms, batteries, and lodgments, taking care that none of their works be flanked or diſcovered from the place. After making a faithful report to the general of what is a-doing, the engineers are to demand a ſufficient number of workmen and utenſils, and whatever elſe is neceſſary.

ENGLAND, the ſouthern diviſion of the iſland of Great Britain. Including Wales, it is of a triangular form, and lies between the 50th and 55th degrees of north latitude, extending about 400 miles in length from ſouth to north, and in ſome places it is 300 miles in breadth. It is bounded by Scotland on the north; by the Engliſh Channel on the ſouth, dividing it from France; by the German Sea on the eaſt; and on the weſt by St George's, or the Iriſh, Channel.

At what time the iſland of Britain was peopled is uncertain; nor do we know whether the ſouthern or northern parts were firſt inhabited. We have no accounts that can be depended upon before the arrival of Julius Ceſar, and it is certain he found the ſouthern parts full of people of a very warlike diſpoſition. Theſe people, according to Cæſar, were a colony of the Gauls; and this opinion is embraced by moſt of the ancient as well as modern writers. It is chiefly founded on the agreement obſerved by the Romans between the two nations in their cuſtoms, manners, language, religion, government, way of fighting, &c. The more northern inhabitants, according to Tacitus,

England.

tus, came from Germany. This he infers from the make of their limbs; but Cæſar ſimply calls them *Aborigenes*.

England, including the principality of Wales, when firſt invaded by the Romans, was divided into 17 petty ſtates. 1. The Danmonii, called alſo *Dunmonii* and *Donmonii*, inhabiting the counties of Cornwal and Devonſhire. 2. The Durotriges, who inhabited the track now called *Dorſetſhire*. 3. The Belgæ poſſeſſed Somerſetſhire, Wiltſhire, and Hampſhire. 4. The Attrebatii, or inhabitants of Berkſhire. 5. The Regni, whoſe country bordered on that of the Attrebatii, and comprehended Surrey, Suſſex, and part of the ſea-coaſt of Hampſhire. 6. The Cantii, inhabiting the county now called *Kent*. 7. The Dobuni are placed by Ptolemy on the north ſide of the Thames, near its head, in the counties of Glouceſterſhire and Oxfordſhire. 8. The Catticuchlani, *Calyeuchlani*, *Cattidudani*, or *Cathicludani*, inhabited Buckinghamſhire, Bedfordſhire, and Hertfordſhire. 9. The Trinobantes, who poſſeſſed the counties of Eſſex and Middleſex. 10. The Iceni, whoſe country comprehended Suffolk, Norfolk, Cambridge, and Huntingdonſhire. Theſe are by Ptolemy called *Simeni*, and by others *Tigeni*. Cambden is of opinion, that they were the ſame whom Cæſar calls *Cenomagni*. 11. The Coritani, whoſe country comprehended Northamptonſhire, Lieceſterſhire, Rutlandſhire, Lincolnſhire, Nottinghamſhire, and Derbyſhire. 12. The Cornavii poſſeſſed Warwickſhire, Worceſterſhire, Staffordſhire, Shropſhire, and Cheſhire. 13. The Silures inhabited the counties of Radnorſhire, Brecknockſhire, Glamorganſhire, with Herefordſhire and Monmouthſhire. 14. The Demetæ inhabited part of Carmardinſhire, Pembrokeſhire, and Cardiganſhire. 15. The country of the Ordovices comprehended Montgomeryſhire, Merionethſhire, Caernarvonſhire, Denbighſhire, and Flintſhire. 16. The Brigantes poſſeſſed the countries of Yorkſhire, the biſhopric of Durham, Lancaſhire, Weſtmoreland, and Cumberland. 17. The county of Northumberland was held by the Ottadini, Ottadeni, or Ottalini. Their country, according to ſome, reached from the Tine to the river Forth; though the moſt common opinion is, that it reached only to the Tweed.

The above-mentioned names of theſe nations are plainly Roman, but the etymology of them is not eaſily aſcertained. Some attempt to derive them from words in the Old Britiſh language; but as this ſubject at beſt muſt be very obſcure and uncertain, we ſhall not enter into it.

Before the time of Julius Cæſar, the Romans had ſcarcely any knowledge of Britain; but that conqueror having ſubdued moſt of the Gallic nations on the oppoſite ſide of the channel, began to think of extending his conqueſts by the reduction of Britain. The motive for this expedition, aſcribed to him by Suetonius, was a deſire of enriching himſelf by the Britiſh pearls, which were then very much eſteemed. The pretence, however, which he made uſe of in order to juſtify his invaſion was, that the Britons had ſent aſſiſtance to the Gauls during his wars with them.

Cæſar undertook his firſt expedition againſt Britain when the ſummer was already far ſpent, and therefore he did not expect to finiſh the conqueſt of the country that campaign. He thought, however, that it would be a conſiderable advantage to view the iſland, and learn ſomething of the manners and cuſtoms of the natives; after which he could more eaſily take ſuch meaſures as would enſure a permanent conqueſt on his return. Having marched all his forces into the country of the Morini, now the province of Picardy, from whence was the ſhorteſt paſſage into Britain; he ordered at the ſame time all the veſſels that lay in the neighbouring ports, and a fleet which he had built the year before for an expedition againſt the Morini, to attend him. The Britons, alarmed at his preparations, ſent ambaſſadors with offers of ſubmiſſion; but Cæſar, though he received them with great kindneſs, did not abandon his intended ſcheme of an invaſion. He waited till the arrival of C. Voluſenus, whom he had ſent out with a ſingle galley to make diſcoveries on the coaſt. Voluſenus did not think proper to land; but, having made what obſervations he could, returned after five days abſence. and Cæſar immediately ſet ſail for Britain. His force conſiſted of two legions embarked on board 80 tranſports; and he appointed 18 more which lay wind-bound about eight miles off, to convey over the cavalry; but theſe laſt orders were too ſlowly executed, which occaſioned ſome difficulty in his landing.

4
Manners, cuſtoms, &c. of the Britons.

The Britons at this time, according to Cæſar and other Roman hiſtorians, were very numerous, and had their country well ſtocked with cattle. Their houſes reſembled thoſe of the Gauls; and they uſed copper or iron plates weighed by a certain ſtandard inſtead of money. Their towns were a confuſed parcel of huts placed at a ſmall diſtance from one another, generally in the middle of a wood, to which all the avenues were ſlightly guarded with ramparts of earth, or with trees. All the nations were in a ſtate of the moſt wretched barbariſm, even when compared with the barbarous Gauls on the continent. The uſe of clothes was ſcarce known in the iſland. Only the inhabitants of the ſouthern coaſt covered their nakedneſs with the ſkins of wild beaſts; and this rather to avoid giving offence to the ſtrangers who came to trade with them, than out of any principle of decency. It was a general cuſtom among the Britons to paint their bodies with the juice of woad; but whether this was deſigned as ornament, or for any other purpoſe, is not known. They ſhaved their beards, all except their upper lip, and wore long hair. They alſo had their wives in common, a cuſtom which made them deteſtable to all other nations.

The arms of the Britons were a ſword, a ſhort lance, and a ſhield. Breaſt-plates and helmets they looked upon rather to be incumbrances, and therefore made no uſe of them. They uſually fought in chariots, ſome of which were armed with ſcythes at the wheels; they were fierce and cruel, and exceedingly bloodthirſty. When driven to diſtreſs, they could ſubſiſt themſelves even on the bark and roots of trees; and Dio Caſſius tells us, that they had ready, on all occaſions, a certain kind of food, of which, if they took but the quantity of a bean, they were not troubled with hunger or thirſt for a conſiderable time after. The ſouthern nations, however, were ſomewhat more civilized; and the Cantii, or inhabitants of Kent, more ſo than any of the reſt.

All the Britiſh nations at this time were very brave

6 and

5
They oppoſe Cæſar's landing.

and reſolute, owing to the continual diſſenſions among themſelves. They proved therefore very formidable enemies to the Romans; but the ſame diſſenſions which had taught them the art of war, alſo prevented them from uniting in the defence of their country. As ſoon as they perceived Cæſar's fleet approaching, a number of cavalry and chariots were diſpatched to oppoſe his landing, while a conſiderable body of infantry haſtened after. What chiefly embarraſſed the Romans in their attempt to land, was the largeneſs of their ſhips, which required a conſiderable depth of water. The ſoldiers therefore were obliged to leap into the ſea while loaded with their armour; and at the ſame time to encounter the enemy, who were quite diſengaged, as they either ſtood on dry ground, or waded but a little way into the water. Cæſar perceiving this diſadvantage, ordered his galleys to advance, with their broad ſides towards the ſhore, in order to drive the Britons from the water-ſide with their ſlings and arrows. On this the Britons, ſurpriſed at the galleys, a ſort of ſhipping they had never before ſeen, began to give ground. The fight, however, continued for ſome time, greatly to the diſadvantage of the Romans; till at laſt Cæſar, obſerving the diſtreſs of his men, cauſed ſeveral boats to be manned, and ſent them to the aſſiſtance of thoſe who were moſt expoſed to the enemy's aſſault. The Romans then ſoon got the better of the undiſciplined barbarians, however brave, and made good their landing; but they were unable to purſue the enemy for want of cavalry, which had not yet arrived.

6
They are defeated and ſue for peace.

7
Their treachery.

The Britons were ſo diſheartened with this bad ſucceſs, that they immediately ſent ambaſſadors to ſue for peace; which was granted, on condition of their delivering a certain number of hoſtages for their fidelity. Part of theſe they brought immediately; and promiſed to return in a few days with the reſt, who, they ſaid, lived at ſome diſtance. But, in the mean time, the 18 tranſports which carried Cæſar's cavalry, being driven back by a violent ſtorm, and the fleet which lay in the road being greatly damaged by the ſame, the Britons thought proper to break their engagements. Having therefore privately aſſembled their forces, they fell unexpectedly on the ſeventh legion while at a diſtance from the reſt and buſied in foraging. Cæſar being appriſed of their danger, haſtened to their aſſiſtance with two cohorts, and at laſt repulſed the enemy.—This, however, proved only a temporary deliverance; for the Britons, thinking it would be poſſible for them to cut off all the Romans at once, diſpatched meſſengers to inform ſeveral of the neighbouring nations of the weakneſs of the enemy's forces, and the happy opportunity that offered itſelf of deſtroying all theſe invaders at one blow.—On this, they drew together a great body of horſe and foot, which boldly advanced to the Roman intrenchments. But Cæſar came out to meet them; and the undiſciplined Britons being by no means able to cope with the Romans were put to flight with great ſlaughter. Having burnt ſeveral towns and villages, the victors returned to their camp, where they were ſoon followed by new deputies from the Britons. Cæſar being in want of horſe, and afraid leſt another ſtorm ſhould deſtroy the remainder of his fleet, granted them peace, on condition of their ſending him double the number of hoſtages into Gaul which they had before promiſed. The ſame night he ſet ſail, and ſoon arrived ſafe in Gaul.

Cæſ
turn

The Britons no ſooner perceived the Romans gone, than, as before, they broke through their engagements. Of all the ſtates who had promiſed to ſend hoſtages, only two performed their promiſes; and this neglect ſo provoked Cæſar, that he determined to return the year following with a far greater force. Having, therefore, cauſed his old veſſels to be refitted, and a great many new ones to be built, he arrived off the coaſt of Britain with a fleet of 600 ſhips and 28 galleys. The Britons made no oppoſition to his landing; but Cæſar, getting intelligence that an army was aſſembled at no great diſtance, marched in queſt of them. He found them encamped on the banks of a river, ſuppoſed to be the *Stour*, about 12 miles diſtant from the place where he had landed. They attempted to oppoſe his paſſage; but being briſkly attacked by the Roman cavalry, they were obliged to retire into a wood, all the avenues of which were blocked up by trees cut down for that purpoſe. This fortification, however, proved inſufficient to protect them. The ſeventh legion having caſt themſelves into a teſtudo, and thrown up a mount againſt their works, drove them from their aſylum; but as the day was far ſpent, a purſuit was not thought adviſable.

Defe
Brit

Next morning Cæſar, with the greateſt part of his army, which he divided into three bodies, marched out in queſt of the enemy. But when he was already come in ſight of their rear, he was overtaken by meſſengers, who informed him, that his fleet was greatly damaged by a violent ſtorm which had happened the preceding night. This put an end to the purſuit for that time; but Cæſar having employed all the carpenters he had with him, and ſent for others from Gaul, in order to repair the damage, reſolved to prevent misfortunes of this kind for the future. He therefore drew all his ſhips aſhore, and incloſed them within the fortifications of his camp. This arduous undertaking employed his whole army for 10 days; after which he again ſet out in queſt of the enemy.

The Briton had made the beſt uſe they could of the reſpite afforded them by the ſtorm. They were headed by Caſſibelaunus king of the Trinobantes. He had formerly made war upon his neighbours; and having rendered himſelf terrible to them, was looked upon to be the moſt proper perſon for leading them on againſt the common enemy; and as ſeveral ſtates had now joined their forces, the Britiſh army was very numerous. Their cavalry and chariots attacked the Roman army while on their march; but were repulſed with loſs, and driven into the woods. The Romans purſued them too eagerly, and thus loſt ſome of their own men; which encouraged the Britons to make another fierce attack; but in this alſo they were finally unſucceſsful, and obliged to retire, though their loſs ſeems not to have been great.

Next day the Britons ſuddenly attacked the Roman legions as they were foraging; but meeting with a vigorous reſiſtance, they ſoon betook themſelves to flight. The Romans purſued them ſo cloſely, that having neither time to rally nor get down from their chariots according to cuſtom, great numbers of them were cut in pieces: and this overthrow had ſuch an effect upon the

auxiliaries

auxiliaries of Caſſibelaunus, that all of them abandoned him; nor did the Britons ever afterwards engage Cæſar with united forces. Cæſar, purſuing his victory, marched towards the Thames, with a deſign to croſs that river, and enter the territories of the Trinobantes. The river was fordable only at one place, and that not without great difficulty; but when he came to it, he found the enemy's forces drawn up in a conſiderable body on the oppoſite bank, which was fortified with ſharp ſtakes. They had likewiſe driven many ſtakes of the ſame kind into the bottom of the river, the tops of which were covered with water. Theſe ſtakes are viſible to this day at a place called *Walton* in Surry. They are made of oak; and though they have been ſo long in the water, are as hard as Brazil, and as black as jet; and have ſometimes been pulled out in order to make knife-handles of them.

