Longitude in

### By Inspection.

The half of the distance 187, and of the departure 105, are found to agree nearest under 34°, and the difference of latitude answering thereto is 155; which doubled is 310 miles.

Again, to middle latitude 47° 25', and departure 105 in the latitude column, the corresponding distance is 155 miles, which doubled is 310 miles, the difference of longitude.

### By Gunter's Scale.

The extent from the distance 374 miles to the departure 210 miles on the line of numbers, will reach from 90° to 34° 10', the course on the line of sines; and the extent from  $90^{\circ}$  to  $55^{\circ}$  50', the complement of the course on sines, will reach from the distance 374 to the difference of latitude 309 miles on numbers.

Again, the extent from 42° 35', the complement of the middle latitude, to 90° on sines, will reach from the departure 210 to the difference of longitude 310 on numbers.

PROB. VIII. Given one latitude, departure, and difference of longitude, to find the other latitude, course, and distance.

Example. A ship from latitude 54° 56' N, longitude 1º 10' W, sailed between the north and east, till by observation she is found to be in longitude 5° 26' E, and has made 220 miles of easting. Required the latitude come to, course, and distance run?

| Longitud  | c left      |      |   | 1° | 10'W   |   |
|-----------|-------------|------|---|----|--------|---|
| Longitude | e come to   | -    |   | 5  | 26 E   |   |
| Differenc | c of longit | tude | - | 6  | 36=396 | 5 |

### By Construction.

Make BC (fig. 24.) equal to the departure 220, and Fig. 24. CD equal to the difference of longitude 396 :- then the middle latitude BCD being measured, will be found equal to 59° 15': hence the latitude come to is 57° 34', and difference of latitude 158°. Now make AB equal to 158, and join AC, which applied to the scale, will measure 271 miles. Also the course BAC being measured on chords will be found equal to 5401.

| By Calculation.                                                  |                              |          |                    |  |  |  |  |

|                                        |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| to the distance 270.9                  | 2.43270                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |

### By Inspection.

As the differences of longitude and departure exceed the limits of the tables, lct, therefore, their halves be taken; these are 198 and 110 respectively. Now these are found to agree exactly in the page marked 5 points at the bottom. Whence the middle latitude is 56° 15', and difference of latitude 158 miles.

Again, the difference of latitude 158 and departure 220 will be found to agree nearly above 54° the course, and the distance on the same line is 271 miles.

### By Gunter's Scale.

The extent from the difference of longitude 396 to the departure 220 on numbers, will reach from 90° to 33° 45', the complement of the middle latitude on sines; and hence the difference of latitude is 158 miles. Now the extent from 158 to 220 on numbers, will reach from 45° to  $54^{\circ}$ ; on tangents; and the extent from the complement of the course  $35^{\circ}\frac{2}{3}$  to 90° on sines, will reach from the difference of latitude 158 to the distance 271 on numbers.

PROB. IX. Given the course and distance sailed, and difference of longitude; to find both latitudes.

*Example*. A ship from a port in north latitude, sailed  $S \to \frac{1}{4}S + \frac{1}{4}S + \frac{1}{4}S$  miles, and differed her longitude 7° 28'. Required the latitude sailed from, and that come to?

### By Construction.

With the course and distance construct the triangle ABC (fig. 25.), and make DC equal to 448 the given difference of longitude. Now the middle latitude BCD will measure  $48^{\circ}$  58', and the difference of latitude AB 324 miles : hence the latitude left is  $51^{\circ}$  40', and that come to  $46^{\circ}$  16'.

### By Calculation.

| To find | the dif | ference of | latitude. |
|---------|---------|------------|-----------|
|---------|---------|------------|-----------|

| As radius -<br>is to the cosine of the course<br>so is the distance -                                                                       | 3 <sup>3</sup> / <sub>4</sub> pts.<br>438       | 10.00000<br>9.86979<br>2.64147           |
|---------------------------------------------------------------------------------------------------------------------------------------------|-------------------------------------------------|------------------------------------------|

#### By Inspection.

To the course  $3\frac{3}{4}$  points, and half the distance 219 miles, the departure is 147.0, and difference of latitude 162.2; which doubled is 324.4. Again, to half the difference of longitude 224 in a distance column, the difference of latitude is 149.9 above  $48^{\circ}$ , and 146.9 over  $49^{\circ}$ .

### Now, as 30 : 29 :: 60' : 58'.

Hence the middle latitude is 48° 58': the latitude sailed from is therefore 51° 40', and latitude come to 46° 16'.

### By Gunter's Scale.

The extent from 8 points to  $4\frac{1}{4}$  points, the complement of the course on sine rhumbs, will reach from the distance 438 miles to the difference of latitude 3245 on numbers. And the extent from the difference of longitude 448, to the distance 438 on numbers, will reach from the course 42° 11' to the complement of the middle latitude 41° 2' on sines. Hence the latitude left is  $51^{\circ}$  40', and that come to 46° 16'.

PROB. X. To determine the difference of longitude made good upon compound courses, by middle latitude sailing.

RULE I. With the several courses and distances find the difference of latitude and departure made good, and the ship's present latitude, as in traverse sailing.

Now enter the traverse table with the given middle latitude, and the departure in a latitude column, the corresponding distance will be the difference of longitude, of the same name with the departure.

*Example.* A ship from Cape Clear, in latitude 51° 18' N, longitude 9° 46' W, sailed as follows:-SWbS 34 miles, WbN 63 miles, NNW 48 miles, and NE<sup>1</sup>/<sub>2</sub>E 85 miles. Required the latitude and longitude come to?

The above method is not always practised to find the difference of longitude made good in the course of

### 666

Middle Latitude Sailing.

Fig. 25.

reator's of a day's run; and will, no doubt, give the difference ulling. of longitude tolerably exact in any probable run a ship may make in that time, especially near the equator. But in a high latitude, when the distances are considerable, this method is not to be depended on .- To illustrate this, let a ship be supposed to sail from latitude 57° N, as follows: E 240 miles, N 240 miles, W 240 miles, and S 240 miles: then, by the above method, the ship will be come to the same place she left. It will, however, appear evident from the following consideration, that this is by no means the case; for let two ships, from latitude  $61^{\circ}$  N, and distant 240 miles, sail directly south till they are in latitude 57° N; now their distance being computed by Problem IV. of Parallel Sailing, will be 269.6 miles; and, therefore, if the ship sailed as above, she will be 29.6 miles west of the place sailed from; and the error in longitude will be equal to 240 × secant 61°-secant 57°  $= 29.6 \times \text{seeant } 57^{\circ} = 54.4.$ 

Theorems might be investigated for computing the Mercator's errors to which the above method is liable. These eor- Sailing. rections may, however, be avoided, by using the following method.

RULE II. Complete the traverse table as before, to which annex five columns; the first column is to contain the several latitudes the ship is in at the end of each course and distance ; the second, the sums of each following pair of latitude; the third, half the sums, or middle latitudes; and the fourth and fifth columns are to contain the differences of longitude.

Now find the difference of longitude answering to each middle latitude and its corresponding departure, and put them in the east or west difference of longitude columns, according to the name of the departure. Then the difference of the sums of the east and west columns will be the difference of longitude made good, of the same name with the greater.

### CHAP. VI. Of Mercator's Sailing.

IT was observed in Middle Latitude Sailing, that the difference of longitude made upon an oblique rhumb could not be exactly determined by using the middle latitude. In Mercator's sailing, the difference of longitude is very easily found, and the several problems of sailing resolved with the utmost acenracy, by the assistance of Mercator's chart or equivalent tables.

In Mereator's chart, the meridians are straight lines parallel to each other; and the degrees of latitude, which at the equator are equal to those of longitude, increase with the distance of the parallel from the equator. The parts of the meridian thus increased are called meridional parts. A table of these parts was first constructed by Mr Edward Wright, by the continual addition of the seeants of each minute of latitude.

For by parallel sailing, R ; cos. of lat. :: part of equat. : similar part of parallel. 4 P 2

And

Practice

Mercator's Sailing.

And because the equator and meridian on the globe are equal; therefore,

R : cos. lat. :: part of meridian : similar part of parallel. Or sec. lat. : R :: part of merid. : similar part of parallel. R secant latitude

Hence, part of meridian, part of parallel

But in Mercator's chart the parallels of latitude are equal, and radius is a constant quality. If, therefore, the latitude be assumed successively equal to '1', 2', 3',' &c. and the corresponding parts of the enlarged meridian be represented by a, b, c, &c.; then,

 $\frac{\text{secant } 1'}{\text{part of mer. } a} = \frac{\text{secant } 2'}{\text{part of mer. } b} = \frac{\text{sccant } 3'}{\text{part of mer. } c}, & & & \\ \text{Hence secant } 1': & \text{part of mer. } a :: & \text{secant } 2': & \text{part of } mer. \\ a :: & \text{secant } 2': & \text{part of } mer. \\ a :: & \text{secant } 2': & \text{part of } mer. \\ a :: & \text{secant } 2': & \text{part of } mer. \\ a :: & \text{secant } 2': & \text{part of } mer. \\ a :: & \text{secant } 2': & \text{part of } mer. \\ a :: & \text{secant } 2': & \text{part of } mer. \\ a :: & \text{secant } 2': & \text{part of } mer. \\ a :: & \text{secant } 2': & \text{part of } mer. \\ a :: & \text{secant } 2': & \text{part of } mer. \\ a :: & \text{secant } 2': & \text{part of } mer. \\ a :: & \text{secant } 2': & \text{part of } mer. \\ a :: & \text{secant } 2': & \text{part of } mer. \\ a :: & \text{secant } 2': & \text{part of } mer. \\ a :: & \text{secant } 2': & \text{part of } mer. \\ a :: & \text{secant } 2': & \text{part of } mer. \\ a :: & \text{secant } 2': & \text{part of } mer. \\ a :: & \text{secant } 2': & \text{part of } mer. \\ a :: & \text{secant } 2': & \text{part of } mer. \\ a :: & \text{secant } 2': & \text{part of } mer. \\ a :: & \text{secant } 2': & \text{part of } mer. \\ a :: & \text{secant } 2': & \text{part of } mer. \\ a :: & \text{secant } 2': & \text{part of } mer. \\ a :: & \text{secant } 2': & \text{part of } mer. \\ a :: & \text{secant } 2': & \text{part of } mer. \\ a :: & \text{secant } 2': & \text{part of } mer. \\ a :: & \text{secant } 2': & \text{part of } mer. \\ a :: & \text{secant } 2': & \text{part of } mer. \\ a :: & \text{secant } 2': & \text{part of } mer. \\ a :: & \text{secant } 2': & \text{part of } mer. \\ a :: & \text{secant } 2': & \text{part of } mer. \\ a :: & \text{secant } 2': & \text{part of } mer. \\ a :: & \text{secant } 2': & \text{part of } mer. \\ a :: & \text{secant } 2': & \text{part of } mer. \\ a :: & \text{secant } 2': & \text{part of } mer. \\ a :: & \text{secant } 2': & \text{part of } mer. \\ a :: & \text{secant } 2': & \text{part of } mer. \\ a :: & \text{secant } 2': & \text{part of } mer. \\ a :: & \text{secant } 2': & \text{part of } mer. \\ a :: & \text{secant } 2': & \text{part of } mer. \\ a :: & \text{secant } 2': & \text{part of } mer. \\ a :: & \text{secant } 2': & \text{part of } mer. \\ a :: & \text{secant } 2': & \text{part of } mer. \\ a :: & \text{secant } 2': & \text{part$ mer. b :: secant 3' : part of mer. c, &c.

Therefore by 12th V. Euclid.

Secant 1': part of mer. a :: secant 1'+secant 2'+secant 3', &c.: parts of a+b+ mer. c, &c.

That is, the meridional parts of any given latitude are equal to the sum of the secants of the minutes in that latitude (E).

And in the triangle CED,

ED : CD :: R : tangent CED;

Therefore, ED : LK :: R2 : secant LD × tangent CED Hence  $LK = \frac{ED \times sec. \times LD \times tang. CED}{R^4} =$ 

 $\frac{\text{ED} \times \text{sec. LD}}{\text{R}} \times \frac{\text{tang. CED}}{\text{R}}$ 

S

Plate

But  $\frac{ED \times sec. LD}{R}$  is the enlarged portion of the meridian answering to ED. Now the sum of all the

quantities  $\frac{ED \times \text{secant } LD}{R}$  corresponding to the sum

of all the ED's contained in AS, will be the meridional parts answering to the difference of latitude AS; and MN is the sum of all the corresponding portions of the equator LK.

Whence  $MN \equiv mer.$  diff. of lat.  $\times$  tangent  $\frac{CED}{R}$ .

That is, the difference of longitude is equal to the meridional difference of latitude multiplied by the tangent of the course, and divided by the radius.

This equation answers to a right-angled rectilineal triangle, having an angle equal to the course ; the adjacent side equal to the meridional difference of latitude, and the opposite side the difference of longitude. This triangle is, therefore, similar to a triangle constructed, with the course and difference of latitude, according to the principles of plane sailing, and the homologous sides CCCLXIV. will be proportional. Hence, if, in fig. 26 the angle A represents the course, AB the difference of latitude, fig. 26. and if AD be made equal to the meridional difference of latitude; then DE, drawn perpendicular to AD, meeting the distance produced to E, will be the difference of longitude.

It is scarcely necessary to observe, that the meridional difference of latitude is found by the same rules as the

proper difference of latitude ; that is, if the given la-Mercator titudes be of the same name, the difference of the cor- Sailing, responding meridional parts will be the meridional difference of latitude; but if the latitudes are of a contrary denomination, the sum of these parts will be the meridional difference of latitude.

PROB. I. Given the latitudes and longitudes of two places, to find the course and distance between them.

Ex. Required the course and distance between Cape Finisterre, in latitude 42° 52' N, longitude 9° 17' W, and Port Praya in the island of St Jago, in latitude 14° 54' N, and longitude 23° 29' W?

| 1678<br>Longitude Cape Finisterre<br>Longitude Port Praya - | 9° 17' W<br>23 29 W  |
| Diff. longitude                                             | 14 12=852.           |

### By Construction.

Draw the straight line AD (fig. 26.) to represent the Fig. 26. meridian of Cape Finisterre, upon which lay off AB,. AD equal to 1678, and 1948, the proper and meridional differences of latitude; from D draw DE perpendicular to AD, and equal to the difference of longitude 852, join AE, and draw BC parallel to DE ; then the difference AC will measure 1831 miles, and the course BAC 23° 37'.

### By Calculation.

| To find the course.                   |               |
|---------------------------------------|---------------|
| As the meridian difference of lat. 19 | 48 - 3.28959  |
| is to the difference of longitude - 8 | 52 - 2.93044  |
| so is radius                          | - 10.00000    |
|                                       |               |
| to the tangent of the course 23° 37'  | - 9.64085     |
| To find the distance.                 |               |
| As radius                             | - 10.00000    |
| is to the secant of the course, 23° 3 | 7' - 10.03798 |
| so is the difference of latitude 167  | 8 - 3.22479   |
|                                       |               |
| to the distance 183                   | 1 - 3.26277   |
|                                       |               |

### By Inspection.

As the meridian difference of latitude and difference of longitude are too large to be found in the tables, let the tenth of cach be taken; these are 194.8 and 85.2 respectively. Now these arc found to agree nearest under 24°; and to 167.8, one-tenth of the proper difference of latitude, the distance is about 183 miles, which multiplied by 10 is 1830 miles.

### By Gunter's Scale.

The extent 1948, the meridional difference of lati-tude, to 852, the difference of longitude on the line of numbers, will reach from 45° to 23° 37', the course on

(E) This is not strictly true; for instead of taking the sum of the secants of every minute in the distance of the given parallel from the equator, the sum of the secants of every point of latitude should be taken.

preator's on the line of tangents. And the extent from 66° 23', ailing. the complement of the course to 90° on sines, will reach from 1678, the proper difference of latitude, to 1831,

the distance on the line of numbers.

PROB. II. Given the course and distance, sailed from a place whose situation is known, to find the latitude and longitude of the place come to.

Example. A ship from Cape Hinlopen in Virginia, in latitude 38° 47' N, longitude 75° 4' W, sailed 267 miles NEbN. Required the ship's present place ?

### By Construction.

With the course and distance sailed, construct the triangle ABC (fig. 27.); and the difference of latitude AB being measured, is 222 miles : hence the latitude come to is 42° 29' N, and the meridional difference of latitude 293. Make AD equal to 293; and draw DE perpendicular to AD, and meeting AC produced in E: then, the difference of longitude DE being applied to the scale of equal parts will measure 196; the longitude come to is therefore 71° 48' W.

### By Calculation.

To find the difference of latitude.

| As radius                                    | 10.00000 |
|----------------------------------------------|----------|
| is to the cosine of the course, - 3 points - | 9.91985  |
| so is the distance - 267 -                   | 2.42651  |
| 1 .101                                       |          |
| to the difference of latitude - 222 -        | 2.34636  |
| Lat. Cape Hinlopen = 38° 47' N. Mer. parts   | 3 2528   |
| Difference of lat 3 42 N.                    | 0        |
|                                              |          |

Latitude come to - 42 29 N. Mer. parts 2821

| Meridional difference of latitude 293<br>To find the difference of longitude.                                          |
|------------------------------------------------------------------------------------------------------------------------|
| As radius                                                                                                              |
| to the difference of longitude - 195.8 2.29176<br>Longitude Cape Hinlopen 75° 4' W<br>Difference of longitude - 3 16 E |
| Longitude come to 71 48 W                                                                                              |

### By Inspection.

To the course 3 points, and distance 267 miles, the difference of latitude is 222 miles : hence the latitude in is 42° 29', and the meridional difference of latitude 293. Again, to course three points, and 146.5 half the mer. difference of latitude, the departure is 97.9, which doubled is 195.8, the difference of longitude.

### By Gunter's Scale.

The extent from 8 points to the complement of the course 5 points, on sine rhumbs, will reach from the distance 267 to the difference of latitude 222 on numbers; and the extent from 4 points to 3 points on tangent rhumbs, will reach from the meridional difference of latitude 293 to the difference of longitude 196 on numbers.

PROB. III. Given the latitudes and bearing of two places; to find their distance and difference of longitude.

Example. A ship from Port Canso in Nova Scotia, Mercator's in latitude 45° 20' N, longitude 60° 55' W, sailed SE Sailing.  $\frac{1}{4}$  S, and by observation is found to be in latitude 41° 14' N. Required the distance sailed, and longitude come to ?

Lat. Port Canso - 45° 20' N - Mer. parts - 3058 Lat. in by observation 41 14 N - Mer. parts - 2720

Difference of lat. - 4 6=246 Mer. diff. lat. 338

### By Construction.

Make AB (fig. 28.) equal to 246, and AD equal Fig. 28. to 338; draw AE, making an angle with AD equal to 3<sup>3</sup>/<sub>4</sub> points, and draw BC, DE perpendicular to AD. Now AC being applied to the scale, will measure 332, and DE 306.

#### By Calculation. To find the distance

| As radius                                     | 10.00000 |
|-----------------------------------------------|----------|
| is to the secant of the course, - 33 points - | 10.13021 |
| so is the difference of latitude - 246        | 2.39093  |
| to the distance                               |          |
| To find the difference of lengitule           | 2.52114  |
| As radius -                                   | TO 00000 |
| s to the tangent of the course 23 points -    | 0.05720  |
| so is the mer. diff. of latitude - 338        | 2.52802  |
|                                               |          |
| to the difference of longitude - 306.3        | 2.48621  |
| Longitude Port Canso - 60° 55' J              | N        |
| Dimerence of longitude - 5 6 h                | 2        |
| Longitude in                                  | V        |
| 0 40                                          | v v      |

### By Inspection.

Under the course 33 points, and opposite to half the difference of latitude 123 in a latitude column is 166 in a distance column, which doubled is 332 the distance; and opposite to 169, half the meridional difference of latitude in a latitude column, is 153 in a departure column, which doubled is 306, the difference of longitude.

### By Gunter's Scale.

The extent from the complement of the course  $4\frac{r}{2}$ points to 8 points on sine rhumbs, will reach from the difference of latitude 246 m. to the distance 332 on numbers; and the extent from 4 points, to the course  $3\frac{3}{4}$  points on tangent rhumbs, will reach from the meridional difference of latitude 338 to the difference of longitude 306 on numbers.

PROB. IV. Given the latitude and longitude of the place sailed from, the course and departure; to find the distance, and the latitude and longitude of the place come to.

Example. A ship sailed from Sallee in latitude 33° 58' N, longitude 6° 20' W, the corrected course was NWbW+W, and departure 420 miles. Required the distance run, and the latitude and longitude come to ?

### By Construction.

With the course and departure construct the triangle ABC (fig. 29.); now AC and AB being measured, Fig. 29. will be found to be equal to 476 and 224 respectively : hence

660

1: 27.

670

Mercator's hence the latitude come to is 37° 42' N, and meridional Sailing. difference of latitude 276. Make AD equal to 276; and draw DE perpendicular thereto, meeting the distance produced in E; then DE applied to the seale will be found to measure 516'. The longitude in is, therefore, 14° 56' W.

## By Calculation.

| 10                   | o find the di  | stance.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |          |

### Longitude in - - 14 56 W

### By Inspection.

Above  $5\frac{1}{2}$  points the course, and opposite to 210 half the departure, are 238 and 112; which doubled, we have 476 and 224, the distance and difference of latitude respectively. And to the same course, and opposite to 138, half the meridional difference of latitude, in a latitude column, is 258 in a departure column; which being doubled is 516, the difference of longitude.

### By Gunter's Scale.

The extent from  $5\frac{\pi}{2}$  points, the course on sine rhumbs, to the departure 420 on numbers, will reach from eight points on sine rhumbs to the distance 476 on numbers; and from the complement of the course  $2\frac{\pi}{2}$ points on sine rhumbs, to the difference of latitude 224 on numbers.

Again, the extent from difference of latitude 224 to the meridional difference of latitude 276 on numbers, will reach from the departure 420 to the difference of longitude 516 on the same line.

PROB. V. Given the latitudes of two places, and their distance, to find the course and difference of longitude.

*Example.* A ship from St Mary's, in latitude  $36^{\circ}$ 57' N, longitude  $25^{\circ}$  9' W, sailed on a direct course between the north and east 1162 miles, and is then by observation in latitude  $49^{\circ}$  57' N. Required the course steered, and longitude come to?

| Lat. come to       | 49 57 N    | Mer. parts  | 2389 Sailing. |         |
| Difference of lat. | - 13 0     | Mer.diff.la | t.1081        |         |

### 780 By Construction.

Make AB (fig. 30.) equal to 780, and AD equal Fig. 30. to 1081; draw BC, DE perpendicular to AD; make AC equal to 1162', and through AC draw ACE. Then the course or angle A being measured, will be found equal to 47° 50', and the difference of longitude DE will be 1194.

By Inspection. Because the distance and difference of latitude exceed the limits of the table, take the tenth of each; these are 116.2 and 78.0: Now these are found to agree nearest above  $4\frac{1}{2}$  points, which is therefore the eourse; and to this course, and opposite to 108.1, one tenth of the meridional difference of latitude, in a latitude column, is 119.3 in a departure column, which

## multiplied by 10 is 1193, the difference of longitude. By Gunter's Scale.

The extent from the distance 1162 m. to the difference of latitude 780 m. on numbers, will reach from  $90^{\circ}$  to  $42^{\circ}$  10' in the line of sincs. And the extent  $45^{\circ}$ , to the course  $47^{\circ}$  50' on the line of tangents, will reach from the meridional difference of latitude 1081 to the difference of longitude 1194 on numbers.

PROB. VI. Given the latitudes of two places, and the departure, to find the course, distance, and difference of longitude.

*Example.* From Aberdeen, in latitude 57° 9' N, longitude 2° 8' W, a ship sailed between the south and east till her departure is 146 miles, and latitude come to 53° 32' N. Required the course and distance run, and longitude come to?

Latitude Aberdeen 57° 9'N Mer. parts 4199 Latitude come to 53 32 N Mer. parts 3817

Difference of latitude 3 37=217' Mer. diff. lat. 382

### By Construction.

With the difference of latitude 217 m. and departure Fig. 31. 146 m. construct the triangle ABC (fig. 31.), make

Practice. Mact

ailing. duce AC to E: Then the course BAC will measure 33° 56', the distance AC 261, and the difference of longitude DE 257.

### By Inspection.

The difference of latitude 217, and departure 146, are found to agree nearest under 34°, and the corresponding distance is 262 miles. To the same course, and opposite to 190.7, the nearest to 191, half the meridional difference of latitude, is 128.6 in a departure column, which doubled is 257, the difference of longitude.

### By Gunter's Scale.

The extent from the difference of latitude 217, to the departure 146 on numbers, will reach from  $45^{\circ}$  to about 34°, the course on the line of tangents; and the same extent will reach from the meridional difference of latitude 382 to 257, the difference of longitude on numbers.—Again, the extent from the course  $34^{\circ}$  to 90 on sines, will reach from the departure 146 to the distance 261 on numbers.

PROB. VII. Given one latitude, distance and departure; to find the other latitude, course, and difference of longitude.

*Example.* A ship from Naples, in latitude 40° 51' N, longitude 14° 14' E, sailed 252 miles on a direct course between the south and west, and made 173 miles of westing. Required the course made good, and the latitude and longitude come to?

### By Construction.

Fig: 2.

With the distance and departure make the triangle ABC (fig. 32.) as formerly.—Now the course BAC being measured by means of a line of chords will be found equal to 43° 21', and the difference of latitude applied to the scale of equal parts will measure 183': hence the latitude come to is 37° 48' N, and meridional difference of latitude 237.—Make AD equal to 237, and complete the figure, and the difference of

| loi<br>in | is | tude | DE will<br>30' E. | measure | 224': | hence | the | longitude | Mercato<br>Sailing |

| 77                               |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |           |

By Inspection.

Under 43° and opposite to the distance 252 m. the departure is 171.8, and under 44°, and opposite to the same distance, the departure is 175.0.

Then as 3.2 : 1.2 :: 60' : 22'.

Hence the course is 43° 22'.

Again, under 43° and opposite to 118.5, half the meridional difference of latitude in a latitude column, is 110.5 in a departure column; also under 44° and opposite to 118.5 is 114.4.

Then as 3.2 : 1.2 :: 3.9 : 1.5.

And 110.5+1.5=112, which doubled is 224, the difference of longitude.

#### By Gunter's Scale.

The extent from the distance 252 on numbers, to  $90^{\circ}$  on sines, will reach from the departure 173 on numbers, to the course  $43\frac{1}{3}$  on sines; and the same extent that will reach from the complement of the course  $46^{\circ}\frac{1}{3}$  on sines will reach to the difference of latitude 183 on numbers.—Again, the extent from  $45^{\circ}$  to  $43^{\circ}\frac{1}{3}$  on tangents will reach from the meridional difference of latitude 237, to the difference of longitude 224, on numbers.

PROB. VIII. Given one latitude, course, and difference of longitude: to find the other latitude and distance.

Example. A ship from Tercera, in latitude 38° 45' N, longitude 27° 6' W, sailed on a direct course, which, when corrected, was N 32° E, and is found by observation to be in longitude 18° 24' W. Required the latitude come to, and distance sailed ?

# NAVIGATION.

### Difference of longitude - - 8 42=522

#### By Construction.

Fig. 33.

672

Make the right-augled triangle ADE (fig. 33.) having the angle A equal to the course 32°, and the side DE equal to the difference of longitude 522: then AD will measure 835, which added to the meridional parts of the latitude left, will give those of the latitude come to 48° 46'; hence, the difference of latitude is 601: make AB equal thereto, to which let BC be drawn perpendicular; then AC applied to the scale will measure 708 miles.

#### By Calculation.

To find the meridional difference of latitude.

| As radius<br>is to the co-tan | -<br>igent of | the course       | 320 0'                    | 10.00000            |
|-------------------------------|---------------|------------------|---------------------------|---------------------|
| so is the different           | ence of       | longitude        | 5 22<br>8252              | 2.71707             |
| Latitude of Te                | rcera         | 30° 45' N<br>Mer | Mer. par<br>. diff. of la | rts 2526<br>it. 835 |
| Latitude come                 | to -          | 48 46N           | Mer. part                 | 3361                |

### Difference of latitude 10 1=601 miles. To find the distance.

| As radius   | -            |          | -        |   | 10.00000 |
|-------------|--------------|----------|----------|---|----------|
| is to the s | ecant of the | course   | - 32° 0' | - | 10.07158 |
| so is the d | ifference of | latitude | - 601    | - | 2.77887  |

## to the distance - - 707.7 - 2.85045

### By Inspection.

To course 32°, and opposite to 130.5, one fourth of the given difference of longitude in a departure column, the difference of latitude is 208.8, which multiplied by 4 is 835, the meridional difference of latitude; hence the latitude in is 48° 46' N, and difference of latitude 601.

Again, to the same course, and opposite to 200, one third of the difference of latitude, the distance is 236, which multiplied by 3 gives 708 miles.

#### By Gunter's Scale.

The extent from the course 32°, to 45° on tangents, will reach from the difference of longitude 522 to the meridional difference of latitude 835 on numbers.— And the extent from the complement of the course 58° to 90° on sines, will reach from the difference of latitude 601, to the distance 708 miles on numbers.

PROB. IX. To find the difference of longitude made good upon compound courses.

RULE. With the several courses and distances, complete the Traverse Table, and find the difference of latitude, departure, and course made good, and the latitude come to as in Traverse Sailing. Find also the meridional difference of latitude.

Now to the course and meridional difference of latitude, in a latitude column, the corresponding departure will be the difference of longitude, which applied to the longitude left will give the ship's present longitude.

*Example.* A ship from port St Julian, in latitude Mercator's 49° 10' S, longitude 68° 44' W, sailed as follows; Sailing. ESE 53 miles, SEbS 74 miles, E by N 68 m. SEbE $\frac{1}{2}$ E 47 miles, and E 84 miles. Required the ship's present place?

|                                                                                                                                                                                                                                                                                                                | Dia                        | Diff. | of Lat.              | Departure.                           |               |  |  |  |

Although the above method is that usually employed at sea to find the difference of longitude, yet as it has been already observed, it is not to be depended on, especially in high latitudes, long distances, and a considerable variation in the courses, in which case the following method becomes necessary.

RULE II. Complete the Traverse Table as before, to which annex five columns. Now with the latitude left, and the several differences of latitude, find the successive latitudes, which are to be placed in the first of the annexed columns; in the second, the meridional parts corresponding to each latitude is to be put; and in the third, the meridional differences of latitude.

Then to each course, and corresponding meridional difference of latitude, find the difference of longitude, by PROB. VI. which place in the fourth or fifth columns, according as the coast is easterly or westerly; and the difference between the sums of these columns will be the difference of longitude made good upon the whole, of the same name with the greater.

#### REMARKS.

1. When the course is north or south, there is no difference of longitude.

2. When the course is east or west, the difference of longitude cannot be found by Mercator's Sailing; in this case the following rule is to be used.

To the nearest degree to the given latitude taken as a course, find the distance answering to the departure in a latitude column: this distance will be the difference of longitude.

Method of resolving the Problems of Mercator's Sailing.

CHAP. VII. Containing the Method of resolving the several Problems of Mercator's Sailing, by the Assistance of a Table of Logarithmic Tangents.

PROB I. Given one latitude, distance, and difference of longitude; to find the course, and other latitude.

RWLE. To the arithmetical complement of the logarithm of the distance, add the logarithm of the difference of longitude in minutes, and the log. cosine of the given latitude; the sum rejecting radius will be the

log. sine of the approximate course. To the given latitude taken as a course in the traverse table, add half the difference of longitude in a distance column; the corresponding departure will be the first correction of the course, which is subtractive Method if the given latitude is the least of the two; otherwise, resolvin additive.

In Table A, under the complement of the course, Mercato and opposite to the first correction in the side column, is the second correction. In the same table find the number answering to the course at the top, and difference of longitude in the side column; and such part of this number being taken as is found in Table B opposite to the given latitude, will be the third correction. Now these two corrections, subtracted from the course corrected by the first correction, will give the true course.