Cæſar was not at all diſmayed at theſe difficulties, which he had intelligence of by priſoners and deſerters. He ordered the cavalry to enter firſt, and the foot to follow. His orders were obeyed, and the ſoldiers advanced with ſuch reſolution, that though the infantry were up to the chin in water, the enemy, unable to ſuſtain their aſſault, abandoned the bank and fled. After this defeat, Caſſibelaunus himſelf deſpaired of ſucceſs, and therefore diſmiſſed all his forces except about 4000 chariots, with which he obſerved the motions of the Romans, haraſſing them by cutting off ſtraggling parties, &c. This, however, was not ſufficient to keep up the ſpirits of his countrymen. On the contrary, they depoſed him from the kingdom and choſe Mandubratius, whoſe father had been murdered by Caſſibelaunus, who thereupon uſurped the kingdom. The young prince had fled to Cæſar, who gave him protection; and the Trinobantes now offered to ſubmit to the conqueror, provided he would give them Mandubratius for their king.

Cæſar readily complied with the requeſt of the Trinobantes upon their ſending him 40 hoſtages: and the ſubmiſſion of the Trinobantes was ſoon followed by that of other ſtates and tribes; for each of the 17 nations already mentioned were compoſed of ſeveral different tribes, of which no particular account can be given.—Cæſar next marched to Verulamium, or Canterbury, which was Caſſibelaunus's capital, and which he ſtill kept poſſeſſion of; but tho' the place was ſtrongly fortified both by nature and art, the Britons were unable to bear the aſſault of the Romans, and therefore ſoon fled out at one of the avenues Many were taken as they attempted to make their eſcape, and many more cut in pieces.

After this loſs, Caſſibelaunus, as his laſt reſource, found means to draw into confederacy with him four kings of the Cantii. But though Cæſar gives them the title of kings, it is probable that they were only petty princes, tributary to the king of that nation. Their names were Cingetorix Corvilius, Taximagulus. and Segonax. Theſe, having raiſed what forces they could, attacked the camp where the ſhips were laid up: but the Romans having made a ſally, repulſed them with great ſlaughter, and then returned to their trenches without any loſs; after which, Caſſibelaunus thought proper to ſubmit to the conqueror. As the ſummer was already far ſpent, Cæſar hearkened to his propoſals. A peace was concluded on the following terms, viz. that the Britons ſhould pay an annual tribute to the Romans, that Caſſibelaunus ſhould leave Mandubratius in peaceable poſſeſſion of his dominions, that he ſhould not moleſt the Trinobantes, and that he ſhould deliver a certain number of hoſtages. Theſe terms being agreed to, Cæſar ſet ſail with his whole fleet from Britain, to which he never returned.

12
He leaves the iſland altogether.

Such is the account given by Cæſar himſelf of his two expeditions into Britain; but other authors have ſpoken very doubtfully of his victories in this iſland. Dio Caſſius tells us, that the Britons utterly defeated the Roman infantry, but were at laſt put in diſorder by their cavalry. Horace and Tibullus, in many parts of their works, ſpeak of the Britons as a people not yet conquered. Tacitus ſays, that Cæſar rather ſhowed the Romans the way to Britain, than put them in poſſeſſion of it; and Lucan tells us plainly, that Cæſar turned his back to the Britons and fled. This laſt, however, conſidering the conſummate military genius of Cæſar, is by no means probable. That he left Britain during the winter, was, in all probability, to prevent inſurrections among the Gauls, which might very readily have happened; and that he did not return to finiſh his conqueſt can be no wonder, ſeeing his ambition would certainly be more gratified by being called emperor of Rome, than conqueror of Britain.

The departure of Julius Cæſar, which happened about 53 years before Chriſt, left the Britons without any fear of a foreign enemy. We are not, therefore, to imagine, that they would regard their promiſes of paying tribute; nor was it probably demanded for a good number of years afterwards. Auguſtus, however, when he had got himſelf fully eſtabliſhed on the throne, had twice a deſign of invading Britain and forcing the inhabitants to pay the tribute promiſed to Julius Cæſar. Both times, however, he was prevented by revolts in different provinces in the empire, ſo that the Britons ſtill continued to enjoy their liberty. They thought proper, however, to court the favour of the Romans as much as they could by pretended ſubmiſſions; but, in the reign of Claudius, the Romans ſet about reducing them to ſubjection in good earneſt. The occaſion of this war is related by Dio Caſſius as follows. "Cunobelinus, the third in ſucceſſion from Caſſibelaunus, being dead, his two ſons, Togodumnus and Caractacus, ſucceeded to the throne; but whether they reigned jointly or ſeparately, is not known. In their reign one Bericus, of whom we alſo know very little, being driven out of the iſland for attempting to raiſe a ſedition, fled with ſome of his partiſans to Rome, and perſuaded Claudius to make war on his countrymen. The Britons, on the other hand, reſented the behaviour of Claudius in receiving theſe vagabonds, and therefore prohibited all intercourſe with the Romans. A much ſmaller offence than this would have been ſufficient at any time to provoke that haughty nation to declare war. An army was therefore immediately ordered into Britain, under the command of Plautius prætor in Gaul. The ſoldiers at firſt refuſed to embark, from a ſuperſtitious notion, that they were going to be ſent without the compaſs of the world; and this mutiny being related to the Britons, they did not make the neceſſary preparations for their own defence. The Roman ſoldiers were ſoon brought to a ſenſe of their duty; and ſet out from three different ports, in order

13
Why the war with the Romans was renewed.

to land in three different places of Britain at once. Being driven back by contrary winds, their fears began to return; but they reſumed their courage on the appearance of a meteor ſhooting from the eaſt, which they imagined was ſent from heaven to direct their courſe. They landed without oppoſition; and the Britons, not having drawn together a ſufficient army, kept in ſmall bodies behind their marſhes, and in woods, in order to ſpin out the war till winter; which they imagined Plautius would, like Cæſar, ſpend in Gaul.

14
The Britons defeated.

The Roman general marched firſt in queſt of the two kings Togodumnus and Caractacus; both of whom he found out, and defeated one after another. He then reduced part of the Dobuni, at that time ſubject to the Cattieuchlani; and leaving a garriſon to keep them in awe, he advanced to a river where the Britons lay careleſsly encamped, ſuppoſing that the Romans could not paſs it without a bridge. But the Germans in the Roman army had been accuſtomed to ſwim acroſs the ſtrongeſt currents in their heavy armour. They therefore paſſed the river firſt; and having, according to their orders, fallen only upon the enemy's horſes which drew their chariots, theſe formidable machines were rendered entirely uſeleſs; and the Britons were put to flight as ſoon as another part of the forces could paſs the river.

The Britons were not diſheartened with this defeat, but engaged the Romans next day with great bravery. Victory continued long doubtful; but at length the Romans prevailed, and the Britons were forced to betake themſelves to flight. This battle is thought to have been fought on the banks of the Severn. From thence the Britons fled to the mouth of the Thames. They were cloſely purſued by the Romans; but the latter being unacquainted with the flats and ſhallows of the river, were often in great danger. The Germans, however, croſſed by ſwimming as before, and the reſt on a bridge ſomewhat farther up the river; ſo that the Britons were in a ſhort time ſurrounded on all ſides, and great numbers of them cut in pieces. Many of the Romans, alſo, purſuing the fugitives with too great eagerneſs, were loſt in the marſhes.—In one of theſe battles Togodumnus was killed; but the Britons were ſo far from being diſheartened, that they ſhowed more eagerneſs than ever to oppoſe the Romans, in order to revenge his death. Plautius, therefore, did not think proper to penetrate farther into the country, but contented himſelf with putting garriſons in the places he had already conquered. He then wrote to the emperor himſelf; who no ſooner received an account of his ſucceſs, than he ſet out for Britain; where, having landed after a ſhort voyage, he joined Plautius on the banks of the Thames.

15
Claudius arrives in Britain.

Soon after the arrival of Claudius, the Romans paſſed the Thames, attacked the Britiſh army, and totally defeated it. The conſequence of this was the taking of Cunobelinus's capital, and the ſubmiſſion of ſeveral of the neighbouring ſtates. The emperor, however, did not make a long ſtay in the iſland, but left Plautius to purſue his conqueſts. This he did with ſuch ſucceſs, that, on his return to Rome, he was met without the gates by the emperor himſelf, who, at his ſolemn entry, gave him the right hand.—The Britons ſeem to have made a very obſtinate reſiſtance to the Roman arms about this time. Veſpaſian, who was afterwards emperor, is ſaid to have fought 30 battles with them; and the exploits of Titus his ſon are alſo much celebrated by the Roman hiſtorians.

In the ninth year of Claudius, P. Oſtorius Scapula was ſent into Britain. By far the greater part of the 17 nations formerly mentioned were at this time unconquered. Some of theſe had broken into the Roman territories; but Oſtorius falling unexpectedly upon them, put great numbers to the ſword, and diſperſed the reſt. To prevent them for the future from making inroads into the territories of the Romans or their allies, he built ſeveral forts on the Severn, the Avon, and the Nen, reducing the country ſouth of theſe rivers to a Roman province. This ſo highly offended the Iceni, that, being joined by the neighbouring nations, they raiſed a conſiderable army, and encamped in an advantageous ſituation, in order to prevent the Romans from penetrating farther into the iſland. Oſtorius, however, ſoon advanced againſt them. The Romans, as uſual, got the victory, and the enemy were purſued with great ſlaughter. The Roman general then, having quelled an inſurrection among the Brigantes, led his army againſt the Silures. They were headed by their king Caractacus, a moſt renowned warrior. He ſhowed his military talents by chooſing a very advantageous place for engaging the enemy. Tacitus tells us, "it was on the ridge of an exceeding ſteep mountain; and where the ſides of it were inclining and acceſſible, he reared walls of ſtone for a rampart. At the foot of the mountain flowed a river dangerous to be forded, and an army of men guarded his entrenchments." This hill is thought to be one called *Caer-Caradoc* in Shropſhire, ſituated near the conflux of the rivers Colun and Teme, and where the remains of ancient entrenchments are ſtill viſible.—On the approach of the enemy, Caractacus drew up his troops in order of battle, animating them with the following ſpeech, according to Tacitus. "That from this day, and this battle, they muſt date their liberty reſcued, or their ſlavery for ever eſtabliſhed. He then invoked the ſhades of thoſe heroes who had expelled Cæſar the dictator; thoſe brave men by whoſe valour they ſtill enjoyed freedom from Roman tribute and taxes, and by which their wives and children were as yet preſerved from proſtitution." The whole army then took a ſolemn oath either to conquer or die, and prepared for the charge with the moſt terrible ſhouts. Oſtorius was ſomewhat diſmayed when he conſidered the uncommon fierceneſs of the enemy, and the other difficulties which he had to encounter. He led on his men, however, to the charge; and the Romans were attended with their uſual good fortune. The Britons were put to flight. Vaſt numbers fell on the field of battle and in the purſuit, and many more were taken priſoners. Among the latter were the wife, the daughter, and the brothers, of Caractacus. The unfortunate prince himſelf fled to Cartiſmundua queen of the Brigantes, by whom he was delivered up to the Roman general, who ſent him in chains to Rome. Caractacus bore his misfortunes with magnanimity; and when he came before the emperor, addreſſed him in the following terms. "If my moderation in proſperity, O Claudius! had been as conſpicuous as my birth and fortune, I ſhould now have entered this city as a friend, and not as a priſoner; nor would you have diſdained

Cara

the friendſhip of a prince deſcended from ſuch illuſtrious anceſtors, and governing ſo many nations. My preſent condition, I own, is to you honourable, to me humiliating. I was lately poſſeſſed of ſubjects, horſes, arms, and riches. Can you be ſurpriſed that I endeavoured to preſerve them? If you Romans have a deſire to arrive at univerſal monarchy, muſt all nations, to gratify you, tamely ſubmit to ſervitude? If I had ſubmitted without a ſtruggle, how much would it have diminiſhed the luſtre of my fall, and of your victory? And now, if you reſolve to put me to death, my ſtory will ſoon be buried in oblivion; but if you think proper to preſerve my life, I ſhall remain a laſting monument of your clemency."—This ſpeech had ſuch an effect upon Claudius, that he immediately pardoned Caractacus and his whole family, and commanded them to be ſet at liberty.

The Silures, notwithſtanding this terrible blow, continued the war with great vigour, and gained conſiderable advantages over the Romans; which ſo much affected Oſtorius, that he died of grief. He was ſucceeded by A. Didius, who reſtrained the incurſions of the Silures, but was not able to reſtore Cartiſmundua queen of the Brigantes, who had been depoſed by her ſubjects. Didius was ſucceeded by Veranius, and he by Suetonius Paulinus, who reduced the iſland of ANGLESEY, as related under that article. But while Paulinus was employed in the conqueſt of this iſland, he was alarmed by the news of an almoſt univerſal revolt among thoſe nations which had ſubmitted to the Romans. The Britons, tho' conquered, had ſtill a deſire of returning to their former ſtate of independence; and the Roman yoke became every day more unſupportable to them through the inſolence and oppreſſions of the Roman ſoldiers. The Britons had been long diſcontented, and were already in a very proper diſpoſition for a revolt, when an event happened which kindled theſe diſcontents into an open flame. Praſutagus, king of the Iceni, a prince renowned for opulence and grandeur, had, by his laſt will, left the Roman emperor joint-heir with his two daughters, in hopes of obtaining his favour and protection by ſo great an obligation. But the event turned out very different. No ſooner was he dead, than his houſes and poſſeſſions were all plundered by the Roman ſoldiers. The queen Boadicea remonſtrated againſt this injuſtice; but, inſtead of obtaining any redreſs, ſhe herſelf was publicly whipped, her daughters raviſhed, and all the relations of the late king reduced to ſlavery. The whole country alſo was plundered, and all the chiefs of the Iceni deprived of their poſſeſſions.

l re-
the
s.

Boadicea was a woman of too haughty a ſpirit tamely to bear ſuch indignities. She therefore perſuaded the Iceni to take up arms, which they very readily did. Then, being joined by the Trinobantes, and ſome other nations, they poured like a torrent on the Roman colonies. Every thing was deſtroyed with fire and ſword. The ninth legion, which had been left for the defence of the country under Petilius Cerealis, was defeated, the infantry totally cut in pieces, and the commander himſelf with the cavalry eſcaped with the utmoſt difficulty. Suetonius, alarmed at this news, immediately left Angleſey, and marched with the greateſt expedition to London. The inhabitants were overjoyed at his arrival, and uſed their utmoſt endeavours to detain him for their defence. But he refuſed to ſtay, and in a ſhort time left the place, notwithſtanding the intreaties of the inhabitants. The whole city lamented his departure; and they had reaſon. Suetonius was ſcarce gone, when Boadicea with her Britons entered, and put all they found in it to the ſword. None were taken priſoners, nor was any ſex or age ſpared, and many were tortured in the moſt cruel manner. Seventy thouſand perſons are ſaid to have periſhed on this occaſion at London and other Roman colonies.

19
They deſtroy 70,000 Romans.

20
They are utterly defeated.

The Britons, now elated with ſucceſs, aſſembled from all quarters in great numbers, ſo that Boadicea's army ſoon amounted to 230,000 men. They deſpiſed the Romans; and became ſo confident of victory, that they brought their wives and children along with them in waggons to be ſpectators of the deſtruction of their enemies. The event was what might naturally have been expected from ſuch ill-judged confidence. The Britons were overthrown with moſt terrible ſlaughter, no fewer than 80,000 being killed in the battle and purſuit; while the Romans had not above 400 killed, and not many more wounded. Boadicea, not able to ſurvive ſo great a calamity, put an end to her life by poiſon.

By this overthrow the Britons who had once been ſubdued were thoroughly prevented from raiſing any more inſurrections, and even thoſe who had not yet ſubmitted to the Roman yoke ſeemed to be intimidated from making incurſions into their dominions. Nothing remarkable therefore happened for ſome time. In the time of Veſpaſian, Petilius Cerealis being appointed governor of Britain, attacked the Brigantes, defeated them in ſeveral battles, and reduced great part of their country. He was ſucceeded by Julius Frontinus; who not only maintained the conqueſts of his predeceſſor, but reduced entirely the warlike nation of the Silures. Frontinus was ſucceeded by the celebrated Cneius Julius Agricola, who completed the conqueſt of all the ſouthern Britons.

21
Britain conquered by Agricola.

Juſt before the arrival of Agricola, the Ordovices had cut in pieces a band of horſe ſtationed on their confines, after which the whole nation had taken arms. The ſummer was pretty far ſpent, and the Roman army was quite ſeparated and diſperſed, the ſoldiers having aſſured themſelves of reſt for the remaining part of the year. Agricola, however, was no ſooner landed, than, having drawn together his legions, he marched againſt the enemy without delay. The Britons kept upon the ridges of the mountains; but Agricola led them in perſon up the aſcents. The Romans were victorious; and ſuch a terrible ſlaughter was made of the Britons that almoſt the whole nation of Ordovices was cut off. Without giving the enemy time to recover from the terror which this overthrow had occaſioned, Agricola reſolved upon the immediate reduction of Angleſey, which had been loſt by the revolt of Boadicea. Being deſtitute of ſhips, he detached a choſen body of auxiliaries who knew the fords, and were accuſtomed to manage their arms and horſes in the water. The Britons, who had expected a fleet and tranſports, were ſo terrified by the appearance of the Roman forces on their iſland, that they immediately ſubmitted, and Angleſy was once more reſtored to the Romans.

With the conqueſt of Angleſey ended the firſt cam-

England.

paign of Agricola; and he employed the winter in reconciling the Britons to the Roman yoke. In this he met with ſuch ſucceſs, through his wiſe and equitable conduct, that the Britons, barbarous as they were, began to prefer a life of ſecurity and peace, to that independency which they had formerly enjoyed, and which continually expoſed them to the tumults and calamities of war. The ſucceeding campaigns of Agricola were attended with equal ſucceſs; he not only ſubdued the 17 nations inhabiting England, but carried the Roman arms almoſt to the extremity of Scotland. He alſo cauſed his fleet to ſail round the iſland, and diſcovered the Orcades, or Orkney iſlands, which had before been unknown to the reſt of the world. His expedition took him up about ſix years, and was completed in the year of Chriſt 84.

Had this commander been continued in Britain, it is probable that both Scotland and England would have been permanently ſubdued; but he was recalled by Domitian in the year 85, and we are then almoſt totally in the dark about the Britiſh affairs till the reign of the emperor Adrian. During this interval the Caledonians had taken arms, and not only refuſed ſubjection to the Roman power themſelves, but ravaged the territories of the Britons who continued faithful to them. Adrian, for what reaſon is not well known, abandoned to them the whole track lying between the Tyne and the Forth. At the ſame time, in order to reſtrain them from making incurſions into the Roman territories, he built a wall 80 miles in length from the river Eden in Cumberland to the Tyne in Northumberland *. He was ſucceeded by Antoninus Pius, in whoſe reign the Brigantes revolted; and the Caledonians, having in ſeveral places broken down the wall built by Adrian, began anew to ravage the Roman territories. Againſt them the emperor ſent Lollius Urbicus, who reduced the Brigantes; and having defeated the northern nations, confined them within narrower bounds by a new wall †, extending probably between the friths of Forth and Clyde. From the time of Antoninus to that of Severus, the Roman dominions in Britain continued to be much infeſted by the inroads of the northern nations. That emperor divided Britain into two governments, the ſouthern and northern; but the governor of the northern diviſion was ſo haraſſed by continual incurſions of the Caledonians, that he was at length obliged to purchaſe a peace with money. The Caledonians kept the treaty for 15 years; after which, breaking into the Roman territories anew, they committed terrible ravages. Virius Lupus the governor, not being in a condition to withſtand them, acquainted the emperor with his diſtreſs intreating him to ſend powerful and ſpeedy ſupplies. Upon this Severus reſolved to put an end to the perpetual incurſions of the enemy by making a complete conqueſt of their country; for which purpoſe he ſet out for Britain, together with his two ſons Caracalla and Geta, at the head of a numerous army. The Caledonians no ſooner heard of his arrival, than they ſent ambaſſadors offering to conclude a peace upon honourable terms But theſe the emperor detained till he was ready to take the field, and then diſmiſſed them without granting their requeſt.

* See Adrian.

† See Antoninus's wall.

22
Expedition of Severus into Britain.

As ſoon as the ſeaſon was fit for action, Severus marched into the territories of the Caledonians, where he put all to fire and ſword. He advanced even to the moſt northerly parts of the iſland; and though no battle was fought in this expedition, yet through the continual ambuſcades of the enemy, and the inhoſpitable nature of the country, he is ſaid to have loſt 50,000 men. At laſt the Caledonians were obliged to ſue for peace; which was granted them on condition of their yielding part of their country, and delivering up their arms. After this the emperor returned to York, leaving his ſon Caracalla to command the army, and finiſh the new wall which had been begun between the friths of Forth and Clyde. But the emperor being taken ill at York, the Caledonians no ſooner heard of his indiſpoſition, than they again took up arms. This provoked Severus to ſuch a degree, that he commanded his ſon Caracalla to enter their country anew with the whole army, and to put all he met to the ſword without diſtinction of ſex or age. Before theſe orders, however, could be put in execution, his two ſons, having concluded a ſhameful peace with the Caledonians, returned to Rome.

A long chaſm now takes place in the hiſtory of the Roman dominions in Britain. In the beginning of Diocleſian's reign, Carauſius a native of Gaul, paſſing over into Britain, took upon him the title of *emperor*, and was acknowledged by all the troops quartered here. He was, however, killed in a battle with one of Conſtantius's officers, after he had enjoyed the ſovereignty for ſix or ſeven years. Conſtantine the Great began his reign in this iſland; and returned ſoon after he had left it, probably with a deſign to put a ſtop to the daily incurſions of the Caledonians. He altered the diviſion of that part of Britain ſubject to the Romans. Severus had divided it only into two provinces; but Conſtantine increaſed the number to three: *viz.* Britannia Prima, Britannia Secunda, and Maxima Cæſarienſis; and this laſt was afterwards divided into two, *viz.* Maxima Cæſarienſis and Flavia Cæſarienſis. The removal of the imperial ſeat from Rome to Conſtantinople, which happened in the reign of Conſtantine, gave the northern nations an opportunity of making frequent incurſions into the Roman provinces; the emperor having carried with him, firſt into Gaul, and then into the Eaſt, not only moſt of the Roman troops, but likewiſe the flower of the Britiſh youth.

About the latter end of the reign of Conſtantius ſon to Conſtantine the Great, the government of the province of Britain and other weſtern parts of the empire, was committed to Julian, afterwards called the *apoſtate*. While he was in his winter-quarters at Paris, he was informed that the Scots and Picts, about this time firſt diſtinguiſhed by theſe names, had broken into the Roman territories and committed every where dreadful ravages. Againſt them Julian diſpatched a body of troops under the command of Lupicinius. He embarked from Bologne in the depth of winter, but was no ſooner arrived at London than he was recalled; the enemy having probably found means to appeaſe Julian by their ſubmiſſions. Till the reign of Valentinian I. theſe nations ſtill continued to infeſt the Roman territories in Britain, and had now reduced the country to a moſt deplorable condition by their continual ravages. Valentinian ſent againſt them Theodoſius, father to the emperor of that name. That general

ral having divided his forces into ſeveral bodies, advanced againſt the enemy, who were roving up and down the country. The Scots and Picts were obliged to yield to the ſuperior valour and diſcipline of the Romans. Great numbers were cut in pieces; they were forced to abandon all the booty and priſoners they had taken, and to retire beyond the friths of Forth and Clyde. Theodoſius then entered London in triumph, and reſtored that city to its former ſplendor, which had ſuffered greatly by the former incurſions of the northern Britons. To reſtrain them from breaking anew into the provinces, Theodoſius built ſeveral forts or caſtles between the two friths; and having thus recovered all the country between Adrian's wall and the friths of Forth and Clyde, he formed of it a fifth province which he called *Valentia*.

Though Britain was now reduced to a ſtate of temporary tranquillity, yet as the Roman empire was daily declining, it is not to be ſuppoſed that ſufficient care could be taken to ſecure ſuch a diſtant province. In the reign of the emperor Honorious, the provincial Britons found themſelves annoyed not only by the Scots and Picts, but alſo by the depredations of the Saxons, who began to commit ravages on the ſea-coaſts. By the care, however, of Stilicho, prime miniſter to Honorius, matters were once more ſettled, and a particular officer was appointed to guard the coaſt againſt the attempts of the Saxons, with the title of *Comes limitis Saxonici*. But, not long after, the empire being over-run by barbarians, moſt of the Roman troops quartered in Britain were recalled, and the country left quite open to the attacks of the Scots and Picts.

13
Bri-
chooſe
nperor
ieir

Upon this the provincials expecting no more aſſiſtance from Honorius, reſolved to ſet up an emperor of their own. Accordingly they inveſted with the imperial dignity one *Mark*, an officer of great credit among them. Him they murdered in a few days, and placed on the throne one Gratian a native of Britain. After a reign of four months, Gratian underwent the fate of his predeceſſor; and was ſucceeded by *Conſtantine*, a common ſoldier, who was choſen merely for the ſake of his name. He ſeems, however, to have been a man of ſome knowledge and experience in war. He drove the Scots and Picts beyond the limits of the Roman territories; but being elated with this ſucceſs, he would now be ſatisfied with nothing leſs than the conqueſt of the whole Roman empire. He therefore paſſed over into Gaul; and took with him not only the few Roman forces that had been left, but ſuch of the provincial Britons as were moſt accuſtomed to arms. That unhappy people, being now left entirely defenceleſs, were haraſſed in the moſt cruel manner by their enemies; who broke into the country, and deſtroyed all with fire and ſword. In this miſerable ſituation they continued from the year 407, when the uſurper Conſtantine paſſed over into Gaul, till the year 410. Having during the laſt three years frequently implored aſſiſtance from Rome without receiving any, they now reſolved to withdraw their allegiance from an empire which was no longer able to protect them. Honorius himſelf applauded their conduct; and adviſed them by letters to provide for their own ſafety, which was in effect an implicit reſignation of the ſovereignty of the iſland.

The provincial Britons now regained their liberty; but they had loſt the martial ſpirit which had at firſt rendered them ſo formidable to the Romans. They ſeem, however, to have met with ſome ſucceſs in their firſt enterpriſes; for Zoſimas tells us, that they delivered their cities from the inſults of an haughty enemy.

24
Implore the aſſiſtance of the Romans.

But being at laſt overpowered, they were again obliged to have recourſe to the Roman emperor, to whom they promiſed a moſt perfect ſubmiſſion, provided they were delivered from the hands of their mercileſs and implacable enemies. Honorius, touched with compaſſion, ſent a legion to their relief. The Roman forces landed in Britain unexpectedly; and having deſtroyed great numbers of the Scots and Picts, they drove them beyond the friths of Forth and Dunbritton. After this they adviſed the natives to build a wall on the iſthmus from ſea to ſea, and to reaſſume their courage, and defend themſelves from their enemies by their own valour. The Romans then quitted the country; being obliged to return, in order to repulſe thoſe barbarians who had broken into the empire from all quarters.

The Britons immediately ſet about building the wall, as they had been deſired, with great alacrity. But as it was conſtructed only of turf, the Scots and Picts ſoon broke it down in ſeveral places; and, pouring in upon the defenceleſs and effeminate provincials, committed more cruel ravages than ever.

25
Send ambaſſadors a ſecond time to Rome.

At laſt, after very many and grievous calamities, the latter ſent ambaſſadors once more to Rome. Theſe appeared with their garments rent and duſt on their heads; and at laſt prevailed on the emperor, by their earneſt intreaties, to ſend another legion to their relief. The troops arrived in Britain before the enemy had the leaſt knowledge of their having ſet ſail. They were therefore quite unprepared for an attack, and roving up and down the country in the utmoſt diſorder. The Romans made a terrible havock among them, and drove the remainder into their own country. As Honorius had ſent them not with any ambitious view of retaining the iſland in ſubjection, but merely out of compaſſion to the unhappy provincials, the Romans told them, they had now no farther aſſiſtance to expect from them. They informed them, that the legion muſt immediately return to the continent, to protect the empire from the barbarians, who had extended their ravages almoſt to every part of it; and therefore, that they muſt now take their laſt farewel of Britain, and totally abandon the iſland. After this declaration Gallio, the commander of the Roman troops, exhorted the provincials to defend themſelves, by fighting bravely for their country, wives, and children, and what ought to be dearer than life itſelf, their liberty; telling them, at the ſame time, that their enemies were no ſtronger than themſelves, provided they would but lay aſide their fears, and exert their ancient courage and reſolution. That they might the better withſtand the attacks of the enemy, he adviſed them to build a wall, not of turf, but of ſtone; offering to aſſiſt them with his ſoldiers, and to direct them himſelf in the execution. Upon this the Britons immediately fell to work; and with the aſſiſtance of the Romans, finiſhed it in a ſhort time, though it was no leſs than eight feet thick, and twelve feet in height. It is thought to have been built on the ſame place where Severus's wall formerly ſtood. Towers were alſo built at con-

26 Britain finally abandoned by the Romans.

venient diſtances on the eaſt coaſt, to prevent the deſcents of the Saxons and other barbarians that came from Germany. Gallio employed the reſt of his time in teaching the provincials the art of war. He left them patterns of the Roman weapons, which he alſo taught them to make; and after many encouraging exhortations, he took his laſt farewel of Britain, to which the Romans never returned. There is a great diſagreement among chronologers as to the year in which the Romans finally abandoned Britain; ſome placing it in 422; others in 423, or 426; and ſome in 431, 435, or 437.