Now the course and distance being known, the difference of latitude is found as formerly.

|                                       |                                                 |                                            |                                            | 1                                          | TABLE B.                                        |                                          |                                        |                                  |                 |                                                         |                                                                         |

This problem was proposed, and resolved, by Mr Robert Hues in his *Treatise on the Globes*, printed at London in the year 1639, p. 181.

It was afterwards proposed by Dr Halley, in the second volume of the *Miscellanea Curiosa*, p. 34. in the following words:

A ship sails from a given latitude, and, having run a certain number of leagues, has altered her longitude by a given angle; it is required to find the course steered. And he then adds—The solution hereof would be very acceptable, if not to the public, at least to the author of this tract, being likely to open some further light into the mysteries of geometry.

Since that time, this problem has been solved in an indirect manner, by several writers on navigation, and others :—As Monsieur Bouguer, in his Nouvean Traité de Navigation; Mr Robertson, in the second volume of his Elements of Navigation; Mr Emerson, in his Theory of Navigation, which accompanies his Mathematical Principles of Geography; Mr Israel Lyons, in the Nautical Almanack for 1772; and Monsieur Bezout, in his Traité de Navigation; and lately, Baron Maseres, with the assistance of Mr Attwood, has given the first direct solution of this problem. For a comparison of the various solutions which have hitherto been made of this problem, the reader is referred to that by Dr Mackay, in the fourth and sixth volumes of Baron Maseres's Scriptores Logarithmici.

It was intended in this place to have given rules, to make allowance for the spheroidal figure of the earth : but as the ratio of the polar to the equatorial semi-axis is not as yet determined with sufficient accuracy, neither is it known if both hemispheres be similar figures; therefore these rules would be grounded on assumption only, and might probably err more from the truth

### CHAP. VIII. Of Oblique Sailing.

OBLIQUE sailing is the application of oblique-angled plane triangles to the solution of problems at sea. This sailing will be found particularly useful in going along shore, and in surveying coasts and harbours, &c.

*Ex.* 1. At 11h A. M. the Girdle Ness borc WNW, and at 2h P. M. it bore  $NW\delta N$ : the course during the interval  $S\delta W$ , five knots an hour. Required the distance of the ship from the Ness at each station ?

### By Construction.

Describe the circle NE, SW (fig. 34.), and draw the diameters NS, EW, at right angles to each other: from the centre C, which represents the first station, draw the WNW line CF; and from the same point draw CH, SbW, and equal to 15 miles the distance sailed.—From H draw HF in a NWbN direction, and the point F will represent the Girdle Ness. Now the distances CF, HF will measure 19.1 and 26.5 miles respectively.

### By Calculation.

In the triangle FCH are given the distance CII 15 miles, the angle FCH equal to 9 points, the interval between the S $\delta$ W and WNW points, and the angle CHF equal to 4 points, being the supplement of the angle contained between the S $\delta$ W and NW $\delta$ N points; hence CFH is 3 points: to find the distances CF, HF.

To find the distance CF.

| As the sine of CFH            | - 3 points                  | - | .9•74474 |
|-------------------------------|-----------------------------|---|----------|

Ex. 2. The distance between the SE point of the island of Jersey and the island of Brehaut is 13 leagues : and the correct bearing and distance of Cape Frehel from the island of Brehaut is SEbE 26 miles. It is also known that the SE point of Jersey bears NNE from Cape Frehel : from whence the distance of these two is required, together with the bearing of the same point from the island of Brehaut ?

### By Construction.

Describe a circle, (fig. 35.) and draw two diameters at right angles, the extremities of which will represent the cardinal points, north being uppermost.—Let the centre B represent Brehaut, from which draw the SE $\delta$ E line BF equal to 26 miles, and the point F will represent Cape Frehel, from which draw the NNE line FI; make BI equal to 39 miles : Then FI applied to the scale will measure  $34\frac{1}{2}$  miles, and the inclination of BI to the meridian will be found equal to  $63^{\circ}\frac{1}{2}$ .

#### By Calculation.

#### ucatation.

In the triangle BIF are given BI and BF equal to 39 miles, and 26 miles respectively; and the angle BFI equal to 7 points: To find the side FI, and angle FBI.

Ex. 3. At noon Dungeness bore per compass N $\delta W$ , distance 5 leagues; and having run N $W\delta W$  7 knots an hour, at 5 P. M. we were up with Beachyhead. Required the bearing and distance of Beachyhead from Dungeness?

#### By Construction.

Describe a circle (fig. 36.) to represent the horizon; from the centre C draw the N $\delta$ W line CD equal to Fig. 36. 15 miles; and the NW $\delta$ W line CB equal to 35 miles; join DB, which applied to the scale will measure about  $26\frac{1}{2}$  miles; and the inclination of DB to the meridian will be found equal to N 79 $\frac{3}{4}$ W.

### By Calculation.

In the triangle DCB are given the distances CD, CB equal to 15 and 35 miles respectively; and the angle BCD equal to 4 points; to find the angles B and D, and the distance BD.

To find the angles.

| Distance CB=35, sum of the<br>CD=15, angle C                                                                                                   | ang. 1                       | б poin<br>4                | ts.                                                      |

To find the distance. As the sine of CDB - 111° 30' 9.96868 is to the sine of BCD - 45.0 9.84948 so is the distance BC - 35 - 1.54407

to the distance BD - 26.6 1.42487

 $E_{x.4}$ . Running up Channel EbS per compass at the rate of 5 knots an hour. At 11<sup>h</sup> A. M. the Eddistone lighthouse bore NbE<sup>+</sup><sub>4</sub>E, and the Start point NEbE<sup>+</sup><sub>4</sub>E; and at 4 P. M. the Eddistone bore NWbN, and the Start N<sup>+</sup><sub>4</sub>E. Required the distance and bearing of the Start from the Eddistone, the variation being 2<sup>+</sup><sub>4</sub> points W?

### By Construction.

Fig. 37.

Let the point C (fig. 37.) represent the first station, from which draw the NbE $_{4}^{L}E$  line CA, the NE $bE_{4}^{L}E$ line CB, and the EbS line CD, which make equal to 25 miles the distance run in the elapsed time; then from D draw the NEbN line DA intersecting CA in A, which represents the Eddistone; and from the same point draw the N $_{4}^{L}E$  line DB cutting CB in B, which therefore represents the Start. Now the distance AB applied to the scale will measure 22.9, and the bearing per compass BAF will measure 73° $_{4}^{r}$ .

#### By Calculation.

In the triangle CAD are given CD equal to 25 miles, the angle CAD equal to  $4\frac{1}{4}$  points, the distance between NbE $\frac{1}{4}$ E and NWbN; and the angle ADC equal to 4 points, the distance between the NWbN and WbN points; to find the distance CA.

### By Construction.

With the meridional difference of latitude, the difference of longitude, and difference of latitude, construct the triangles ADE, ABC (fig. 38.) as in Mer-Fig. 38. cator's Sailing ; then A will represent the northernmost, and C the southernmost port, The distance AC applied to the scale will measure 53 miles, and the bearing BCA will be 25°4. From the points A and C, with distances equal to 82 and 100 miles respectively, describe arches intersecting each other in M, which will therefore be the place of meeting .- Now the angle ABM, the ship's course from the southernmost port, will measure N  $80^{\circ}_{3}E$ ; and the other ship's course, or angle BAM, will be  $67^{\circ}_{3}$ , or ESE. From M draw the parallel MNP, and AN will be the difference of latitude made by the one ship, and CP that by the other ship : hence either of these being measured and applied to its correspondent latitude, will give 56° 38', the latitude in. Make AF equal to 57, the me-ridional difference of latitude between the northernmost port and latitude in : from F draw FG perpendicular to AF, and produce AM to G, then FG will be the difference of longitude, which applied to the scale will measure 139 : hence the longitude in, is 0° 10' E.

### By Calculation.

In the triangle ADE, ABC, are given AD equal to 87, DE equal to 41, and AB equal to 48; to find the angle BAC and distance AC.

### CHAP. IX. Of Windward Sailing.

O II

WINDWARD sailing is, when a ship by reason of a contrary wind is obliged to sail on different tacks in order to gain her intended port; and the object of this sailing is to find the proper course and distance to be run on each tack.

Ex. 1. A ship is bound to a port 48 miles directly to the windward, the wind being SSW, which it is intended to reach on two boards; and the ship can lie

3

# within six points of the wind. Required the course Windward

and distance on each tack? Sailing.

### By Construction.

Draw the SSW line CB (fig. 39.) equal to 48 miles. Fig. 39. Make the angles ACB, ABC, each equal to 6 points. Hence the first course will be W, and the second SE : also the distance CA, or AB, applied to the scale, will measure  $62\frac{3}{4}$  miles, the distance to be sailed on each board.

### By Calculation.

From A draw AD perpendicular to BC; then in the triangle ADC are given CD equal to 24 miles; and the angle ACD, equal to 6 points, to find the distance AC.

| As radius<br>is to the secant of C<br>so is CD | - 6 points<br>24 miles | <br>10.00000<br>10.41716<br>1.38021 |
|------------------------------------------------|------------------------|-------------------------------------|
| to CA                                          | 62.7                   | 1.79737                             |

Ex. 2. The wind at NW, a ship bound to a port 64 miles to the windward, proposes to reach it on three boards; two on the starboard, and one on the larboard tack, and each within 5 points of the wind. Required the course and distance on each tack?

### By Construction.

Draw the NW line CA (fig. 40.) equal to 64 miles; Fig. 40. from C draw CB WbS, and from A draw AD parallel thereto, and in an opposite direction; bisect AC in E, and draw BED parallel to the NbE rhumb, meeting CB, AD in the points B and D: then CB=AD applied to the scale will measure 364 miles, and BD= 2CB=72<sup>1</sup>/<sub>2</sub> miles.

### By Calculation.

From B draw BF perpendicular to AC; then, in the triangle BFC are given the angle BCF equal to 5 points, and CF equal to one-fourth of CA=16 m. to find CB.

| As radius,    |         | -   |            |   | 10.00000 |
|---------------|---------|-----|------------|---|----------|
| is to the sec | cant of | BCF | - 5 points |   | 10.25526 |
| so is CF      |         | ÷., | - 16 m.    | - | 1.20412  |
|               |         |     |            |   |          |
| to CB         |         | -   | 36.25      | - | 1.55938  |
|               |         |     | 0 0        |   | 5575     |

Ex. 3. A ship which can lie within  $5\frac{1}{2}$  points of the wind, is bound to a port 36 miles to the windward, the wind being NE6N, which it is intended to reach on four boards, the first being on the larboard tack. Required the course and distance on each ?

#### By Construction.

Draw the NE6N line CA (fig. 41.) equal to 36 Fig. 41. miles, and bisect it in B; from C and B draw lines parallel to the  $E_{\frac{1}{2}}S$  rhumb; and from A and B draw lines parallel to the SSEIE point, meeting the former in the points D and E. Now the distances AD, BD, BE, and CE, arc equal ; and any one of them applied to the scale will measure 19.1 miles.

### By Calculation.

From E draw EF perpendicular to AC; and in the triangle CFE are given CF=9m. and the angle FCE  $=5\frac{1}{2}$  points, to find CE.

## NAVIGATION.

| Windward<br>Sailing. | As radius<br>is to the secant of<br>so is CF - | f FCE | - | 54 points<br>9 miles | 10.00000<br>10.32661<br>0.95424 |
|----------------------|------------------------------------------------|-------|---|----------------------|---------------------------------|
| 4                    | to the distance C                              | E     | - | 19.1 miles           | 1.28085                         |

*E.x.* 4. A ship bound to a port bearing NbW distant 40 miles, with the wind at NbE $\frac{1}{2}$ E, intends to reach it on two boards. Required the course and distance on each tack, the ship lying within  $5\frac{1}{2}$  points of the wind?

### By Construction.

Draw the NbW line CA (fig. 42.) equal to 40 miles; and because the wind is NbE $\pm E$ , and the ship can lie within  $5\pm$  points of the wind, the course on the larboard tack will be EbN, and on the starboard NW. Therefore, from the centre C draw the EbN line CB, and from it draw the NW line AB, meeting CB in B; then CB and AB applied to the scale will measure

26.7 and 48.1 m. respectively.

### By Calculation.

In the triangle ACB, given AC=40 miles, and the angles A, B, and C, equal to 3, 5, and 8 points respectively, to find AB and BC.

 $E_{N.5}$ . A ship close hauled within 5 points of the wind, and making one point of leeway, is bound to a port bearing SSW distant 54 miles, the wind being SbE: It is intended to make the port at three boards, the first of which must be on the larboard tack in order to avoid a reef of rocks. Required the course and distance on cach tack?

### By Construction.

Draw the SSW line CA (fig. 43.) equal to 54 m. and as the wind is SbE, and the ship makes her course good within 6 points of the wind, therefore the course on the larboard tack will be SWbW, and on the starboard EbS: hence from C draw the SWbW line CB, and from A draw AD parallel thereto; bisect CA in E, and draw BED parallel to the EbS line; then will CB and AD be the distances on the larboard tack, which applied to the scale, each will be found to measure 37.4; and the distance on the starboard tack BD will measure 42.4 miles.

### By Calculation.

The triangles CBE, EAD are equal and similar: hence in the first of these are given CE, equal to 27 miles, half the distance between the ship and port; the angles C, B, and E, equal to 3, 4, and 9 points respectively, to find CB and BE.

To find CB, the distance on the larboard tack. Current 9.84948, Sailing. 4 points As the sine of B 9 points is to the sine of E 9.99157 27 miles so is the distance CE 1.43136 to the distance BC 37.45 1.57345 To find BE half the distance on the starboard tack. 4 points 9.84948 As the sinc of B 3 points is to the sine of C 9.74474 27 miles 1.43136 so is the distance CE 1.32662 to the distance BE 21.21

Whole distance AC - 42.42

Ex. 6. A ship plying to the windward, with the wind at NNE, after sailing 51 miles on each of two tacks, is found by observation to have made 36 miles of difference of latitude. How near the wind did she make her way good?

### By Construction.

Make CA (fig. 44.) equal to 36 miles; draw AB Fig. 44. perpendicular to CA, and draw the NNE line CB, meeting AB in B; make CD, BD each equal to 51 miles, and these being measured, will be found equal to 6 points.

#### By Calculation.

| In the triangles CAB, BCD, are g   | vcn AB equal to   |
|------------------------------------|-------------------|
| 36 m. CD=BD=51, and the angle      | ACB equal to 2    |

### CHAP. X. Of Current Sailing.

THE computations in the preceding chapters have been performed upon the assumption that the water has no motion. This may no doubt answer tolerably well in those places where the ebbings and flowings are regular, as then the effect of the tide will be nearly counterbalanced. But in places where there is a constant current or setting of the sea towards the same point, an allowance for the change of the ship's place arising therefrom must be made: And the method of resolving these problems, in which the effect of a current, or heave of the sca, is taken into consideration, is called *current sailing*.

In a calm, it is evident a ship will be carried in the direction and with the velocity of the current. Hence, if a ship sails in the direction of the current, her rate will be augmented by the rate of the current; but if sailing directly against it, the distance made good will be equal to the difference between the ship's rate as given by the log and that of the current. And the absolute motion of the ship will be a-head, if her rate exceeds that of the current; but if less, the ship will make sternway. If the ship's course be oblique to the current, the distance made good in a given time will be represented by the third side of a triangle, whereof the distance given by the log, and the drift of the current in the same time, are the other sides ; and the true course will be the angle contained between the meridian and the line actually described by the ship.

### Practice

Plate

Fig. 45.

1. 46.

Ex. I. A ship sailed NNE at the rate of 8 knots an Current Sailing. hour, during 18 hours, in a current setting NWbW21 miles an hour. Required the course and distance made good ?

### By Construction.

CCLXV. Draw the NNE line CA (fig. 45.) equal to 18×8 =144 miles; and from A draw AB parallel to the NW6W rhumb, and equal to  $18 \times 2\frac{1}{2} = 45$  miles : now BC being joined will be the distance, and NCB the course. The first of these will measure 159 miles, and the second 6° 23'.

### By Calculation.

In the triangle ACB, are given AC=144 miles, AB=45 miles, and the angle CAB=9 points, to find BAC and BC.

| Lo nna the course                 | made good. |           |

Ex. 2. A ship from a port in latitude 42° 52' N, sailed SbW<sup>1</sup>/<sub>2</sub>W 17 miles in 7 hours, in a current setting between the north and west; and then the same port bore ENE, and the ship's latitude by observation was 42° 42' N. Required the setting and drift of the current?

### By Construction.

Draw the  $S\delta W_{\frac{1}{2}}W$  line CA (fig. 46.) equal to 17 miles, and make CB equal to 10 miles, the difference of latitude : through B draw the parallel of latitude BD, and draw the WSW line CD, intersecting BD in D: AD being joined, will represent the drift of the current, which applied to the scale will measure 20.2, and the angle DAE will be its setting, and will be found equal to 72°.

Ex. 3. A ship, from latitude 38° 20' N, sailed 24 hours in a current setting NWbN, and by account is in latitude 38° 42' N, having made 44 miles of easting; but the latitude by observation is 38° 58' N. Required the course and distance made good, and the drift of the current.

#### By Construction.

Make CE (fig. 47.) equal to 22 miles, the difference Fig. 47! of latitude by D, R, and EA=54 miles, the departure, and join CA; make CD=38 miles, the difference of latitude by observation ; draw the parallel of latitude DB, and from A draw the NW6N line AB, intersecting DB in B, and AB will be the drift of the current in 24 hours : CB being joined, will be the distance made good, and the angle DCB the true coursc. Now, AB and CB applied to the scale, will measure 19.2 and 50.5 respectively: and the angle DCB will be 41°1.

### By Calculation.

From B draw BF perpendicular to AE, then in the triangle AFB are given BF=16 miles, and the angle ABF=3 points; to find AB and AF.

To find the drift of the current AB.

| As radius<br>is to the secant of ABF - 3 points<br>so is BF 16 miles                                   | - Per | 10.00000<br>10.08015<br>1.20412 |

Ex. 4. In the Straits of Sunda, at 2 P. M. steering SEbS at the rate of 5 knots an hour, I passed close by the small islands off Hog point. At 6, not having changed our course, came to anchor on the Java shore. Upon setting the said island from this anchoring place, I find it bears due north, its distance by the chart being 22 miles. It follows from hence, that our course has been affected by a current. Required its velocity and direction ?

### By Construction.

From A (fig. 48.) draw the SEbS line AB=20, which will represent the ship's apparent track through the water; draw AC equal to 22 miles south, and C will be the ship's real place; and BC being joined will be the current's drift in four hours; which applied to the scale will measure 12.3; from A draw AD parallel to BC, and the angle CAD will be the direction of the current, and will be found to measure 64°.

### By Calculation.

In the triangle ABC, given AB=20 m. AC=22 m. and the included angle  $\Lambda=3$  points; to find the remaining parts.

To find the setting of the current. Distance AC=22 m. Included angle =3 points.

| AB=20                                                                                                                     | B+C=13                                                                                     |                                                 |

### CHAP. XI. Instruments proposed to solve the various Problems in Sailing, independent of Calculation.

VARIOUS methods, besides those already given, have been proposed to save the trouble of calculation .--One of these methods is by means of an instrument composed of rulers, so disposed as to form a rightangled triangle, having numbers in a regular progression marked on their sides. These instruments are made of different materials, such as paper, wood, brass, &c. and are differently constructed, according to the fancy of the inventor. Among instruments of this kind, that by John Cooke, Esq. seems to be the best. A number of other instruments, very differently constructed, have been proposed for the same purpose; of these, however, we shall only take notice of the rectangular instrument, by A. Mackay, LL.D. F.R.S.E. &c.

### I. Of COOKE'S Triangular Instrument.

Description. The stock a b c d (fig. 50.) is a pa-Fig. 50. rallelopiped : The length from a to b is two feet, the breadth from a to d two inches, and the depth is one inch and a half. The stock is perforated longitudinally, so as to be capable of containing within it ef, a cylindrical piece of wood one inch diameter; g h is an aperture on the surface of the stock about a quarter of an inch wide, which discloses one-twelfth part of the surface of the cylinder contained; the cdgc d c is divided into twelve parts, each of these is subdivided into six parts, and each of these again into ten parts. The surface of the cylinder is divided longitudinally into twelve parts, and on each of them is engraved a portion

# NAVIGATION.

portion of a line of meridional parts 22 feet long, ments to which contains the meridional parts for every minute We Pro- from the equator as far towards the pole as navigation Sailing is practicable; and the smallest division on it is not less than to the of an inch. By rolling and sliding this cy-Calcula- linder, any part of any line on it may be brought into any position which may be required; the box i is engrooved into the edge of the stock a b, so that it may move freely from a to b; a limb from this box extends to k, which serves to mark that degree of the perpendicular il which is parallel to the centre of the semicircle m; i l is two feet long, and graduated on both edges as the stock; it is perpendicular to the stock, and is fixed in the box i, by which it may be moved from a to b; o p n is a semicircle of six inches radius, engraved, as appears in the plate, which slides freely from c to d in a groove in the edge of the stock c d; m q is the index moving on the centre m, the edge of which marks the course on the semicircle; it is two feet long, and divided into 72 parts; and these are subdivided in the same manner as those on the stock and perpendicular, to which they are equal; r is a vernier attached to the index to show minutes; S is a vernier composed of concentric semicircles, which slides along the edge q m, to the intersection of the perpendicular and index, where it serves as a vernier to both; below x is a small piece of ivory, with a mark on it to point out the degree of the line d c, which is perpendicularly under the centre of the semicircle. Fig. 51. is a view of the back part of the instrument.

Use. The method of working every case which occurs in navigation, is to make the instrument similar to that ideal triangle which is composed of the difference of latitude, departure, and distance; or, to that composed of the meridional difference of latitude, difference of longitude, and enlarged distance; or, to that composed of the difference of longitude, departure, and sine of the middle latitude; which is done by means of the data procured from the compass, log-line, and quadrant : whence it follows, from the nature of similar triangles, or from the relation which exists between the sides of triangles and the sines of their opposite angles, that the parts of the instrument become proportional to those which they represent; and will ascertain the length of the lines, or the extent of the angles sought, by its gradations.

In the practice of this instrument, a small square is necesary in order to bring the centre of the semicircle perpendicularly over the meridional degree corresponding to the latitude.

### Plane Sailing.

PROB. I. The course and distance sailed being given, to find the difference of latitude and departure.

Example. A ship from latitude 24° 18' N, sailed NW6N 168 miles. Required the latitude come to, and departure?

Set the centre of the semicircle perpendicularly over the given latitude 24° 18', and the index to the course 3 points; move the perpendicular until it cut the index at the given distance 168; then at the point of intersection on the perpendicular is 93.3 miles, the departure, and on the base, by the edge of the box, is 26° 38', the latitude come to.

Vol. XIV. Part II.

PROB. II. Both latitudes and course given, to find the distance and departure.

Example. Let the latitude sailed from be 43° 50'N, that come to 47° 8' N, and the course NNE. Required in Sailing, the distance and departure ?

Move the centre of the semicircle to the latitude left 43° 50', and the edge of the box to the latitude come , to 47° 8'; fix the index at the given course 2 points : then at the point of intersection of the index and perpendicular is the distance 214 miles on the index, and the departure 82 miles on the perpendicular.

PROB. III. Given the course and departure, to find the distance and difference of latitude.

Example. Let the latitude sailed from be 32° 38'N, the course SWIS, and the departure 200 miles. Required the distance and latitude come to?

Move the centre of the semicircle to the latitude left 32° 38', set the index to the given course 3 points, and move the perpendicular till the given departure 200 cuts the index ; at this point on the index is 360 miles, and the edge of the box will cut the latitude come to 27° 39' N.

PROB. IV. Given the difference of latitude and distance, to find the course and departure.

Example. Let the latitude left be 17° 10' N, the latitude come to 21° 40' N, and the distance sailed on a direct course between the north and west 300 miles. Required the course and departure ?

Move the semicircle and box to the given latitudes, and the index until the distance found thereon meets the perpendicular; then at the point of contact on the perpendicular is 130.8, the departure, and on the semicircle by the index is 25° 50', the course.

PROB. V. The distance and departure given, to find the course and difference of latitude.

Example. The distance sailed is 246 miles between the south and east, the departure is 138 miles, and the latitude left 51° 10' N. Required the course and latitude come to ?

Set the centre of the semicircle to 51° 10', the latitude sailed from; find the distance 246 on the index, and the departure 138 on the perpendicular; then move both till these points meet, and the course 34° 10' will be found on the semicircle by the index, and the latitude in 47° 47' N, by the edge of the box.

PROB. VI. Both latitudes and departure given, to find the course and distance.

Example. A ship from latitude 43° 10' N, sailed between the north and west till she was in latitude 47° 14' N, and has made 170 miles of departure. Required the course and distance ?

Move the centre of the semicircle over 43° 10', and the edge of the box to  $47^{\circ}$  14'; find the departure on the perpendicular, and bring the edge of the index thereto; now at the point of intersection is the distance 297.4 miles on the index, and the course 34° 52' on the semicircle.

### Traverse Sailing.

Example. A ship from latitude 46° 48' N, sailed SSW2W 24 miles, SbW 36 miles, and S2E 40 4 R miles

63:

Instruments to solve Pro.

without Calcula-

tion. ~

miles. Required the latitude in, together with the diments to rect course and distance?

### Set the semicircle to the latitude sailed from 46° 48', and the index to the course SSW \* W; mark the diin Sailing, stance 24 on the index, and bring the perpendicular to meet it; then the index will cut the departure 11.3 on the perpendicular, and the perpendicular will cut the latitude 46° 27' N on the base. For the next course and distance, bring the semicircle to the latitude marked by the perpendicular, and lay down the course SbW : if it be towards the first meridian, move the last marked departure until it meets the index, and the limb of the box will mark the present departure ; but if the course be from the first meridian, bring the last departure 11.3 to the limb of the box, the index will mark the departure made good 18.3 on the perpendicular, and the latitude arrived at 40° 52' will be marked on the base hy the perpendicular : proceed in the same manner with all the courses of which the traverse consists, then the difference of latitude 1° 36' will be intercepted between the latitude sailed from 46° 48', and the latitude come to 45° 12' last marked by the perpendicular; and also the departure made good will be intercepted between that point on the perpendicular where the first departure commenced, and that where the last terminated. Now, with the difference of latitude 1° 36' and the departure, the course will be S 8° 30' W, and distance 97 miles, by last problem in Plane Sailing.

### Parallel Sailing.

PROB. I. The difference of longitude between two places in one parallel of latitude given, to find the distance between them.

Example. Let the common latitude be 49° 30' N, and the difference of longitude 3° 30'. Required the distance ?

Set the index to  $40^{\circ}$  30', the complement of the latitude on the semicircle ; mark the difference of longitude in miles on the index; then move the perpendicular until it meets the termination of the difference of longitude on the index, and the part of the perpendicular intercepted between the limb of the box and the point of intersection will be the distance 136.4 miles.

PROB. II. The distance between two places in one parallel of latitude given, to find the difference of longitude between them.

Example. Let the latitude of the given parallel be 49° 30' N, the distance sailed 136.4 E. Required the difference of longitude?

Set the index to the complement of the latitude 40° 30', and mark the distance sailed on the perpendicular; then move it until it meets the index, and the point of intersection will show the difference of longitude 210' or 3° 30' on the index.

PROB. III. Given the distance sailed on a parallel, and the difference of longitude, to find the latitude of that parallel.

Example. The distance sailed due east is 136.4, and the difference of longitude 3° 30'. Required the latitude of the parallel?

Find the difference of longitude 210 on the index, and the distance 136.4 on the perpendicular, and move

both until these numbers meet, and the complement of the latitude 4° 30' will be shown by the index on the ments to semicircle.

### Mercator's and Middle Latitude Sailing.

PROB. I. The latitudes and longitudes of two places given, to find the direct course and distance between them.

Example. Required the course and distance between two places whose latitudes and longitudes are 50° 30' N, 19° 0' W, and 54° 30' N, 15° 30' W, respectively?

### By Mercator's Sailing.

To find the course. Move the centre of the semicircle perpendicularly over the meridional degree answering to latitude 56° 50' N, then move the box until the edge of the perpendicular cuts the meridional parts of the other latitude 54° 30' N, and move the index until it cuts the difference of longitude 3° 30' on the perpendicular, and the index will mark the course 30° 10', or NNE 1E. nearly on the semicircle.

#### To find the distance.

Screw the index to this course, and move the centre of the semicircle to the latitude  $50^{\circ}$  50' N, and the edge of the perpendicular to the latitude  $54^{\circ}$  30' N, then the perpendicular will cut the distance 254.7 on the index.

### By Middle Latitude Sailing. To find the departure.

Move the centre of the semicircle to the latitude 50° 50', and the edge of the index to the complement of the middle latitude 37° 20' on the semicircle; then move the box until the edge of the perpendicular intersects the termination of the difference of longitude 210 miles on the index, which point of intersection will mark the departure 128 on the perpendicular.

To find the course and distance.

Move the edge of the perpendicular to the other latitude 54° 30', and the index until it cuts the departure 128 on the perpendicular; then will the perpendicular mark the distance on the index 254.7 miles, and the index will mark the course on the semicircle 30° 10', or NNE<sub>4</sub>E nearly.

PROB. II. Both latitudes and course given, to find the distance and difference of longitude.

Example. A ship from latitude 50° 50' N, longitude 19° o' W, sailed N 30° 10' E, until she is in lati-tude 54° 30' N. Required the distance and difference of longitude?

### By Mercator's Sailing.

### To find the difference of longitude.

Move the box and semicircle as in the former problem to the meridional parts of the given latitudes, then set the index to the course, and it will mark the difference of longitude 3° 30' on the perpendicular: Hence the longitude in is 15° 30' W. To find the distance.

Move the perpendicular and semicircle to the given latitudes, and put the index to the given course; then the perpendicular will cut the distance 254.7 miles on the index. By

### By Middle Latitude Sailing.

To find the distance and departure.

Move the semicircle and perpendicular to the given latitudes, and the index to the course ; then the perpendicular will show the departure 128 miles, and the Calcula- index the distance 254.7 miles at the point of interseetion.

### To find the difference of longitude.

Set the index to the complement of the middle latitude on the semicircle, and move the box until the termination of the departnrc on the perpendicular meets the index, which will mark the difference of longitude thereon 210 m. or 3° 30'.

PROB. III. Both latitudes and distance given, to find the course and difference of longitude.

Example. From latitude 50° 50' N, longitude 19° 0' W, a ship sailed 254.7 miles between the north and east, and by observation is in latitude 54° 30' N. Required the course and difference of longitude ?

# By Mercator's Sailing. To find the course.

Move the perpendicular and semicircle to the given latitudes, and the index until the distance sailed marked on it meets the perpendicular; then the index will mark the course N 30° 10' E on the semicircle.

### To find the difference of longitude.

Screw the index to the course, move the perpendicular and semicircle to the meridional parts of the given latitudes, and the space intercepted between the limb of the box and the index will be the difference of longitude 3° 30'

### By Middle Latitude Sailing.

### To find the departure and course.

Move the semicircle and perpendicular to the given latitudes, and the index until the distance sailed on it cuts the perpendicular; then the perpendicular will show the departure 128 miles, and the semicircle the course N 30° 10' E. To find the difference of longitude.

Set the index to 37° 20', the complement of the middle latitude on the semicircle, and move the perpendicular until the termination of the departure on it euts the index: then the point of intersection will mark the difference of longitude 210 miles on the index.

PROB. IV. Both latitudes and departure given, to find the course, distance, and difference of longitude.

Example. Let the latitude and longitude sailed from be 56° 40' S and 28° 55' E respectively, the latitude come to 61° 20' S, and departure 172 miles. Required the course, distance, and difference of longitude ?

#### By Mercator's Sailing.

To find the course and distance.

Move the perpendicular and semicircle to the given latitude (H); then move the index till it meets the extremity of the departure on the perpendicular; the distance will be marked on the index 329, and the Instrucourse S 31° 35' E, or SSE<sup>1</sup>/<sub>4</sub>E nearly, on the semi- ments to cirele.

### To find the difference of longitude.

Move the perpendicular and semicircle to the meri- in Sailing, dional parts of the given latitudes, and the index will Calculacut the difference of longitude on the perpendicular tion. 5° 35'.