The final departure of the Romans was no ſooner known to the Scots and Picts, than they poured in upon the provincial Britons from all quarters, like hungry wolves breaking into a ſheep-fold. When the Scots approached the new built-wall, they found it completely finiſhed, and guarded by great numbers of armed men. But ſo little had the provincial Britons profited by the military inſtructions of the Romans, that inſtead of placing proper guards and centinels, and relieving one another by turns, their whole number had ſtaid ſeveral days and nights upon the ramparts without intermiſſion. Being therefore quite benumbed and wearied out, they were able to make but very little reſiſtance.

27 Britons miſerably haraſſed by the Scots and Picts.

Many were pulled down with hooks from the battlements, and daſhed in pieces. The reſt were driven from their ſtations with ſhowers of darts and arrows. They betook themſelves to flight; but that could not ſave them. The Scots and Picts purſued them cloſe, made a dreadful havock among the fugitives, and took poſſeſſion of the frontier towns, which they found deſerted by the inhabitants. As they now met with no more oppoſition, they over-ran the whole country, putting every thing to fire and ſword. Their ravages ſoon occaſioned a famine; and this was followed by a kind of civil war. The provincials, unable to ſupport themſelves, were obliged to plunder each other of the little the common enemy had left them. The whole country at laſt became ſo incapable of ſupporting thoſe who were left in it, that many fled into the woods, in order to ſubſiſt themſelves there by hunting.

28 Implore the aſſiſtance of the Romans.

In this extremity of diſtreſs, they had once more recourſe to the Romans; and wrote in the moſt mournful ſtyle that can poſſibly be imagined to Aetius, who was then conſul the third time. Their letter they directed thus: "The groans of the Britons to the conſul Aetius." The contents of this letter were anſwerable to the direction. "The barbarians (ſay they) drive us to the ſea; the ſea drives us back to the barbarians; between which we have only the choice of two deaths, either to be ſwallowed up by the waves, or to be cruelly maſſacred by the enemy."

To this letter the Roman general gave no ſatisfactory anſwer, and the provincials were thereupon reduced to deſpair. Great numbers of them fled over to Armorica, where they ſettled along with others who had formerly gone over with an uſurper called *Maximus*; while others ſubmitted to the Scots and Picts. Some, however, more reſolute than the reſt, had once more recourſe to arms.

29 They at laſt repulſe their enemies.

They ſallied out in parties from the woods and caves where they had been obliged to hide themſelves, and, falling unexpectedly on the enemy, cut great numbers of them in pieces, and obliged the reſt to retire. Having thus obtained ſome reſpite, they began again to cultivate their lands; which, having lain fallow for a long time, now produced all ſorts of corn in the greateſt plenty. This plenty, according to the hiſtorian Gildas, occaſioned the moſt conſummate wickedneſs and corruption of manners among all ranks of men. The clergy, ſays he, who ſhould have reclaimed the laity by their example, proved the ringleaders in every vice; being addicted to drunkenneſs, contention, envy, &c.—It is poſſible, however, that this deſcription might be exaggerated by Gildas, who was himſelf a monk. But however this was, the Britons had not long enjoyed peace, when they were alarmed by a report, that the Scots and Picts were about to return with a far greater force than before, utterly to extirpate the name of their ſouthern neighbours, and ſeize upon the country for themſelves.

30 Are aga
threaten
with an
vaſion.

This report threw them into a terrible conſternation; and to add to the reſt of their misfortunes, they were now viſited by a dreadful plague, which raged with ſuch violence, that the living were ſcarce ſufficient to bury the dead. The contagion no ſooner ceaſed, than they found their country invaded by the Scots and Picts, who deſtroyed every thing with fire and ſword; ſo that the provincials were ſoon reduced to the ſame miſerable ſtate they had formerly been in.

At this time the chief, if not the only, king of the ſouthern diviſion of Britain, was one *Vortigern*. He is ſaid to have been a cruel, debauched tyrant, regardleſs of the public welfare, and totally incapable of promoting it. Being now rouſed from his ſenſibility, however, by a ſenſe of his own danger, he ſummoned a council of the chief men of the nation, in order to deliberate about the proper means for delivering the country from thoſe calamities under which it groaned.

31 They r
ſolve to
in the S
ons.

In this council the moſt pernicious meaſure was adopted that could poſſibly have been reſolved on; namely, to invite to their aſſiſtance the *Saxons*, a people famous for their piracies and cruelty, and juſtly dreaded by the Britons themſelves *. This fatal expedient being agreed upon, ambaſſadors were immediately diſpatched into Germany with advantageous propoſals to the Saxons in caſe they would come over to their aſſiſtance.

The Britiſh ambaſſadors ſoon arrived in Germany, and, according to Witichind, a Saxon hiſtorian of the ninth century, made the following ſpeech before an aſſembly of the Saxons.—"Illuſtrious Saxons, the fame of your victories having reached our ears, the diſtreſſed Britons, haraſſed by the continual inroads of a neighbouring enemy, ſend us to implore your aſſiſtance. We have a fertile and ſpacious country, which we are commanded to ſubmit to you. We have hitherto lived under the protection of the Roman empire; but our ancient maſters having abandoned us, we know no nation more powerful than you, and better able to protect us. We therefore recur to your valour. Forſake us not in our diſtreſs, and we ſhall readily ſubmit to what terms you yourſelves ſhall think fit to preſcribe to us."—If this abject and ſhameful ſpeech was really made, it muſt give us a very ſtrange idea of the national ſpirit of the provincial Britons at that time. It is, however, probable that the whole is a fiction, deſigned only to excuſe the perfidious treatment which theſe Britons afterwards received from the Saxons,

---

ons.

Saxons. The moſt reſpectable even of the Saxon hiſtorians make no mention of ſuch a ſpeech; and it is certain, that when the Saxons themſelves wanted to quarrel with the Britons, they never inſiſted upon the promiſe made by the Britiſh ambaſſadors; which they moſt certainly would have done, had any ſuch promiſe ever been made.

The Britiſh ambaſſadors were very favourably received by the Saxons. The latter embraced their propoſal with joy; and the rather, becauſe their ſoothſayers foretold that they ſhould plunder their Britiſh allies for 150 years, and reign over them for twice that time. Three long ſhips, in the Saxon language called *chiules*, were therefore fitted out, under the conduct of Hengiſt and Horſa. Theſe were two brothers much celebrated both for their valour and nobility. They were ſons of Witigiſil, ſaid to be great-grandſon to the Saxon god Woden; a circumſtance which added much to their authority. Having embarked about 1600 men on board their three veſſels, the two brothers arrived in the iſle of Thanet, in the year 449 or 450.

2 Saxons e in in, and t the and

They were received by the inhabitants with the greateſt demonſtrations of joy: the iſle in which they had landed was immediately appointed for their habitation; and a league was concluded, in virtue of which the Saxons were to defend the provincial Britons againſt all foreign enemies; and the provincials were to allow the Saxons pay and maintenance, beſides the place allotted them for their abode. Soon after their arrival, king Vortigern led them againſt the northern nations who had lately broke into the kingdom, and advanced as far as Stanford in the county of Lincolnſhire. Here a battle was fought, in which the Scots and Picts were utterly defeated, and obliged to relinquiſh their booty.

Vortigern was ſo highly pleaſed with the behaviour of his new allies, that he beſtowed large poſſeſſions in the country they had newly delivered, upon the two commanders Hengiſt and Horſa. It is ſaid, that, even at this time, Hengiſt was taken with the wealth and fertility of the country; and at the ſame time obſerving the inhabitants to be quite enervated with luxury, began to entertain hopes of conquering part of it. He therefore, with Vortigern's conſent, invited over ſome more of his countrymen; giving them notice at the ſame time of the fruitfulneſs of the country, the effeminacy of the inhabitants, and how eaſily a conqueſt might be effected.

3 ſup- of ns ar-

The Saxons readily complied with the invitation; and, in 452, as many more arrived in 17 veſſels, as, with thoſe already in Britain, made up an army of 5000 men. Along with theſe, according to Nennius, came over Rowena the daughter of Hengiſt. Vortigern fell in love with this lady; and in order to obtain her in marriage, divorced his lawful wife. Hengiſt pretended to be averſe to the match; but Vortigern obtained his conſent by inveſting him with the ſovereignty of Kent. The Saxon hiſtorians, indeed, make no mention of Rowena; but rather inſinuate, that their countrymen made themſelves maſters of Kent by force of arms. It ſeems moſt probable, however, that Vortigern had as yet continued in friendſhip with the Saxons, and even put more confidence in them than in his own ſubjects. For, not long after the arrival of this firſt reinforcement, Hengiſt obtained leave to ſend for a ſecond, in order, as was pretended, to defend the king from the attempts of his rebellious ſubjects, as well as of the Scots and Picts. Theſe embarked in 40 ſhips, under the command of Octa and Ebuſa, the ſon and nephew, or, according to ſome, the brother and nephew of Hengiſt. They landed at the Orkney iſlands; and having ravaged them, as well as all the northern coaſts of Scotland, they conquered ſeveral places beyond the Frith, and at laſt obtained leave to ſettle in Northumberland.

34 They quarrel with the Britons.

The pretence made for this ſettlement was, that the Saxons under Octa and Ebuſa might defend the northern frontiers of the kingdom, as thoſe under Hengiſt and Horſa did the ſouthern parts. Many more Saxons were, under various pretences, invited over; till at laſt the countries from which they came were in a manner depopulated. And now their numbers being greatly increaſed, the Saxons began to quarrel with the natives. They demanded larger allowances of corn, and other proviſions; threatening to lay waſte the whole country if their demands were not complied with. The Britons, inſtead of complying with theſe demands, deſired them to return home, ſince their numbers exceeded what they were able to maintain. Upon this, the Saxons concluded a peace with the Scots and Picts; and, turning their arms againſt the unhappy provincials, over-ran the whole country. The Saxons committed every where the greateſt cruelties. All buildings, whether public or private, they levelled with the ground. The cities were pillaged and burnt; and the people maſſacred without diſtinction of ſex or age, and that in ſuch numbers, that the living ſcarce ſufficed to bury the dead. Some of thoſe who eſcaped the general ſlaughter, took refuge among inacceſſible rocks and mountains; but there great numbers periſhed with hunger, or were forced to ſurrender themſelves as ſlaves to their enemies. Some croſſed the ſea and ſettled either in Holland or in Armorica, now the province of Brittany in France.

35 They are defeated and driven out by Vortimer.

Vortigern, we are told by Nennius, was ſo far from being reclaimed by theſe calamities, that he added inceſt to his other crimes, and married his own daughter. At laſt, his own ſubjects, provoked at his enormous wickedneſs, and the partiality he ſhowed to the Saxons, depoſed him, and raiſed his ſon Vortimer to the throne. He was a young man of great valour, and willingly undertook the defence of his diſtreſſed country. He firſt fell upon the Saxons with what troops he could aſſemble, and drove them into the iſle of Thanet. Here they were beſieged, till, being reinforced by freſh ſupplies from Germany, they opened themſelves a way through the Britiſh troops. Vortimer, however, was not yet diſheartened. He engaged the Saxons on the banks of the Derwent in Kent, where he obtained a complete victory, and cut in pieces great numbers of the enemy. Another battle was fought at Aylesford in Kent. Some aſcribe the victory at this time to the Saxons, and ſome to the Britons. It is certain, however, that Horſa the brother of Hengiſt was killed in this engagement. He is ſaid to have been buried at a place in the neighbourhood, which from him obtained the name of *Horſted*.—A third battle was fought, in which the victory was uncertain, as is alſo the place where it happened. The fourth battle, however, according to Nennius, proved deciſive

deciſive in favour of the Britons. Vortimer engaged his enemies, according to ſome, at Folkſtone; according to others, at a place called *Stonar*, in the iſle of Thanet. The Saxons were defeated with great ſlaughter, and driven back to their ſhips. So complete is this victory ſaid to have been, that the Saxons quitted the iſland, without making any attempt upon it for five years afterwards. Theſe battles, however, reſt entirely upon the credit of Nennius, and the hiſtorians who have followed him. They are taken notice of neither by Gildas nor Bede. The former only acquaints us, that the Saxons retired. This, by moſt hiſtorians, is underſtood of their returning home; tho' it is poſſible he might mean no more, than that, after they had laid waſte the country, they retired into the territories allotted them by Vortigern, in Kent and Northumberland.

Vortimer is ſaid to have died after a reign of ſix years. On his death-bed, he deſired his ſervants to bury him near the place where the Saxons uſed to land; being perſuaded, that the virtue of his bones would effectually prevent them from ever touching the Britiſh ſhore. This command, however, was neglected; and Vortimer was buried at Lincoln, according to ſome, or London, according to others. Hengiſt was no ſooner informed of his death, than he invaded Britain anew with a numerous body of Saxons. He was oppoſed by Vortigern, who had been reſtored to the throne after the death of his ſon Vortimer. Several battles were fought on this occaſion; but at laſt the provincials being overthrown at a place called *Crecanford*, with the loſs of 4000 men, were obliged to abandon Kent to their enemies, and retire to London. This happened about the year 458 or 459; and from this time moſt hiſtorians date the erection of the firſt Saxon kingdom in Britain, viz. that of Kent. Hengiſt aſſumed the title of *king*, and choſe Eſk his ſon for his colleague.

36
They return and defeat the Britons, and erect a kingdom in Kent.

The Britons under Vortigern ſtill continued the war. Hengiſt finding himſelf unable to gain a deciſive advantage over them in the field, had recourſe to treachery. He pretended to be deſirous of concluding a peace with the Britiſh monarch, and of renewing his ancient friendſhip with him; and therefore required an interview. To this Vortigern readily conſented, and accepted of an entertainment prepared for him by Hengiſt. The king was attended by 300 nobility all unarmed, but the Saxons had concealed daggers below their garments. The Britiſh nobility were all treacherouſly maſſacred in the height of their mirth; Vortigern himſelf was taken and put in fetters; nor could his liberty be procured, but by ceding to the Saxons thoſe provinces now called *Eſſex*, *Suſſex*, and *Middleſex*. Thus the Saxons got ſuch a footing in Britain that they could never afterwards be expelled. Vortigern, after being ſet at liberty, is ſaid to have retired to a vaſt wilderneſs near the fall of the Wye in Radnorſhire, where he was ſome time after conſumed by lightning, together with a city called *Kaer Gourtigern* which he had built in that place.

37
Treachery of the Saxons.

On the retreat of Vortigern, the command of the Britiſh forces devolved upon Aurelius Ambroſius, or, as Gildas calls him, Ambroſius Aurelianus. He was a Roman, and perhaps the laſt that remained in the iſland. He is ſaid to have gained ſeveral victories over the Saxons. Notwithſtanding this, however, they ſtill continued to gain ground; and in the year 491, the foundation of a ſecond Saxon kingdom was laid in Britain. This at firſt comprehended only the county of Suſſex, but ſoon after extended over moſt of the countries lying ſouth of the Humber. It was called the *kingdom of the South Saxons*.

38
Second
on king
dom.

The German nations being now informed of the good ſucceſs which had attended the Saxons in Britain, new adventurers daily flocked over to ſhare the good fortune of the others. They were chiefly compoſed of three nations, the Saxons, Angles, and Jutes. All theſe paſſed under the common appellation ſometimes of *Saxons*, ſometimes of *Angles*. They ſpoke the ſame language, and agreed very much in their cuſtoms and inſtitutions, ſo that all of them were naturally led to combine againſt the natives. The moſt active of theſe adventurers was Cerdic a Saxon, ſaid to be the tenth in deſcent from Woden. He landed with his ſon Cenric, and as many men as he could convey in five ſhips, at Yarmouth in Norfolk. The provincials immediately attacked him with great vigour; but after a ſhort engagement, they were totally defeated. Many other battles were fought, the event of which was always favourable to the Saxons, ſo that the Britons were forced to abandon their ſea-coaſts to them.

In 497, *Porta*, another Saxon, with his two ſons *Bleda* and *Magla*, arrived at *Portſmouth*, ſo called, as ſome imagine, from this chieftain. The provincials, under the command of a young prince a native of the country, attempted to oppoſe the landing of the Saxons: but his army was defeated with great ſlaughter, and he himſelf killed in the engagement; after which Porta made himſelf maſter of all the neighbouring country. The progreſs of Cerdic, however, alarmed the Britons more than that of all the other Saxon princes. About the year 508, therefore, *Nazaleod*, ſtyled, by Henry of Huntingdon, the *greateſt of all the Britiſh kings*, aſſembled almoſt the whole ſtrength of the provincial Britons in order to drive him out of the iſland. Cerdic on the other hand took care to ſtrengthen himſelf by procuring aſſiſtance from all the Saxons already in the iſland. He then advanced againſt the Britons, commanding the right wing himſelf, and his ſon Cenric the left. As the two armies drew near each other, Nazaleod perceived the enemy's right wing to be much ſtronger than the left. He therefore attacked it with the flower of his army; and after an obſtinate reſiſtance, obliged Cerdic to ſave himſelf by flight. Being too eager in the purſuit, however, Cenric fell upon his rear, and the battle was renewed with great vigour. The Britiſh army was at laſt entirely defeated; and 5000 men, among whom was Nazaleod himſelf, were left dead on the ſpot.

39
Nazale
king
Britain
feated a
killed.

Who ſucceeded Nazaleod in the kingdom of Britain, is not known. The Welſh annals leave an interregnum of about ſix years; after which they place the beginning of the reign of Arthur, the moſt renowned Britiſh prince mentioned in hiſtory. The hiſtory of king Arthur is ſo much obſcured by fables, and many abſurd, romantic, and ridiculous ſtories, that ſome have ſuppoſed that no ſuch perſon ever exiſted. On this ſubject Milton gives the following reaſons againſt the exiſtence of king Arthur: 1. He is not mentioned by Gildas,

40
Wheth
ſuch a
ſon as
Arthur
ver exi

Gildas, or any Britiſh hiſtorian except Nennius, who is allowed on all hands to have been a very credulous writer, and to have publiſhed a great many fables. 2. Though William of Malmeſbury and Henry of Huntingdon have both related his exploits, yet the latter took all he wrote from Nennius; and the former, either from the ſame fabulous writer, or ſome Monkiſh legends in the abbey of Glaſtenbury; for both theſe writers flouriſhed ſeveral centuries after king Arthur. 3. In the pretended hiſtory of Geoffroy of Monmouth, ſuch contradictions occur concerning this monarch's victories in France, Scotland, Ireland, Norway, Italy, &c. as muſt cauſe us to look upon him as an hero altogether fabulous and romantic.

In anſwer to this it has been ſaid, 1. That his not being mentioned by Gildas cannot ſeem ſtrange to us, ſeeing it was not that author's deſign to write an exact hiſtory of his country, but only to give a ſhort account of the cauſes of its ruin by the Scots, Picts, and Saxons. He had alſo a particular ſyſtem to ſupport, namely, That the ruin of the Britons was owing to the judgements of God upon them for their wickedneſs. He lies therefore under a great temptation to conceal the ſucceſſes of the Britons, and to relate only their miſfortunes. 2. Though Nennius was a credulous writer, it is unreaſonable to think that the whole hiſtory of king Arthur was an invention of his. It is more probable that he copied it from other more ancient authors, or took it from the common tradition of his countrymen. That the Saxon annals make no mention of this king is not to be wondered at, ſeeing it is natural to think that they would wiſh to conceal the many defeats he gave their nation 3. The moſt convincing proof of the exiſtence of king Arthur is, that his tomb was diſcovered at Glaſtenbury in Somerſetſhire, and his coffin dug up, in the reign of Henry II. with the following inſcription upon it in Gothic characters: "Hic jacet ſepultus inclytus rex Arturius in inſula Avalonia." We are told that on his body were plainly to be ſeen the marks of 10 wounds, only one of which ſeemed to be mortal.

This renowned prince is ſaid to have defeated the Saxons under Cerdic in 12 pitched battles. The laſt of theſe was fought on Badon-hill, ſuppoſed to be Banſdown near Bath; in which the Saxons received ſuch a terrible overthrow, that for many years they gave the Britons no further moleſtation. As new ſupplies of Saxons, however, were continually flocking over, a third and fourth kingdom of them were ſoon formed. The third kingdom comprehended the counties of Devon, Dorſet, Somerſet, Wiltſhire, Hampſhire, and Berkſhire; to which was afterwards added Cornwal. This was called the *kingdom of the Weſt Saxons*. The other kingdom, which was called the *kingdom of the Eaſt Saxons*, comprehended Eſſex, Middleſex, and part of Hertfordſhire.

In the year 542, happened the death of the great king Arthur, ſaid to have been killed in battle with a treacherous kinſman of his own. Five years afterwards, was erected the Saxon kingdom of Northumberland. It extended, however, much farther than the preſent bounds of that country; for it comprehended all Yorkſhire, Lancaſhire, Durham, Cumberland, Weſtmoreland, amd Northumberland, with part of Scotland, as far as the frith of Forth. Between theſe Saxon, kings frequent contentions now aroſe; by which means the Britons enjoyed an uninterrupted tranquillity for at leaſt 44 years. This interval, however, according to Gildas, they employed only in corrupting their manners more and more, till at laſt they were rouſed from their ſecurity by the ſetting up of a ſixth Saxon kingdom, called the kingdom of the *Eaſt Angles*. It was founded in 575, and comprehended the counties of Norfolk, Suffolk, Cambridgeſhire, and the Iſle of Ely. The Saxons once more attacked the Britons, and overthrew them in many battles. The war was continued for ten years; after which, another Saxon kingdom called *Mercia* was ſet up. It comprehended 17 counties; viz. Glouceſter, Hereford, Worceſter, Warwick, Leiceſter, Rutland, Northampton, Lincoln, Huntington, Bedford, Buckingham. Oxford, Stafford, Nottingham, Derby, Shropſhire, Cheſhire, and part of Hertfordſhire.

43
The Britons defeat the Saxons, but are obliged to retire into Wales.

The provincial Britons were now confined within very narrow bounds. However, before they entirely gave up the beſt part of their country to their enemies, they once more reſolved to try the event of a battle. At this time they were aſſiſted by the Angles, who were jealous of the overgrown power of the Weſt Saxons. The battle was fought in Wiltſhire, at Woden's Bearth, a place near the ditch called *Wanſdike* or *Wodenſdike*; which runs through the middle of the county. The battle was very obſtinate and bloody; but at laſt the Saxons were entirely defeated, and almoſt their whole army cut off. The victory, however, proved of little ſervice to the Britons: for being greatly inferior in number to the Saxons, and haraſſed by them on the one ſide, and by the Scots and Picts on the other, they were daily more and more confined; and at laſt obliged to take refuge among the craggy and mountainous places in the weſt of the iſland, where their enemies could not purſue them. At firſt they poſſeſſed all the country beyond the rivers Dee and Severn, which anciently divided Cambria, or Wales, from England; the towns which ſtand on the eaſtern banks of theſe rivers having moſtly been built in order to reſtrain the incurſions of the Welſh. But the Engliſh, having paſſed the Severn, by degrees ſeized on the country lying between that river and the Wye. Nay, in former time, ſome parts of Flintſhire and Denbighſhire were ſubject to the kings of Mercia: for Uffa, the moſt powerful king of that country, cauſed a deep ditch to be drawn, and a high wall built, as a barrier between his dominions and the territories of the Welſh, from the mouth of the Dee, a little above Flint-caſtle, to the mouth of the Wye. This ditch is ſtill to be ſeen in ſeveral places; and is called by the Welſh *Claudh Uffa*, or the Ditch of Uffa. The inhabitants of the towns on the eaſt ſide of this ditch are called by the ſame people *Guyr y Mers*; that is, the men of Mercia.

44
Account of the heptarchy.

Thus, after a violent conteſt of near 150 years, the Saxons entirely ſubdued the Britons whom they had come to defend, and had erected ſeven independent kingdoms in England, now commonly denominated the *Saxon Heptarchy*. By theſe conquerors the country was now reduced to a degree of barbarity almoſt as great as it had been in when firſt invaded by the Romans. The provincial Britons, during their ſubjection to that people, had made conſiderable advances in civilization.

vilization. They had built 28 conſiderable cities, beſides a number of villages and country-ſeats; but now theſe were all levelled with the ground, the native inhabitants who remained in England were reduced to the moſt abject ſlavery, and every art and ſcience totally extinguiſhed among them.

Before theſe fierce conquerors could be civilized in any degree, it was neceſſary that all the ſeven kingdoms ſhould be reduced under one head; for as long as they remained independent, their continual wars with each other ſtill kept them in the ſame ſtate of barbarity and ignorance.

The hiſtory of theſe ſeven kingdoms affords no event that can be in the leaſt intereſting. It conſiſts only of a detail of their quarrels for the ſovereignty. This was at laſt obtained by Egbert king of the Weſt Saxons, or Weſſex, in 827. Before this time, Chriſtianity had been introduced into almoſt all the kingdoms of the heptarchy; and however much corrupted it might be by coming through the impure channel of the church of Rome, and miſunderſtood through the ignorance of thoſe who received it, it had conſiderably ſoftened the barbarous manners of the Saxons. It had alſo opened a communication between Britain and the more polite parts of Europe, ſo that there was now ſome hope of the introduction of arts and ſciences into this country. Another effect was, that, by the ridiculous notions of preſerving inviolable chaſtity even between married people, the royal families of moſt of the kingdoms were totally extinct; and the people, being in a ſtate of anarchy, were ready to ſubmit to the firſt who aſſumed any authority over them.

All theſe things contributed to the ſucceſs of Egbert in uniting the heptarchy under his own dominion. He was of the royal family of Weſſex; and a nearer heir than Brithric, who had been raiſed to the kingdom in 784. As Egbert was a prince of great accompliſhments, Brithric, knowing that he had a better title to the crown than himſelf, began to look upon him with a very jealous eye. Young Egbert, ſenſible of his danger, privately withdrew to France; where he was well received by Charlemagne, the reigning monarch. The French were reckoned at this period the moſt valiant and polite people in Europe; ſo that this exile proved of great ſervice to Egbert.

He continued at the court of France till he was recalled by the nobility to take poſſeſſion of the kingdom of Weſſex. This recal was occaſioned by the following accident. Brithric the king of Weſſex had married Eadburga, natural daughter of Offa king of Mercia; a woman infamous for cruelty and incontinence. Having great influence over her huſband, ſhe often perſuaded him to deſtroy ſuch of the nobility as were obnoxious to her; and where this expedient failed, ſhe herſelf had not ſcrupled to become their executioner. She had mixed a cup of poiſon for a young nobleman, who had acquired a great ſhare of her huſband's friendſhip: but, unfortunately, the king drank of the fatal potion along with his favourite, and ſoon after expired. By this and other crimes Eadburga became ſo odious to the people, that ſhe was forced to fly into France, whence Egbert was at the ſame time recalled, as above mentioned.

Egbert aſcended the throne of Weſſex in the year 799. He was the ſole deſcendant of thoſe conquerors who firſt invaded Britain, and who derived their pedigree from the god Woden. But though this circumſtance might have given him great advantages in attempting to ſubdue the neighbouring kingdoms, Egbert for ſome time gave them no diſturbance; but turned his arms againſt the Britons, who had retired into Cornwall, whom he defeated in ſeveral battles. He was recalled from his conqueſts in that country, by hearing that Bernulf king of Mercia had invaded his dominions. Egbert quickly led his army againſt the invaders, whom he totally defeated at Ellendun in Wiltſhire. He then entered their kingdom on the ſide of Oxfordſhire with an army, and at the ſame time ſent his eldeſt ſon Ethelwolf with another into Kent. The young prince expelled Baldred the tributary king of Kent, and ſoon made himſelf maſter of the country. The kingdom of Eſſex was conquered with equal eaſe; and the Eaſt Angles, who had been reduced under ſubjection by the Mercians, joyfully put themſelves under the protection of Egbert. Bernulf himſelf marched againſt them, but was defeated and killed; and Ludecan his ſucceſſor met with the ſame fate two years after.

Theſe misfortunes greatly facilitated the reduction of Mercia. Egbert ſoon penetrated into the very heart of the Mercian territories, and gained an eaſy victory over a diſpirited and divided people; but in order to engage them to ſubmit with the leſs reluctance, he allowed Wiglef, their countryman, to retain the title of *king*, whilſt he himſelf exerciſed the real power of a ſovereign. Northumberland was at preſent in a ſtate of anarchy: and this tempted Egbert to carry his victorious arms into that kingdom alſo. The inhabitants, being deſirous of living under a ſettled form of government, readily ſubmitted, and owned him for their ſovereign. To them, however, he likewiſe allowed the power of electing a king; who paid him a tribute, and was dependent on him.