### By Middle Latitude Sailing.

The course and distance are found as before. To find the difference of longitude.

Set the index to 31°, the complement of the middle latitude on the semicircle, and move the perpendicular until the departure marked on it cuts the index, and this point of intersection will mark the difference of longitude on the index 335 m. or 5° 35'.

PROB. V. One latitude, course, and distance given, to find the difference of latitude and difference of longitude.

*Example.* Let the latitude left be  $56^{\circ} 40'$  S, longitude  $28^{\circ} 55'$  E, the course S  $31^{\circ} 35'$  E, and distance 329 m. Required the latitude and longitude come to?

### By Mercator's Sailing.

### To find the latitude come to.

Set the semicircle to the latitude sailed from, and the index to the course, and bring the perpendicular to the distance, which at the same time will mark the latitude come to 61° 20' S.

### To find the difference of longitude.

Screw the index to the course, and move the semicircle and perpendicular to the meridional parts of both latitudes ; then the index will cut the difference of longitude on the perpendicular 5° 35'.

### By Middle Latitude Sailing.

The latitude arrived at is found as above.

### To find the departure.

The semicircle and perpendicular being set to both latitudes, and the index to the course, it will show the departure 172.7 on the perpendicular. To find the difference of longitude.

Set the index to 31° the complement of the middle latitude on the semicircle, and move the perpendicular until the departure marked on it cuts the index, and the division on the index at the point of intersection will be the difference of longitude 335.

PROB. VI. One latitude, course, and departure given, to find the distance, difference of latitude, and difference of longitude.

Example. Let the latitude sailed from be 56° 40' N, longitude 28° 35' W, the course N 31° 35' W, and departure 172.7. Required the distance, and the latitude and longitude come to?

### By Mercator's Sailing.

To find the distance and latitude come to.

Move the semicircle to the latitude left, and the index to the course; mark the departure on the perpen-4 R 2

dicular.

(H) In southern latitudes, the end of the cylinder where the numbers begin must be turned towards the north pointed out by the semicircle ; and in northern latitudes, it must be reversed.

solve Probleuis without

Instru- dicular, and move it until the termination thereof ments to meets the index, then the point of intersection will solve Pro- show the distance 329 miles on the index, and the perin Sailing, pendicular will show the latitude arrived at 61° 20' N without on the base.

To find the difference of longitude.

Screw the index, and move the perpendicular and semicircle to the meridional parts of both latitudes, then the index will cut the difference of longitude 5° 35' on the perpendicular.

### By Middle Latitude Sailing.

Find the distance sailed and latitude in as above, and the difference of longitude as in Problem IV. by middle latitude sailing.

PROB. VII. One latitude, the distance sailed, and departure given, to find the course, difference of latitude, and difference of longitude.

Example. The latitude sailed from is 48° 30' N, and longitude 14° 40' W; the distance run is 345 miles between the south and east, and the departure 200 miles. Required the course, and the latitude and longitude come to ?

### By Mercator's Sailing.

To find the course and latitude come to. Move the semicircle to the latitude left, mark the distance on the index, and the departure on the perpendicular, move both until these points meet ; then will the index show the course S  $35^{\circ}$  26' E on the semicircle, and the latitude come to  $43^{\circ}$  49' on the base.

The difference of longitude is found as in the preceding problem.

### By Middle Latitude Sailing.

The course and latitude come to are found as above, and the difference of longitude as in Problem IV, by middle latitude sailing.

### II. Of DR MACKAY'S Rectangular Instrument. Description. Fig. 52. is a representation of this in-

Plate Fig. 52.

CCCLXVI strument, of about one-third of the original size .---The length CA is divided into 100 equal parts, and the breadth CB into 70; but in this plate every second division only is marked, in order to avoid confusion; through these divisions parallels are drawn, terminating at the opposite sides of the instrument. Upon the upper and right hand sides are two scales ; the first contains the degrees of the quadrant, and the other the points and quarters of the compass. M is an index moveable about the centre C, and divided in the same manner as the sides (1). Fig. 53. is a portion of the enlarged meridian, so constructed that the first degree is equal to three divisions on the instrument; and therefore, in the use of this line, each division on the instrument is to be accounted 20 minutes. The size of the plate would not admit of the continuation of the line.

Use. From a bare inspection of this instrument, it

is evident that any triangle whatever may be formed on it. In applying it to nautical problems, the course ments to is to be found at top, or right-hand side, in the column solve Proof degrees or points, according as it is expressed; the in Sailing, distance is to be found on the index, the difference of latitude at either side column, and the departure at the Calculahead or foot of the instrument. The numbers in these columns may represent miles, leagues, &c.; but when used in conjunction with the enlarged meridional line, then 10 is to be accounted 100 miles, 20 is to be esteemed 200 miles, and so on, each number being increased in a tenfold ratio; and the intermediate numbers are to be reckoned accordingly.

#### Plane Sailing.

PROB. I. The course and distance sailed given, to find the difference of latitude and departure.

Example. Let the course be NEIN, distance 44. miles. Required the difference of latitude and departure ?

Move the index until the graduated edge be over 31 points, and find the given distance 44 miles on the index : this distance will be found to cut the parallel of 34 miles, the difference of latitude in the side column, and that of 28 miles, the departure at the top.

PROB. II. Given the course and difference of latitude, to find the distance and departure.

Example. Required the distance and departure answering to the course 28°, and difference of latitude 60 miles?

Lay the index over the given course 28° .: find the difference of latitude 60 miles in the side column; its parallel will cnt the index at 68 miles, the distance and the corresponding departure at the top is 32 miles.

PROB. III. The course and departure given, to find the distance and difference of latitude.

Example. Let the course be SSW and the departure 36 miles. Required the distance and difference of latitude?

Lay the index over two points; find the departure at the top, and its parallel will cut the index at 94 miles the distance, and the difference of latitude on the side column is 87 miles.

PROB. IV. Given the distance and difference of latitude, to find the course and departure.

Example. The distance is 35 leagues, and the difference of latitude 30 leagues. Required the course and departure ?

Bring 35 leagues on the index to the parallel of 30 leagues in the side ; then the departure at the top is 18 leagues, and the course by the edge of the index on the line of rhumbs is 23 points.

PROB. V. Given the distance and departure, to find the course and diffèrence of latitude.

Example. Let the distance be 58 miles, and the departure

(1) In the original instrument are two slips, divided like the side and end of the instrument. One of these slips is moveable in a direction parallel to the side of the instrument, and the other parallel to the end.

### Practice

Instruwithout tion.

nstrucents to lve Problems without

tion.

ractice.

### parture 15 miles. Required the course and difference of latitude ?

Move the index until 58 found thereon cuts the parallel of 15 from the top: this will be found to inter-Sailing, sect the parallel of 56 miles, the difference of latitude; alcula- and the course by the edge of the ruler is 15°.

### PROB. VI. The difference of latitude and departure being given, to find the course and distance.

Example. Let the difference of latitude be 30 miles, the departure 28 miles. Required the course and distance?

Bring the index to the intersection of the parallels of 30 and 28; then the distance on the index is 41 miles, and the course by its edge is 43°.

### Traverse Sailing.

Find the difference of latitude and departure answering to each course and distance by Problem I. of Plane Sailing, and from thence find the difference of latitude and departure made good ; with which find the course and distance by the last problem.

An example is unnecessary.

### Parallel Sailing.

PROB. I. Given the difference of longitude between two places on the same parallel, to find the distance between them.

Example. Let the latitude of a parallel be 48°, and the difference of longitude between two places on it 3° 40'. Required their distance?

Put the index to 48°, the given latitude, and find the difference of longitude 220 on the index, and the corresponding parallel from the side will be 147, the distance required.

PROB. II. The latitude of a parallel, and the distance between two places on that parallel, being given, to find the difference of longitude between them.

Example. The latitude of a parallel is 56°, and the distance between two places on it 200 miles. Required their difference of longitude?

Put the index to the given latitude, and find the distance in the side column, and the intersection of its parallel with the index will give 358, the difference of longitude sought.

PROB. III. Given the distance and difference of longitude between two places on the same parallel, to find the latitude of that parallel.

Example. The number of miles in a degree of longitude is 46.5. Required the latitude of the parallel?

Bring 60 on the index to cut the parallel of 46.5 from the side, then the edge of the index will give 39° II', the latitude required.

### Middle Latitude and Mercator's Sailing.

PROB. I. The latitudes and longitudes of two places being given, to find the course and distance between them.

Example. Required the course and distance between Genoa, in latitude 44° 25' N, longitude 8° 36' E, and Palermo, in latitude 38° 10' N, longitude 13° 38' E?

### By Mercator's Sailing.

Take the interval between 38° 10' and 44° 25' on

the enlarged meridian, which laid off from C upwards Instruwill reach to 500; now find the difference of longitude ments to 302 at the top, and bring the divided edge of the in- solve Prodex to the intersection of the corresponding parallels, in Sailing and the index will show the course 31° 8' on the line of without degrees; then find the difference of the latitude 375 on Calculathe side column, and its parallel will intersect the index tion. at 438, the distance.

### By Middle Latitude Sailing.

Put the index to 41° 18', the complement of the middle latitude on degrees, and the difference of longitude 302 on the index will intersect the parallel of 227, the departure, in the side column. Now move the index to the intersection of the parallels of 375 and 227, the first being found in the side column, and the other at top or bottom; then the distance answering thereto on the index will be 438, and the course on the scale of degrees is 41° 10'.

PROB. II. Given one latitude, course, and distance, to find the other latitude and difference of longitude.

Example. Let the latitude and longitude sailed from be 39° 22' N, and 12° 8' W respectively, the course NNW W, and distance 500 miles. Required the latitude and longitude come to.2.

### By Mercator's Sailing.

Put the index to the course  $2\frac{1}{2}$  points, and find the distance 500 miles thereon; then the corresponding difference of latitude will be 441 miles, and the departure 2351 miles, hence the latitude in is 46° 43' N. Now take the interval between the latitudes of 39° 22' and 46° 43' on the enlarged meridian, which laid off from © will reach to about 605, the parallel of which will intersect the vertical parallel of the difference of longitude 323 at the edge of the index : hence the longitude in is 17° 31' W.

### By Middle Latitude Sailing.

Find the difference of latitude and departure as before, and hence the latitude in is 46° 43' N, and the middle latitude 43° 3'. Now put the index to 43° 3', and the horizontal parallel of the departure 235<sup>1</sup>/<sub>2</sub> will intersect the index at 322, the difference of longitude.

PROB. III. Both latitudes and course given, to find the distance and difference of longitude.

Example. The latitude sailed from is 22° 54' S, and longitude 42° 40' W, the course is SE by E, and latitude come to 26° 8' S. Required the distance sailed, and longitude in?

### By Mercator's Sailing.

Bring the index to 5 points, the given course, and the parallel of 194, the difference of latitude found in the side column, will intersect the index at 349, the distance; and it will cut the vertical parallel of 290, the departure.

Take the interval between the given latitudes  $22^{\circ}$ 54 and 26° 8' on the enlarged meridian; lay off that extent from the centre on the side column, and it will reach to 213 : the parallel of this number will intersect the vertical parallel of 319, the difference of longitude. Hence the longitude in is 37° 21' W.

By

### By Middle Latitude Sailing.

With the given course and difference of latitude find solve Prob- the distance and departure as before; then bring the index to the middle latitude 24° 31'; find the departure 290 in the side column, and its parallel will intersect the index at 319, the difference of longitude.

> PROB. IV. One latitude, course, and departure, given, to find the other latitude, distance, and difference of longitude.

> Example. The latitude and longitude left are 20° 30' N, and 49° 17' W, respectively; the course is NEIN, and departure 212 miles. Required the latitude and longitude come to, and distance sailed ?

### By Mercator's Sailing.

Put the index to the given course  $3\frac{x}{4}$  points, and the vertical parallel of 212 will cut the index at 356, the distance, and the horizontal parallel of 286, the difference of latitude; the latitude come to is therefore

25° 16' N. Now take the interval between the latitudes 20° 30', and 25° 16' on the enlarged meridian, which laid off from the centre C will reach to 311; and this parallel will intersect the vertical parallel of the difference of longitude 230, at the edge of the index. Hence the longitude in is 45° 27' W.

### By Middle Latitude Sailing.

Find the distance and difference of latitude as directed above; then bring the index to 22° 53', the middle latitude, and the horizontal parallel of 212, the departure, will intersect the index at 230, the difference of longitude.

PROB. V. Both latitudes and distance given, to find the course and difference of longitude.

Example. The distance sailed is 500 miles between the north and west; the latitude and longitude left are 40° 1C' N, and 92 20' W respectively, and the latitude in is 46° 40' N. Required the course and longitude in?

### By Mercator's Sailing.

Bring the distance 500 on the index to intersect the horizontal parallel of the difference of latitude 390; then the course 38° 44' is found on the line of degrees by the edge of the index, and the vertical parallel of the above point of intersection is that answering to 313, the departure.

Take the interval between the latitudes 40° 10', and 46° 40', which lay off from the centre C, and its horizontal parallel will intersect the vertical parallel of 431, the difference of longitude, by the edge of the index, it being in the same position as before. Hence the longitude in is 16° 31' W.

### By Middle Latitude Sailing.

The course and departure are found as formerly, and the middle latitude is 43° 25', to which bring the edge of the index, and the horizontal parallel of 313, the departure, will intersect the index at 431, the difference of longitude.

PROB. VI. Both latitudes and departure given, to find the course, distance, and difference of longitude.

Example. Let the latitude sailed from be 42° 52' N,

long. 9º 17' W, the departure 250 miles W, and the Sea Charts latitude come to 36° 18' N. Required the course and distance sailed, and the longitude come to ?

### By Mercator's Sailing.

Find the point of intersection of the horizontal parallel of 394, the difference of latitude, and the vertical parallel of 250, the departure ; to this point bring the index, and the corresponding division thereon will be 467 miles, and the course on the scale of degrees by the edge of the index will be 32° 24'.

Take the interval between the latitudes on the enlarged meridian; which being laid off from the centre will reach to 512: now the horizontal parallel of 512 will cut the vertical parallel of 325, the difference of longitude, at the edge of the index. The longitude come to is therefore 14° 42' W.

### By Middle Latitude Sailing.

The course and distance are to be found in the same manner as above. Then bring the index to 39° 35', the middle latitude, and the horizontal parallel of 250 will intersect the edge of the index at 324<sup>1</sup>/<sub>2</sub>, the difference of longitude.

PROB. VII. Given one latitude, distance, and departure, to find the other latitude, course, and difference of longitude.

Example. A ship from latitude 32° 38'N, longitude 17° 6' W, sailed 586 miles between the south and west, and made 336 miles of departure :-- Required the course, and the latitude and longitude come to?

### By Mercator's Sailing.

Move the index till the distance 586 intersects the vertical parallel of the departure 336; then the corresponding horizontal parallel will be 480, the difference of latitude, and the course 35°. Hence the latitude in is 24° 38' N.

Now take the interval between the latitudes on the enlarged meridian, which laid off from the centre will reach to 547, the horizontal parallel of which will cut the vertical parallel of 383, the difference of longitude. The longitude in is therefore 23° 29'W.

### By Middle Latitude Sailing.

Find the course and difference of latitude as before, and hence the middle latitude is 28° 38', to which bring the index, and the horizontal parallel of 336, the departure, will intersect the index at 383, the difference of longitude.

It seems unnecessary to enlarge any further on the use of this instrument, as the above will make it sufficiently understood.

### CHAP. XII. Of Sea-Charts.

THE charts usually employed in the practice of navigation, are of two kinds, namely, Plane and Mercator's Charts. The first of these is adapted to represent a portion of the earth's surface near the equator; and the last for all portions of the earth's surface. For a particular description of these, reference has already been made from the article CHART, to these of PLANE and MERCATOR : and as these charts are particularly described under the above articles, it is therefore sufficient in this place to describe their use

Use

686 Instru-

ments to

lems

in Sailing,

without

Calcula-

tion.

### Use of the Plane Chart.

PROB. I. To find the latitude of a place on the chart. RULE. Take the least distance between the given place and the nearest parallel of latitude; now this distance applied the same way on the graduated meridian, from the extremity of the parallel, will give the latitude of the proposed place.

Thus the distance between Bonavista and the parallel of 15 degrees, being laid from that parallel upon the graduated meridian, will reach to 16° 5', the latitude required.

PROB. II. To find the course and distance between two given places on the chart.

RULE. Lay a ruler over the given places, and take the nearest distance between the centre of any of the compasses on the chart and the edge of the roler; move this extent along, so as one point of the compass may touch the edge of the rule, and the straight line joining their points may be perpendicular thereto; then will the other point show the course: The interval between the places, being applied to the scale, will give the required distance.

Thus the course from Palma to St Vincent will be found to be about SSW1 W, and the distance 13 T or 795 m.

PROB. III. The course and distance sailed from a known place being given, to find the ship's place on the chart.

RULE. Lay a ruler over the place sailed from, parallel to the rhumb, expressing the given course ; take the distance from the scale, and lay it off from the given place by the cdge of the ruler; and it will give the point representing the ship's present place. Thus, suppose a ship had sailed SW&W 160 miles

from Cape Palmas ; then by proceeding as above, it will be found that she is in latitude 2° 57' N. The various other problems that may be resolved by

mcans of this chart require no further explanation, being only the construction of the remaining problems in Plane Sailing on the chart.

### Use of Mercator's Chart.

The method of finding the latitude and longitude of a place, and the course of bearing between two given places by this chart, is performed exactly in the manner as in the Plane Chart, which see.

PROB. I. To find the distance between two given places on the chart.

CASE I. When the given places are under the same meridian.

RULE. The difference or sum of their latitudes, according as they are on the same or on opposite sides of the equator, will be the distance required.

CASE II. When the given places are under the same parallel.

RULE. If that parallel be the equator, the difference or sam of their longitudes is the distance; otherwise, take half the interval between the places, lay it off upwards and downwards on the meridian from the given parallel, and the intercepted degrees will be the distance between the places.

Or, take an equal extent of a few degrees from the Method meridian on each side of the parallel, and the number of of finding extents, and parts of an extent, contained between the the Latiplaces, being multiplied by the length of an extent, will Longitude give the required distance.

at Sea.

~

CASE III. When the given places differ both in latitude and longitude.

RULE. Find the difference of latitude between the given places, and take it from the equator or graduated parallel; then lay a ruler over the two places, and move one point of the compass along the edge of the ruler until the other point just touches a parallel ; then the distance between the place where the point of the compass rested by the edge of the ruler, and the point of intersection of the ruler and parallel, being applied to the equator, will give the distance between the places in degrees and parts of a degree, which multiplied by 60. will reduce it to miles.

PROB. II. Given the latitude and longitude in, to find the ship's place on the chart.

RULE. Lay a roler over the given latitude, and lay off the given longitude from the first meridian by the edge of the ruler, and the ship's present place will be obtained.

PROB. III. Given the course sailed from a known place, and the latitude in, to find the ship's present place on the chart.

RULE. Lay a ruler over the place sailed from, in the direction of the given course, and its intersection with the parallel of latitude arrived at will be the ship's present place.

PROB. IV. Given the latitude of the place left and the course and distance sailed, to find the ship's present place on the chart.

RULE. The ruler being laid over the place sailed from, and in the direction of the given course, take the distance sailed from the equator, put one point of the compass at the intersection of any parallel with the ruler, and the other point of the compass will reach to a certain place by the edge of the ruler. Now this point remaining in the same position, draw in the other point of the compass until it just touch the above parallel when sweeped round : apply this extent to the equator, and it will give the difference of latitude. Hence the latitude in will be known, and the intersection of the corresponding parallel with the edge of the ruler will be the ship's present place.

The other problems of Mercator's Sailing may be very easily resolved by this chart; but as they are of less use than those given, they are, therefore, omitted, and may serve as an exercise to the student.

### BOOK II.

Containing the method of finding the Latitude and Longitude of a Ship at Sea, and the Variation of the the Compass.

### CHAP. I. Of Hadley's Quadrant.

HADLEY's quadrant is the chief instrument in use at present for observing altitudes at sea. The form of this instrument, according to the present mode of construction,

actice. -Charts.

Method of finding the Latitude and Longitude at Sea.

Plate

CCCLXVII

Fig. 54.

Sce ASTRONOMY and QUADRANT. Fig. 54. represents a quadrant of the common construction, of which the following are the principal parts.

1. ABC, the frame of the quadrant.

2. BC, the arch or limb.

3. D, the index; a b, the subdividing scale.

construction, is an octagonal sector of a circle, and

therefore contains 45 degrees; but because of the

double reflection, the limb is divided into 90 degrees.

- 4. E, the index-glass.
- 5. F, the fore horizon-glass.
- 6. G, the back horizon-glass.
- 7. K, the coloured or dark glasses.
- 8. HI, the vancs or sights.

### Of the Frame of the Quadrani.

The frame of the quadrant consists of an arch BC, firmly attached to the two radii AB, AC, which are bound together by the braces LM, in order to strengthen it, and prevent it from warping.

### Of the Index D.

The index is a flat bar of brass, and turns on the centre of the octant : at the lower end of the index there is an oblong opening; to one side of this opening the vernier scale is fixed, to subdivide the divisions of the arch; at the end of the index there is a piece of brass, which bends under the arch, carrying a spring to make the subdividing scale lie close to the divisions. It is also furnished with a screw to fix the index in any desired position. The best instruments have an adjusting screw fitted to the index, that it may be moved more slowly, and with greater regularity and accuracy, than by the hand. It is proper, however, to observe, that the index must be previously fixed near its right position by the above-mentioned screw.

### Of the Index Glass E.

Upon the index, and near its axis of motion, is fixed a plane speculum, or mirror of glass quicksilvered. It is set in a brass frame, and is placed so that its face is perpendicular to the plane of the instrument. This mirror being fixed to the index moves along with it, and has its direction changed by the motion thereof; and the intention of this glass is to receive the image of the sun, or any other object, and reflect it upon either of the two horizon-glasses, according to the nature of the observation.

The brass frame with the glass is fixed to the index by the screw c; the other screw serves to re-place it in a perpendicular position, if by any accident it has been deranged.

#### Of the Horizon-Glasses F, G.

On the radius AB of the octant are two small speculums: the surface of the upper one is parallel to the index-glass, and that of the lower one perpendicular thereto, when o on the index coincides with o on the limb. These mirrors receive the reflected rays, and transmit them to the observer.

The horizon-glasses are not entirely quicksilvered; the upper one F is only silvered on its lower half, or that next the plane of the quadrant, the other half being left transparent, and the back part of the frame

3

cut away, that nothing may impede the sight through Method the unsilvered part of the glass. The edge of the foil of finding of this glass is nearly parallel to the plane of the in- the Latistrument, and ought to be very sharp, and without a Longitude flaw. The other horizon-glass is silvered at both ends. at Sea. In the middle there is a transparent slit through which the horizon may be seen.

Each of these glasses is set in a brass frame, to which there is an axis passing through the wood work, and is fitted to a lever on the under side of the quadrant, by which the glass may be turned a few degrees on its axis, in order to set it parallel to the index-glass. The lever has a contrivance to turn it slowly, and a button to fix it. To set the glasses perpendicular to the plane of the instrument, there are two sunk screws, one before and one behind each glass : these screws pass through the plate on which the frame is fixed into another plate; so that by loosening one and tightening the other of these screws, the direction of the frame with its mirror may be altered, and set perpendicular to the plane of the instrument.

### Of the Coloured Glasses K.

There are usually three coloured glasses, two of which are tinged red and the other green. They are used to prevent the solar rays from hurting the eye at the time of observation. These glasses are set in a frame, which turns on a centre, so that they may be used separately or together as the brightness of the sun may require. The green glass is particularly useful in observations of the moon; it may be also used in observations of the sun, if that object be very faint. In the fore-observation, these glasses are fixed as in fig. 54.; but when the back observation is used, they are removed to N.

### Of the two Sight Vanes, H, I.

Each of these vanes is a perforated piece of brass, designed to direct the sight parallel to the plane of the quadrant. That which is fixed at I is used for the fore, and the other for the back, observation. The vane I has two holes, one exactly at the height of the silvered part of the horizon-glass, the other a little higher, to direct the sight to the middle of the transparent part of the mirror.

### Of the divisions on the Limb of the Quadrant.

The limb of the quadrant is divided from right to left into 90 primary divisions, which are to be considered as degrees, and each degree is subdivided into three equal parts, which are therefore of 20 minutes each : the intermediate minutes are obtained by means of the scale of divisions at the end of the index.

### Of the Vernier, or Subdividing Scale.

The dividing scale contains a space equal to 21 divisions of the limb, and is divided into 20 equal parts. Hence the difference between a division on the dividing scale and a division on the limb is one-twentieth of a division on the limb, or one minute. The degree and minute pointed out by the dividing scale may be easily found thus.

Observe what minute on the dividing scale coincides with a division on the limb : this division being added to the degree and part of a degree on the limb, immediately

688

ractice.

ne Latide and at Sea.

· 55.

lethod diately preceding the first division on the dividing scale, finding will be the degree and minute required.

Thus suppose the fourteenth minute on the dividing ngitude seale coincided with a division on the limb, and that the preceding division on the limb to o on the vernier was 56° 40'; hence the division shown by the vernier is 56° 54'. A magnifying glass will assist the observer to read off the coinciding divisions with more accuracy.

### Adjustments of Hadley's Quadrant.

The adjustments of the quadrant consist in placing the mirrors perpendicular to the plane of the instrument. The fore horizon-glass must be set parallel to the speculum, and the planes of the speculum and back horizon-glass produced must be perpendicular to each other when the index is at o.

ADJUSTMENT I. To set the index-glass perpendieular to the plane of the quadrant.

Method 1. Set the index towards the middle of the limb, and hold the quadrant so that its plane may be nearly parallel to the horizon : then look into the index-glass; and if the portion of the limb scen by reflection appears in the same plane with that seen directly, the speculum is perpendicular to the plane of the instrument. If they do not appear in the same plane, the error is to be reetified by altering the position of the serews behind the frame of the glass.

Method 2. This is performed by means of the two adjusting too's, fig. 55, 56, which are two wooden frames, having two lines on each, exactly at the same distance from the hottom.

Place the quadrant in a horizontal position on a table; put the index about the middle of the areh; turn hack the dark glasses; place one of the above-mentioned tools near one end of the arch, and the other at the opposite end, the side with the lines being towards the index-glass ; then look into the index-glass, directing the sight parallel to the plane of the instrument, and one of the tools will be seen by direct vision, and the other by reflection. By moving the index a little, they may be brought exactly together. If the lines coincide, the position of the mirror is right; if not, they must be made to coincide by altering the screws behind the frame, as before.

ADJUSTMENT II. To set the fore horizon-glass perpendicular to the plane of the instrument.

Set the index to o; hold the plane of the quadrant parallel to the horizon; direct the sight to the horizon, and if the horizons seen directly and by reflection are apparently in the same straight line, the fore horizon-glass is perpendicular to the plane of the instrument; if not, one of the horizons will appear higher than the other. Now if the horizon seen by reflection is higher than that seen directly, rclease the nearest serew in the pedestal of the glass, and serew up that on the farther side, till the direct and reflected horizons appear to make one continued straight line. But if the reflected horizon is lower than that seen directly, unserew the farthest, and serew up the nearest screw till the eoineidence of the horizons is perfect, observing to leave both serews equally tight, and the fore horizon-glass will be perpendicular to the plane of the quadrant.

ADJUSTMENT III. To set the fore horizon-glass parallel to the index-glass, the index being at o.

Vol., XIV. Part II.

Set o on the index exactly to o on the limb, and fix Method it in that position by the serew at the under side ; hold of finding the plane of the quadrant in a vertical position, and the Latidirect the sight to a well-defined part of the horizon; tude and then if the horizon seen in the silvered part coincide; Longitude then if the horizon seen in the silvered part coincides with that seen through the transparent part, the horizonglass is adjusted; but if the horizons do not coincide, unserew the milled serew in the middle of the lever on the other side of the quadrant, and turn the nut at the end of the lever until both horizons coincide, and fix the lever in this position by tightening the milled serew.

As the position of the glass is liable to be altered by fixing the lever, it will therefore be necessary to re-examine it, and if the horizons do not coincide, it will be necessary either to repeat the adjustment, or rather to find the error of adjustment, or, as it is usually ealled, the index-error ; which may be done thus :

Direct the sight to the horizon, and move the index until the reflected horizon coincides with that seen direetly; then the difference between o on the limb and o on the vernier is the index error; which is additive when the beginning of the vernier is to the right of o on the limb, otherwise subtractive.

ADJUSTMENT IV. To set the back horizon glass perpendicular to the plane of the instrument.

Put the index to o; hold the plane of the quadrant parallel to the horizon, and direct the sight to the horizon through the back sight vane. Now if the reflected horizon is in the same straight line with that seen through the transparent part, the glass is perpendicular to the plane of the instrument. If the horizons do not unite, turn the sunk serews in the pedestal of the glass until they are apparently in the same straight line.

ADJUSTMENT V. To set the back horizon-glass perpendicular to the plane of the index-glass produced, the index being at o.

Let the index be put as much to the right of o as twice the dip of the horizon amounts to; hold the quadrant in a vertical position, and apply the eye to the back vane; then if the reflected horizon coincides with that seen directly, the glass is adjusted; if they do not coincide, the screw in the middle of the lever on the other side of the quadrant must be released, and the nut at its extremity turned till both horizons eoineide. It may be observed, that the reflected horizon will be inverted; that is, the sea will be apparently uppermost and the sky lowermost.

As this method of adjustment is esteemed troublesome, and is often found to be very difficult to perform at sea, various contrivances have therefore been proposed to render this adjustment more simple. Some of these are the following.

### 1. Mr Dollond's method of adjusting the back hor :zon-glass.

In this method an index is applied to the back horizon-glass, by which it may be moved so as to be parallel to the index-glass, when o on the vernier coincides with o on the limb. When this is effected, the index of the back horizon-glass is to be moved exactly 90° from its former position, which is known by means of a divided arch for that purpose; and then the plane of the back horizon-glass will be perpendicular to the plane of the index-glass produced. +

4 S

Practice.

Method of finding the Latitude and Longitude at Sca.

690

2. Mr Blair's method of adjusting the back horizon-glass.

All that is required in this method is to polish the lower edge of the index-glass, and expose it to view. The back horizon-glass is adjusted by means of a reflection from this polished edge, in the very same method as the fore horizon-glass is adjusted by the common method.

In order to illustrate this, let RIHE (fig. 57.) represent a pencil of rays emitted from the object R, incident on the index-glass I, from which it is reflected to the forc horizon-glass H, and thence to the eye at E. By this double reflection, an image of the object is formed at r. RHE represents another pencil from the same object R, coming directly through the forc horizon-glass to the eye at E; so that the double reflected image r appears coincident with the object R itself, seen directly.

When this coincidence is perfect, and the object R so very distant as to make the angle IRH insensible, the position of the speculums I and H will differ insensibly from parallelism; that is, the quadrant will be adjusted for the fore observation. Now it is from the ease and accuracy with which this adjustment can at any time be made, that the fore-observation derives its superiority over the back observation. But by grinding the edge of the index-glass perpendicular to its reflecting surface, and polishing it, the observation is rendered capable of an adjustment equally easy and accurate as the fore horizon glass: for by a pencil of rays emitted from the object S, incident on the reflecting edge of the index-glass D, thence reflected to the back horizonglass B, and from that to the eye at e, an image will be formed at s; which image being made to coincide with the object S itself, seen directly, ascertains the position of the back horizon-glass relative to the indexglass, with the same precision, and in a manner equally direct, as the former operation does that of the fore horizon-glass.

### Directions for adjusting the Back Horizon-Glass.

The method of adjusting the quadrant for the backobservation is this. If it is to be done without making use of the telescope, place the index at o, and, applying the eye to the hole in the sight vane (K), or tube for directing the sight, direct it through the back horizon-glass to the horizon, if that is the object to be used for adjusting. The two horizons are then to be made to coincide, holding the quadrant first in a vertical and then in a horizontal position; by which means both adjustments will be effected as in the fore-observation.

There will be no difficulty in finding the reflected horizon, if the observer first directs his eye to that part of the horizon-glass where he observes the image of the polished edge of the index-glass, which will ap-

pear double. When the direct horizon is made to appear in this case, the reflected one will be seen close by of finding it, unless the instrument wants a great adjustment. In the Latitude and this case, a little motion of the back horizon-glass backwards and forwards will presently bring it in view.

When the horizon, or any obscure terrestrial object, is to be made use of for adjusting by means of the reflecting edge, there is a precaution to be taken, without which the observer will sometimes meet with what will appear an unaccountable difficulty; for if the sky, or other object behind him, should happen to be pretty bright, he will not be able to discern the horizon at all. This arises from the image of the object behind him, which is reflected from the silvered surface of the index-glass, appearing to coincide with the horizon; in which case, the bright picture of the former, which is formed in the bottom of the eye, prevents the fainter impression of the latter from being This will be avoided either by applyperceived. ing a black screen over the silvered surface of the index glass, or, without being at this trouble, by standing at a door or window, so that only the dark objects within can be reflected from the index-glass : but if the observation is to be made in the open air, a hat, or any such dark obstacle, held before the silvered surface of the index-glass, will very effectually remove this inconvenience.

It may be remarked, that some observers, instead of making the principal adjustment, place the speculums parallel, by moving the index without altering the position of the horizon-glass: and the difference between o on the vernier and o on the limb is the index error, which must be subtracted from all angles measured by the back-observation, when o on the index, is to the right of o on the limb; and added when to the left.

3. Mr Wright's method of adjusting the back horizon-glass of his improved patent quadrant.

Fig. 58. Is a representation of the quadrant com-Fig. 58. plete in all its parts for use. A, is the reflecting surface of the index-glass, which is made of the usual length, and 20 of an inch broad. The bottom part is covered in front by the brass frame, and the reflecting surface is  $\frac{7}{70}$  on the back. B, the fore horizon-glass, placed as usual: O, the back horizon-glass, now placed under the fore sight-vane on the first radius of the quadrant I: C, the sight-vane of the fore horizonglass : D, the sight-vane of the back horizon-glass : E, the coloured glasses in a brass frame, in the proper place for the fore observation : F, a hole in the frame to receive the coloured glasses when an observation is to be taken with the back horizon-glass in the common way, by turning the back to the sun : G, a hole in the frame of the farthest radius K, to receive the coloured glasses when an observation is to be taken by the new method; which is by looking through the lower hole in the sight-vane of the back horizon-glass, directly at

Fig. 57.

 $<sup>(\</sup>kappa)$  Besides the hole in the sight-vane, commonly made, there must be another nearcr to the horizon-glass, and so placed that an eye directed through it to the centre of the horizon-glass shall there perceive the image of the polished edge of the index-glass. This hole must not be made small like the other, but equal to the ordinary size of the pupil of the eye, there being on some occasions no light to spare.

62.

Method at the sun in the line of sight DN; the horizon from of finding behind will then be reflected from the back of the inhe Lati- dex-glass to the horizon-glass, and from thence to the Longitude eye. (See fig. 62.) H, a brass clamp on the upper at Se. end of the index, having a milled screw underneath, which fastens the round plate to the index when re-quired. (See fig. 59.). IK, the graduated arch of the quadrant divided into 90 degrees : L, the brass index which moves over the graduated arch : M, the vernier to subdivide the divisions on the arch into single minutes of a degree.

Fig. 59. shows the upper part of the index L on a larger scale, with part of the brass frame that fastens the index-glass, and the three adjusting screws D to adjust its axis vertical to the plane of the quadrant : B, the centre on which the milled plate O moves over the index: The dotted line BF is the distance it is required to move : K, the adjusting screw to stop it in its proper place for adjusting the back observationglass : G, a piece of brass fastened to the index opposite to the clamp H, to keep the plate O always close to the index L.

Fig. 60. represents the parallel position of the index and horizon glasses after adjustment by the sun: BC, a ray from the sun incident on the index-glass C, and from thence reflected to the fore horizon-glass D, and again to the eye at E, in the line D E, where the eye sees the sun at A by direct vision, and the image by reflection, in one; the parallel lines AE and BC being so near to each other, that no apparent angle can be observed in the planes of the index and horizon-glass, when adjusted by a distant object.

In fig. 61. the index-glass is removed 45 degrees from the planc of the fore horizon-glass, and fixed in its proper place for adjusting the back horizon-glass parallel to its plane, in the same manner as the fore horizon-glass is adjusted.

In fig. 62. the index-glass (after the adjustment of the fore and back horizon-glasses) is carried forward by the index on the arch 90 degrees, and makes an angle of 45° with the plane of the fore horizon-glass, and is at right angles to the plane of the back horizon-glass. The eye at E now sees the sun in the horizon at H, reflected by the index and horizon glasses from the zenith at Z, the image and object being 90 degrees distant. The back horizon K is now reflected from the back surface of the index-glass C to the horizon-glass M, and from thence to the eye at D, in a right line with the forc horizon F. In order to make an exact contact of the fore and back horizons at F. the index must be advanced beyond the 90th degree on the arch, by a quantity equal to twice the dip of the horizon.

The quadrant is adjusted for the fore observation as usual, having previously fixed the index-glass in its proper place by the milled screw at H, as represented in fig. 59.

### To adjust the Quadrant for the Back-observation.

Fasten the index to 90° on the limb ; loosen the screw H (fig. 59.), and turn the plate O by the milled edge until the end of the adjusting screw K touch the edge of the clamp M; and by means of a distant object observe if the glasses are then parallel, as at fig. 60. : if they are, fasten the screw H ; if not, with a screw-dri691

ver turn the screw K gently to the right or left to make Method them perfect, and then fasten the screw. Now remove of finding the index back to O on the limb, and the index-glass the Latiwill be parallel to the back horizon glass E, fig. 61.; tude and If not make them so by tunning the adjusting the distingtion of the second se If not, make them so by turning the adjusting screw at Sea. of the glass E, the eye being at the upper hole in the sight-vane D, and the sight directed to the horizon, or any distant object in the direction DN (fig. 58.). Now the index remaining in this position, the indexglass is to returned, to stop at the pin E, and it will be parallel to the fore horizon-glass as at first : then the quadrant will be adjusted for both methods of observation.

### To observe the Sun's Altitude by the Back-observation.

Remove the coloured glasses to G (fig. 58.), and look through the lower hole in the sight-vane D, in the line of direction DN, directly to the sun, and move the index forward on the arch exactly in the same manner as in the fore-observation : make the contact of the sun's limb and the back horizon exact, and the degrees and minutes shown by the index on the limb is the sun's zenith distance. It may be observed, that the horizon will be inverted. If the sun's lower limb be observed, the semidiameter is to be subtracted from the zenith distance; but if the upper limb is observed, the semidiameter is to be added.

The observation may be made in the usual manner, by turning the back to the sun. In this case the coloured glasses are to be shifted to F, and proceed according to the directions formerly given.

### Use of Hadley's Quadrant.

The altitude of any object is determined by the position of the index on the limb, when by reflection that object appears to be in contact with the horizon.

If the object whose altitude is to be observed be the sun, and if so bright that its image may be seen in the transparent part of the fore horizon-glass, the cye is to be applied to the upper hole in the sight vane; otherwise, to the lower hole : and in this case, the quadrant is to be held so that the sun may be bisected by the line of separation of the silvered and transparent parts of the glass. The moon is to be kept as nearly as possible in the same position ; and the image of the star is to be observed in the silvered part of the glass adjacent to the line of separation of the two parts.

There are two different methods of taking observations with the quadrant. In the first of these the face of the observer is directed towards that part of the horizon immediately under the sun, and is therefore called the fore-observation. In the other method, the observer's back is to the sun, and it is hence called the back-observation. This last method of observation is to be used only when the horizon under the sun is obscured, or rendered indistinct by fog or any other impediment.

In taking the sun's altitude, whether by the fore or back observation, the observer must turn the quadrant about upon the axis of vision, and at the same time turn himself about upon his heel, so as to keep the sun always in that part of the horizon-glass which is at the same distance as the cye from the plane of the quadrant. In this way the reflected sun will describe an arch of a parallel circle round the true sun, whose convex side

4 S 2

Method will be downwards in the fore-observation and upof finding wards in the back; and consequently, when by moving the Latitude and Longitude servation, or highest in the back, is made to touch the at Sea horizon, the quadrant will stand in a vertical plane, Practice hact

tire freedom from looseness, or *shake*, as the workmen term it. By strictly complying with these directions of finding the error in question may indeed be greatly diminished; so far, perhaps, as to render it nearly insensible, where the index is made strong, and the proper medium between the two extremes of a shake at the centre on one hand, and too much stiffness there on the other, is nicely hit; but it cannot be entirely corrected. For to more or less of bending the index will always be subject; and some degree of resistance will remain at the centre, unless the friction there could be totally removed, which is impossible.

Of the reality of the error to which he is liable from this cause, the observer, if he is provided with a quadrant furnished with a screw for moving the index gradually, may thus satisfy himself. After finishing the observation, lay the quadrant on a table, and note the angle; then eautiously loosen the screw which fastens the index, and it will immediately, if the quadrant is not remarkably well constructed, be seen to start from its former situation, more or less according to the perfection of the joint and the strength of the This starting, which is owing to the index index. recoiling after being released from the confined state it was in during the observation, will sometimes amount to several minutes; and its direction will be opposite to that in which the index was moved by the screw at the time of finishing the observation. But how far it affects the truth of the observation, depends on the manner in which the index was moved in setting it to o, for adjusting the instrument; or in finishing the observations necessary for finding the index error.

The casiest and best rule to avoid these errors seems to be this: In all observations made by Hadley's quadrant, let the observer take notice constantly to finish his observations, by moving the index in the same direction which was used in setting it to o for adjusting; or in the observations necessary for finding the index error. If this rule is observed, the error arising from the spring of the index will be obviated. For as the index was bent the same way, and in the same degree in adjusting as in observing, the truth of the observations will not be affected by this bending.

To take Altitudes by the Fore-observation.

### I. Of the Sun.

TURN down either of the coloured glasses before the horizon-glass, according to the brightness of the sun; direct the sight to that part of the horizon which is under the sun, and move the index until the coloured image of the sun appear in the horizon-glass; then give the quadrant a slow vibratory motion about the axis of vision; move the index until the lower or upper limb of the sun is in contact with the horizon, at the lowest part of the arch described by this motion; and the degrees and minutes shown by the index on the limb will be the altitude of the sun.

### II. Of the Moon.

Pur the index to o, turn down the green glass, place the eye at the lower hole in the sight-vane, and observe the moon in the silvered part of the horizonglass; move the index gradually, and follow the moon's reflected image until the enlightened limb is in contact with

horizon, the quadrant will stand in a vertical plane, and the altitude above the visible horizon will be properly observed. The reason of these operations may be thus explained : The image of the sun being always kept in the axis of vision, the index will always show on the quadrant the distance between the sun and any object seen directly which its image appears to touch ; therefore, as long as the index remains unmoved, the image of the sun will describe an arch everywhere equidistant from the sun in the heavens, and consequently a parallel circle about the sun, as a pole. Such a translation of the sun's image can only be produced by the quadrant's being turned about upon a line drawn from the eye to the sun, as an axis. A motion of rotation upon this line may be resolved into two, one upon the axis of vision, and the other upon a line on the quadrant perpendicular to the axis of vision; and consequently a proper combination of these two motions will keep the image of the sun constantly in the axis of vision, and cause both jointly to run over a parallel circle about the sun in the heavens : but when the quadrant is vertical, a line thereon perpendicular to the axis of vision, becomes a vertical axis; and as a small motion of the quadrant is all that is wanted, it will never differ much in practice from a vertical axis. The observer is directed to perform two motions rather than the single one equivalent to them on a line drawn from the eye to the sun : because we are not capable, while looking towards the horizon, of judging how to turn the quadrant about upon the elevated line going to the sun as an axis, by any other means than by combining the two motions above mentioned, so as to kcep the sun's image always in the proper part of the horizon-glass. When the sun is near the horizon, the line going from the eye to the sun will not be far removed from the axis of vision; and consequently the principal motion of the quadrant will be performed on the axis of vision, and the part of motion made on the vertical axis will be but small. On the contrary, when the sun is near the zenith, the line going to the sun is not far removed from a vertical line, and consequently the principal motion of the quadrant will be performed on a vertical axis, by the observer's turning himself about, and the part of the motion made on the axis of vision will be but small. In intermediate altitudes of the sun, the motions of the quadrant on the axis of vision, and on the vertical axis, will be more equally divided.

Observations taken with the quadrant are liable to errors, arising from the bending and elasticity of the index, and the resistance it meets with in turning round its centre : whence the extremity of the index, on being pushed along the arch, will sensibly advance before the index-glass begins to move, and may be seen to recoil when the force acting on it is removed. Mr Hadley seems to have been apprehensive that his instrument would be liable to errors from this cause; and in order to avoid them, gives particular directions that the index be made broad at the end next the centre, and that the centre, or axis itself, have as easy a motion as is consistent with steadiness; that is, an en-

4
Le and Sea.

l'actice.

ethod with the horizon, at the lower part of the arch describinding ed by the vibratory motion as before, and the index will show the altitude of the observed limb of the moon. agitude If the observation is made in the day-time, the coloured glass is unnecessary.

#### III. Of a Star or Planet.

THE index being put to o, direct the sight to the star through the lower hole in the sight-vane and transparent part of the horizon-glass ; move the plane of the quadrant a very little to the left, and the image of the star will be seen in the silvered part of the glass. Now move the index, and the image of the star will appear to descend : continue moving the index gradually until the star is in contact with the horizon at the lowest part of the arch described; and the degrees and minutes shown by the index on the limb will be the altitude of the star.

To take Altitudes by the Back-observation.

#### I. Of the Sun.

Put the stem of the coloured glasses into the perforation between the horizon-glasses, turn down either according to the brightness of the sun, and hold the quadrant vertically; then direct the sight through the hole in the back sight-vane, and the transparent slit in the horizon-glass to that part of the horizon which is opposite to the sun; now move the index till the sun is in the silvered part of the glass, and by giving the quadrant a vibratory motion, the axis of which is that of vision, the image of the sun will describe an arch whose convex side is upwards; bring the limb of the sun, when in the upper part of this arch, in contact with the horizon ; and the index will show the altitude of the other limb of the sun.

#### II. Of the Moon.

THE altitude of the moon is observed in the same manner as that of the sun, with this difference only, that the use of the coloured glass is unnecessary unless the moon is very bright; and that the enlightened limb, whether it be the upper or lower, is to be brought in contact with the horizon.

#### III. Of a Star or Planet.

Look directly to the star through the vane and transparent slit in the horizon-glass ; move the index until the opposite horizon, with respect to the star, is seen in the silvered part of the glass; and make the contact perfect as formerly. If the altitude of the star is known nearly, the index may be set to that altitude, the sight directed to the opposite horizon, and the observation made as before.

#### SECT. II. Of finding the Latitude of a Place.

THE observation necessary for ascertaining the latitude of a place, is that of the meridional altitude of a known celestial object; or two altitudes when the objeet is out of the meridian. The latitude is deduced with more certainty and with less trouble from the firstof these methods, than from the second ; and the sun, for various reasons, is the object most proper for this purpose at sea. It, however, frequently happens, that

by the interposition of clouds, the sun is obscured at Method. noon; and by this means the meridian altitude is lost. of finding In this case, therefore, the method by double altitudes the Lati-becomes necessary. The latitude may be deduced from Longitude three altitudes of an unknown object, or from double at Sea. altitudes, the apparent times of observation being given.

693

The altitude of the limb of an object observed at sea, requires four separate corrections in order to obtain the true altitude of its centre : these are for semidiameter, dip, refraction, and parallax. (See ASTRONOMY, and the respective articles). The first and last of these corrections vanish when the observed object is a fixed star.

When the altitude of the lower limb of any object is observed, its semidiameter is to be added thereto in order to obtain the central altitude; but if the upper limb be observed, the semidiameter is to be subtracted. If the altitude be taken by the back-observation, the contrary rule is to be applied. The dip is to be subtracted from, or added to, the observed altitude, according as the fore or back observation is used. The refraction is always to be subtracted from, and the parallax added to, the observed altitude.

PROB. I. To reduce the sun's declination to any given meridian.

RULE. Find the number in Table IX. answering to the longitude in the table nearest to that given, and to the nearest day of the month. Now, if the longitude is west, and the declination increasing, that is, from the 20th of March to the 22d of June, and from the 22d of September to the 22d of December, the above number is to be added to the declination : during the other part of the year, or while the deelination is deereasing, this number is to be subtracted. In east longitude, the contrary rule is to be applied.

Ex. 1. Required the sun's deelination at noon 16th April 1810, in longitude 84° W?

| Number from Table IX                   | 9° 59.2' IN.<br>+ 5.0 |
|----------------------------------------|-----------------------|
| Reduced declination                    | 10 4.2.               |
| Ex. 2. Required the sun's declination  | at noon 22d           |
| Sun's declination at noon at Greenwich | N'cs on               |
| Equation from Table X                  | - 10.                 |
| State Summer State State State State   |                       |
| Reduced declination                    | 0 12 N                |

PROB. II. Given the sun's meridian altitude, to find the latitude of the place of observation.

RULE. The sun's semidiameter is to be added to, or subtracted from, the observed altitude, according as the lower or upper limb is observed; the dip answering to the height from Table V. is to be subtracted if the fore-observation is used; otherwise, it is to be added; and the refraction answering to the altitude from Table IV. is to be subtracted : hence the true altitude of the sun's centre will be obtained. Call the altitude south or north, according as the sun is south or north at the time of observation; which subtracted from 90°, will give the zenith distance of a contrary denomination.

Reduce the sun's declination to the meridian of the place of observation, by Prob. I.; then the sum or difference

tude an Longitut at Sea

ference of the zenith distance and declination, accord-Method of finding ing as they are of the same or of a contrary denominathe Lati- tion, will be the latitude of the place of observation, of Longitude the same name with the greater quantity.

~ Latitude 17 39 S The dip in Table V. answers to an entirely open and unobstructed horizon. It, however, frequently happens, that the sun is over the land at the time of observation, and the ship nearer to the land than the visible horizon would be if unconfined. In this case, the dip will be different from what it would otherwise have been, and is to be taken from Table VI. in which the height is expressed at the top, and the distance from the -land in the side column in nautical miles .- Seamen, in -general, can estimate the distance of any object from 2

the ship with sufficient exactness for this purpose, espe- Method cially when that distance is not greater than six miles; of finding which is the greatest distance of the visible horizon the Lat. from an observer on the deck of any ship.

PROB. III. Given the meridian altitude of a fixed star, to find the latitude of the place of observation.

RULE. Correct the altitude of the star by dip and refraction, and find the zenith distance of the star as formerly; take the declination of the star from Table XI. and reduce it to the time of observation. Now, the sum or difference of the zenith distance and declination of the star, according as they are of the same or of a contrary name, will be the latitude of the place of observation.

Ex. 1. December 1. 1810, the meridian altitude of Sirius was 59° 50' S, height of the eye 14 feet. Required the latitude?

#### Latitude

6 42 N Remark. If the object be on the meridian below the pole at the time of observation, then the sum of the true altitude and the complement of the declination is the latitude, of the same name as the declination or altitude.

Ex. 1. July 2. 1812, in longitude 15° W, the altitude of the sun's lower limb at midnight was 8° 58', height of the eye 18 feet. Required the latitude? Observed altitude sun's lower limb 8°: 58' Semidiameter +0 16 Dip and refraction -0 10 True altitude of sun's centre -4 N ----Compl. declin. reduced to time and place 66 57 N Latitude 76 IN

PROB. VI. Given the latitude by account, the declination and two observed altitudes of the sun, and the interval of time between them, to find the true latitude.

RULE. To the log. secant of the latitude by account, add the log. sceant of the sun's declination ; the sum, rejecting 20 from the index, is the logarithm ratio. To this add the log. of difference of the natural sines of the two altitudes, and the log. of the half elapsed time from its proper column.

Find this sum in column of middle time, and take out the time answering thereto; the difference between which and the half elapsed time will be the time from noon when the greater altitude was observed.

Take the log. answering to this time from column of rising, from which subtract the log. ratio, the remainder is the logarithm of a natural number; which being added to the natural sine of the greater altitude, the sum is the natural cosine of the meridian zenith distance; from which and the sun's declination the latitude is obtained as formerly.

If the latitude thus found differs considerably from . that by account, the operation is to be repeated, using the computed latitude in place of that by account (L).

Example 1.

(L) This method is only an approximation, and ought to be used under certain restrictions ; namely,

The observations must be taken between nine o'clock in the forenoon and three in the afternoon. If both observations be in the forenoon, or both in the afternoon, the interval must not be less than the distance of the time of observation of the greatest altitude from noon. If one observation be in the forenoon and the other in the afternoon, the interval must not exceed four hours and a half; and in all cases, the nearer the greater altitude is to noon the better.

If the sun's meridian zenith distance be less than the latitude, the limitations are still more contracted. If the : latitude be double the meridian zenith distance, the observations must be taken between half past nine in the morning and half past two in the afternoon, and the interval must not exceed three hours and a half. The observations must be taken still nearer to noon, if the latitude exceed the zenith distance in a greater proportion. See Maskelyne's British Mariner's Guide, Dr Mackay's Treatises on the Longitude and Navigation, &c. and Bequisite Tables, 2d edit.

As this latitude differs only 5' from that used in the computation, it may therefore be depended upon as the true latitude.

PROB. VII. Given the latitude by account, the sun's declination, two observed altitudes, the elapsed time, and the course and distance run between the observations; to find the ship's latitude at the time of observation of the greater altitude.

RULE. Find the angle contained between the ship's course and the sun's bearing at the time of observation of the least altitude, with which enter the Traverse Table as a course, and the difference of latitude answering to the distance made good will be the reduction of altitude.

Now, if the least altitude be observed in the forenoon, the reduction of altitude is to be applied thereto by addition or subtraction, according as the angle between the ship's course and the sun's bearing is less or more than eight points. If the least altitude be observed in the afternoon, the contrary rule is to be used.

The difference of longitude in time between the observations is to be applied to the elapsed time by addition or subtraction, according as it is east or west. This is, however, in many cases so inconsiderable as to be neglected.

With the corrected altitudes and interval, the latitude by account and sun's declination at the time of observation of the greatest altitude, the computation is to be performed by the last problem.

Ex. 1. July 6. 1793, in latitude 58° 14' N by account, and longitude 16° E, at 10h 54' A. M. per watch, the altitude of the sun's lower limb was 53° 17', and at 1h 17' P. M. the altitude was 52° 51', and bearing per compass SWbW; the ship's course during the elapsed time was  $SbW_{\frac{1}{2}}W$ , and the hourly rate of sailing 8 knots, the height of the eye 16 feet. Required the true latitude at the time of observation of the greater altitude?

Latitude

57 9 N.

As this latitude differs only 4 miles from that used in the computation, it may therefore be depended on as the true latitude

*Remark.* If the sun come very near the zenith, the sines of the altitude will vary so little as to make it uncertain which ought to be taken as that belonging to the natural sine of the meridian altitude. In this case, the following method will be found preferable.

To the log. rising of the time from noon found as before, add the log. secant of half the sum of the estimate meridian altitude, and greatest observed altitude; from which subtract the log. ratio, its index being increased by 10, and the remainder will be the log. sine Vol. XIV. Part. II. of an arch; which added to the greatest altitude will Method give the sun's meridian altitude.

*Ex.* 2. December 21st 1793, in latitude 22° 40' S, the Latitude and by account at 11h 57' the correct altitude of the sun's Longitude centre was 89° 10', and at 12h 4' 40", the altitude was  $88^{\circ}$  50'. Required the true latitude ?

PROB. VIII. Given the altitudes of two known stars, observed at the same or at different times; and if at different times, the interval between the observations; to find the latitude.

RULE. If both altitudes be observed at the same time, call the difference between their right ascensions the reduced interval.

But if the altitudes be taken at different times, reduce the interval between the observations to sidereal time, by adding thereto the proportional part answering to the interval, and 3' 56", the daily acceleration of the fixed stars. Now to the right ascension of the first observed star, add the interval in sidereal time, and the difference between this sum and the right ascension of the other star will be the reduced interval.

2

To the logarithm rising of the reduced interval, add the logarithmic cosines of the stars declinations; subtract the natural number answering to the sum of these logarithms from the natural cosine of the difference or sum of the stars declinations, according as they are of the same or of a contrary name, and the remainder will be the natural sine of arch first.

To the logarithmie cosine of arch first add the logarithmic seeant of declination of the star having the least polar distance, and the logarithm half elapsed time of the reduced interval, the sum will be the logarithm half elapsed time of arch second.

From the natural cosine of the difference between arch first and the altitude of the star having the greatest polar distance, subtract the natural sine of the altitude of the other star, and find the logarithm of the remainder; to which add the logarithm secant of arch first, and the logarithmic secant of the altitude of the star having the greatest polar distance, the sum will be the logarithm rising of arch third. The difference between arches second and third is arch fourth.

To the logarithm rising of arch fourth add the logarithmie cosines of the declination and altitude of the star having the greatest polar distance; subtract the corresponding natural number from the natural cosine of the difference between the altitude and declination, the polar distance being less than 90°; otherwise, from their sum, and the remainder will be the natural sine of the altitude.

#### CHAP. II. Containing the Method of finding the Longitude at Sea by Lunar Observations.

#### SECT. I. Introduction.

THE observations necessary to determine the longitude by this method are, the distance between the sun and moon, or the moon and a fixed star near the ecliptic, together with the altitude of each. The stars used in the Nautieal Almanack for this purpose are the following : namely, & Arietis, Aldebaran, Pollux, Regulus, Spica Virginis, Antares, & Aquilæ, Fomalhaut, and a Pegasi; and the distances of the moon's centre from the sun, and from one or more of these stars, are contained in the viii. ix. x. and xi. pages of the month, at the beginning of every third hour apparent time, by the meridian of Greenwich. The distance between the moon and the sun, or one of these stars, is observed with a sextant; and the altitudes of the objects are taken as usual with a Hadley's quadrant.

In the practice of this method, it will be found convenient to be provided with three assistants; two of these are to take the altitudes of the sun and moon, or moon and star, at the same time the principal observer is taking the distance between the objects; and the third assistant is to observe the time, and write down

#### Practice. Method

)Jbservations.

of finding down the observations. In order to obtain accuracy, le Longi it will be necessary to observe several distances, and de at Sea the corresponding altitudes; the intervals of time beby Lunar tween them being as short as possible; and the sum of each divided by the number will give the mean distance and mean altitudes; from which the time of observation at Greenwich is to be computed by the rules to be explained.

> If the sun or star from which the moon's distance is observed be at a proper distance from the meridian, the time at the ship may be inferred from the altitude observed at the same time with the distance : in this case, the watch is not necessary ; but if that object be near the meridian, the watch is absolutely necessary, in order to connect the observations for ascertaining the apparent time at the ship and at Greenwich with each other.

> An observer without any assistants may very easily take all the observations, by first taking the altitudes of the objects, then the distance, and again their altitudes, and reduce the altitudes to the time of observation of the distance; or, by a single observation of the distance, the apparent time being known, the longitude may be determined.

> A set of observations of the distance between the moon and a star, and their altitudes, may be taken with accuracy during the time of the evening or morning twilight; and the observer, though not much acquainted with the stars, will not find it difficult to distinguish the star from which the moon's distance is to be observed. For the time of observation nearly, and the ship's longitude by account being known, the estimate time at Greenwich may be found ; and by entering the Nautical Almanac with the reduced time, the distance between the moon and given star will be found nearly. Now set the index of the sextant to this distance, and hold the plane of the instrument so as to be nearly at right angles to the line joining the moon's cusps, direct the sight to the moon, and by giving the sextant a slow vibratory motion, the axis of which being that of vision, the star, which is usually one of the brightest in that part of the heavens, will be seen in the transparent part of the horizon glass.

#### SECT. II. Of the Sextant.

This instrument is constructed for the express purpose of measuring with accuracy the angular distance between the sun and moon, or between the moon and a fixed star, in order to ascertain the longitude of a place by lunar observations. It is, therefore, made with more care than the quadrant, and has some additional appendages that are wanting in that instrument.

Fig. 63. represents the sextant, so framed as not to (LXVIII. be liable to hend. The arch AA is divided into 120 degrees; each degree is divided into three parts; each of these parts, therefore, contains 20 minutes, which are again subdivided by the vernier into every half minute or 30 seconds. The vernier is numbered at every fifth of the longer divisions, from the right towards the left, with 5, 10, 15, and 20; the first division to the right being the beginning of the scale.

In order to observe with accuracy, and make the images come precisely in contact, an adjusting screw

B is added to the index, which may thereby be mov- Of finding ed with greater accuracy than it can be hy hand; the Longibut this screw does not act until the index is fixed by tude at Sea the fuger serew C. Carc should be taken not to force Observathe adjusting screw when it arrives at either extemity of its adjustment. When the index is to be moved 4 any considerable quantity, the screw C at the back of the sextant must be loosened; but when the index is brought nearly to the division required, this back screw should be tightened, and then the index may be moved gradually by the adjusting serew.

There are four tinged glasses D, cach of which is set in a separate frame that turns on a centre. They are used to defend the eye from the brightness of the solar image and the glare of the moon, and may be used separately or together as occasion requires.

There are three more such glasses placed behind the horizon glass at E, to weaken the rays of the sun or moon when they are viewed directly through the horizon glass. The paler glass is sometimes used in observing altitudes at sea, to take off the strong glare of the horizon.

The frame of the index glass I is firmly fixed by a strong cock to the centre plate of the index. The horizon glass F is fixed in a frame that turns on the axes or pivots, which move in an exterior frame; the holes in which the pivots move may be tightened by four screws in the exterior frame. G is a screw by which the horizon glass may be set perpendicular to the plane of the instrument : should this screw become loose, or move too easy, it may be easily tightened by turning the capstan headed serew H, which is on one side of the socket through which the stem of the finger screw passes.

The sextant is furnished with a plain tube (fig. 64.) Fig. 64 without any glasses; and to render the objects still more distinct, it has two telescopes, one (fig. 65.) re- Fig. 6 5 presenting the objects ercet, or in their natural position : the longer one (fig. 66.) shows them inverted ; Fig. 66. it has a large field of view, and other advantages, and a little use will soon accustom the observer to the inverted position, and the instrument will be as readily managed by it as by the plain tube alone. By a telescope the contact of the images is more perfectly distinguished; and by the place of the images in the field of the telescope, it is easy to perceive whether the sextant is held in the proper place for observation. By sliding the tube that contains the eye-glasses in the inside of the other tube, the object is suited to different. eyes, and made to appear perfectly distinct and well defined.

The telescopes are to he screwed into a circular ring at K; this ring rests on two points against an exterior ring, and is held thereto by two screws : by turning one or other of these screws, and tightening the other, the axis of the telescope may be set parallel to the plane of the sextant. The exterior ring is fixed on a triangular brass stem that slides in a socket, and by means of a screw at the back of the quadrant may be raised or lowcred so as to move the centre of the telescope to point to that part of the horizon glass which shall be judged the most fit for observation. Fig. 67. is a circular head, with tinged glasses to screw Fig. 67. on the eye end of either of the telescopes or the plain tube. The glasses are contained in a circular plate 4 T 2 which

699

Plate

Offinding which has four holes; three of these are fitted with the Longi- tinged glasses, the fourth is open. By pressing the fintude at Sea ger against the projecting edge of this plate, and turning it round, the open hole, or any of the tinged glasses, by Lunar may be brought between the eye-glass of the telescope Observations. and the eye.

Fig. 68. is a magnifying glass, to assist the observer to read off the angle with more accuracy : and fig. 69. a screw-driver.

Mr Hoppe of Church-street, Minories, London, has lately contrived a sextant, with two arches, which is, therefore, preferable to the common sextant.

#### Adjustments of the Sextant.

The adjustments of a sextant are, to set the mirrors perpendicular to its plane and parallel to each other when the index is at zero, and to set the axis of the telescope parallel to the plane of the instrument. The three first of these adjustments are performed nearly in the same manner as directed in the section on the quadrant: as however the sextant is provided with a set of coloured glasses placed behind the horizon glass, the index error may be more accurately determined by measuring the sun's diameter twice, with the index placed alternately before and behind the beginning of the divisions : half the difference of these two measures will be the index error, which must be added to, or subtracted from, all observations, according as the diameter measured with the index to the left of o is less or greater than the diameter measured with the index to the right of the beginning of the divisions.