4
Egber
firſt k
Engl

Egbert became ſole maſter of England about the year 827. A favourite opportunity was now offered to the Anglo-Saxons of becoming a civilized people, as they were at peace among themſelves, and ſeemed free from any danger of a foreign invaſion. But this flattering proſpect was ſoon overcaſt. Five years after Egbert had eſtabliſhed his new monarchy, the Danes landed in the iſle of Shepey, plundered it, and then made their eſcape with ſafety. Encouraged by this ſucceſs, next year they landed from a fleet of 35 ſhips. They were encountered by Egbert at Charmouth in Dorſetſhire. The battle was obſtinate and bloody. Great numbers of the Danes were killed, but the reſt made good their retreat to their ſhips. They next entered into an alliance with the Britons of Cornwall; and landing two years after in that country, they made an irruption into Devonſhire. Egbert met them at Hengeſdown, and totally defeated them; but before he had time to form any regular plan for the defence of the kingdom, he died, and left the government to his ſon Ethelwolf.

4
Daniſ
vaſion

Ethe

The new king was weak and ſuperſtitious. He began with dividing the kingdom, which had ſo lately been united, with his ſon Athelſtan. To the young prince he gave the counties of Eſſex, Kent, and Suſſex. But though this diviſion might have been productive of of bad conſequences at another time, the fear of the Danes kept every thing quiet for the preſent. Theſe barbarians had ſome how or other conceived ſuch hopes of enriching themſelves by the plunder of England, that they ſcarce ever failed of paying it an annual viſit. The Engliſh hiſtorians tell us, that they met with many ſevere repulſes and defeats; but on the whole it appears that they had gained ground: for in 851 a body of them took up their winter-quarters in England. Next year they received a ſtrong reinforcement of their countrymen in 350 veſſels; and advancing from the iſle of Thanet, where they had ſtationed themſelves, they burnt the cities of London and Canterbury. Having next put to flight Brichtric the governor of Mercia, they marched into the heart of Surry, laying waſte the whole country through which they paſſed.

Ethelwolf, though naturally little fitted for military enterpriſes, was now obliged to take the field. He marched againſt the Danes at the head of the Weſt Saxons, and gained an indeciſive and bloody victory over his enemies. The Danes ſtill maintained their ſettlement in the iſle of Thanet. They were attacked by Ealher and Huda, governors of Kent and Surry; both of whom they defeated and killed. Afterwards they removed to the iſle of Shepey, where they took up their winter-quarters, with a deſign to extend their ravages the next year.

The deplorable ſtate of the kingdom did not hinder Ethelwolf from making a pilgrimage to Rome, whither he carried his fourth and favourite ſon Alfred, then only ſix years of age. He paſſed a twelvemonth in that city; made preſents to the principal eccleſiaſtics there; and made a grant of 300 mancuſes (a ſilver coin about the weight of our half-crown) annually to the ſee of Rome. One-third of this was to ſupport the lamps of St Peter's, another thoſe of St Paul's, and the third was for the Pope himſelf. In his return to England, Ethelwolf married Judith, daughter of the emperor Charles the Bald; but when he landed, he found himſelf deprived of his kingdom by his ſon Ethelbald. That prince aſſumed the government of Athelſtan's dominions, who was lately dead; and, with many of Ethelwolf's nobles, formed a deſign of excluding him from the throne altogether, on account of his weakneſſes and ſuperſtitions. Ethelwolf, however, delivered the people from the calamities of a civil war, by dividing the kingdom with his ſon. He gave to Ethelbald the goverment of the weſtern, and reſerved to himſelf that of the eaſtern part of the kingdom. Immediately after this, he ſummoned the ſtates of the whole kingdom, and conferred on the clergy a perpetual donation of tythes, for which they had long contended, and which had been the ſubject of their ſermons for ſeveral centuries.

This conceſſion was deemed ſo meritorious by the Engliſh, that they now thought themſelves ſure of the favour of heaven; and therefore neglected to uſe the natural means for their ſafety which they might have done. They even agreed, that, notwithſtanding the deſperate ſituation of affairs at preſent, the revenues of the church ſhould be exempted from all burdens, though impoſed for the immediate ſecurity and defence of the nation. Ethelwolf died two years after he had made the above mentioned grant, and left the kingdom to his two eldeſt ſons Ethelbald and Ethelbert. Both theſe princes died in a few years, and left the kingdom to Ethered their brother, in the year 866.

48
Ethered.

The whole courſe of Ethered's reign was diſturbed by the irruptions of the Danes. The king defended himſelf againſt them with great bravery, being ſeconded in all his military enterprizes by his younger brother Alfred, who afterwards aſcended the throne. In this reign, the Danes firſt landed among the Eaſt Angles. That people treacherouſly entered into an alliance with the common enemy; and furniſhed them with horſes, which enabled them to make an irruption into Northumberland. There they ſeized upon the city of York. Oſbricht and Ælla, two Northumbrian princes who attempted to reſcue the city, were defeated and killed. Encouraged by this ſucceſs, the Danes penetrated into the kingdom of Mercia, took up their winter-quarters at Nottingham, and thus threatened the kingdom with a final ſubjection. From this poſt, however, they were diſlodged by Ethered and Alfred, who forced them to retire into Northumberland. Their reſtleſs and ſavage diſpoſition, however, did not ſuffer them to continue long in one place. They broke into Eaſt Anglia; defeated and took priſoner Edmund the tributary king of that country, whom they afterwards murdered; and committed every where the moſt barbarous ravages. In 871, they advanced to Reading; from whence they infeſted the neighbouring country by their incurſions. The Mercians, deſirous of recovering their independency, refuſed to join Ethered with their forces; ſo that he was obliged to march againſt the Danes, attended only by the Weſt Saxons, who were his hereditary ſubjects. Several actions enſued, in which the Danes are ſaid to have been unſucceſsful; but being continually reinforced from their own country, they became every day more and more formidable to the Engliſh. During the confuſion and diſtreſs in which the nation was now neceſſarily involved, king Ethered died of a wound he had received in an action with the Danes; and left to his brother Alfred the kingdom almoſt totally ſubdued by a foreign power.

49
Alfred the Great.

Alfred, who may properly be called the founder of the Engliſh monarchy, aſcended the throne in the year 871, being then only 22 years of age. His great virtues and ſhining talents ſaved his country from ruin, which ſeemed almoſt unavoidable. His exploits againſt the Danes, his dangers and diſtreſſes, are related under the article ALFRED. Having ſettled the nation in a much better manner than could have been expected, he died in 901, leaving the kingdom to his ſecond ſon Edward the Elder.

50
Edward the elder.

The beginning of this monarch's reign was diſturbed by thoſe inteſtine commotions from which the wiſe and politic Alfred had taken ſo much pains to free the nation. Ethelwald, ſon to king Ethelbert, Alfred's elder brother, claimed a right to the throne. Having armed his partiſans, he took poſſeſſion of Winburne, where he ſeemed determined to hold out to the laſt extremity. On the approach of Edward, however, with a powerful army, he firſt fled into Normandy, and afterwards into Northumberland. He hoped to find the Northumbrians ready to join him, as moſt of them were Danes, lately ſubdued by Alfred, and very impatient of peace. The event did not diſappoint his expectations. The Northumbrians declared for him; and Ethelwald having thus connected himſelf with the Daniſh tribes, went beyond ſea, whence he returned with a great body of theſe banditti. On his return, he was joined by the Danes of Eaſt Anglia and Mercia. Ethelwald, at the head of the rebels, made an irruption into the counties of Glouceſter, Oxford, and Wilts; and having ravaged the country, retired with his booty before the king could approach him. Edward, however, took care to revenge himſelf, by conducting his forces into Eaſt Anglia, and ravaging it in like manner. He then gave orders to retire; but the Kentiſh men, greedy of more plunder, ſtaid behind, and took up their quarters at Bury. Here they were aſſaulted by the Danes; but the Kentiſhmen made ſuch an obſtinate defence, that though their enemies gained the victory, it was bought by the loſs of their braveſt men, and, among the reſt, of the uſurper Ethelwald himſelf.

The king, now freed from the attempts of ſo dangerous a rival, concluded an advantageous peace with the Eaſt Angles. He next ſet about reducing the Northumbrians; and for this purpoſe equipped a fleet, hoping that thus they would be induced to remain at home to defend their own country, without attempting to invade his territories. He was diſappointed in his expectations. The Northumbrians were more eager to plunder their neighbours than to ſecure themſelves. Imagining that the whole of Edward's forces were embarked on board his fleet, they entered his territories with all the troops they could raiſe. The king, however, was better prepared for them than they had expected. He attacked them on their return at Tetenhall in the county of Stafford, put them to flight, recovered all the booty, and purſued them with great ſlaughter into their own country.

The reſt of Edward's reign was a ſcene of continued and ſucceſsful action againſt the Northumbrians, Eaſt Angles, the Danes of Mercia, and thoſe who came from their native country in order to invade England. He put his kingdom in a good poſture of defence, by fortifying the towns of Cheſter, Eddeſbury, Warwick, Cherbury, Buckingham, Towceſter, Maldon, Huntingdon, and Colcheſter. He vanquiſhed Thurketill a Daniſh chieftan, and obliged him to retire with his followers into France. He ſubdued the Eaſt Anglians, Northumbrians, and ſeveral tribes of the Britons; and even obliged the Scots to make ſubmiſſions. He died in 925, and was ſucceeded by Athelſtan his natural ſon.

51 Athelſtan.

This prince, notwithſtanding his illegitimate birth, aſcended the throne without much oppoſition, as the legitimate children of Edward were too young to rule a nation ſo much liable both to foreign invaſions and domeſtic troubles as England at preſent was. One Alfred, however, a nobleman of conſiderable power, entered into a conſpiracy againſt him. It is ſaid, that this nobleman was ſeized upon ſtrong ſuſpicions, but without any certain proof. He offered to ſwear to his innocence before the pope; and in thoſe ages it was ſuppoſed that none could take a falſe oath in preſence of ſuch a ſacred perſon, without being viſited by an immediate judgment from God. Alfred was accordingly conducted to Rome, and took the oath required of him before Pope John. The words were no ſooner pronounced, than he fell into convulſions, of which he expired in three days. The king, fully convinced of his guilt, confiſcated his eſtate, and made a preſent of it to the monaſtery of Malmeſbury.

This accident proved the means of eſtabliſhing the authority of Athelſtan in England. But finding the Northumbrians bore the Engliſh yoke with impatience, he gave Sithric, a Daniſh nobleman, the title of king of Northumberland; and in order to ſecure his friendſhip, gave him his own ſiſter Editha in marriage. This was productive of bad conſequences. Sithric died the year after his marriage with Editha; upon which Anlaf and Godfrid, Sithric's ſons by a former marriage, aſſumed the ſovereignty without waiting for Athelſtan's conſent. They were, however, ſoon obliged to yield to the ſuperior power of that monarch. The former fled to Ireland; and the latter to Scotland, where he was protected by Conſtantine king of that country. The Scottiſh monarch was continually importuned by Athelſtan to deliver up his gueſt, and even threatened with an invaſion in caſe he did not comply. Conſtantine, deteſting this treachery, adviſed Godfrid to make his eſcape. He did ſo, turned pirate, and died ſoon after. Athelſtan, however, reſenting this conduct of Conſtantine, invaded his kingdom, and reduced him, it is ſaid, ſo low, that he was obliged to make the moſt humble ſubmiſſions. This, however, is denied by all the Scottiſh hiſtorians.

52 Defeats enemies.

Conſtantine, after the departure of Athelſtan, entered into a confederacy with Anlaf, who ſubſiſted by his piracies, and with ſome of the Welſh princes who were alarmed at the increaſe of Athelſtan's power. All theſe confederates made an irruption into England at once; but Athelſtan meeting them at Brumſbury in Northumberland, gave them a total overthrow. Anlaf and Conſtantine made their eſcape with difficulty, leaving the greateſt part of their men dead on the field of battle. After this period, Athelſtan enjoyed his crown in tranquillity. He died in 941, after a reign of 16 years. He paſſed a remarkable law, for the encouragement of commerce; *viz.* that a merchant, who had made three long ſea-voyages on his own account, ſhould be admitted to the rank of a thane or gentleman.

53 Edmund

Athelſtan was ſucceeded by his brother Edmund. On his acceſſion, he found the kingdom diſturbed by the reſtleſs Northumbrians, who watched for every opportunity of riſing in rebellion. They were, however, ſoon reduced; and Edmund took care to enſure the peace of the kingdom, by removing the Danes from the towns of Mercia where they had been allowed to ſettle, becauſe it was found that they took every opportunity to introduce foreign Danes into the kingdom. He alſo conquered Cumberland from the Britons. This country, however, he beſtowed upon Malcolm king of Scotland, upon condition that he ſhould do homage for it, and protect the north of England from all future incurſions of the Danes.

54 Murdered by Leolf.

Edmund was unfortunately murdered in Gloceſter, by one Leolf a notorious robber. This man had been formerly ſentenced to baniſhment; yet had the boldneſs to enter the hall where the king himſelf dined, and to ſit at table with his attendants. Edmund immediately ordered him to leave the room. The villain refuſed to obey; upon which the king leaped upon him,

him, and ſeized him by the hair. Leolf then drew a dagger, and gave the king a wound, of which he inſtantly died, A. D. 946, being the ſixth year of his reign.