#### Adjustment IV. To set the Axis of the Telescope parallel to the Plane of the Instrument.

Turn the eye end of the telescope until the two wires are parallel to the plane of the instrument; and let two distant objects be selected, as two stars of the first magnitude, whose distance is not less than 90° or 100°; make the contact of these objects as perfect as possible at the wire nearest the plane of the instrument ; fix the index in this position; move the sextant till the objects are seen at the other wire, and if the same points are in contact, the axis of the telescope is parallel to the plane of the sextant; but if the objects are apparently separated, or do partly cover each other, correct half the error by the screws in the circular part of the supporter, one of which is above and the other between the telescope and sextant : turn the adjusting screw at the end of the index till the limbs are in contact; then bring the objects to the wire next the instrument ; and if the limbs are in contact, the axis of the telescope is adjusted; if not, proceed as at the other wire, and continue till no error remains.

It is sometimes necessary to know the angular distance between the wires of the telescope; to find which, place the wires perpendicular to the plane of the sextant, hold the instrument vertical, direct the sight to the horizon, and move the sextant in its own plane till the horizon and upper wire coincide; keep the sextant in this position, and move the index till the reflected horizon is covered by the lower wire : and the division shown by the index of the limb, corrected by the index error, will be the angular distance between the wires. Other and better methods will readily occur to the observer at land.

#### Use of the Sextant.

When the distance between the moon and the sun tude at Sca or a star is to be observed, the sextant must be held so Observathat its plane may pass through the eye of the observer and both objects ; and the reflected image of the most luminous of the two is to be brought in contact with the other seen directly. To effect this, therefore, it is evident, that when the brightest object is to the right of the other, the face of the sextant must be held upwards ; but if to the left, downwards. When the face of the sextant is held upwards, the instrument should be supported with the right hand, and the index moved with the left hand. But when the face of the sextant is from the observer, it should be held with the left hand, and the motion of the index regulated by the right hand.

Sometimes a sitting posture will be found very convenient for the observer, particularly when the reflected object is to the right of the direct one ; in this case, the instrument is supported by the right hand, the clbow may rest on the right knee, the right leg at the same time resting on the left knee.

If the sextant is provided with a ball and socket, and a staff, one of whose ends is attached thereto, and the other rests in a belt fastened round the body of the observer, the greater part of the weight of the instrument will by this means be supported by his body.

#### To observe the Distance between the Moon and any Celestial Object.

#### I. Between the Sun and Moon.

Put the telescope in its place, and the wircs parallel to the plane of the instrument; and if the sun is very bright, raise the plate before the silvered part of the speculum ; direct the telescope to the transparent part of the horizon glass, or to the line of separation of the silvered and transparent parts according to the brightness of the sun, and turn down one of the coloured glasses; then hold the sextant so that its plane produced may pass through the sun and moon, having its face either upwards or downwards according as the sun is to the right or left of the moon ; direct the sight through the telescope to the moon, and move the index till the limb of the sun is nearly in contact with the enlightened limb of the moon; now fasten the index, and by a gentle motion of the instrument make the image of the sun move alternately past the moon; and, when in that position where the limbs arc nearest each other, make the coincidence of the limbs perfect by means of the adjusting screw : this being effected, read off the degrees and parts of a degree shown by the index on the limb, using the magnifying glass; and thus the angular distance between the nearest limbs of the sun and moon is obtained.

2. Between the Moon and a Star.

Direct the middle of the field of the telescope to the linc of separation of the silvered and transparent parts of the horizon glass; if the moon is very bright, turn down the lightest coloured glass; and hold the sextant so that its plane may be parallel to that passing through the eye of the observer and both objects; its face being upwards if the moon is to the right of the star, but if to the left, the face is to be held from the observer; now direct the sight through the telescope to the star, and

Fig. 68.

of finding move the index till the moon appears by the reflection the Longi-to be nearly in contact with the star; fasten the index, de at Sea and turn the adjusting screw till the coincidence of the star and enlightened limb of the moon is perfect : and the degrees and parts of a degree shown by the index will be the observed distance between the moon's enlightened limb and the star.

The contact of the limbs must always be observed in the middle between the parallel wires.

It is sometimes difficult for those not much accustomed to observations of this kind, to find the reflected image in the horizon glass: it will perhaps in this case be found more convenient to look directly to the object, and, by moving the index, to make its image coincide with that scen directly.

#### SECT. III. Of the Circular Instrument of Reflection.

This instrument was proposed with a view to correct the error to which the sextant is liable; particularly the error arising from the inaccuracy of the divisions on the limb. It consists of the following parts; a circular ring or limb, two moveable indices, two mirrors, a telescope, coloured glasses, &c.

The limb of this instrument is a complete circle of metal, and is connected with a perforated central plate by six radii: it is divided into 720 degrees; each degree is divided into three equal parts; and the division is carried to minutes by means of the index scale as usual.

The two indices are moveable about the same axis, which passes exactly through the centre of the instrument:—the first index carries the central mirror, and the other the telescope and horizon glass; each index being provided with an adjusting screw for regulating its motion, and a scale for showing the divisions on the limb.

The central mirror is placed on the first index immediately above the centre of the instrument, and its plane makes an angle of about 30° with the middle line of the index. The four screws in its pedestal for making its plane perpendicular to that of the instrument have square heads, and are therefore easily turned either way by a key for that purpose.

The horizon glass is placed on the second index near the limb, so that as few as possible may be intercepted of the rays proceeding from the reflected object when to the left. The perpendicular position of this glass is rectified in the same manner as that of the horizon glass of a sextant, to which it is similar. It has another motion, whereby its plane may be disposed so as to make a proper angle with the axis of the telescope, and a line joining its centre, and that of the central mirror.

The telescope is attached to the other end of the index. It is an achromatic astronomical one, and therefore inverts objects; it has two parallel wires in the common focus of the glasses, whose angular distance is between two and three degrees; and which, at the time of observation, must be placed parallel to the plane of the instrument. This is easily done, by making the mark on the eye-piece coincide with that on the tube. The telescope is moveable by two screws in a vertical direction with regard to the plane of the instrument, but is not capable of receiving a lateral motion.

There are two sets of coloured glasses, each set con-

taining four, and differing in shade from each other. Of finding The glasses of the larger set, which belongs to the cen-the Longitral mirror, should have each about half the degree of the at Sea shade with which the correspondent glass of the set belonging to the horizon mirror is tinged. These glasses are kept tight in their places by small pressing screws, and make an angle of about  $85^{\circ}$  with the plane of the instrument; by which means the image from the colonred glass is not reflected to the telescope. When the angle to be measured is between  $5^{\circ}$  and  $34^{\circ}$ , one of the glasses of the largest set is to be placed before the horizon glass.

The handle is of wood, and is screwed to the back of the instrument, immediately under the centre, with which it is to be held at the time of observation.

Fig. 70. is a plan of the instrument, wherein the limb Fig. 70. is represented by the divided circular plate; A is the central mirror; a a, the places which receive the stems a a of the glass, fig. 73.; EF, the first or central index with its scale and adjusting screw; MN, the second or horizon index; GH, the telescope; IK, the screws for moving it towards or from the plane of the instrument; C, the plane of the coloured glass, fig. 72.; and D, its place in certain observations.

Fig. 71. is a section of the instrument, wherein the Fig. 71. several parts are referred to by the same letters as in fig. 70.: Fig. 72. represents one of the horizon coloured glasses; and fig. 73. one of the central coloured glasses : Fig. 74. is the key for turning the adjusting screws of the mirrors: Fig. 75. is the handle : Fig. 76. a section of one of the radii towards its middle : Fig. 77. is used in some terrestrial observations for diminishing the light of the direct object, whose place at the time of observation is D : Fig. 78. is the tool for adjusting the central mirror; and for rectifying the position of the telescope with regard to the plane of the same size. The height of these is nearly equal to that of the middle of the central mirror.

#### Adjustments of the Circular Instrument.

I. To set the horizon glass so that none of the rays from the central mirror shall be reflected to the telescope from the horizon mirror, without passing through the coloured glass belonging to this last mirror.—Place the coloured glass before the horizon mirror; direct the telescope to the silvered part of that mirror, and make it nearly parallel to the plane of the instrument; move the first index; and if the rays from the central mirror to the horizon glass, and from thence to the telescope, have all the same degree of shade with that of the coloured glass used, the horizon glass is in its proper position; otherwise the pedestal of the glass must be turned until the uncoloured images disappear.

II. Place the two adjusting tools on the limb, about  $350^{\circ}$  of the instrument distant, one on each side of the division on the left, answering to the plane of the central mirror produced : then the eye being placed at the upper edge of the nearest tool, move the central index till one half only of the reflected image of this tool is seen in the central mirror towards the left, and move the other tool till its half to the right is hid by the same edge of the mirror; then, if the upper edge of both tools are apparently in the same straight line, the

Of finding the central mirror is perpendicular to the plane of the the Longi- instrument ; if not, bring them into this position by the tude at Sea screws in the pedestal of the mirror.

# by Lunar

702

Observations.

III. To set the horizon mirror perpendicular to the plane of the instrument .- The central mirror being previously adjusted, direct the sight through the telescope to any well-defined distant object; then if, by moving the central index, the reflected image passes exactly over the direct object, the mirror is perpendicular; if not, its position must be rectified by means of the screws in the pedestal of the glass.

A planct, or star of the first magnitude, will be found

a very proper object for this purpose. IV. To make the line of collimation parallel to the plane of the instrument .- Lay the instrument horizontally on a table; place the two adjusting tools on the limb, towards the extremities of one of the diameters of the instrument; and at about 15 or 20 feet distant let a well defined mark be placed, so as to be in the same straight line with the tops of the tools; then raise or lower the telescope till the plane, passing through its axis and the tops of the tools, is parallel to the plane of the instrument, and direct it to the fixed objects; turn either or both of the screws of the telescope till the mark is apparently in the middle between the wires ; then is the telescope adjusted; and the difference, if any, between the divisions pointed out by the indices of the screws will be the error of the indices. Hence this adjustment may in future be easily made.

In this process the eye tube must be so placed as to obtain distinct vision.

V. To find that division to which the second index being placed the mirrors will be parallel, the central index being at zero.-Having placed the first index exactly to o, direct the telescope to the horizon mirror, so that its field may be bisected by the line of separation of the silvered and transparent parts of that mirror; hold the instrument vertically, and move the second index until the direct and reflected horizons agree; and the division shown by the index will be that required.

This adjustment may be performed by measuring the sun's diameter in contrary directions, or by making the reflected and direct images of a star or planet to + coincide.

#### Use of the Circular Instrument.

To observe the Distance between the Sun and Moon.

I. The sun being to the right of the moon.

Set a proper coloured glass before the central mirror, if the distance between the objects is less than 35°; but if above that quantity, place a coloured glass before the horizon mirror : make the mirrors parallel, the first index being at o, and hold the instrument so that its plane may be directed to the objects, with its face downwards, or from the observer : direct the sight through the telescope to the moon; move the second index, according to the order of the divisions on the limb, till the nearest limbs of the sun and moon are almost in contact : fasten that index, and make the coincidence of the limbs perfect by the adjusting screw belonging thereto; then invert the instrument, and move the central index towards the second by a quantity equal to twice the arch passed over by that index: direct the plane of the instrument to the objects : look

2

directly to the moon, and the sun will be seen in the Of finding field of the telescope : fasten the central index, and the Longimake the contact of the same two limbs exact by means tude at Sea by Lunar of the adjusting screw : Then half the angle shown by Observathe central index will be the distance between the neartions. est limbs of the sun and moon.

II. The sun being to the left of the moon:

Hold the instrument with its face upwards, so that its plane may pass through both objects ; direct the telescope to the moon, and make its limb coincide with the nearest limb of the sun's reflected image, by moving the second index : now put the instrument in an opposite position; direct its plane to the objects, and the sight to the moon, the central index being previously moved towards the second by a quantity equal to twice the measured distance; and make the same two limbs that were before observed coincide exactly, by turning the adjusting screw of the first index : then half the angle shown by the first index will be the angular distance between the observed limbs of the sun and moon. This instrumont has of late been greatly improved by Captain Mendoza.

#### To observe the Angular Distance between the Moon and a Fixed Star or Planet.

I. The star being to the right of the moon.

In this case the star is to be considered as the direct object; and the enlightened limb of the moon's reflected image is to be brought in contact with the star or planet, both by a direct and inverted position of the instrument, exactly in the same manner as described in the last article. If the moon's image is very bright, the lightest tinged glass is to be used.

II. The star being to the left of the moon.

Proceed in the same manner as directed for observing the distance between the sun and moon, the sun being to the right of the moon, using the lightest tinged glass, if necessary.

#### SECT. IV. Of the Method of determining the Longitude from Observation.

PROB. I. To convert degrees or parts of the equator into time.

RULE. Multiply the degrees and parts of a degree by 4, beginning at the lowest denomination, and the product will be the corresponding time. Observing that minutes multiplied by 4 produce seconds of time, and degrees multiplied by 4 give minutes.

*Ea.* 1. Let 26° 45' be reduced to time.  

$$26^{\circ} 45'$$
  
 $4$   
1h 47' 0"=time required.  
*Ex.* 2. Reduce 83° 37' to time.  
83° 37'  
4

Corresponding time=5 34 28

PROB. II. To convert time into degrees. RULE. Multiply the given time by 10, to which add the half of the product. The sum will be the corresponding degrees.

RULE. Reckon the given time from the preceding noon, to which add the longitude in time if east, but subtract it if west; and the sum or remainder will be the corresponding time under the given meridian.

*Ex.* 1. What is the expected time of the beginning of the lunar eclipse of February 25. 1793, at a ship in longitude  $109^{\circ}$  48' E?

Beg. of eclipse at Greenwich per Naut. Alm. 9h 23' 45' Ship's longitude in time - - 7 19 12

Time of beginning of eclipse at ship, 16 42 57

*Ex.* 2. At what time may the immersion of the first satellite of Jupiter be observed at Port St Julian, in longitude 68° 44' W, which, by the Nautical Almanack, happens at Greenwich 24th March 1792, at 17h 53' 1"? App. time of immersion at Greenwich 17h 53' 1" Longitude of Port St Julian in time 4 34 56 W.

App. time of immer. at Port St Julian 13 18 5

PROB. V. To find the equation of equal altitudes.

RULE. To the cosecant of half the interval of time in degrees add the tangent of the latitude, and to the eotangent of half the interval add the tangent of the declination. Now if the altitude and declination be of a contrary name, add the corresponding natural numbers; but if of the same name, subtract them.— Then to the ar. co. log. of this sum or difference add the proportional logarithm of one-fourth of the interval Of finding expressed in time, and the proportional logarithm of the the Longidaily variation of declination; the sum will be the protude at Sea portional logarithm of the equation of equal altitudes in minutes and seconds, which are to be esteemed seconds and thirds.

*Example.* Let the latitude of the place of observation be  $57^{\circ}$  9' N, the interval of time between the observations of the equal altitudes 5h 17', the sun's declination  $17^{\circ}$  48' S, and the daily change of declination  $16' 19''^{\frac{1}{2}}$ : Required the equation of equal altitudes?

Half the interval = 2h  $38'_{2}$  = 39° 37'.  $\frac{1}{2}$  int.=39° 37' eost. 0.19542 cotang. 0.08209 Lat. 57 9 tan. 0.18997 dec. 17° 48' ta. 9.50659

Equation of equal altitudes 20" 14""P.L.0.9490 PROB. VI. To find the error of a watch by equal altitudes of the sun.

RULE. In the morning, when the sun is more than two hours distant from the meridian, let a set of observations be taken, consisting, for the sake of greater accuracy, of at least three altitudes, which, together with the corresponding times per watch, are to be wrote regularly, the time of each observation being increased by 12 hours. In the afternoon, observe the instants when the sun comes to the same altitudes, and write down each opposite to its respective altitude. Now half the sum of any two times answering to the same altitude will be the time of noon per watch uncorrected. Find the mean of all the times of noon thus deduced from each corresponding pair of observations, to which the equation of equal altitudes is to be applied by addition or subtraction according as the sun is receding from or approaching to the elevated pole, and the sum or difference will be the time per watch of apparent noon, the difference between which and noon will be the error of the watch for apparent time; and the watch will be fast or slow according as the time of noon thereby is more or less than 12 hours.

*Example.* January 29. 1786, in lat. 57° 9' N, the following equal altitudes of the sun were observed : Required the error of the watch ?

| $\begin{array}{rrrrrrrrrrrrrrrrrrrrrrrrrrrrrrrrrrrr$ | A. 2h          | 55'<br>54<br>52<br>51 | 43"P.<br>42<br>41.2<br>38 | Μ.    |

703

Practice.

704

The mean time of noon per watch is found by ap-Of finding the Longi-plying the equation of time with a contrary sine.

In practice it will be found convenient to put the tude at Sea by Lunar index of the quadrant to a certain division, and to wait Observatill either limb of the sun attains that altitude. tions

> PROB. VII. Given the latitude of a place, the altitude and declination of the sun, to find the apparent time, and the error of the watch.

RULE. If the latitude and declination are of differ- Of finding ent names, let their sum be taken ; otherwise, their the Longidifference. From the natural cosine of this sum or tude at Sea difference subtract the natural sine of the corrected al-titude, and find the logarithm of the remainder; to which add the log. secants of the latitude and declination : the sum will be the log. rising of the horary distance of the object from the meridian, and hence the apparent time will be known.

Ex. 1. September 15. 1792, in latitude 33° 56'S, and longitude 18° 22'E, the mean of the times per watch was 8h 12' 10" A. M. and that of the altitudes of the sun's lower limb 24° 48'; height of the eye 24 feet. Required the error of the watch?

#### Watch slow

Time per watch

PROB. VIII. Given the latitude of a place, the altitude of a known fixed star, and the sun's right ascension, to find the apparent time of observation and error of the watch.

4 37

4

8 T.

RULE. Correct the observed altitude of the star, and reduce its right ascension and declination to the time of observation.

With the latitude of the place, the true altitude and

declination of the star, compute its horary distance from the meridian by last problem; which being added to, or subtracted from, its right ascension, according as it was observed in the western or eastern hemisphere, the sum or remainder will be the right ascension of the meridian.

From the right ascension of the meridian subtract the sun's right ascension, as given in the Nautical Almanack

#### NAVIGATION.

tions

PROB. IX. Given the altitude of the moon, the latitude of a place, and the apparent time at Greenwich; to find the apparent time at the place of observation.

RULE. Correct the altitude of the moon's limb by Problem V. p. 731, and reduce its right ascension and declination, and the sun's right ascension, to the Greenwich time of observation. Now with the latitude of the place, the declination and altitude of the moon, compute its meridian distance as before : Which being applied to its right ascension by addition or subtraction, according as it is in the western or eastern hemisphere, will give the right ascension of the meridian. Then the sun's right ascension subtracted from the right ascension of the meridian, will give the apparent time of observation.

Example. March 3. 1792, in latitude 51° 38' N, at 11h 29' 7" P. M. per watch, the altitude of the moon's lower limb was 37° 31', the height of the eye being 10 feet, and the time at Greenwich 13<sup>h</sup> 43'. Required the error of the watch?

| Altitude of the moon's lower limb | $=37^{\circ}31'$ | Moon's right ascent  | sion at Green. time | $- 7^{h} 22' 54''$       |

PROB. XI. To find the time at Greenwich answering to a given distance between the moon and the sun, or one of the stars, used in the Nautical Almanack.

RULE. If the given distance is found in the Nautical Almanack opposite to the given day of the month, or to that which immediately precedes or follows it, the time is found at the top of the page. But if this distance is not found exactly in the ephemeris, subtract the prop. log. of the difference between the distances which immediately precede and follow the given distance from the prop. log. of the difference between the given and preceding distances; the remainder will be the prop. log. of the excess of the time corresponding to the given distance, above that answering to the preceding distance: And hence the apparent time at Greenwich is known.

*Example.* September 21. 1792, the true distance between the centres of the sun and moon was 68° 13' 8". Required the apparent time at Greenwich?

| Given distance<br>Dist. at ix. hours<br>Dist. at xii. hours | 68° 13'<br>67 53<br>69 30 | 8"<br>27 D<br>6 D | iff. <u></u> =0°<br>iff.≡1 | 19' 41<br>36 39 | "P<br>P | . log. 9 | 9612<br>2701 |

| App. time                                                   | at Gree                   | nwich             | 9                          | 36 35           | -       |          |              |

PROB. XII. The latitude of a place and its longitude by account being given, together with the distance between, and the altitude of the moon and the sun, or one of the stars in the Nautical Almanack; to find the true longitude of the place of observation.

RULE. Reduce the estimate time of observation to the meridian of Greenwich by Problem III, and to this time, take from the Nautical Almanack, page 7. of the month, the moon's horizontal parallax and semidiameter. Increase the semidiameter by the augmentation answering to the moon's altitude.

Find the apparent and true altitudes of each object's centre, and the apparent central distance; with which compute the true distance by Problem X. and find the apparent time at Greenwich answering thereto by the last problem.

If the sun or star be at a proper distance from the meridian at the time of observation of the distance, compute the apparent time at the ship. If not, the error of the watch may be found from observations taken either before or after that of the distance; or the apparent time may be inferred from the moon's altitude taken with the distance, by Problem IX.

The difference between the apparent times of observation at the ship and Greenwich, will be the longitude of the ship in time; which is east or west according as the time at the ship is later or earlier than the Greenwich time.

Ex. 1. March 17. 1792, in latitude 34° 53' N, and longitude by account 27° W, about 9h. A. M. the distance between the nearest limbs of the sun and moon was  $68^{\circ}3'_{4}$ ; the altitude of the sun's lower limb 33° 18'; that

Of finding *Example* 2. September 2. 1792, in latitude 13° 57' N, and longitude by account 56° E, several observations of Of finding the Longi- the moon and Altair were taken; the mean of the times per watch was 1<sup>h</sup> 18' 59" A. M. that of the distance be-the Longitude at Sea tween Altair and the moon's nearest limb 58° 45' 26"; the mean of the altitude of the moon's lower limb 70° 33'; tude at Sea by Lunar Observa- and that of Altair 25° 27'.4; height of the eye 13 feet. Required the true longitude? tions. tions.

Variation of the Compass.

CHAP. III. Of the Variation of the Compass.

THE variation of the compass is the deviation of the points of the mariner's compass from the corresponding points of the horizon; and is denominated east or west variation, according as the north point of the compass is to the east or west of the true north point of the horizon.

A particular account of the variation, and of the several instruments used fer determining it from observation, may be seen under the articles AZIMUTH, COM-PASS, and VARIATION : and for the method of communicating magnetism to compass needles, see MAGNE-TISM.

PROB. I. Given the latitude of a place, and the sun's magnetic amplitude, to find the variation of the compass.

RULE. To the log. secant of the latitude, add the log. sine of the sun's declination, the sum will be the log. cosinc of the true amplitude ; to be reckoned from the north or south according as the declination is north or south.

The difference between the true and observed amplitudes, reckoned from the same point, and if of the same name, is the variation ; but if of a different name, their sum is the variation.

If the observation be made in the eastern hemisphere, the variation will be east or west according as the observed amplitude is nearer to or more remote from the north than the true amplitude. The contrary rule holds good in observations taken in the western hemisphere.

Ex. 1. May 15. 1794, in latitude 33° 10' N, longitude 18' W, about 5h A. M. the sun was observed to rise EbN. Required the variation ?

Sun's dec. May 15. at no Equation to 7h from noon to 18° W	on 18° n $-^{\circ}$ $+^{\circ}$	58' 4 1	N.

Compass.

Variation -11 32; which is west, because the observed amplitude is more distant from the north than the true amplitude ; the observation being made in the eastern hemisphere.

longitude 83° W,	the sun was ob:	in latitude	31° 38' S,
quired the variati	on ?	served to se	t SW. Re-
Latitude -	31° 38'	Secant	0.06985
Declination	23 28	Sine	9.60012
True amplitude Observed ampl.	S 62 7 W S 45 0 W	Cosinc	9.66997

Variation 17 7; which is east, as the closerved amplitude is farther from the north than the true amplitude, the observation being made at sunsetting.

It may be remarked, that the sun's amplitude ought to be observed at the instant the altitude of its lower limb is equal to the sum of 15 minutes and the dip of the horizon. Thus, if an observer be elevated 18 feet above the surface of the sea, the amplitude should be taken at the instant the altitude of the sun's lower limb is 19 minutes.

PROB. II. Given the magnetic azimuth, the altitude and declination of the sun, together with the latitude of the place of observation ; to find the variation of the compass.

RULE. Reduce the sun's declination to the time and place of observation, and compute the true altitude of the sun's centre.

Find the sum of the sun's polar distance and altitude and the latitude of the place, take the difference between the half of this sum and the polar distance.

To the log. secant of the altitude add the log. secant of the latitude, the log. cosine of the half sum, and the log. cosine of the difference; half the sum of these will be the log. sine of half the sun's true azimuth, to be reckoned from the south in north latitude, but from the north in south latitude.

The difference between the true and observed azimuths will be the variation as formerly.

Ex. 1. November 18. 1793, in latitude 50° 22' N, longitude 24° 30' W, about three quarters past eight A. M. the altitude of the sun's lower limb was 8° 10', and bearing per compass S, 23° 18' E : height of the eye 20 feet. Required the variation of the compass ?

CHAP. IV. Of a biop 5 four mart	CH/	IP.	IV.	Of a	Ship	35 7	ournal.
---------------------------------	-----	-----	-----	------	------	------	---------

A JOURNAL is a regular and exact register of all the various transactions that happen aboard a ship whether at sea or land, and more particularly that which concerns a ship's way, from whence her place at noon or any other time may be justly ascertained.

That part of the account which is kept at sea is called sea work; and the remarks taken down while the ship is in port are called harbour work.

At sea, the day begins at noon, and ends at the noon of the following day: the first 12 hours, or those contained between noon and midnight, are denoted by P. M. signifying after mid day; and the other 12 hours, or those from midnight to noon, are denoted by A. M. signifying before mid day. A day's work marked Wednesday March 6. began on Tuesday at noon, and ended on Wednesday at noon. The days of the week are usually represented by astronomical characters. Thus () represent Sunday;) Monday; & Tuesday; & Wednesday; 2 Thursday; 2 Friday; and h Saturday.

• When a ship is bound to a port so situated that she will be out of sight of land, the bearing and distance of the port must be found. This may be done by Mercator's or Middle-latitude Sailing; but the most expeditious method is by a chart. If islands, capes, or headlands intervene, it will be necessary to find the several courses and distances between each successively. The true course between the places must be reduced to the course per compass, by allowing the variation to the

right or left of	the true	course,	according	as it is	west
or cast.					

At the time of leaving the land, the bearing of some known place is to be observed, and its distance is usually found by estimation. As perhaps the distance thus found will be liable to some error, particularly in hazy or foggy weather, or when that distance is considerable, it will therefore be proper to use the following method for this purpose.

Let the bearing be observed of the place from which the departure is to be taken ; and the ship having run a certain distance on a direct course, the bearing of the same place is to be again observed. Now having one side of a plain triangle, namely the distance sailed, and all the angles, the other distances may be found by Prob. I. of Oblique Sailing.

The method of finding the course and distance sailed in a given time is by the compass, the log-line, and halfminute-glass. These have been already described. In the royal navy, and in ships in the service of the East India Company, the log is hove once every hour; but in most other trading vessels only every two hours.

The several courses and distances sailed in the course of 24 hours, or between noon and noon, and whatever remarks are thought worthy of notice, are set down with chalk on a board painted black, called the log-board, which is usually divided into six columns : the first column on the left hand contains the hours from noon to noon; the second and third the knots and parts of a knot sailed every hour, or every two hours, according as the log is marked; the fourth column contains the courses steered; the fifth the winds; and in the sixth the various

various remarks and phenomena are written. The Ship's Journal. log-board is transcribed every day at noon into the log-book, which is ruled and divided after the same manner.

The courses steered must be corrected by the variation of the compass and leeway. If the variation is west, it must be allowed to the left hand of the course steered; but if east, to the right hand, in order to obtain the true course. The leeway is to be allowed to the right or left of the course steered, according as the ship is on the larboard or starboard tack. The method of finding the variation, which should be determined daily if possible, is given in the preceding chapter; and the leeway may be understood from what follows.

When a ship is close hauled, that part of the wind which acts upon the hull and rigging, together with a considerable part of the forec which is exerted on the sails, tends to drive her to the leeward. But since the bow of a ship exposes less surface to the water than her side, the resistance will be less in the first ease than in the second ; the velocity in the direction of her head will therefore in most cases be greater than the velocity in the direction of her side; and the ship's real course will be between the two directions. The angle formed between the line of her apparent course and the line she really describes through the water is called the angle of. leeway, or simply the leeway.

There are many circumstances which prevent the laying down rules for the allowance of leeway. The eonstruction of different vessels, their trim with regard to the nature and quantity of their eargo, the position and magnitude of the sail set, and the velocity of the ship, together with the swell of the sea, are all susceptible of great variation, and very much affect the leeway. The following rules, are, however, usually given for this purpose.

1. When a ship is close hauled, has all her sails set, the water smooth, with a light breeze of wind, she is then supposed to make little or no leeway.

2. Allow one point when the top-gallant sails are. handed.

3. Allow two points when under clese reefed topsails.

4. Allow two points and a half when one top-sail is handed.

5. Allow three points and a half when both top-sails are handed.

6. Allow four points when the fore course is handed.

7. Allow five points when under the main-sail only.

8. Allow six points when under balanced mizen.

9. Allow seven points when under bare poles.

These allowances may be of some use to work up the day's work of a journal which has been neglected; but a prudent navigator will never be guilty of this neglect. A very good method of estimating the leeway is to observe the bearing of the ship's wake as frequently as may he judged necessary; which may be conveniently enough done by drawing a small semicircle on the tafferel, with its diameter at right angles to the ship's length. and dividing its circumference into points and quarters. The angle contained hetween the semidiameter which points right aft, and that which points in the direction of the wake, is the leeway. But the best and most rational way of bringing the leeway into the day's log is to have a compass or semicircle on the tafferel, as before

described, with a low crutch or swivel in its centre ; af- Ship's ter heaving the log, the line may be slipped into the Journal. crutch just before it is drawn in, and the angle it makes on the limb with the line drawn right aft will show the leeway very accurately; which as a necessary article, ought to be entered into a separate column against the hourly distance on the log-board.

In hard blowing weather, with a contrary wind and a high sea, it is impossible to gain any advantage by sailing. In such cases, therefore, the object is to avoid as much as possible being driven back. With this intention it is usual to lie to under no more sail than is sufficient to prevent the violent rolling which the vessel would otherwise acquire, to the endangering her masts, and straining her timbers, &c. When a ship is brought to, the tiller is put close over to the leeward, which brings her head round to the wind. The wind having then very little power on the sails, the ship loses her way through the water; which ceasing to act on the rudder, her head falls off from the wind, the sail which she has set fills, and gives her fresh way through the water; which acting on the rudder brings her head again to the wind. Thus the ship has a kind of vibratory motion, coming up to the wind and falling off from it again alternately. Now the middle point between those upon which she comes up and falls off is taken for herapparent course; and the leeway and variation is to be allowed from thenee, to find the true course.

The setting and drift of currents, and the heave of the sea are to be marked down. These are to be correeted by variation only.

The computation made from the several courses corrected as above, and their corresponding distances, is ealled a day's work; and the ship's place, as deduced therefrom, is called her place by account, or dead reckoning.

It is almost constantly found that the latitude by account does not agree with that hy observation. From an attentive consideration of the nature and form of the common log, that its place is alterable by the weight of the line, by eurrents, and other causes, and also the errors to which the course is liable, from the very often wrong position of the compass in the binnaele, the variation not being well ascertained, an exact agreement of the latitudes eannot be expected.

When the difference of longitude is to be found by dead reckoning, if then the latitudes by account and observation disagree, several writers on navigation have proposed to apply a conjectural correction to the departure or difference of longitude. Thus, if the course be near the meridian, the error is wholly attributed to the distance, and the departure is to be increased or diminishcd accordingly: if near the parallel, the course only is supposed to be erroneous; and if the course is towards the middle of the quadrant, the course and distance are both assumed wrong. This last correction will, according to different authors, place the ship upon opposite sides of her meridian by account. As these corrections are, therefore, no better than guessing, they should be absolutely rejected.

If the latitudes are not found to agree, the navigator ought to examine his log-line and half-minute-glass, and correct the distance accordingly. He is then to consider if the variation and leeway have been properly ascertained; if not, the courses are again to be corrected,

and

N

712

Ship's and no other alteration whatever is to be made on them. Journal. He is next to observe if the ship's place has been affected by a current or heave of the sca, and to allow for them according to the best of his judgment. By applying these corrections, the latitudes will generally be found to agree tolerably well; and the longitude is not to receive any farther alteration.

It will be proper, however, for the navigator to determine the longitude of the ship from observation as often as possible; and the reckoning is be earried forward in the usual manner from the last good observation; yet it will perhaps be very satisfactory to keep a separate account of the longitude by dead reckoning.

General Rules for working a Day's Work.

Correct the several courses for variation and leeway; place them, and the corresponding distances, in a table prepared for that purpose. From whence, by Traverse Sailing, find the difference of latitude and departure made good; hence the corresponding course and distance, and the ship's present latitude, will be known.

Find the middle latitude at the top or bottom of the Traverse Table, and the distance, answering to the departure found in a latitude column, will be the difference of longitude : Or, the departure answering to the course made good, and the meridional difference of la-

titude in a latitude column, is the difference of longi-Ship's tude. The sum, or difference of which, and the longi- 'Journal. tude left, according as they are of the same or of a centrary name, will be the ship's present longitude of the same name with the greater.

Compute the difference of latitude between the ship and the intended port, or any other place whose bearing and distance may be required : find also the meridional difference of latitude and the difference of longitude. Now the course answering the meridional difference of latitude found in a latitude eolumn, and the difference of longitude in a departure column, will be the bearing of the place, and the distance answering to the difference of latitude will be the distance of the ship from the proposed place. If these numbers exceed the limits of the Table, it will be necessary to take aliquot parts of them; and the distance is to be multiplied by the number by which the difference of latitude is divided.

It will sometimes be necessary to keep an account of the meridian distance, especially in the Baltic or Mediterranean trade, where charts are used in which the longitude is not marked. The meridian distance on the first day is that day's departure ; and any other day it is equal to the sum or difference of the preeeding day's meridian distance and the day's departure, according as they are of the same or of a contrary denomination.

As there is no land in sight this day at noon, and from the course and distance run since the last bearing of the Eddistone light was taken, it is not to be supposed that any part of England will be seen, the departure is therefore taken from the Eddistone ; and the distance of the ship from that place is found by resolving an oblique-angled plane triangle, in which all the angles are given, and one side, namely, the distance run (16 miles) between the observations. Hence the distance of the Eddistone at the time the last bearing of the light was taken will be found equal to 18 miles; and as the bearing of the Eddistone from the ship at that time was NE, the ship's bearing from the Eddistone was SE. Now the variation $2\frac{x}{4}$ points W, being allowed to the left of SW, gives $8bW_4^4W$, the true course. The other courses are in like manner to be corrected, and inserted in the following table, together with their respective distances, beginning at 10 o'clock A. M. the time when the last bearing of the Eddistone was taken. The difference of latitude, departure, course, and distance made good, are to be found by Traverse Sailing.

S 38° W 99		77.7 1° 8'		61.6				
Yesterday's lat. by obser. $=499$ N Latitude by account $=4751$ N Sum 97 ° Middle latitude - 483° To middle latitude $48\frac{1}{2}$ °, and departure 61.6 in a latitude column, the corresponding difference of longi- tude in a distance column is $93' = 1^{\circ}33'$ W. Yesterday's longitude - 918 W.								

It is now necessary to find the bearing and distance of the intended port, namely, Funchal; but as that place is on the opposite side of the island with respect to the ship, it is therefore more proper to find the bearing of the east or west end of Madeira; the east end is, however, preferable. But as the small island of Porto Sancto lies a little to the NE of the east end of Madeira, it therefore seems more eligible to find the bearing and distance of that island. To find the bearing and distance of Porto Sancto.

Hence the bearing of Porto Sancto is S 12° W, and distance 870 miles; the course per compass is therefore

NAVIGATION.

A Journal from England to Madeira.

Hours.	Kn.	Fa.	Courses.	Winds.	Remarks, 9 October 11. 1793.
I 2 3 4 5 6 7 8 9 10 11 12 1 2 3 4 5 6 7 8 9 10 11 12 12 10 11 12	4 3 2 3 4 4 4 4 5 5 5 5 5 6 6 6 6 6 6 6 7 7 8 8	6 4 5 2 7 2 3	SWUS	ESE E ENE	 Moderate wind and fair weather. Shortened sail and set up the topmast rigging. Do. weather. Variation per amplitude 21° W. A fine steady breeze. By an observation of the moon's distance from a Pegasi, the ship's longitude at half past 8 was 12° 28' W. Clear weather. Do. weather. Set studding sails, &c. One sail in sight. Do: weather, good observation.
Course	2.	Dist.	D.L. Dep N. Lat Ace.	itude by) Obs. D. Lorg	W. Long. by Ace. Obs. Observed. Bearing. Distance.
S 12° 45'	W.	128	125 28 45° 4'	44° 59′ 41° W.	I3° I3' I2° 59' 21° S I2° W. 737 miles.

The observed variation 21° being allowed to the left of SW&S gives S 12° 45' W, the corrected course, and the distance summed up is 127.9, or 128 miles. Hence the difference of latitude is 124.8, and the departure 28.2. The latitude by account is therefore 45° 4' N, and the middle latitude 46° 6', to which, and the departure 28.2 in a latitude column, the difference of longitude in a distance column is 41' W; which being added to 12° 32' W, the yesterday's longitude gives 13° 13' W, the longitude in by account. But the longitude by observation was 12° 28' W at half past 8 P. M.; since that time the ship has run 96 miles; hence the departure in that interval is 21.2 m. Now half the difference of latitude 47 m. added to 44° 59', the latitude by observation at noon, the sum 45° 46' is the middle latitude; with which and the departure 21.2, the difference of longitude is found to be 31' W; which, therefore, added to 12° 28', the longitude observed, the sum is 12° 59. W, the longitude by observation reduced to noon.

To find the bearing and distance of Porto Sancto.

Latitude ship - Lat. Porto Sancto	-	44 ⁰ 32	59 N. 58 N.	Mer. parts - Mer. parts -	3028 2097	Longitude Longitude	 12° 59' W 16,25 W
							granter granter from the second
Difference of latitude		12	1=721	M. D. la	at. 931	D. Longitude	 3 26=206'

Hence the bearing of Porto Sancto is S 12° W, and distance 737 miles. The course to be steered is therefore S 33° W, or SWlS nearly. 719 Ship's

A Journal from England to Madcira.

Hours.	Kn.	Fa.	Course.	Winds	S.	Remarks, h October 12. 1793.

Half a point of leeway is allowed on each course; but as the variation is expressed in degrees, it will be more convenient and accurate to reduce the several courses into one, leeway only being allowed upon them. The course thus found is then to be corrected for variation, with which and the distance made good the difference of latitude and departure are to be found.

A Journal

Ship's Journal.

NAVIGATION.

A Journal from England towards Madeira.

	1		The second	L .	
Hours.	Kn.	Fa.	Course.	Winds.	Remarks, h October 17. 1793.
1 2 3 4 5 6	555556		SSW S	NE6E	Moderate wind and clear. Saw the island of Porto Sancto, SW&S. Hauled up to round the east end of Porto Sancto. Bent the cables.
7 8 9 10	6 78 7		SW6W	1.4.5	Squally weather. Port Sancto SWbS.
II I2 I 2 2	766 56		SSW		Ditto with rain. Porto Sancto NE. The Deserters SW6S.
4	7		2 - 2 - 1	1 - 1 - 1 - 1 - 1 - 1 - 1 - 1 - 1 - 1 -	The Deserters WSW. 3 or 4 leagues.
56 7			Various.		Hauled up round the east end of the Deserters.
8		1 -	NNW NW6N		Violent squalls; clewed up at all times.
10			1111011		Running into Funchal Roads.
					Anchored in Funchal Roads, with the best bower in 30 fathoms black sand and mud. Brazen head EdS ₁ S, Loo Rock NW, the Great Church NNE, and the southermost Deserter SE ₁ S; off shore two- thirds of a mile. Saluted the fort with 13 guns; re- turned by ditto. Found here his majesty's ship Ve- nus, and 7 English merchants.

This journal is performed by inspection agreeable to the precepts given. Other methods might have been used for the same purpose; for which the two instruments already described and explained seem well adapted. We cannot, however, omit recommending the sliding gunter, which will be found very expeditions, not only in performing a day's work, but also in resolving most other nautical problems. See *SLIDING-Gunter*.

It will be found very satisfactory to lay down the ship's place on a chart at the noon of each day, and her situation with respect to the place bound to, and the nearest land, will be obvious. The bearing and distance of the intended or any other port, and other requisites, may be easily found by the chart as already explained; and indeed, every day's work may be performed on the chart; and thus the use of tables superseded.

EXPLANATION OF THE TABLES.

TABLE I. To reduce points of the compass to degrees, and conversely.

The two first and two last columns of this table contain the several points and quarter-points of the compase; the third column contains the corresponding number of points and quarters; and the fourth, the degrees &c. answering thereto. The manner of using this table is obvious.

4

TABLE II. The miles and parts of a mile in a degree of longitude at every degree of latitude.

The first column contains degrees of latitude, and the second the corresponding miles in a degree of longitude; the other columns are a continuation of the first and second. If the given latitude consists of degrees and minutes, a proportional part of the difference between the miles answering to the given and following degrees of latitude is to be subtracted from the miles answering to the given degree.

Example. Required the number of miles in a degree of longitude, in latitude 57° 9'?

The difference between the miles answering to the latitudes of 57° and 58° is 0.89.

Then as 60': 9':: 0.89: 0.13

Miles answering to 57^o 32.68

Milesanswering to 57°9' 32.55

This table may be used in Parallel and Middle Latitude Sailing.

TABLE III. Of the Sun's Semidiameter.

This table contains the angle subtended by the sun's. semidiameter at the earth, for every sixth day of the year. The months and days are contained in the first column, and the semidiameter expressed in minutes and seconds in the second column. It is useful in correcting altitudes of the sun's limb, and distances between the sun's limb and the moon.

725 Ship's Journal.

TABLE IV. Of the Refraction in Altitude.

The refraction is necessary for correcting altitudes and distances observed at sea; it is always to be subtracted from the observed altitude, or added to the zenith distance. This table is adapted to a mean state of the atmosphere in Britain, namely, to 29.6 inches of the barometer, and 50° of the thermometer. If the height of the mercury in these instruments be different from the mean, a correction is necessary to reduce the tabular to the true refraction. See REFRACTION.

TABLES V. VI. Of the Dip of the Horizon.

The first of these tables contains the dip answering to a free or unobstructed horizon; and the numbers therein, as well as in the other table, are to be subtracted from the observed altitude when the fore-observation is used; but added, in the back-observation.

When the sun is over the land, and the ship nearer it than the visible horizon when unconfined; in this case, the sun's limb is to be brought in contact with the line of separation of the sea and land; the distance of that place from the ship is to be found by estimation or otherwise; and the dip answering thereto, and the height of eye, is to be taken from Table VI.

TABLE VII. Of the Correction to be applied to the time of high water at full and change of the moon, to find the time of high water on any other day of the moon.

The use of this table is fully explained at Section II. Chap. I. Book I. of this article.

TABLES VIII. IX. X. Of the Sun's Declination, &c.

The first of these tables contains the sun's declination, expressed in degrees, minutes, and tenths of a minute, for four successive years, namely, 1793, 1794, 1795, and 1796: and by means of Table X. may easily be reduced to a future period; observing that, after the 28th of February 1800, the declination answering to the day preceding that given is to be taken.

Ex. 1. Required the sun's declination May 1. 1816?

May 1. 1812 is four years after	the same	day in	1812.
Sun's declination May 1. 1812		15°	6'.7 N
Equation from Table X		+0	0.6
Sun's declination May 1. 1799	-	15	7.3 N

Ex. II. Required the sun's declination August 20. Explanation of the Tables.

The given year is 12 years after 1793, and the time is after the end of February 1800. Now, Sun's dec. August 19. 1793 - 12° 34'.6 Equation from Table X. to 12 years _____ 1.9

Sun's declination August 20. 1805 - 12 32.7

The declination in Table VIII. is adapted to the meridian of Greenwich, and Table IX. is intended to reduce it to any other meridian, and to any given time of the day under that meridian. The titles at the top and bottom of this table direct when the reduction is to be added or subtracted.

TABLE XI. Of the Right Ascensions and Declinations of Fixed Stars.

This table contains the right ascensions and declinations of 60 principal fixed stars, adapted to the beginning of the year 1793. Columns fourth and sixth contain the annual variation arising from the precession of the equinoxes, and the proper motion of the stars; which serves to reduce the place of a star to a period a few years after the epoch of the table with sufficient accuracy. When the place of a star is wanted, after the beginning of 1793, the variation in right ascension is additive; and that in declination is to be applied according to its sign. The contrary rule is to be used when the given time is before 1793.

Example. Required the right ascension and declination of Bellatrix, May 1. 1798?

Right ascension January 1. 1793 Variation = $3'' \cdot 21 \times 5\frac{1}{3}$ y.		5h 14' 3" +0 0 17
Right Ascension, May 1. 1798 Declination Variation $= 4'' \times 5\frac{1}{3} y$.	11 11 11	5 14 20 6° 8' 53"N +0 0 21
Declination May 1. 1798	=	6 9 14 N

The various other tables necessary in the practice of navigation are to be found in most treatises on that subject. Those used in this article are in Mackay's Treatises on the Longitude and Navigation.

NAVIGATION

NAVIGATION of the Ancients. See PHOENICIA and Navigation, Inland Na-TRADE.

Inland NAVIGATION, the method of conveying comvigation. modities from one part of a country to another by means of rivers, lakes, canals, or arms of the sea. See CANAL.

We have already, under CANAL, taken notice of a method proposed by Dr Anderson of raising and lowering vessels by means of mechanical powers, instead of dams and locks. We shall describe another mechanical contrivance proposed by Mr Leach for the same purpose. This machinery is compounded of an inclined plane and wheel in axis. The inclined plane is a parallelogram whose length reaches from the end of one canal to the beginning of another, or to the sea or navigable river, to which the vessel is next to be conveyed; the breadth ought to be $22\frac{1}{2}$ feet, It may be made of good oak or deal plank, and sufficiently strong to bear the weight to be laid upon it; and it must be very strongly supported by beams of oak or other wood. It ought to be divided in the middle by a ledge or rib of 12 inches square, the side ribs being nine by 12 inches. The elevation must depend upon CCCLXIX particular circumstances. Fig. 1. shows the inclined part of the machine ; AB being the wooden part just described, placed between the side of the hill W and the navigable river F. According to the dimensions already given, the two paths A and B on which the vessels move are exactly ten feet wide. G represents the canal, brought perhaps from the distance of several miles to the top of the precipice WW. At the end of the canal, and quite across from R to R, must be built a very strong wall; in which are two sluices with flood gates at K and L, to let out the water occasionally. Between the head of the plane AB, and the end of the canal G, is a horizontal platform divided into two parts, as is represented in the figure by the letters HI. At the end of the canal arc six rollers M and N, of use in carrying the boats and lighters in and out of the canal. Near the end of the canal, at S, and T, are two other sluices, with their flood-gates, for letting out a quantity of fluid to drive the other part of the machine. O and P represent the two ends of the towing paths, one on each side of the canal.

Fig. 2.

Fig. 2. shows the vehicle by which the lighters are conveyed up and down the inclined plane, by the two paths A and B, fig. 1. AA (fig. 2.) represents part of the inclined plane, B the vehicle in the position in which it rolls up and down the two paths. C is the body of the vehicle, which is made hollow, to contain a quantity of water occasionally used as a counterbalance for its corresponding vehicle. DDD are three rollers between the bottom of the vehicle and the plane, for the purpose of rolling the boats up and down. HHH are six rollers; four by the horizontal part of the vehicle on which the boat E is to rest in its passage up and down the plane; the other two rollers are in a movcable part, which is fastened to the body of the vehicle with a pair of very strong hinges : * and in the passage of the vehicle up and down the plane, it turns up between the head of the boat and the planc, preventing the former from rubbing against the plane. When the vehicle gets up to the top, this

moveable part falls down on the platform marked HI. Inland Nabecoming parallel with the horizontal part of the ve- vigation. hicle; after which it serves for a launch and passage to place the boat upon the rollers MN (fig. 1.) at the end of the canal. This passage part of the vchicle, together with the three rollers at the end of the canal, is likewise of great use in towing a boat out of the canal, in order to place it on the horizontal part. At the bottom of the cavity of the vehicle is a large hole F, with a valve opening inwardly. Through this hole the water enters when the vehicle sinks into the navigable river F, for the purpose of receiving a boat on the top or horizontal part of the vehicle, till it is quite full, and then will sink entirely under water, while the boat is towed in on the horizontal part. A small rope K is fastened to the valve, on purpose to lift it up and to keep it so, while the vehicle and boat are ascending up the plane out of the canal; that so the water may discharge itself till as much as is necessary bc got out, or till it becomes an equal balance for the corresponding vehicle and its contents, which are descending by the other path. Hence we see, that every machine must have two of these vehicles furnished with rollers as already described, and so constructed that one may be as nearly as possible a counterbalance to the other. As it is necessary that the vehicles should be water tight, the insides of them must be caulked very tight; and they should be capacious enough to hold as much water as will balance the largest boat with its contents. Here it may be observed, that every vessel will be balanced by as many cubic feet of water as it displaces by being put into the water when loaded. The quantity may easily be known, by observing how far the boat sinks in the water, and calculating the bulk of the part immersed.

The machine which puts the vehicles in motion, may either be constructed with an under-shot or breast-water wheel: or by an over-shot water wheel: or by two walking-wheels, for men to walk in as in cranes, &c.

Fig. 3. shows a front view of the under-shot water-Fig. 3. wheel movement; where A is the end of the axis or cylinder of the cog or spur wheel; the diameter of which axis is four fect, and its length not less than 22 feet, as it must be extended quite across the canal from one side to the other, and placed on the top of very strong supporters on each side of the canal, about seven feet above the surface of the water, as the loaded boat is to pass backwards and forwards under the cylinder, and at a convenient distance from the wall RR (fig. 1.); and placed between the two sluices S and T; on the end of which cylinder is the cogwheel B (fig. 3.). The wheel B is supposed to be 20 feet of diameter, having on its cdge 120 cogs, and underneath the cog-wheel is the breast-water one C, 24 feet in diameter, from the tip of one aller-board to the tip of its opposite. On the end of the axis of the water-wheel D is a trundle two fcct and a half in diameter, with 15 rounds and staves contained therein. This must be placed between the two sluices S and T, to let the water out of the canal; which, falling on the float-boards, will turn the wheel round from the right hand towards the left, when the sluice on the left hand of the wheel is opened; but the contrary way when that of the right is opened .- The water falling

Plate

fig. I.

Inland Na-falling upon the boards passes along with the wheel in vigation. the circular cavity EGF, and is discharged at G, what-

To the axis or cylinder of this machine, which must always be horizontal, are fixed a pair of strong ropes ; the ends of each pair fastened to the upper part of the cylinder; it being necessary that they should act in contrary directions. Each must extend the whole length of the plane, and their strength must be pro-portioned to the weight necessary to be sustained. The two vchicles already mentioned are fastened to the other ends of the ropes; so that one pair of the ropes are wound up by the cylinder turning one way, and the other by its turning the contrary way. Thus when one of the vehicles is at the upper part of the path A, ready to discharge its boat and cargo into the upper canal, the other boat will be at the foot of the path B, all under water in the lower canal, and ready for the reception of a boat to be towed in on the horizontal part of it; so that as one vehicle rolls up on one side of the plane, the other will roll down on the other side, and vice versa.

Fig. 4. shows the movement by means of an overshot water-wheel. It consists of a water-wheel C, and two spur or cog-wheels A and B. The waterwheel is 18 feet in diameter, and has two rows of buckets placed contrariwise to one another, that it may turn round in contrary directions, according as the one or the other sluice, S, or T, is opened. On its axis F is a trundle of three feet diameter, having 18 rounds or staves which fall into the cogs of the second spur-wheel B, causing it to turn round in a direction contrary to that of the water-wheel. This second wheel is likewise 18 feet in diameter, with a trundle of three feet having 18 rounds or staves .----The diameter of the upper spur-wheel A is also 18 feet, but the diameter of its axis is six feet. On the edge of the wheel are 108 cogs. These fall in between the staves of the axis of the other spur-wheel; and thus the third wheel turns round the same way with the water wheel C. The cylinder of this upper spurwheel must be placed across the canal betwixt the two sluices, on very strong supporters, as explained in the former movement, and the two pair of ropes in the same manner.

The movement of the walking wheel is shown (fig. 5.). At and A2 are two wheels for men to walk in, each of them 24 feet in diameter. BI and B2 are the axes or cylinders of the two wheels, of equal lengths; viz. II feet each, and four in diameter .--At one end of each of the two cylinders CI and C2, is a wheel of the same diameter with the cylinder. On the edges of these wheels are tecth of an equal number in each wheel; and as the teeth of the wheels mutually fall into each other, the revolutions of both must be performed in the same time. By this contrivance also the cylinders will turn different ways ; and the ropes on the two different cylinders will constantly one pair be wound up, and the other wound down, by the natural moving of the machine. DDD is the frame that supports the whole, which must be made very firm and secure.

Let us now suppose, that there is a boat in the upper canal to be brought down, but none to go up for a balance. In this case, as one of the vehicles must be

at the top to receive the boat, the other will be at the Inland Nabottom to take in water. Let then any of the movements just described be set to work, and it is plain, that as the upper vehicle with its boat descends, the under vehicle will ascend with the water; the valve being in the mean time lifted up till a sufficient quantity of water has flowed out, to make the one nearly a counterbalance to the other; so that the vessel may slide down gently and without any violence.

If it happens that a boat is to go up while none is to come down, one of the vehicles being at the foot of the plane under water, and in readiness to have the boat towed upon its horizontal part, one of the sluiees at K or L is to be opened, and a quantity of water let into the eistern of the upper vehicle sufficient to counterbalance the boat with the contents which is to ascend. This being done, the machine is set to work, the valve of the under vehicle kept open till the water is all discharged; and then the boat will roll up to the top of the plane.

From this description of the canal and machinery for raising and lowering the vessels, the reader can be at no loss to understand the principles on which it depends. It would be superfluous to adduce examples, or follow our author through his calculations relative to particular cases. We shall only observe, that the difference of time in which vessels may be raised or lowered by the machinery just described, in comparison with what can be done in the common way by dams and locks, must give a very favourable idea of the new method. According to Mr Leach's computations, a boat with its cargo weighing 10 tons might be raised by the walking machine in 12 or 14 minutes, by the under-shot wheel in 15 minutes, and by the over-shot wheel in 30 minutes; and that through a space of no less than 30 fathoms measured on the inclined plane, or 114 feet perpendicular.

NAVIGATORS ISLANDS. See OPOUN.

NAULUM, in Roman antiquity, a piece of money put into the mouth of a person deceased, to enable him to pay Charon the ferryman for his passage. It was to be of the current coin of the reigning emperor; so that from this money the time of the person's death may be known. The sum for poor men was a farthing, but the rich in general were very liberal to Charon, as appears from the number of coins often found in the neighbourhood of Rome on opening the graves of great men. Charon was looked upon as a very morose and obstinate old fellow, who would not carry over any man without his fare : and hence the proverbial use of that verse in Juvenal,

Furor est post omnia perdere naulam.

A similar custom took place among the Greeks: The money put into the mouth of the deceased was by them called *Aurexy*.

NAUMACHIA, in antiquity, a show or spectacle among the ancient Romans, representing a sea fight. These mock sea fights are supposed to have originated at the time of the first Punic war, when the Romans first instructed their men in the knowledge of naval affairs. Afterwards they were intended to entertain the populace, as well as to improve the seamen. They were often, like other shows, exhibited at the expence of individuals, to increase their popularity.

INLAND NAVIGATION.

PLATE CCCLXIX.

In these spectacles they sometimes strove to excel Naumachia each other in swiftness; and sometimes engaged in a Nauplius, warlike manner. The naumachiæ of Cladius indeed

was a most savage diversion. The combatants used to destroy each other to amuse a tyrant aud a cruch mob. As they passed before him, they used this melancholy greeting, "Ave Imperator, morituri te salu-tant." The emperor replied, "Avete vos." This they understood as an answer of kindness, and a grant of their lives; but they soon discovered that it proceeded from wanton cruelty, and barbarous insensibility. In the time of the emperor Domitian, such a vast number of vessels engaged as would have nearly formed two regular fleets for a real fight, and the channel of water was equal in magnitude to a natural river. The emperor Heliogabalus is reported to have filled the channel where the vessels were to ride with wine instead of water. Tritons and sea monsters were frequently exhibited during the engagement. Suctonius and Dio Cassius inform us, that at one of these sea fights of Domitian a violent shower fell; the emperor, however, continued till the end of the engagement, often changing his clothes, nor would he suffer any one to depart; and as the rain continued for several hours, many were seized with distempers, and some even died, Suet. cap. 4. Dio. lib. lxvii. Naumachiæ were also places fitted up for these shows, a sort of circi or amphitheatres, with seats and porticoes, &c. There were several of them at Rome; three built by Augustus, one by Claudius, another by Domitian, and another by Nero: which served for the reverse of his medals. Claudius used the lake Fucinus as a naumachia.

NAUMBURG, a town of Germany, in the circle of Upper Saxony, capital of the county of Saxe-Naumburg, situated on the siver Sala, in E. Long. 11. 20. N. Lat. 51. 12.

NAUPACTUS, or NAUPACTUM, in Ancient Geography, a city of Ætolia, at the mouth of the Evenus. The word is derived from vaus and mayvum, because it was there that the Heraclidæ built the first ship which carried them to Peloponnesus. It first belonged to the Locri Ozolæ, and afterwards fell into the hands of the Athenians, who gave it to the Messenians, who had been driven from Peloponnesus by the Lacedæmonians. It became the property of the Lacedæmonians after the battle of Ægospotomos, and it was restored to the Locri. Philip of Macedon afterwards took it, and gave it to the Ætolians; from which circumstance it has generally been called one of the chief citics of their country. E. Long. 22. 20. N. Lat. 38. 0.

There was on the shore a temple of Neptune, and near it a cave filled with offerings, and dedicated to Venus, where widows resorted to request new husbands of the goddcss. Pausan. lib. x. p. 898.

NAUPLIA, in Ancient Geography, a maritime city of Peloponnesus. It was the naval station of the Argives. The fountain Canathos was in its neighbourhood.

NAUPLIUS, in fabulous history, a son of Neptune and Amymone, king of Eubœa. He was the father of the famous Palamedes, who was so unjustly sacrificed to the artifice and resentment of Ulysses by the Greeks at the Trojan war. The death of Palamedes highly enraged Nauplius; and to revenge the injustice of the Grecian princes, he endeavoured to debauch their

wives, and ruin their characters. When the Greeks Nauplius returned from the Trojan war, Nauplius was pleased Nauscopy. to see them distressed in a storm on the coasts of Eubœa; and to make their disaster still more universal, he lighted fires on such places as were surrounded with the most dangcrous rocks, that the fleet might be shipwrecked upon the coast. This had the desired effect; but Nauplius was so disappointed when he saw Ulysses and Diomedes escape from the general distress, that he threw himself into the sea. According to some mythologists there were two persons of this name : one a native of Argos, who went to Colchis with Jason. He was son of Neptune and Amymone .- The other was king of Eubœa, and lived about the time of the Trojan war. He was, as some observe, son of Clytonas, one of the descendants of Nauplius the Argonaut. The Argonaut was remarkable for his knowledge of sea affairs and of astronomy. He built the town of Nauplia, and sold Auge daughter of Aleus to King Teuthras, to screen her from her father's resentment.

NAUPORTUS, or NAUPORTUM, in Ancient Geography, a town on a cognominal river, towards its source, in Pannonia Superior. The reason of the name, according to Pliny, is that the ship Argo, after coming up the Danube, the Savc, and the Laubach, was thence carried on men's shoulders over the Alps into the Adriatic. The river Nauportus rises in the Alps, near Longaticum, at the distance of six miles from the town Nauportum; which was a colony of the Taurisci, a people on the confines of Noricum. Now Upper Laubach in Carinthia, on the river Laubach. E. Long. 14. 40. N. Lat. 46. 28.

NAUSCOPY, the art of discovering the approach of ships or the neighbourhood of land at a considerable distance. This pretended art was discovered by M. Bottineau, employed in the king and company's service in the island of France, from the year 1782 to 1784; the account of it is as follows:

"This knowledge is not derived either from the undulation of the waves, or from the subtility of sight, or from any particular sensation; but merely from observation of the horizon, which discovers signs indicating the proximity of ships or of land.

"On the approximation of a ship toward the land, or towards another ship, there appears in the atmosphere a meteor of a particular nature, visible to every one without any painful attention. It is not by any kind of accident that this metcor appears under these circumstances; on the contrary, it is the necessary result of the approximation of one vessel towards another, or towards the land. The existence of the meteor, and the knowledge of its different modifications, are what constitute the certainty and the precision of my information.

"If I am asked, how it is possible that the approach of a ship towards land should give birth to any meteor whatsocver in the atmosphere, and what connexion there can be between two objects at such a distance from each other? I reply, that I am not obliged to give an account of the hows and the wherefores : that it is sufficient for me to have discovered the fact, without being ohliged to account for its principle."

The writer coucludes, by desiring to be called on for experimental proofs, and by promising in future a complete treatise of Nauscopy, with maps, plates, &c.

This

Nauscopy. Castle.

This complete treatise, as far as we know, has not Naworth yet been published; nor do we expect ever to see such a treatise on the subject as will satisfy the minds of these who are persuaded that every effect must have an adequate cause. The whole seems to be the work of fancy

NAUSEA, or SICKNESS; a retching or propensity and endeavour to vomit, arising from something which irritates the stomach.

NAUTILUS, a genus of animals belonging to the order of vermes testacea. See CONCHOLOGY Index.

NAVY, the fleet or shipping of a prince or state. See MARINE,

The management of the British royal navy, under the lord high admiral of Great Britain, is intrusted to principal officers and commissioners of the navy, who hold their places by patent. The principal officers of the navy are four, viz. the treasurer, whose business it is to receive money out of the exchequer, and to pay all the charges of the navy, by warrant from the principal officers : comptroller, who attends and controuls all payment of wages, is to know the rates of stores, to examine and audit all accounts, &c. : surveyor, who is to know the states of all stores, and see wants supplied; to estimate repairs, charge boatswains, &c. with what stores they receive, and at the end of each voyage to state and audit accounts : clerk of the acts, whose business it is to record all orders, contracts, bills, warrants, &c.

The commissioners of the navy are five : The first executes that part of the comptroller's duty which relates to the comptrolling the victualler's accounts; the second, another part of the said comptroller's duty relating to the account of the storekeepers of the yard; the third has the direction of the navy at the port of Portsmouth ; the fourth has the same at Chatham; and the fifth at Plymouth. There are also other commissioners at large, the number more or less according to the exigencies of public affairs; and since the increase of the royal navy, these have several clerks under them, with salaries allowed by the king.

The victualling of the royal navy hath formerly been undertaken by contract; but is now managed by commissioners, who hold their office on Tower-hill, London. The navy office is where the whole business concerning the navy is managed by the principal offreers and commissioners.

The royal navy of Great Britain is now in a very flourishing state, having been diligently kept up in late reigns, as the natural strength of the kingdom. When it is complete, it is divided into three squadrons, ditinguished by the colours of the flags carried by the respective admirals belonging to the same, viz. red, white, and blue; the principal commander of which bears the title of admiral; and each has under him a vice admiral and a rear admiral, who are likewise flag officers.