As the children of Edmund were too young at the time of his deceaſe, his brother Edred ſucceeded to the throne. The beginning of his reign, as well as thoſe of his predeceſſors, was diſturbed by the rebellions and incurſions of the Northumbrian Danes, who looked upon the ſucceſſion of every new king to be a favourable opportunity for ſhaking off the Engliſh yoke. On the appearance of Edred with an army, however, they immediately ſubmitted; but before the king withdrew his forces, he laid waſte their territories as a puniſhment for their offence. He was no ſooner gone, than they roſe in rebellion a ſecond time. They were again ſubdued; and the king took effectual precautions againſt their future revolts, by placing Engliſh garriſons in all their towns, and appointing an Engliſh governor to watch their motions, and ſuppreſs their inſurrections on the firſt appearance. In the reign of Edred, celibacy of the clergy began to be preached up under the patronage of St Dunstan. This man had obtained ſuch an aſcendant over Edred, who was naturally ſuperſtitious, that he not only directed him in affairs of conſcience, but in the moſt important matters of ſtate. He was placed at the head of the treaſury; and being thus poſſeſſed of great power at court, he was enabled to accompliſh the moſt arduous undertakings. He profeſſed himſelf a partiſan of the rigid monaſtic rules; and having introduced celibacy among the monks of Glaſtenbury and Abingdon, he endeavoured to render it univerſal among the clergy throughout the kingdom. The monks in a ſhort time generally embraced the pretended reformation; after which they inveighed bitterly againſt the vices and luxury of the age. When other topics of defamation were wanting, the marriages of clergymen became a ſure object of invective. Their wives received the appellation of *concubines* or ſome other more opprobrious name. The ſecular clergy, on the other hand, who were numerous and rich, defended themſelves with vigour, and endeavoured to retaliate upon their adverſaries. The people were thrown into the moſt violent ferments; but the monks, being patroniſed by king Edred, gained ground greatly upon their opponents. Their progreſs, however, was ſomewhat retarded by the king's death, which happened in 955, after a reign of nine years. He left children; but as they were infants, his nephew Edwy, ſon to Edmund, was placed on the throne.

The new king was not above 16 or 17 years of age at the time of his acceſſion. His reign is only remarkable for the tragical ſtory of his queen Elgiva. She was a princeſs of the royal blood, with whom Edwy was deeply enamoured. She was his ſecond or third couſin, and therefore within the degrees of affinity prohibited by the canon law. Edwy, however, hearkening only to the dictates of his paſſion, married her, contrary to the advice of the more dignified eccleſiaſtics. The monks on this occaſion were particularly violent; and therefore Edwy determined not to ſecond their ambitious projects. He ſoon found reaſon to repent his having provoked ſuch dangerous enemies. On his coronation day, while his nobility were indulging themſelves in riotous mirth in a great hall where they had aſſembled, Edwy withdrew to another apartment to enjoy the company of his beloved queen and her mother. Dunſtan gueſſed the reaſon of his abſence. With unparalleled impudence, he burſt into the queen's apartment; and upbraiding Edwy with his laſciviouſneſs, as he termed it, puſhed him back to the hall where the nobles were aſſembled. The king determined to reſent ſuch a daring inſult. He required from Dunſtan an account of his adminiſtration of the treaſury during the late reign. The monk, probably unable to give a juſt account, refuſed to give any; upon which Edwy accuſed him of malverſation in his office, and baniſhed him the kingdom.

This proved the worſt ſtep that could poſſibly have been taken. Dunſtan was no ſooner gone than the whole nation was in an uproar about his ſanctity and the king's impiety. Theſe clamours, as they had been begun by the clergy, ſo they were kept up and increaſed by them, till at laſt they proceeded to the moſt outrageous violence. Archbiſhop Odo ſent a party of ſoldiers to the palace. They ſeized the queen, and burned her face with a red-hot iron, in order to deſtroy her beauty by which ſhe had enticed her huſband; after which they carried her by force into Ireland, there to remain in perpetual exile. The king, finding it in vain to reſiſt, was obliged to conſent to a divorce from her, which was pronounced by Archbiſhop Odo. A cataſtrophe ſtill more diſmal awaited Elgiva. She had been cured of her wounds, and had even found means to efface the ſcars with which her perſecutors had hoped to deſtroy her beauty. She then came to England, with a deſign to return to the king, whom ſhe ſtill conſidered as her huſband. Unfortunately, however, ſhe was intercepted by a party of ſoldiers ſent for that purpoſe by the primate. Nothing but her moſt cruel death could now ſatisfy that wretch and his accomplices. She was hamſtringed at Glouceſter, and expired in a few days.

59
Tragical death of the queen.

The minds of the Engliſh were at this time ſo much ſunk in ſuperſtition, that the monſtrous inhumanity above mentioned was called a judgment from God upon Edwy and his ſpouſe for their diſſolute life, *i. e.* their love to each other. They even proceeded to rebellion againſt their ſovereign; and having raiſed to the throne Edgar, the younger brother of Edwy, at that time only 13 years of age, they ſoon put him in poſſeſſion of Mercia, Northumberland, and Eaſt Anglia. Edwy being thus confined to the ſouthern counties, Dunſtan returned, and took upon him the government of Edgar and his party; but the death of Edwy ſoon removed all difficulties, and gave Edgar peaceable poſſeſſion of the government.

60
Edgar.

The reign of Edgar proved one of the moſt fortunate mentioned in the ancient Engliſh hiſtory. He took the moſt effectual methods both for preventing tumults at home and invaſions from abroad. He quartered a body of diſciplined troops in the north, in order to repel the incurſions of the Scots, and to keep the Northumbrians in awe. He built a powerful navy; and that he might keep the ſeamen in the practice of their duty, as well as preſent a formidable armament to his enemies, he commanded the fleet from time to time, to make the circuit of his dominions.

61 His licentious amours

The greatneſs of king Edgar, which is very much celebrated by the Engliſh hiſtorians, was owing to the harmony which reigned between him and his ſubjects; and the reaſon of this good agreement was, that the king ſided with Dunſtan and the monks, who had acquired a great aſcendant over the people. He enabled them to accompliſh their favourite ſcheme of diſpoſſeſſing the ſecular canons of all the monaſteries; and he conſulted them not only in eccleſiaſtical, but alſo in civil affairs. On theſe accounts, he is celebrated by the monkiſh writers with the higheſt praiſes; though it is plain, from ſome of his actions, that he was a man who could be bound neither by the ties of religion nor humanity. He broke into a convent, and carried off by force, and raviſhed, a nun called *Editha*. His ſpiritual inſtructor, Dunſtan, for this offence, obliged the king, not to ſeparate from his miſtreſs, but to abſtain from wearing his crown for ſeven years!

Edgar, however, was not to be ſatisfied with one miſtreſs. He happened once to lodge at the houſe of a nobleman who had a very beautiful daughter. Edgar, enflamed with deſire at the ſight of the young lady, without ceremony aſked her mother to allow her to paſs a night with him. She promiſed compliance; but ſecretly ordered a waiting-maid, named *Elfleda*, to ſteal into the king's bed when the company were gone, and to retire before day-break. Edgar, however, detained her by force, till day-light diſcovered the deceit. His love was now transferred to the waiting-maid; who became his favourite miſtreſs, and maintained a great aſcendant over him till his marriage with Elfrida.

62 His marriage with Elfrida.

The circumſtances of this marriage were ſtill more ſingular and criminal than thoſe above mentioned. Elfrida was daughter and heireſs to Olgar Earl of Devonſhire. She was a perſon of ſuch exquiſite beauty, that her fame was ſpread all over England, though ſhe had never been at court. Edgar's curioſity was excited by the accounts he had heard of her, and therefore formed a deſign of marrying her. He communicated his intention to Earl Athelwold his favourite; and ordered him, on ſome pretence or other, to viſit the Earl of Devonſhire, and bring him a certain account concerning Elfrida. Athelwold went as he was deſired; but fell ſo deeply in love with the lady himſelf, that he reſolved to ſacrifice his fidelity to his paſſion. He returned to Edgar, and told him, that Elfrida's charms were by no means extraordinary, and would have been totally overlooked in a woman of inferior ſtation. After ſome time, however, turning the converſation again upon Elfrida, he told the king that he thought her parentage and fortune made her a very advantageous match; and therefore, if the king gave his conſent, he would make propoſals to the Earl of Devonſhire on his own behalf. Edgar conſented, and Athelwold was married to Elfrida.—After his marriage, he uſed his utmoſt endeavours to keep his wife from court, that Edgar might have no opportunity of obſerving her beauty. The king, however, was ſoon informed of the truth; and told Athelwold that he intended to pay him a viſit in his caſtle, and be made acquainted with his new-married wife. The Earl could make no objections; only he deſired a few hours to prepare for the viſit. He then confeſſed the whole to Elfrida, and begged of her to appear before the king as much to the diſadvantage as poſſible. Inſtead of this, ſhe dreſſed herſelf to the greateſt advantage. Edgar immediately conceived a violent paſſion for her; and, in order to gratify it, ſeduced Athelwold into a wood under pretence of hunting, where he ſtabbed him with his own hand, and afterwards married his widow.

63 Wolve tirpate from E land.

The reign of Edgar is remarkable among hiſtorians for the encouragement he gave to foreigners to reſide at his court and throughout the kingdom. Theſe foreigners, it is ſaid, corrupted the former ſimple manners of the nation. Of this ſimplicity, however, there ſeems to be no great reaſon to boaſt; ſeeing it could not preſerve them from treachery and cruelty, the greateſt of all vices: ſo that their acquaintance with foreigners was certainly an advantage to the people, as it tended to enlarge their views, and cure them of thoſe illiberal prejudices and ruſtic manners to which iſlanders are often ſubject.—Another remarkable incident, is the extirpation of wolves from England. The king took great pleaſure in hunting and deſtroying theſe animals himſelf. At laſt he found that they had all taken ſhelter in the mountains and foreſts of Wales. Upon this he changed the tribute impoſed upon the Welſh princes by Athelſtan, into an annual tribute of 300 wolves heads; and this produced ſuch diligence in hunting them, that the animal has never ſince appeared in England.

64 Edwar martyr

Edgar died in 957, after a reign of 16 years. He left a ſon named *Edward*, whom he had by his firſt wife the daughter of Earl Ordmer; and another, named *Ethelred*, by Elfrida. The mental qualifications of this lady were by no means anſwerable to the beauty of her perſon. She was ambitious, haughty, treacherous, and cruel. The principal nobility, therefore, were greatly averſe from the ſucceſſion of her ſon Ethelred, which would unavoidably throw too much power into the hands of his mother, as he himſelf was only ſeven years of age. Edward, afterwards ſurnamed the *Martyr*, was therefore pitched upon; and was certainly the moſt proper perſon, as he was 15 years of age, and might ſoon be able to take the government into his own hands. Elfrida oppoſed his advancement with all her might: but Dunſtan overcame every obſtacle, by anointing and crowning the young prince at Kingſton; upon which the whole kingdom ſubmitted without farther oppoſition.

65 Mirac St Du

The only remarkable occurrence in this reign was the complete victory gained by the monks over the ſecular clergy, who were now totally expelled from the convents. Though this had been pretty nearly accompliſhed by Edgar, the ſecular clergy ſtill had partiſans in England who made conſiderable oppoſition; but theſe were all ſilenced by the following miracles. In one ſynod, Dunſtan, finding the majority of votes againſt him, roſe up, and declared that he had that inſtant received from heaven a revelation in favour of the monks. The whole aſſembly was ſo much overawed by this intelligence, that they proceeded no farther in their deliberations. In another ſynod, a voice iſſued from the crucifix, acquainting the members, that the eſtabliſhment of the monks was founded on the will of heaven, and could not be oppoſed without impiety. But the third miracle was ſtill more alarming. In another

other ſynod the floor of the hall ſunk, and great numbers of the members were killed or bruiſed by their fall. It was remarked that Dunſtan had that day prevented the king from attending the ſynod, and that the beam on which his own chair ſtood was the only one which did not ſink. Theſe circumſtances, inſtead of making him ſuſpected as the author of the miracle, were regarded as proofs of the interpoſition of Providence in his favour.

Edward lived four years after he was raiſed to the throne, in perfect innocence and ſimplicity. Being incapable of any treacherous intention himſelf, he ſuſpected none in others. Though his ſtepmother had oppoſed his ſucceſſion, he had always behaved towards her with the greateſt reſpect; and expreſſed on all occaſions the moſt tender affection for his brother Ethelred. Being one day hunting in the neighbourhood of the caſtle where Elfrida reſided, he paid her a viſit unattended by any of his retinue. After mounting his horſe with a deſign to return, he deſired ſome liquor to be brought him. But while he was holding the cup to his head, a ſervant of Elfrida ſtabbed him behind. The king, finding himſelf wounded, clapped ſpurs to his horſe; but ſoon becoming faint by the loſs of blood, he fell from the ſaddle, and his foot being entangled in the ſtirrup, he was dragged along till he expired. His body was found and privately interred at Wereham by his ſervants. The Engliſh had ſuch compaſſion for this amiable prince, that they beſtowed on him the appellation of *Martyr*, and even fancied that miracles were wrought at his tomb. Elfrida built monaſteries, and ſubmitted to many penances, in order to atone for her guilt; but, even in that barbarous age, ſhe could never regain the good opinion of the public.

ing
red.

ed.

After the murder of Edward, his brother Ethelred ſucceeded to the throne without oppoſition. As he was a minor when he was raiſed to the throne, and, even when he came to man's eſtate, never diſcovered any vigour or capacity of defending the kingdom againſt invaders, the Danes began to renew their incurſions. Before they durſt attempt any thing of importance, however, they firſt made a ſmall incurſion by way of trial. In the year 981, they landed in Southampton from ſeven veſſels; and having ravaged the country, they retired with impunity, carrying a great booty along with them. In 987, they made a ſimilar attempt on the weſt coaſt, and were attended with the like ſucceſs. Finding that matters were now in a favourable ſituation for their enterpriſes, they landed in Eſſex under the command of two chieftains; and, having defeated and killed Brithnot duke of that county, laid waſte all the neighbouring provinces. In this extremity, Ethelred, ſurnamed, on account of his prepoſterous conduct, the *Unready*, bribed the enemy with L.10,000 to depart the kingdom. This advice was given by Siricius archbiſhop of Canterbury, and ſome of the degenerate nobility; and was attended with the ſucceſs that might have been expected. The Danes appeared next year off the eaſtern coaſt. But, in the mean time, the Engliſh had determined to aſſemble at London a fleet capable of repulſing the enemy. This failed of ſucceſs through the treachery of Alfric Duke of Mercia. Having been formerly baniſhed the kingdom, and found great difficulty in getting himſelf reſtored to his former dignity, he truſted thenceforth, not to his ſervices or the affections of his countrymen, but to the influence he had over his vaſſals, and to the public calamities. Theſe laſt he determined always to promote as far as he could; becauſe in every revolution his aſſiſtance would be neceſſary, and conſequently he muſt receive a continual acceſſion of power. The Engliſh had formed a plan for ſurrounding and deſtroying the Daniſh fleet in the harbour; but Alfric not only gave the enemy notice of this deſign, but alſo deſerted with his ſquadron the night before the engagement. The Engliſh by this means proved unſucceſsful; and Ethelred, in revenge, took Alfgar, Alfric's ſon, and ordered his eyes to be put out. This piece of cruelty could be productive of no good effect. Alfric had become ſo powerful, that, notwithſtanding his treachery, it was found impoſſible to deprive him of the government of Mercia.

anes.