NAVY Exercise. See EXERCISE.

NAVY Discipline, or Regulations. Sec MARITIME State.

NAWORTH CASTLE, in Cumberland, 10 miles from Carlisle, near the Gelt. This castle is still entire and inhabited. It is a large pile, square, and built round a court. On the north it stands over the river Ithing, at a great height, the banks shagged with

wood. The whole house is a very irregular building; Naworth the rooms numerous, accessible by 16 staircases, with most frequent and sudden ascents and descents, &c .--Naxus. The great hall has a gallery at one end, adorned with four vast crests carved in wood, viz. a griffin and dolphin, with the scallops; an unicorn, and an ox with a coronet round his neck. In front is a figure in wood of an armed man; two others, perhaps vassals, in short jackets and caps. The top and upper end of the room is painted in squares, representing the Saxon kings and heroes. This castle was built by one of the Dacres about the reign of Henry III. In the garden walls were stones with Roman inscriptions, which the late earl of Carlisle gave to Sir Thomas Robinson, and were by him removed to his museum at Rooksby: On one of these stones is this inscription, peditum centum quinquaginta Britanorum; whence its appears that the Romans, when in possession of Britain, sometimes indulged the national troops with the favour of garrisoning their own territorics.

NAXIA, or NAXOS, a considerable island of the Archipelago, 25 miles in length, and 88 in circumference. The whole island is covered with orange, olive, lemon, cedar, citron, pomegranate, fig, and mulberry trees; and there are a great many springs and brooks. This island has no harbour; and yet they carry on a considerable trade in barley, wine, figs, cotton, silk, flax, cheese, salt, oxen, sheep, mules, and oil. They burn only oil of mastich, though olive oil is exceedingly cheap. It is inhabited both by Greeks and Latins, who live in great dread of the Turks; for when the meanest of their ships appear here, they always wear red caps like galley-slaves, and tremble before the lowest officer; but as soon as they are gone, they put on their caps of velvet. The ladies are so vain, that when they return out of the country they have 40 women in their train, half on foot and half on asses, one of whom carries a napkin or two, another a petticoat, another a pair of stockings, and so on; which is a very ridiculous sight to strangers. There are four archbishops sees in this island, and a great many villages; but so thin of people, that the whole island does not contain above 8000 inhabitants. The highest mountain is Zia, which signifies "the mountain of Jupiter." There are but few antiquities, except some small remains of the temple of Bacchus. Some say they have mines of gold and silver; however, there is one of emery, which is so common here and so clicap, that the English often ballast their ships therewith.

NAXOS, or NAXIA, a considerable town, and capital of the isle of Naxos, over against the isle of Paros, with a castle and two archbishops sees, the onc Greek and the other Latin. The greatest part of the inhabitants are Greeks. E. Long. 25. 51. N. Lat. 37. 8.

NAXUS, now NAXIA, formerly Strongyle, Dia, Dionysias, Callipolis, and Little Sicily. It was called Strongylc, from a Greek word, signifying "round," though in reality it is rather square than round. . The names of Dia or Divine, and Dionysias, were given it as being consecrated in a peculiar manner to the fabulous god Dionysus or Bacchus. The appellation of Callipolis, Pliny and Solinus derive from the metropolis of the island, formerly a most beautiful city, which

Castle

~

Na

Naxus.

which is the import of the word Callipolis. The great fertility of the country gave rise to the name of Little Sicily, Naxus being the most fruitful of all the Cyclades, as Agathamerus informs us, and no less fertile than Sicily itself. As for the name of Naxus, some assert that it was borrowed from one Naxus, under whose conduct the Carians possessed themselves of the island ; others pretend it received its name from Naxus, the son of Endymion. Stephanus, Suidas, and Phavorinus, derive the name of Naxos, from the Greek word naxai, signifying, "to sacrifice," and will have it to have been so called from the many sacrifices officred here to Bacchus. With these Bochart agrees, as to its being called Naxos from the sacrifices performed here in honour of Bacchus, but will have the word naxos to be a corruption of the Phœnician nasca, or nicsa, signifying "a sacrifice, offering." Naxos is, according to Pliny, 75, but reckoned by the prcsent inhabitants 100 miles, in compass. It has Paros to the west, Myconos and Delos to the north, and los to the south. This island is the most fruitful of the Archipelago, and was formerly famed for the excellent wines it produced. Archilochus, as quoted by Athenæus, compares them to the nectar of the gods; and Asclepiades, cited by Stephanus, assures us, that Bacchus took more delight in Naxos than in any other place whatsocver, having himself taught the inhabitants to cultivate their vines. The wine of Naxos maintains to this day its ancient reputation, being by some deemcd the best of the Levant. Besides wine, this island abounds with all sorts of delicious fruits, the plains being covered with orange, olive, lemon, cedar, citron, pomegranate, mulberry, and fig trees. It was formerly famous for quarries of that sort of marble which the Greeks called ophites, from its being green, and speckled with white spots like the skin of a serpent. The best emerald is found here on the mountains near the western coast, whence the neighbouring cape is called by the Italians capo smeriglio, or the emerald cape. As to the inhabitants of Naxos, Diodorus relates that the island was first peopled by the Thracians. These were in a little time subdued by a body of Thessalians, who, having possessed the island for the space of 200 years and upwards, were compelled to abandon it by a drought and famine.

After the Trojan war, the Carians settled here, and called the island Naxos, from their king, who was the son of Polemon. He was succeeded by his son Leucippus, and Leucippus by his son Smardius, in whose reign Theseus, coming out of Cretc, landed here with Ariadne, whom he was, in his sleep, commanded by Bacchus to leave in this island. In process of time a colony of Cnidians and Rhodians settled here under the conduct of Hippothous and Xuthus : and last of all the Ionians, who, in time, possessed the whole island; whence the Naxians are, by Herodotus, called Ionians, and ranged among the Athenian colonies. E. Long. 26. 5. N. Lat. 36. 30. It is about 105 miles in circumference, and about 30 broad.

NAXUS, in Ancient Geography, a town of Crete, famous for its hones, called lapis Naxius. Another of Sicily, built by the Chalcidians; situated on the south side of Mount Taurus, destroyed by Dionysius the VOL. XIV. Part II. +

tyrant : from its ruins Tauromenium, built by Timoleon, either arose or was increased, (Plutarch).

NAYRES, the nobility of the Malabar coast. We Nazareth. may with truth affirm that they are the oldest nobility in the world; for the most ancient writers mention them, and quote the law that permits the Nayre ladies to have many husbands; every one being allowed four. Their houses, which stand single, have as many doors as the lady has husbands. When one of them visits her, he walks round the house, striking with his sabre on his buckler; he then opens his door, and leaves a domestic with his arms in a kind of porch, who scrves to inform others that the lady is engaged. It is said, that one day in the week the four doors are all opened, and all her husbands visit her, and dine together with her. Each husband gives a sum of money, or portion, at the time of marriage; and the wife only has the charge of the children. The Nayres, even the Samorin, and the other princes, have no other heirs than the children of their sisters. This law was established, that the Nayres, having no family, might be always ready to march against the enemy. When the nephews are of age to bear arms, they follow their uncles. The name of father is unknown to a Nayre child. He speaks of the husbands of his mother and of his uncles, but never of his father.

NAZARETH, a little city in the tribe of Zebulun, in Lower Galilee, to the west of Tabor, and to the east of Ptolemais. Eusebius says, it is 15 miles from Legion towards the east. This city is much celebrated in the Scriptures, for having been the usual place of the residence of Jesus Christ for the first 33 years of his life, Luke ii. 51. It was there our Saviour became incarnate, where he lived in obedience to Joseph and Mary, and from whence he took the name of a Nazarean. After he had begun to execute his mission, he preached there sometimes in the synagogue, Id. iv. 16. But because his countrymen had no faith in him, and were offended at the meanness of his original, he did not many miracles there, Matth. xiii. 54, 58. nor would he dwell therein; so he fixed his habitation at Capernaum for the latter part of his life, Id. iv. 13. The city of Nazareth was situated upon an eminence; and on one side there was a precipice, from whence the Nazarcans one day had a design of throwing down our Saviour, because he upbraided them with their ineredulity, Luke iv. 29.

St Epiphanius says, that in his time Nazareth was only a village, and that to the reign of Constantine it was inhabited by Jews alone, exclusive of all Christians. Adamnanus, a writer of the seventh age, says, that in his time there were two great churches to be seen at Nazareth, one in the midst of the city, built upon two arches, in the place where our Saviour's house had stood. Under the two arches now mentioned, was a very fine fountain, which furnished water to the whole city, and from whence water was drawn also by the help of a pulley for the use of the church above. The second church of Nazareth was built in a place where the house stood wherein the angel Gabriel revealed to the virgin Mary the mystery of our Lord's incarnation ; and we are assured that the church of the Incarnation, which is supported by two arches, is still in being to 5A this

Naxus

1

Vaz:

Nazareth, this day. Mr Maundrell tells us, that there is a con-Nazarite. vent built over what is said to be the place of annunciation; for the chamber where she received the angel's salutation was about 500 years ago removed from Nazareth, and, according to the Roman legends, transported by angels to Loretto, then a small village in the pope's dominions, now become a bishop's sec .---However, Calmet's opinion (which is certainly the true one) upon the different translations of this famous house of Loretto, is, that they were no other than so many different buildings made upon the model of the church of Nazareth, just as in several places sepulchres have been built upon the model of that at Jerusalem. Mariti tells us, that in the eastern part of the city stands the church dedicated to the Blessed Virgin : the zeal of the Coenobites raised it from the ruins of that which had been destroyed by the Saracens. It is a very handsome building, and consists of three naves; in the middle of which is the principal altar; to which there is an ascent by two magnificent stairs, much admired for their iron ballustrades, the work of an ingenious monk of the convent. The descent to the grotto or annunciation chapel below is by steps of beautiful marble, cut with great taste. Two beautiful columns of oriental granite strike the eye of the observer in the entrance. They appear to have been constructcd both to support and ornament the grotto. The altar of this subterranean chapel is extremely elegant; and the different kinds of marble with which it is ornamented, receive an additional lustre from the combined light of several silver lamps presented by Christian princes. On solemn festivals, the walls and the pilasters are ornamented with various pieces of tapestry, representing the mysteries of the virgin; a superb present from the House of Austria. In the western part of the city stands a Christian church, built, as it is said, on the site of the ancient synagogue where Jesus showed the Jews the accomplishment of the prophecies in his person. This place served a long time as a shelter for flocks, but at present it is in good repair. In the neighbourhood may be seen a fountain of excellent water, which is, however, esteemed by the people on another account. They conjecture that it was contiguous to the habitation of the virgin, and that it was used by her. At some distance is a large stone of a round form, called Christ's Table. It is pretended that he came hither more than once with his disciples to eat. The inhabitants of Nazareth pay it a kind of worship, burning perfumes and incense around it. It is situated in 35° E. Long. and in 32° N. Lat.; and formerly held the third rank under the patriarch of Jerusalem. At present it is part of the domains of the chief of Acre. The ancient city, after the ravages of fanaticism, was reduced to a miserable hamlet, containing only a few Arab huts .-- Under the protection of Daher Omar, however, it recovered very considerably, and is now of far more importance.

: NAZARITE, or NAZAREAN, or Nazarines, a term which may signify, I. One that is of Nazareth, or any native of this city. 2. It was given to Jesus Christ and his disciples, and is commonly taken in a sense of derision and contempt in such authors as have written against Christianity. 3. It has been taken for a sect of heretics called Nazareans. 4. For a Nazarite, a man that has laid himself under the obligation of a vow

to observe the rules of Nazariteship, whether it be for Nazarites his whole life, as Samson and John the Baptist, or only for a time, as those mentioned in Numbers vi. 18, 19, 20. Amos ii. 11, 12. Lastly, The name Nazarite, in some passages of Scripture, denotes a man of particular distinction and great dignity in the court of some prince. But we must speak of these several sorts of Nazarites something more distinctly.

The name of Nazarene belongs to Jesus Christ, not only because of his having lived the greatest part of his life at Nazareth, and because this city has always been considered as his country, but also because the prophets had foretold that he should be called a Nazarene, Matth. ii. 23. " And he came and dwelt in a city " called Nazareth, that it might be fulfilled which was " spoken by the prophets, He shall be called a Naza-" rene." We find no particular place in the prophets in which it is said that the Messiah should be called a Nazarene; and St Matthew only quotes the prophets in general. Perhaps he would insinuate, that the consecration of the Nazarites, and the great purity of which they made profession, was a type and a sort of prophecy of those of our Saviour, or else that the name cir or Nazarite given to the patriarch Joseph, Gen. xlix. 26. Deut. xxxiii. 16. was a prophecy which was to be fulfilled in the person of Jesus Christ, of whom Joseph was a figure. Lastly, St Jerome was of opinion, that St Matthew here alludes to that passage of Isaiah xi. 1. and lx. 21. "And " there shall come forth a rod out of the stem of Jesse, " and a branch (in Hebrew Nezer) shall grow out of " his roots." This branch or Nezer, and this rod, are certainly intended to denote Jesus Christ, by the general consent of all the fathers and interpreters.

When the word Nazarean is put for the heretics known by this name, it denotes Christians converted from Judaism, whose chief error consisted in defending the necessity or expediency of the works of the law, and who obstinately adhered to the practice of the Jewish ceremonies. The name of Nazarenes at first had nothing odious in it, and it was often given to the first Christians. The fathers frequently mention the gospel of the Nazarenes, which differs nothing from that of St Matthew, which was either in Hebrew or Syriac, for the use of the first converts, but was afterwards corrupted by the Ebionites. These Nazarcans preserved this first gospel in its primitive purity. Some of them were still in being in the time of St Jerome, who does not reproach them with any error. They were very zealous observers of the law of Moses, but held the traditions of the Pharisees in very great contempt.

Nazarite, when put to signify those under the ancient law who made a vow of observing a more than ordinary degree of purity (Numb. ubi. cit.), denotes a man or woman who engage themselves by a vow to abstain from wine and all intoxicating liquors, to let their hair grow without cutting or shaving, not to enter into any house that was polluted by having a dead corpse in it, nor to be present at any funeral. And if by chance any one should have died in their presence, they began again the whole ceremony of their consecration and Nazariteship. This ceremony generally lasted eight days, sometimes a month, and sometimes their whole lives. When the time of their Nazariteship

Nazarite, ship was accomplished, the priest brought the person v- to the door of the temple, who there offered to the Lord a he lamb for a burnt-offering, a she lamb for an expiatory sacrifice, and a ram for a peace-offering. They offered likewise loaves and eakes, with wine necessary for the libations. After all this was saerificed and offered to the Lord, the priest or some other shaved the head of the Nazarite at the door of the tabernacle, and burnt his hair, throwing it upon the fire of the altar. Then the priest put into the hand of the Nazarite the shoulder of the ram roasted, with a loaf and a cake, which the Nazarite returning into the hands of the priest, he offered them to the Lord, lifting them up in the presence of the Nazarite. And from this time he might again drink wine, his Nazariteship being now accomplished.

> As to those that were perpetual Nazarites, as were Samson and John the Baptist, it appears that they were consecrated to their Nazariteship by their parents, and continued all their lives in this state without drinking wine or cutting their hair.

> Those that made a vow of Nazariteship out of Palestine, and could not come to the temple when their vow was expired, contented themselves with observing the abstinence required by the law, and after that cutting their hair in the place where they were : as to the offerings and sacrifices preseribed by Moses, which were to be offered at the temple by themselves, or by others for them, they deferred this till they could have a convenient opportunity. Hence it was, that St Paul being at Corinth, and having made the vow of a Nazarite, he had his hair cut off at Cenchrea, and put off fulfilling the rest of his vow till he should arrive at Jcrusalem, Acts xviii. 18. When a person found that he was not in a condition to make a vow of Nazariteship, or had not leisure to perform the ceremonies helonging to it, he contented himself by contributing to the expence of the sacrifice and offerings of those that had made and fulfilled this vow; and by this means he became a partaker in the merit of such Nazariteship. When St Paul came to Jerusalem, in the year of Christ 58, the apostle St James the Less, with the other brethren, said to him, Acts xxi. 23, 24. that to quiet the minds of the converted Jews, who had been informed that he everywhere preached up the entire abolition of the law of Moses, he ought to join himself to four of the faithful who had a vow of Nazariteship upon them, and contribute to the charge of the eeremony at the shaving of their heads; by which the new converts would perceive that he continued to keep the law, and that what they had heard of him was not true.

> The Hebrew word Nazir, or Nazarite, which is made use of to express a man exalted to great dignity, as it is said of the patriarch Joseph, Gen. xlix. 26. and Deut. xxxiii. 16. " that he was separated from his brethren," as it is in our translation ; or as the Vulgate and others understand the Hebrew, " that he was a Nazarite among his brethren," is variously understood. Some think that the Hebrew word כויד, Nazir, in these places, signifies one who is erowned, chosen, separated, or distinguished : the word כויד, Nazır, signifies a erown. The Septuagint translate this word a chief, or him that is honoured. Calmet thinks that this was a term of dignity in the courts of eastern princes, and that at this day in the court of Persia the word Nazir signifies the

superintendant general of the king's household, the Nazarite chief officer of the crown, the high steward of his family, treasures, and revenues; and that in this sense Neapolis. Joseph was the Nazir of the court of Pharoh. Le Clerc translates the Nazir, a prince, and calls Joseph " the prince of his brethren," in the two places already quoted. Mr Pool declares in favour of this last translation. See Joseph. Chardin. Chrysost. St Jerome, &c.

NAZIANZEN. See Gregory Nazianzen.

NAZIM, the lord lieutenant, viceroy, or governor of a province in Hindostan; the same as Subahdar, or Nabob.

NEALED, among seamen, is used when the sounding is deep water close to the shore; as also when the shore is sandy, elayey, oozy, or foul and rocky ground.

NEALING, or rather ANNEALING, a term used for the preparing of several matters, by heating of baking them in the oven, or the like.

NEALING of glass, is the baking of glass, to dry, harden, and give it the due consistence, after it has been blown, and fashioned into the proper works .- This is usually performed in a kind of a tower called the leer, built over the melting furnace. See GLASS.

Nealing of glass is also used for the art of staining glass with metalline colours. " One fine use of silver (says Mr Boyle) was only discovered since the art of annealing upon glass came to be practised. For prepared silver, or even the crude metal, being burnt on a glass plate, will tinge it of a fine yellow or golden colour. And there are several mineral earths, and other coarse matters, of use in this art, which by means of fire impart transparent colours to glass, and sometimes very different ones from those of the bodies themselves.

NEALING of steel, is the heating it in the fire to a blood-red heat, and then taking it out, and letting it eool gently of itself. This is done to make it softer, in order to engrave and punch upon it. See TEMPER-ING and ENGRAVING.

NEALING is also used for the art or aet of burning or baking earthen or other ware in an oven. The miners at Mendip, when they meet with a rock they eannot eut through, anneal it by laying on wood and coal, and contriving the fire so that they quit the mine before the operation begins, it being dangerous to enter it again before it be quite eleared of the smoke.

NEALING of tile is used in aneient statutes for the burning of tile. The word is formed of the Saxon onælan, accendere, to light, burn.

NEAP or NEEP TIDES, are those tides which hapnen when the moon is in the middle of the second and fourth quarters. The neap tides are low tides, in respect of their opposites the spring tides. As the highest of the spring tides is three days after the full or change, so the lowest of the neap is four days before the full or ehange. On which oceasion the seamen say that it is deep neap.

NEAPED. When a ship wants water, so that she cannot get out of the harbour, off the ground, or out of the doek, the seamen say she is neaped, or bencaped.

NEAPOLIS, in Ancient Geography, a city of the Higher Egypt, in the Nomos Panopolitanus, between Thebæ to the south, and Panopolis to the north, on the east side of the Nile; otherwise called Caæne. A 5A2 second

Necessity.

Neapolis second Neapolis of Babylonia, situated near the Euphrates on the south side .- A third of Campania, an ancient town and a colony from Cumæ. (Sce Velleius, Pliny, Strabo); accounted a Greek city, and a great stickler for Greek usages, (See Livy, Tacitus). Its hot baths were in nothing inferior to those of Baiæ, according to Strabo ; at two miles distance from it stands the monument of Virgil, held in religious veneration by learned posterity. The Younger Pliny relates, that Virgil's birth day was more religiously observed by Silius Italicus than his own, especially at Naples, where he resorted to his tomb as to a temple. The city is washed by the river Sebethus. Virgil feigns the nymph Sebethis to preside over the stream. Now Naples, ca-pital of the kingdom of that name. Sec NAPLES .--A fourth, Ncapolis of Caria, near the Meander, (Ptolemy) .- A fifth, an inland town of Cyrenaica, situated between Ptolemais and Arsinoe, (Ptolemy); and to be distinguished from the Cænopolis, or Neapolis, on the east border of the same province, (id.) A sixth of Ionia, (Strabo); which belonged first to the Ephesians, but afterwards to the Samians, who exchanged Marathesium, a more distant city, for a ncarer .- A seventh, Neapolis of Macedonia Adjecta, situated at the distance of 12 miles to the cast of Philippi, (Antonine) .- An eighth, Neapolis of Pisidia, on the borders of Galatia, situated between Amblada and Pappa, (Ptolemy) .- A ninth of Samaria, the ancient Sichem, which see; so called upon its restoration by the Romans, (Coin, Pliny, Josephus) .- A tenth of Sardinia, situated on the south-west side of the island, 30 miles to the north of Metalla; now called Neapoli .- An eleventh, of the Regio Syrtica, called also Leptis.-A twelfth, of Zeugitana on the Mediterranean, to the east of Clypea, and south of the Promontorium Mercurii.

NEAT or NET Weight, the weight of a commodity alone, clear of the eask, bag, case, or even filth. See NET.

NEBEL, or NABLUM, a musical instrument among the Jews. See NABLUM.

NEBIO, or NEBBIO, a ruined city, on the north side of the island of Corsica, with a bishop's see, whose bishop resides at San Fiorenzo, from which it is a mile distant.

NEBO, in Ancient Geography, a very high mountain, a part of the mountains of Abarim, and their highest top, whither Moses was ordered to ascend to. take a view of the land of Canaan, and there die. Situated in the land of Moab over against Jericho: with a cognominal town at its foot (Isaiah) belonging to the Reubenites, which afterwards returned to the Moabites; in Jerome's time desolate; eight miles to the south of Heshbon.

NEBO, or Nabo. Sec NABO.

NEBUCHADNEZZAR. See NABUCHADNEZ-ZAR.

NEBULY, or NEBULEE, in Heraldry, is when a coat is charged with several little figures, in form of words running within one another, or when the outline of a bordure, ordinary, &c. is indented or waved.

NECESSITY, whatever is done by a cause or power that is irresistible; in which sense it is opposed to freedom. Man is a necessary agent, if all his actions be so determined by the eauses preceding each action,

that not one past action could possibly not have come Necessity. to pass, or have been otherwise than it hath been; nor one future action can possibly not come to pass, or be otherwise than it shall be. But he is a free agent, if he bc able, at any time, under the circumstanecs and causes he then is, to do different things; or, in other words, if he be not unavoidably determined in every point of time, by the circumstances he is in, and the causes he is under, to do that one thing he does, and not possibly to do any other thing. Whether man is a necessary or a free agent, is a question which has been debated with much ingenuity by writers of the first eminence, from Hobbes and Clarke, to Priestley and Gregory. See METAPHYSICS, Part III. chap. v. and PREDESTINATION.

NECESSITY, in Mythology, a power superior to all other powers, and equally irresistible by gods and by mcn. Herodotus, as he is quoted by Cudworth, mentions an oracle which declared that "God himself could not shun his destined fate." And among the fragments of Philemon collected by Le Clerc, is the following sentence:

Δουλοι βασιλεων εσμεν, οί βασιλεις θεων, ό θεος αναγκης.

"We are subject to kings, kings to the gods, and God to Neccssity." Hence it is, that, in the Iliad, we find Jove himself, the sire of gods and men, regretting that he was restrained by Necessity from rescuing his favourite son from the sword of Patroclus. Nay to such a height was this impiety carried in the earliest ages of Greece, that we find Hesiod and Homer teaching that the gods themselves were generated by Necessity, of Night and Chaos.

This power, though always represented as blind and unintelligent, was however worshipped as a goddess, bearing in her hand large iron nails, wedges, anchors, and melted lead *, as emblems of the inflexible severity * Horace, of her nature. "In the city of Corinth she had a lib i. ode temple, in which the goddess Violence likewise resided, 35. and into which no person was ever permitted to enter but the priest who officiated in sacris +." Pausanias

Learned men have exercised their ingenuity in vain in Corinth. attempts to trace this portentous notion to its origin. cap. iv. Some, who wished to interpret it in a pious sense, have supposed that the gods who are subject to Necessity were only those who were the ministers of the supreme numen ; and that by necessity itself was meant nothing more than divinc providence. But this is not consistent with Hesiod and Homer's Generation of the Gods, or with the epithets sæva necessitas, dura necessitas, by which this power was perpetually distinguished. Others, and among them Mosheim, have supposed that this monstrous fable was invented by the Pagan priests, and diligently inculcated upon the minds of the people, in order to excuse the villanies of the objects of their worship. For, says he, who could be indignant at Jupiter's numberless adulteries, after it was known that in all his actions lie was the servant of blind necessity : In the thefts of Mercury, the whoredoms of Venus, and the frequent squabbles of the other gods, there could be no moral turpitude, if they were under the influence of # Martial. a superior power.

Numina cum videas duris obnoxia fatis, Invidia possis exoncrare deos ‡.

Epigram. lib. ix. N. 88. Ed. Amstel.

This 1701.

Necessity. This account of the matter is at least as plausible as any other which is usually given; but the real case undoubtedly was, that when men " did not like to retain God in their knowledge, God gave them over to a reprobate mind to do those things which are not convenient; when their foolish heart was darkened, and professing themselves to be wise, they became fools." See PARCÆ.

> NECESSITY, in Law, as it implies a defect of will, excuses from the guilt of crimes. See CRIME.

> Compulsion and inevitable necessity are a constraint upon the will, whereby a man is urged to do that which his judgment disapproves; and which, it is to be presumed, his will (if left to itself) would reject. As punishments are therefore only inflicted for the abuse, of that free will which God has given to man, it is highly just and equitable that a man should be excused for those acts which are done through unavoidable force and compulsion.

> 1. Of this nature, in the first place, is the obligation of civil subjection, whereby the inferior is constrained by the superior to act contrary to what his own reason and inclination would suggest : as when a legislator establishes iniquity by a law, and commands the subject to do an act contrary to religion or sound morality. How far this excuse will be admitted in foro conscientia, or whether the inferior in this case is not bound to obey the divine rather than the human law, it is not our business to decide; though among the casuists, it is believed the question will hardly bear a doubt. But, however that may be, obedience to the laws in being is undoubtedly a sufficient extenuation of civil guilt before the municipal tribunal. The sheriff who burnt Latimer and Ridley, in the bigotted days of Queen Mary, was not liable to punishment from Elizabeth for executing so horrid an office; being justified by the commands of that magistracy which endeavoured to restore Superstition, under the holy auspices of its merciless sister, Persecution.

As to persons in private relations, the principal case where constraint of a superior is allowed as an excuse for criminal misconduct, is with regard to the matrimonial subjection of the wife to her husband : for neither a son nor a servant are excused from the commission of any crime, whether capital or otherwise, by the command or coercion of the parent or master; though in some cases the command or authority of the husband, either express or implied, will privilege the wife from punishment, even from capital offences. And therefore, if a woman commit theft, burglary, or other civil offences against the law of society, by the coercion of her husband, or even in his company, which the law construes a coercion, she is not guilty of any crime; being considered as acting by compulsion, and not of her own will. This doctrine is at least 1000 years old in this kingdom, being to be found among the laws of King Ina the West Saxon. And it appears, that among the northern nations on the continent, this privilege extended to any woman transgressing in concert with a man, and to any servant that committed a joint offence with a freeman: the male or freeman only was punished, the female or slave dismissed ; procul dubio quod alterum libertas, alterum necessitas impelleret. But (besides that, in our law,

which is a stranger to slavery, no impunity is given to Necessity. servants, who are as much free agents as their masters) even with regard to wives, this rule admits of an exception in crimes that are mala in se, and prohibited by the law of nature; as murder, and the like: not only because these are of a deeper dye, but also, since in a state of nature no one is in subjection to another, it would be unreasonable to screen an offender from the punishment due to natural crimes, by the refinements and subordinations of civil society. In treason also (the highest crime which a member of society can, as such, be guilty of), no plea in coverture shall excuse the wife; no presumption of the husband's coercion shall extenuate her guilt; as well because of the odiousness and dangerous consequence of the crime itself, as because the husband, having broken through the most sacred tie of social community by rebellion against the state, has no right to that obedience from a wife, which he himself as a subject has forgotten to pay. In inferior misdemeanours also, we may remark another exception, that a wife may be indicted and set in the pillory with her husband, for keeping a brothel: for this is an offence touching the domestic economy or government of the house, in which the wife has a principal share; and is also such an offence as the law presumes to be generally conducted by the intrigues of the female sex. And in all cases where the wife offends alone, without the company or coercion of her husband, she is responsible for her offence as much as any femmesolc.

2. Another species of compulsion or necessity is what our law calls duress per minas; or threats and menaces, which induce a fear of death or other bodily harm, and which take away for that reason the guilt of many crimes and misdemeanours, at least before the human tribunal. But then that fear which compels a man to do an unwarrantable action ought to be just and well grounded; such, " qui cadere possit in virum constantem, non timidum et meticulosum," as Bracton expresses it in the words of the civil law. Therefore in time of war or rebellion, a man may be justified in doing many treasonable acts by compulsion of the enemy or rebels, which would admit of no excuse in the time of peace. This, however, seems only, or at least principally, to hold as to positive crimes, so created by the laws of society, and which therefore society may excuse ; but not as to natural offences, so declared by the law of God, wherein human magistrates are only the executioners of divine punishment. And therefore though a man be violently assaulted, and hath no other possible means of escaping death but by killing an innocent person, this fear and force shall not acquit him of murder; for he ought rather to die himself than escape by the murder of an innocent. But in such a case he is permitted to kill the assailant ; for there the law of nature. and self-defence its primary canon, have made him his own protector.

3. There is a third species of necessity, which may be distinguished from the actual compulsion of external force or fear ; being the result of reason and reflection, which act upon and constrain a man's will, and oblige him to do an action which without such obligation would be criminal. And that is, when a man has his choice of two evils set before him, and being under a necessity of choosing one, he chooses the least pernicious.

Ly Nec

N

* De

Necessity. pernicious of the two. Here the will cannot be said freely to excrt itself, being rather passive than active ; or, if active, it is rather in rejecting the greater evil than in choosing the less. Of this sort is that necessity, where a man by the commandment of the law is bound to arrest another for any capital offence, or to disperse a riot, and resistance is made to his authority: it is here justifiable, and even necessary, to beat, to wound, or perhaps to kill the offenders, rather than permit the murderer to escape, or the riot to continue. For the preservation of the pcace of the kingdom, and the apprehending of notorious malefactors, are of the utmost consequence to the public; and therefore excuse the felony, which the killing would otherwise amount to.