In 993, the Danes under the command of Sweyn their king, and the Norwegians conducted by Olave king of that country, ſailed up the Humber, and deſtroyed all around them. A powerful army was aſſembled to oppoſe theſe invaders; but through the treachery of the three leaders, all men of Daniſh extraction, the Engliſh were totally defeated. Encouraged by this ſucceſs, the Danes entered the Thames in 94 veſſels, and laid ſiege to London. The inhabitants, however, made ſuch a brave defence, that the beſiegers were finally obliged to give over the attempt. Out of revenge for this diſappointment, they laid waſte Eſſex, Suſſex, and Hampſhire. In theſe counties they procured horſes; by which means they were enabled to penetrate into the more inland parts, and threatened the kingdom with total ſubjection. Ethelred and his nobles had now recourſe to their former expedient. They ſent ambaſſadors to the two northern kings, to whom they promiſed ſubſiſtence and tribute, provided they would, for the preſent, put an end to their ravages, and ſoon after depart the kingdom. They agreed to the terms, and peaceably took up their quarters at Southampton. Olave even paid a viſit to Ethelred, and received the rite of confirmation from the Engliſh biſhops. The king alſo made him many preſents; and Olave promiſed never more to infeſt the Engliſh territories; which promiſe it is ſaid he afterwards religiouſly obſerved.

After the departure of Olave with his Norwegians, Sweyn, though leſs ſcrupulous than the king of Norway, was obliged to leave the kingdom alſo. But this ſhameful compoſition procured only a ſhort relief to the nation. The Danes ſoon after appeared in the Severn; and having ravaged Wales as well as Cornwall and Devon, they ſailed round, and, entering the mouth of the Tamar, completed the ruin of theſe two counties. Then, returning to the Briſtol channel, and penetrating into the country by the Avon, they over-ran all that country, and carried fire and ſword even into Dorſetſhire. In 998, they changed the ſeat of war; and, after ravaging the iſle of Wight, they entered the Thames and Medway, where they laid ſiege to Rocheſter, and defeated the Kentiſh men in a great battle. After this victory, the whole province of Kent was made a ſcene of ſlaughter and devaſtation. The extremity of theſe miſeries forced the Engliſh into counſels for common defence both by ſea and land: but the weakneſs of the king, the diviſions among the nobility, the treachery of ſome, the cowardice of others, the

the want of concert in all, fruſtrated every endeavour; and their fleets and armies either came too late to attack the enemy, or were repulſed with diſhonour. The Engliſh, therefore, devoid both of prudence and unanimity in council, had recourſe to the expedient which by experience they had found to be ineffectual. They offered the Danes a large ſum if they would conclude a peace and depart the kingdom. Theſe ravagers continually roſe in their demands; and now required the payment of L.24,000, which the Engliſh ſubmitted to give. The departure of the Danes procured them a temporary relief; which they enjoyed as if it was to be perpetual, without making any effectual preparations for giving them a more vigorous reception upon their next return.

Beſides the receiving this ſum, the Danes were at preſent engaged by another motive to depart from England. They were invited over by their countrymen in Normandy, who at this time were hard preſſed by Robert king of France, and who found it difficult to defend their ſettlements againſt him. It is probable alſo, that Ethelred, obſerving the cloſe connection of all the Danes with one another, however they might be divided in government or ſituation, was deſirous of procuring an alliance with that formidable people. For this purpoſe, being at preſent a widower, he made his addreſſes to Emma, ſiſter to Richard II. Duke of Normandy. He ſoon ſucceeded in his negociations; the princeſs came over to England, and was married to the king in the year 1001.

69 Marriage of the king with the princeſs of Normandy.

Though the Danes had been for a long time eſtabliſhed in England, and though the ſimilarity of their language with the Saxon had invited them to an early coalition with the natives; they had as yet found ſo little example of civilized manners among the Engliſh, that they retained all their ancient ferocity, and valued themſelves only on their national character of military bravery. The Engliſh princes had been ſo well acquainted with their ſuperiority in this reſpect, that Athelſton and Edgar had been accuſtomed to keep in pay large bodies of Daniſh troops, who were quartered about the country, and committed many violences upon the inhabitants. Theſe mercenaries had attained to ſuch an height in luxury, according to the old Engliſh writers, that they combed their hair once a-day, bathed themſelves once a-week, changed their clothes frequently; and by all theſe arts of effeminacy, as well as by their military character, had rendered themſelves ſo agreeable to the fair ſex, that they debauched the wives and daughters of the Engliſh, and had diſhonoured many families. But what moſt provoked the inhabitants was, that, inſtead of defending them againſt invaders, they were always ready to betray them to the foreign Danes, and to aſſociate themſelves with every ſtraggling party which came from that nation.

70 Danes ſacred.

The animoſities between the native Engliſh and the Danes who inhabited among them, had from theſe cauſes riſen to a great height; when Ethelred, from a policy commonly adopted by weak princes, took the cruel reſolution of maſſacring the Danes throughout the kingdom. On the 13th of November 1002, ſecret orders were diſpatched to commence the execution every where on the ſame day; and the feſtival of St Brice, which fell on a Sunday, the day on which the Danes uſually bathed themſelves, was choſen for this purpoſe. Theſe cruel orders were executed with the utmoſt exactneſs. No diſtinction was made betwixt the innocent and the guilty; neither ſex nor age was ſpared; nor were the cruel executioners ſatisfied without the tortures, as well as death, of the unhappy victims. Even Gunilda, ſiſter to the king of Denmark, who had married Earl Paling, and had embraced Chriſtianity, was, by the advice of Edric Earl of Wilts, ſeized and condemned to death by Ethelred, after ſeeing her huſband and children butchered before her face. This unhappy princeſs foretold, in the agonies of deſpair, that her murder would ſoon be avenged by the total ruin of the Engliſh nation (A).

71 New ſion by Sweyn

The prophecy of Gunilda was exactly fulfilled. In 1003, Sweyn and his Danes, who wanted only a pretence to renew their invaſions, appeared off the weſtern coaſt, and threatened revenge for the ſlaughter of their countrymen. The Engliſh took meaſures for repulſing the enemy; but theſe were defeated thro' the treachery firſt of Alfric; and then of Edric, a ſtill greater traitor, who had married the king's daughter, and ſucceeded Alfric in the command of the Britiſh armies. The Danes therefore ravaged the whole country. Agriculture was neglected, a famine enſued, and the kingdom was reduced to the utmoſt degree of miſery. At laſt the infamous expedient of buying a peace was recurred to; and the departure of the Danes was purchaſed, in 1007, at the expence of L.30,000.

The Engliſh endeavoured to employ this interval in making preparations againſt the return of the Danes, which they had reaſon ſoon to expect. A law was made, ordering the proprietors of eight hides of land to provide themſelves of a horſeman and a complete ſuit of armour; and thoſe of 310 hides to equip a ſhip for the defence of the kingdom. By this means a formidable armament was raiſed. There were 243,600 hides in England; conſequently the ſhips equipped muſt be 785. The cavalry was 30,450 men. All hopes of ſucceſs from this equipment, however, were diſappointed by the factions, animoſities, and diſſentions

---

(A) On the ſubject of this maſſacre, Mr Hume has the following obſervations: "Almoſt all the ancient hiſtorians ſpeak of this maſſacre of the Danes as if it had been univerſal, and as if every individual of that nation throughout England had been put to death. But the Danes were almoſt the ſole inhabitants in the kingdoms of Northumberland and Eaſt Anglia, and were very numerous in Mercia. This repreſentation of the matter was abſolutely impoſſible. Great reſiſtance muſt have been made, and violent wars enſued; which was not the caſe. This account given by Wallingford, though he ſtands ſingle, muſt be admitted as the only true one. We are told that the name of *lurdane, lord Dane,* for an idle lazy fellow who lives at other peoples expence, came from the conduct of the Danes who were put to death. But the Engliſh princes had been entirely maſters for ſeveral generations; and only ſupported a military corps of that nation. It ſeems probable, therefore, that theſe Danes only were put to death."

gland.

tions of the nobility. Edric had cauſed his brother Brightric to advance an accuſation of treaſon againſt Wolfnoth governor of Suſſex, the father of the famous Earl Godwin; and that nobleman, knowing the power and malice of his enemy, conſulted his own ſafety by deſerting with 20 ſhips to the Danes. Brightric purſued him with a fleet of 80 ſail; but his ſhips being ſhattered in a tempeſt, and ſtranded on the coaſt, he was ſuddenly attacked by Wolfnoth, and all his veſſels were burnt or otherwiſe deſtroyed. The treachery of Edric fruſtrated every plan of future defence; and the whole navy was at laſt ſcattered into the ſeveral harbours.

By theſe fatal miſcarriages, the enemy had leiſure to over-run the whole kingdom. They had now got ſuch a footing, indeed, that they could hardly have been expelled though the nation had been ever ſo unanimous. But ſo far did mutual diffidence and diſſention prevail, that the governors of one province refuſed to march to the aſſiſtance of another; and were at laſt terrified from aſſembling their forces for the defence of their own. At laſt the uſual expedient was tried. A peace was bought with L.48,000; but this did not procure even the uſual temporary relief. The Danes, knowing that they were now maſters of the kingdom, took the money, and continued their devaſtations. They levied a new contribution of L 8000 on the county of Kent alone; murdered the archbiſhop of Canterbury, who had refuſed to countenance this exaction; and the Engliſh nobility ſubmitted every where to the Daniſh monarch, ſwearing allegiance to him, and giving hoſtages for their good behaviour. At laſt, Ethelred himſelf, dreading equally the violence of the enemy and the treachery of his own ſubjects, fled into Normandy, whither he had already ſent queen Emma and her two ſons Alfred and Edward. The Duke received his unhappy gueſts with a generoſity which does honour to his memory.

dy.

The flight of king Ethelred happened in the end of the year 1013. He had not been above ſix weeks in Normandy, when he heard of the death of Sweyn, which happened at Gainſborough before he had time to eſtabliſh himſelf in his new dominions. At the ſame time he received an invitation from the prelates and nobility to reſume the kingdom; expreſſing alſo their hopes, that, being now better taught by experience, he would avoid theſe errors which had been ſo fatal to himſelf and his people. But the miſconduct of Ethelred was incurable; and, on his reſuming the government, he behaved in the very ſame manner that he had done before. His ſon-in-law Edric, notwithſtanding his repeated treaſons, retained ſuch influence at court, that he inſtilled into the king jealouſies of Sigefert and Morcar, two of the chief nobles of Mercia. Edric enticed them into his houſe, where he murdered them; while Ethelred partook of the infamy of this action, by confiſcating their eſtates, and confining the widow of Sigefert in a convent. She was a woman of ſingular beauty and merit; and in a viſit which was paid her, during her confinement, by prince Edmund the king's eldeſt ſon, ſhe inſpired him with ſo violent an affection, that he releaſed her from the convent, and ſoon after married her without his father's conſent.

In the mean time, Canute, the ſon and ſucceſſor of Sweyn, proved an enemy no leſs terrible to the Engliſh than his father had been. He ravaged the eaſtern coaſt with mercileſs fury; and put aſhore all the Engliſh hoſtages at Sandwich, after having cut off their hands and noſes. He was at laſt obliged, by the neceſſity of his affairs, to return to Denmark. In a ſhort time, however, he returned, and continued his depredations along the ſouthern coaſt. He then broke into the counties of Dorſet, Wilts, and Somerſet; where an army was aſſembled againſt him under the command of Prince Edmund and Duke Edric. The latter ſtill continued his perfidious machinations; and after endeavouring in vain to get the prince into his power, found means to diſſipate the army, and then deſerted to Canute with 40 veſſels.

England.

Edmund was not diſheartened by this treachery. He again aſſembled his forces, and was in a condition to give the enemy battle. Ethelred, however, had now ſuch frequent experience of the treachery of his ſubjects, that he had loſt all confidence in them. He remained in London, pretending ſickneſs, but in reality from an apprehenſion that they intended to buy their peace by delivering him into the hands of his enemies. The army called aloud for their ſovereign to march at their head againſt the Danes; and on his refuſal to take the field, they were ſo diſcouraged, that all the preparations which had been made became ineffectual for the defence of the kingdom. Edmund, deprived of all regular reſources for the maintenance of the ſoldiers, was obliged to commit ſimilar ravages to thoſe practiſed by the Danes; and after making ſome fruitleſs expeditions into the north, which had ſubmitted entirely to Canute's power, he returned to London, where he found every thing in confuſion by the death of the king.

74
Edmund Ironſide divides the kingdom with the Danes.

Ethelred died in 1016, after an unhappy reign of 35 years; and was ſucceeded by his eldeſt ſon Edmund, ſurnamed *Ironſide* on account of his great ſtrength and valour. He poſſeſſed abilities ſufficient to have ſaved his country from ruin, had he come ſooner to the throne; but it was now too late. He bravely oppoſed the Danes, however, notwithſtanding every diſadvantage; till it laſt the nobility of both nations obliged their kings to come to a compromiſe, and divide the kingdom between them by treaty. Canute reſerved to himſelf Mercia, Eaſt Anglia, and Northumberland, which he had entirely ſubdued. The ſouthern parts were left to Edmund. This prince ſurvived the treaty only about a month; being murdered at Oxford by two of his chamberlains, accomplices of Edric.

75
Canute.

After the death of Edmund, nothing was left for the Engliſh but ſubmiſſion to Canute. The leaſt ſcrupulous of mankind, however, dare not at all times openly commit injuſtice. Canute, therefore, before he ſeized the dominions of Edwin and Edward, the two ſons of Edmund, ſuborned ſome of the nobility to depoſe, that, in the laſt treaty with Edmund, it had been verbally agreed, that, in caſe of Edmund's death, Canute ſhould either be ſucceſſor to his dominions, or tutor to his children; for hiſtorians differ with regard to this particular. This evidence, ſupported by the great power of Canute, was ſufficient to get him elected king of England. Immediately after his acceſſion to the throne, he ſent the two ſons of Edmund to the court of Sweden, on pretence of being there educated;

but charged the king to put them to death as ſoon as they arrived. The Swediſh monarch did not comply with this requeſt; but ſent them to Solomon king of Hungary, to be educated in his court. The elder, Edwin, was afterwards married to Solomon's ſiſter: but he dying without iſſue, that prince gave his ſiſter-in-law, Agatha, daughter of the emperor Henry II. in marriage to Edward, the younger brother; and ſhe bore him Edgar Atheling; Margaret, afterwards queen of Scotland; and Chriſtina, who retired into a convent.

76 Marries Ethelred's widow.