4. There is yet another case of necessity, which has occasioned great speculation among the writers upon general law; viz. whether a man in extreme want of food or clothing may justify stealing either, to relieve his present necessities. And this both Grotius and Puffendorff, together with many other of the foreign jurists, hold in the affirmative; maintaining by many ingenious, humane, and plausible reasons, that in such cases the community of goods, by a kind of tacit concession of society, is revived. And some even of our lawyers have held the same ; though it seems to be an unwarranted doctrine, borrowed from the notions of some civilians; at least it is now antiquated, the law of England admitting no such excuse at present. And this its doctrine is agreeable not only to the sentiments of many of the wisest ancients, particularly Cicero, who holds, That suum cuique incommodum ferendum est, potius quam de alterius commodis detrahendum ; but also to the Jewish law, as certified by King Solomon himself: " If a thief steal to satisfy his soul when he is hungry, he shall restore sevenfold, and shall give all the substance of his house :" which was the ordinary punishment for theft in that kingdom. And this is founded upon the highest reason : for men's properties would be under a strange insecurity, if liable to be invaded according to the wants of others; of which wants no man can possibly be an adequate judge but In England the party himself who pleads them. especially, there would be a peculiar impropriety in admitting so dubious an abuse: for by the laws such sufficient provision is made for the poor by the power of the civil magistrate, that it is impossible that the most needy stranger should ever be reduced to the necessity of thieving to support nature. The case of a stranger is, by the way, the strongest instance put to Baron Puffendorff, and whereon he builds his principal arguments : which, however they may hold upon the continent, where the parsimonious industry of the natives orders every one to work or starve, yet must lose all their weight and efficacy in England, where charity is reduced to a system, and interwoven in our very constitution. Therefore our laws ought by no means to be taxed with being unmerciful, for denying this privilege to the necessitons; especially when we consider, that the king, on the representation of his ministers of justice, hath a power to soften the law, and to extend mercy in cases of peculiar hardship. An advantage which is wanting in many states, particularly those which are democratical : and these have in its stead introduced and adopted, in the body of

the law itself, a multitude of circumstances tending to alleviate its rigour. But the founders of our constitution thought it better to vest in the crown the power of pardoning particular objects of compassion, than to countenance and establish theft by one general undistinguishing law.

NECHO, king of Egypt, began his reign 690 B. C. and was killed eight years after by Sabacon king of Ethiopia. Psammiticus his son succeeded him, and was the father, as Herodotus informs us, of Necho II. who reigned in the 616 B.C. This Necho II. is celebrated in history for attempting, though in vain, to cut a canal from the Nile to the Arabian gulf. He carried his arms as far as the Euphrates, and conquered the city of Carchemish. This prince is not only known in Scripture under the name of Necho, but also in profane history. He no sooner succeeded to the crown than he raised great land armies, and fitted out vast fleets, as well upon the Mediterranean as upon the Red sea: he gave battle to the Syrians near the city of Migdol; routed them, and made himself master of the city of Cadytis. The learned, however, are not agreed about this city Cadytis. Some will have it to be Cades in Arahia Petræa, others Jerusalem; and others say it is the city of Cedes, or Kedesh, in Galilee, in the tribe of Naphtali.

The Scriptures aquaint us with the whole expedition of Necho in all its particulars, 2 Kings xxiii. 29. &c. and 2 Chr. xxxv. 20, 21, &c. In the year of the world 3394, this prince having drawn out his army into the field to make war with the Assyrians or Babylonians, and to take the city of Carchemish, otherwise called Circusium, upon the Euphrates, Josiah king of Judah, who was a tributary to the king of Babylon, marched to oppose his passage. Necho, who had no designs against him, sent to tell him, " What have I to do with you, king of Judah? It is not against you that I am come forth, but against another people, against whom the Lord has commanded me to make war. Leave off therefore to set yourself against me, for fear the Lord should punish you for your resistance." But Josiah would not hearken to the remonstrances of Necho, but gave him battle at Megiddo, where he received the wound of which he died. The people of Jerusalem set up Jehoahaz for king of Judah, and Necho soon passed forward, without making any longer stay in Judea.

But at his return from his expedition, which was very successful, he halted at Riblah in Syria; and sending for Jehoahaz king of the Jews, he deposed him, loaded him with chains, and sent him into Egypt. Then coming to Jerusalem, he set up Eliakim, or Jehoiakim, in his place, and exacted the payment of 100 talents of silver and one talent of gold from the country. Jeremiah (xlvi. 2.) acquaints us that the city of Carchemish was taken from Necho by Nebuchadnezzar king of Babylon, in the fourth year of Jehoiakim king of Judah; so that Necho did not enjoy his conquest above four years. Josephus adds, that the king of Babylon pursuing his victory, brought under his dominion all the country which is between the Euphrates and Egypt, excepting Judea. Thus Necho was again reduced within the limits of his own country.

NECK, in Anatomy, is the slender part situated be-

tween the head and trunk of the body. See ANA-Neck 11 TOMY. Necroman-

NECROLIUM, a word used by some of the alcheey. mical writers to express a remedy almost always capable of averting death, and continuing life to its utmost period.

NECROLOGY, necrologium, formed of vereos, " dead," and hoyos, " discourse or enumeration," a book anciently kept in churches and monasterics, wherein were registered the benefactors of the same, the time of their deaths, and the days of their commemoration; as also the deaths of the priors, abbots, religious, canons, &c. This was otherwise called calender and obituary

NECROMANCY, the art of revealing future events by a pretended communication with the dead.

This superstitious and impious imposture appears to have had its origin at a very early period in Egypt, and to have been thence propagated in every nation with the manners of which history has made us acquainted. The conquests of Sesostris might introduce it into India; the Israclites would naturally borrow it from the people among whom they sojourned 400 years ; and it would easily find its way into Phœnicia, from the vicinity of that country to the land of its nativity. From the Egyptians and Phœnicians it was adopted, with the other rites of paganism, by the Greeks; and it was imported into Rome with Grecian literature and Grecian manners. It was not however confined to the pagan nations of antiquity : it spread itself through all the modern nations of Europe, and took such deep root as to be long retained even after those nations were converted to the Christain faith.

* Deut. tviii. IO, II, I2.

Of its early antiquity we have complete evidence in the writings of Moses, where it is severely condemned as an abomination to the Lord *; and though it appears to have been even then spread into Phœnicia, we might yet conclude its birthplace to have been Egypt, because, at their exody, the Israelites were corrupted only by Egyptian superstitions, and because necromancy seems to be one of those whoredoms which the prophet Ezekiel represents his countrymen as having brought with them from Egypt, and continued to practise till they were carried captives into Babylon.

If from sacred we proceed to consult profane authors, we shall find them not only affirming Egypt to have been the birthplace of necromancy, but in some degree accounting for the origin of so impious a delusion. From Diodorus the Sicilian t we learn that the Gre-Lib. i. 6 2. cian fable of Charon the ferryman of hell, of Styx, Cocytus, the Elysian Fields, Tartarus, the judgment of Minos and Rhadamanthus, &c. with the whole scenery of the infernal regions, were imported from Egypt into Grecce. The ancient Egyptians, and indeed all the people of the east, made use of caves for burying places, which were well suited to the solemn sadness of the surviving friends, and proper receptacles for those who were never more to behold the light. In Egypt, many

of those subterraneous cavities being dug out of the na- Necromantural rock, still remain, and command the admiration CY. of travellers; and near to the pyramids in particular there are some apartments of a wonderful fabric, which though they extend in length 4400 feet, and are about 30 feet in depth, appear to have been, if not entirely dug, at least reduced to form by the chissel or pickaxe of the artist.

E

C

N

From the practice of burying in such caverns sprung the opinion that the infernal mansions were situated somewhere near the centre of the earth, which by the Egyptians was believed to be not very distant from its surface ‡. In these dreary mansions, it was very easy Analysis of for such adepts as the priests of Egypt to fabricate Ere-Mythobus, Tartarus, the Elysian Fields, and all those scenes logy. which were displayed before the initiated (see MYSTE-RIES), and by them described to the million of the people. As it was in those dark abodes that necromancy was practised, it would be no difficult matter for such magicians as withstood Moses to impose so far upon the credulous vulgar, as to make them believe, that in consequence of their invocations they actually saw the ghosts of their friends ascend out of the earth. It appears from the book of Exodus, that the Israelitish women were, even in the wilderness, well acquainted with the use of the mirror, which was therefore undoubtedly known to the Egyptians. But a mirror of a particular form and properly illuminated at the instant required, might be easily made to reflect, in a cavern from which all other light was carefully excluded, the image of the dcceased, who was called upon by the necromancer; and we can readily conceive, that with respect to the question to be proposed, a person might be concealed, prepared to give such ambiguous answers as would satisfy the inquirer, and at the same time save the credit of the oracle. The terrified imaginations of the spectators would aid the delusion, and make a very slight resemblance pass for the ghost or udwhor of their departed friend; or the necromancer might assign plausible reasons why a spectre, after having dwelt for some time in the infernal regions, should lose something of its resemblance to the body which it animated. Such juggling tricks, though performed by artists less accomplished than Jannes and Jambres, have gained credit among people much more enlightened than the Egyptians can possibly have been when the science of necromancy was invented by their priests.

That the Israelites, notwithstanding the prohibition of their legislator, continued to practise the rites of necromancy, is apparent from Saul's transaction with the witch of Endor (see MAGIC). From the same transaction, it is likewise apparent that the witches of Israel, and therefore in all probability the necromancers of Egypt, pretended to evocate the ghosts of the dead by a demon or familiar spirit, which they had at their command to employ upon every emergency. This demon was called OB; and therefore Saul desires his servants to find him a woman who was mistress of an OB (A). Tt

(A) The original, or radical, signification of this word occurs, in Job xxxii. ver. 19.; where Elihu compares his belly to new bottles, which he calls oboth, the plural of ob. But as bottles were then made of leather, new bottles filled with wine and ready to burst, as Elihu describes them, would of course be of a form nearly globular.

1

Necroman- It is probable that those wretched impostors had in their pay some persons who occasionally acted the part of the demon, and when the execution of the plot required their agency, cmitted, by means of a cavity dug for that purpose, a low hollow voice from below the ground. Hence we find Isaiah, in his dcnunciations against Ariel *, saying, "Thou shalt be brought down, and shalt speak out of the ground; and thy speech shall be low out of the dust, and thy voice shall be as of one that hath a familiar spirit (an OB) out of the ground, and thy speech shall whisper out of the dust."

But though the Egyptian priests were undoubtedly the inventors of the whole mystery of necromancy, and though it was from them imported into Greece by the SELLI or priests of Dodona, it does not appear that the Grecian necromancers pretended to be masters of OBS or familiar spirits. Mopsus, Orpheus, Linus, Eumolpus, &c. who either travelled into Egypt in quest of knowledge, or were actually natives of that country, instructed the early Greeks in this occult science : but whatever might be the practice of these apostles themselves, their disciples professed to do all the feats of magic by performing certain rites, by offering certain sacrifices, by muttering a certain form of words, by charms, spells, and exorcisms. By these they pretended to evocate the dead as certainly as the Egyptians and Jews did by their familiar spirits. By a small display of critical learning this might be easily proved from the popular story of Orpheus and Eurydice, which certainly was founded on one of these necromantic deceptions exhibited in a cave near Dodona, where the priests had a hades or infernal mansion, in humble imitation of those with which the first of them were well acquainted in Egypt. It is indeed evident, without the aid of criticism: no man of any letters is ignorant, that whatever superstitions of this kind prevailed among the Romans were borrowed from the Greeks. But we all know that Virgil makes one of his shepherds, by means of certain herbs, poisons, and senseless charms, raise up ghosts from the bottoms of their graves; and Lucian has fabricated a story of this kind, which may be considered as an exact parallel to the witch of En-+ Lib. vi. dor. Just before the battle of Pharsalia he makes + ver. 570. et young Pompey travel by night to a Thessalian sorceress, and anxiously inquire of her the issue of the war. This female necromancer, by a tedious process of charms and incantations, conjures up the ghost of a soldier who had

>seq.

been lately slain. The phantom, after a long preamble, denounces a prediction much of the same kind with that which the king of Israel received from Samuel at Endor; and though we have elsewhere shown, that nothing but the spirit of God could have foreseen the inevitable destruction of Saul, his sons, and his army, (see

MAGIC), it was very easy for any man of tolerable sa- Necromangacity to foresee the defeat of Pompey's raw and undisciplined troops by the hardy veterans of the victorious Cæsar. It would be endless to enumerate all the fallacious

evocations of ghosts, and the ambiguous responses returned by those pretended spirits, of which we have accounts from the poets and historians of the celebrated nations of antiquity. We shall therefore proceed to mention a few which occur in the fabulous history of more modern nations, and then leave the subject to the meditation of our readers. In Mallet's Northern Antiquities, we have the following account of a necromantic exploit, between which, and the descent of the ancient heroes into hell, it is impossible not to remark a striking similitude.

" Odin the sovereign of man arises. He saddles his horse Sleipner; he mounts, and is conveyed to the subterraneous abode of Hela. The dog which guards the gates of death meets him. His breast and his jaws are stained with blood. He opens his voracious mouth to bite, and barks a long time at the father of magic. Odin pursues his way; and the infernal cavern resounds and trembles under his horse's hoofs. At length he reaches the deep abode of death, and stops near the eastern gate, where stands the tomb of the prophetess. He sings with a voice adapted to call up the dead; he looks towards the world ; he engraves Runic characters on her tomb; he utters mysterious words; and he demands an answer, until the prophetess is constrained to arise and thus utter the words of the dead .- " Who is this unknown that dares to disturb my repose, and drag me from the grave, in which I have been dead so long, all covered with snow, and moistened with the rains ?" &c.

The Gaelic druids pretended to be masters of the same secret. This is evident from the name of a species of divination, not uncommon among the Scotch Highlanders so lately as in the beginning of the 18th century. By a gentleman excellently versed in the antiquities of that people, and a steady friend to the writer of this article, we have been informed, that not many years ago some of the Highlanders relied implicitly upon certain oracular responses, called in their language taghairm. This word seems to be compounded of ta, which in some parts of the Highlands is still used to denote a spirit or ghost, and ghairm, which signifies calling upon or invoking. Taghairm, therefore, in its original import, is necromancy in the most proper sense of that word.

There were different kinds of taghairm, of which one was very lately practised in Skye. The diviner covered himself with a cow's hide, and repaired at night to some deep-sounding cave, whither the person who consulted

lar. Hence it may be inferred that the original import of ob was round or globular: but b and p being labials, are often changed into each other; and therefore, from the Hebrew ob is derived the Greek of, oculus, onlowar, video, and the Latin ops, a name under which the earth was worshipped. Upis was a name of Diana or the moon : the father of one of the Dianas was likewise Upis ; but this Upis was undoubtedly the sun. Now the difference between upis and opis is nothing ; hence we are led to believe, that as they are all derived from ob, this word was employed by the early idolaters of Egypt to denote the first and greatest of Pagan gods, the sun. If so, those wretches who pretended to be mistresses of obs, were exactly the same kind of impostors with the Pythonesses of the Greeks.

* Chap. xxix. 4.

cy.

ev.

Secroman- sulted him followed soon after without any attendants. At the mouth of the cave he proposed aloud the questions of which he wanted solutions ; and the man within pronounced the responses in a tone of voice similar to that with which the OBS, or pretended demons of antiquity, gave from beneath the ground their oracular answers. That in the latter days of taghairm, the Gaelic diviners pretend to evocate ghosts, and from them to extort solutions of difficulties proposed, we have no positive evidence ; but that such was the original pretence there can be little doubt, when we reflect either upon the place where this species of divination was practised, or upon the import of the word by which it was denominated.

As we have been led to mention taghairm, we shall beg leave to make a few observations on another species of it, called taghairm an uisge, or "taghairm by water." This too was last practised in the Isle of Skye, by a man of the name of M'Cuidhean, whose ancestors had long been famous for the art. He lived near a beautiful cascade on a small river ; and when consulted on any matter of consequence, he covered his whole hody with a cow's hide, that necessary implement of Highland divination, and placed himself between the water of the cascade and the rock over which it flowed. Then another man with a heavy pole gave repeated strokes to the water, and the diviner behind it crying out now and then in Gaelic, " Is this a stock o arn?" This operation was continued till M'Cuidhean was perceived to be frantic or furious, when he was considered as in a condition to answer the most important questions. He was frequently consulted about futurity; and though he could not, in the proper sense of the word, be called a necromancer, his responses were listened to as proceeding from something more than human. A degree of phrenzy, either real or affected, seems to have accompanied the predictions of certain kinds of divincrs in all ages; and we cannot help remarking the similarity between the madness of M'Cuidhean and that of the Sibyl in the sixth book of the Æneid; though we cannot suppose the one to have been borrowed from the other.

At, Phabi nondum patiens, immanis in antro Baechatur vates, magnum si peetore possit Excusisse Deum : tanto magis ille fatigat Os rabidum, fera corda domans, fingitque premendo.

Struggling in vain, impatient of her load, And lab'ring underneath the pond'rous god ; The more she strove to shake him from her breast, With more and far superior force he press'd.

DRYDEN.

That all these pretences, whether ancient or modern, to the power of divination by means of familiar spirits, or by the art of necromancy, were groundless as well as impious, it would be affronting the understandings of our readers to offer any proof. Under the article MAGIC we have said enough on the subject, and perhaps more than enough, to those who know that demons, if they have any existence, and the departed spirits of good and bad men, are all under the controul of Him who governs the intellectual as well as material world by fixed and equal laws .- These details of superstition, however, will not be useless, if, by showing VOL. XIV. Part II.

how poor and wretched a creature man becomes when Necroman left to his own inventions, they shall make any one grateful for the benefits of good government, and the Nectarium. blessings of revealed religion.

NECROPOLIS, a suburb of Alexandria in Egypt. It signifies " the City of the Dead ;" wherein there were temples, gardens, and superb mausoleums. Here Cleopatra is said to have applied the aspic to her breast, to prevent being led in triumph by Augustus, who endeavoured to save her.

NECROSIS, rixgoris, in Medicine, a complete mortification of any part; called also sideratio and sphacelus.

NECTANEBUS, or NECTANABIS, a king of Egypt, who defended his country against the Persians. His grandson of the same name made an alliance with Agesilaus king of Sparta, and with his assistance he quelled a rebellion of his subjects. Some time after he was joined by the Sidonians, Phœnicians, and inhabitants of Cyprus, who had revolted from the king of Persia. This powerful confederacy was soon attacked by Darius the king of Persia, who marched at the head of his troops. Nectanehus, to defend his frontiers against so dangerous an enemy, levied 20,000 mercenary soldiers in Greece, the same number in Libya, and 60,000 were furnished in Egypt. This numerous body was not equal to the Persian forces, and Nectanebus, defeated in a battle, gave up all bopes of resistance, and fled into Ethiopia, where he found a safe asylum. His kingdom of Egypt became from that time tributary to the king of Persia.

NECTAR, among ancient poets, the drink of the fabulous deities of the heathens; in contradistinction from their solid food, which was called ambrosia.

NECTARINE, a fruit differing in nothing from the common peach, of which it is a species, but in having a smoother rind and a firmer pulp. See PER-SICA

NECTARIUM, from nectar, the fabled " drink of the gods ;" defined by Linnæus to be a part of the corolla, or appendage to the petals, appropriated for containing the honey, a species of vegetable salt under a fluid form, that oozes from the plant, and is the principal food of bees and other insects.

Notwithstanding this definition, which seems to consider the nectarium as necessary a part of the corolla as the petals, it is certain that all flowers are not provided with this appendage, neither indeed is it essential to fructification.

There is, besides, a manifest impropriety in terming the nectarium a part of the corolla. Linnæus might, Milne's with equal propriety, have termed it a part or appen-Bot. Dict. dage of the stamina, calyx, or pointal, as the appearance in question is confined to no particular part of the flower, but is as various in point of situation as of form. The truth is, the term nectarium is exceedingly vague ; and, if any determinate meaning can be affixed to it, is expressive of all the singularities which are observed in the different parts of flowers.

The tube, or lower part of flowers with one petal, Linnæus considers as a true nectarium, because it is generally found to contain the sweet liquor formerly mentioned. This liquor Pontedera compares to that called amnios in pregnant animals, which enters the fertile or impregnated seeds : but that this is not at 5 B least

Nectarium least its sole use, is evident from this circumstance, that the honey or liquor in question is to be found in flowers where there are either no seeds, or those which, from the want of male organs, eannot be impregnated. Thus the male flowers of nettle and willow, the female flowers of sea-side laurel and black bryony, the male and female flowers of clutia, kiggelaria, and butcher's broom, all abound with the honey or nectar alluded

Vaillant was of opinion, that the neetarium was an essential part of the corolla ; for which reason he distinguished the singular appearances in fennel flower and columbine by the name of petals : the coloured leaves which are now termed the petals he denominates the flower cup.

That the nectarium, however, is frequently distinct from the petals, is evident both from the well known examples just mentioned, as likewise from the flowers of monkshood, hellebore, isopyrum, fennel flower of Crete, barrenwort, grass of Parnassus, choeolate nut, cherleria, and sauvagesia.

These general observations being premised, we proceed to take a nearcr and more particular view of the principal diversities, both in form and situation, of this striking appendage to the flower. I. In many flowers the nectarium is shaped like a spur or horn; and that either in flowers of one petal, as valerian, water milfoil (utricularia), butterwort, and calves-snout; or in such as have more than one, as larkspur, violet, fumitory, balsam, and orchis. 2. In the following plants, the nectarium is properly a part of the eorolla, as lying within the substance of the petals : ranuneulus, lily, iris, crown imperial, water leaf, mouse tail, ananas, or pine apple, dog's-tooth violet, piperidge bush, vallisneria, hermannia, uvularia, and swertia. 3. The nectarium is frequently placed in a series or row within the petals, though entirely unconnected with their substance. In this situation it often resembles a cup, as in narcissus. A nectarium of this kind is said by Linnæus to crown the corolla. The following are examples : daffodil, sea daffodil, campion, viscous campion, swallow-wort, stapelia, cynanchum, nepenthes, cherleria, balsam-tree, African spiraa, witch-hazel, olax, and passion-flower. 4. In Indian-cross, buckler, mustard, Barbadocs cherry, and monotropa, the nectarium is situated upon or makes part of the calyx. 5. The nectarium in bastard flower-fence is scated upon the autheræ or tops of the stamina ; whenee the name adenanthera, or glandular anthera, which has been given to this genus of plants. In the following list it is placed upon the filaments ; bean-caper, bay, fraxinella, marvel of Peru, bell-flower, lead-wort, roella, and commelina. 6. In hyacinth, flowering-rush, stock July flower, and rocket, the neetarium is placed upon the seed-bud. 7. In honey-flower, orpine, buckwheat, collinsonia, lathræa, navelwort, mereury, elutia, kiggelaria, sea-side laurel, and African spirzea, it is attached to the common receptacle. Lastly, In ginger, nettle, dyer's weed, heart seed, costus, turmeric, grewia, bastard orpine, vanelloe, shew-tree, and willow, the nectarium is of a very singular construction, and cannot properly fall under any of the foregoing heads.

In discriminating the genera, the neetarium often furnishes an essential character.

Plants which have the nectarium distinct from the

5

petals, that is, not lodged within their substance, are Nectarium affimed by Linnæus to be generally poisonous. The following are adduced as examples : monkshood, helle- Needham. bore, columbine, fennel-flower, grass of Parnassus, bar-ren-wort, oleander, marvel of Peru, bean-caper, sueeulent swallow-wort, fraxinella, and honey-flower.

NECUIA, in Botany, a name given by the aneient Greeks to a species of mullein.

The Greeks and Romans both used the stalks of a pceuliar kind of mullein, called thryallis by Nicander, for the making of wicks of lamps. We have a kind of mullein called lychnites, and candle-wick mullein, from the Augures of Dioseorides; but it is not certain that ours is the same plant.

The ancients used the stalks of many different plants for the wicks of their candles and lamps. The rush, stripped of its bark, was as commonly in use with them as with us for that purpose ; and they also used the nettle, this mullein, and many other plants, whose stalks were composed of tough filaments, for the same purpose; beating them out like hemp, and when dry dipping them in melted resin, and other such inflammable substances. When thus prepared, they are readily inflammable, like our flambeau ; and this mullein, having stalks more long and large, and more firm than all the others, was used to make those lights with which they set fire to the funcral pile, for consuming the ashes of their dead friends.

NECYDALIS, a genus of inscets belonging to the order of colcoptera. See ENTOMOLOGY Inder.

NEEDHAM, JOHN TUBERVILLE, was born at London the 10th of September in the year 1713. His parents were descended from ancient and noble famil'es. His father, who had onee possessed a considerable patrimony at Hilston, in the county of Monmouth, was of the younger and Catholic branch of the Needham family: the head of the elder and Protestant branch was Lord Kilmory, created viseount in the year 1625. The father of Mr Needham died young, and left but a small fortune to his four children. His eldest son, who is the subject of this article, prosecuted his studies under the secular clergy of the English college of Douay, where he took orders, taught rhetoric for several years, gave eminent proofs of sagacity and genius, and surpassed all the other professors of that seminary in the knowledge of experimental philosophy. In 1740, he was engaged by his superiors in the service of the English mission, and was entrustcd with the direction of the school erected at Twyford, near Winchester, for the education of the Roman Catholie youth. In 1744, he was appointed professor of philosophy in the English college at Lishon, where, on account of his bad health, he remained only 15 months. After his return, he passed several years at London and Paris, which were principally employed in microscopical observations, and in other branches of experimental philosophy. The results of these observations and experiments were published in the Philosophieal Transactions of the Royal Society of London in 1749, and in a volume in 12n10 at Paris in 1750; and an account of them was also given by M. de Buffon, in the first volumes of his Natural History. There was an intimate connexion between this illustrious French naturalist and Mr Needham: they made their experiments and observations together;

Needle.

Needham, gether ; though the results and systems which they deduced from the same objects and operations were totally different. Mr Needham was admitted to a place in the Royal Society of London in the year 1747, and in the Antiquarian Society some time after. From the year 1751 to 1767 be was chiefly employed in finishing the education of several English and Irish noblemen, by attending them as tutor in their travels through France, Italy, and other countries. He then retired from this wandering life to the English seminary at Paris, and in 1768 was chosen by the Royal Academy of Sciences in that city a corresponding member.

> When the regency of the Austrian Netherlands, in order to the revival of philosophy and literature in that country formed the project of an Imperial academy, which was preceded by the ercetion of a small literary society to prepare the way for its execution, Mr Necdham was invited to Brussels by Count Cobentzel and the president Neny, and was appointed successively chief director of both these foundations. He held this place, together with some ceclesiastical preferments in the Low Countries, until his death, which happened the 30th of December 1781. " His piety, temperance, and purity of manners (we follow the expressions of the abbé Mann) were eminent : his attachment to the doetrines and duties of Christianity was inviolable. His zealous opposition to modern infidels was indefatigable, and even passionate. His probity was untainted. He was incapable of every species of duplicity; his beneficence was universal, and his unsuspicious candour rendered him often a dupe to perfidy." These and other good qualities the panegyrist attributes to his deceased friend; and the learned authors of the Monthly Review, to whom Mr Needham was known, admit the justness of the panegyric. He was undoubtedly (say they), both an honest man and a worthy citizen; but though his death be a real loss to the literary world, yet he died seasonably for himself; for had he lived to see Joseph II. and the Great making so free with the paint, patches, and trinkets of the mother church, confiscating her lands, abolishing her convents, suppressing her holidays, introducing common sense into her worship, erecting political conductors to disperse the thunder of the Vatican, and achieving many other things in this style of improvement, it would have vexed full sore his feeling heart. For this honest man was narrow even to superstition and bigotry in his religious system; and we never knew a man in whom there was such an unaccountable mixture of implicit faith and philosophical curiosity as in Mr Needham. He was a keen and judicious observer of nature, had a peculiar dextcrity in confirming his observations by experiments, and he was always occupied (sometimes indeed with too much fancy and precipitation) in generalizing facts, and reducing them to his system. "His pen (says Abbć Mann) was neither remarkable for fecundity nor method : his writings are rather the great lines of a subject expressed with energy, and thrown upon paper in a hurry, than finished treatises." His works are well known both in Britain and in France.

> NEEDHAM, a town in Suffolk, 73 miles from London, stands on the Orwell, 9 miles from Ipswich. Its population in 1811 was 1301.

NEEDLE, a very common little instrument or uten-

sil made of steel, pointed at one end, and pierced at the Needle. other, used in sewing, embroidery, tapestry, &c.

Needles make a very considerable article in commerce, though there is scarce any commodity cheaper, the consumption of them being almost incredible .---The sizes are from Nº 1. the largest, to Nº 25, the smallest. In the manufacture of needles, German and Hungarian steel is of most repute.

In the making of them, the first thing is to pass the steel through a coal fire, and under a hammer, to bring it out of its square figure into a cylindrical one. This done, it is drawn through a large hole of a wire-drawing iron, and returned into the fire, and drawn through a second hole of the iron smaller than the first; and thus successively from hole to hole, till it has acquired the degree of fineness required for that species of needles; observing 'every time it is to be drawn, that it be greased over with lard, to render it more manageable. The steel, thus reduced to a fine wire, is cut in pieces of the length of the needles intended. These pieces are flattened at one end on the anvil, in order to form the head and eye : they are then put into the fire to soften them farther; and thence taken out and picreed at each extreme of the flat part on the anvil, by force of a puncheon of well-tempered steel, and laid on a leaden block to bring out, with another puncheon, the little piece of steel remaining in the eye. The corners are then filed off the square of the heads, and a little eavity filed on each side of the flat of the head ; this done, the point is formed with a file, and the whole filed over: they are then laid to heat red hot on a long narrow iron, crooked at one end, in a charcoal fire; and when taken out thence, are thrown into a bason of cold water to harden. On this operation a good deal depends; too much heat burns them, and too little leaves them soft ; the medium is learned by experience. When they are thus hardened, they are laid in an iron shovel, on a fire more or less brisk in proportion to the tbickness of the needles; taking eare to move them from time to time. This serves to temper them, and take off their brittleness; great care here too must be taken of the degree of heat. They are then straightencd one after another with the hammer, the coldness of the water used in hardening them, having twisted the greatest part of them.

The next process is the polishing them. To do this, they take 12,000 or 15,000 needles, and range them in little heaps against each other on a piece of new buckram sprinkled with emery dust. The needles thus disposed, emery dust is thrown over them, which is again sprinkled with oil of olives; at last the whole is made up into a roll, well bound at both ends. This roll is then laid on a polishing table, and over it a thick plank loaded with stones, which two men work backwards and forwards a day and a half, or two days, successively; by which means the roll thus continually agitated by the weight and motion of the plank over it, the needles withinside being rubbed against each other with oil and emery, are insensibly polished. After polishing they are taken out, and the filth washed off them with hot water and soap : they are then wiped in hot bran, a little moistened, placed with the needles in a round box, suspended in the air by a cord. which is kept stirring till the bran and needles be dry. The needles thus wiped in two or three different brans, 5 B 2 are

Needle. are taken out and put in wooden vessels, to have the good separated from those whose points or eyes have been broken either in polishing or wiping; the points are then all turned the same way, and smoothed with an emery stone turned with a wheel. This operation finishes them, and there remains nothing but to make them into packets of 250 each. Needles were first made in England by a native of India, in 1545, but the art was lost at his death; it was, however, recovered by Christopher Greening in 1560, who was settled with his three children, Elizabeth John, and Thomas, by Mr Damar, ancestor of the present Lord Milton, at Long Crendon in Bucks, where the manufactory has been carried on from that time to the present day.

Plate CCCLXIX. fig. 1.

• Dipping-NEEDLE, or Inclinatory Needle, a magnetical needle, so hung, as that, instead of playing horizontally, and pointing out north and south, one end dips, or inclines to the horizon, and the other points to a certain degree of elevation above it.

The dipping-needle was invented in the year 1576, by one Robert Norman, a compass-maker at Wapping. The occasion of the discovery, according to his own account, was, that it being his custom to finish and hang the needles of his compasses before he touched them, he always found, that immediately after the touch, the north-point would bend or incline downward, under the horizon; insomuch that, to balance the needle again, he was always forced to put a piece of wax on the south end as a counterpoise. The constancy of this effect led him at length to observe the precise quantity of the dip, or to measure the greatest angle which the needle would make with the horizon; and this at London he found to be 71° 50'. In 1723 Mr Graham made a great many observations on the dipping-needle, and found the angle to be between 74 and 75 degrees. Mr Nairn, in 1772 found it to be somewhat above 72°. It is not certain whether the dip varies, as well as the horizontal direction, in the same place. The triffing difference between Mr Norman and Mr Nairne would lead us to imagine that the dip was unalterable; but Mr Graham, who was a very accurate observer, makes the difference more considerable. It is certain, however, from a great number of experiments and obscrvations that the dip is variable in different latitudes, and that it increases in going northwards. It appears from a table of observations made with the marine dipping-needle in a voyage towards the north polc in 1733, that in lat. 60. 18. the dip was 75°; and in lat. 70. 45. it was 77° 52'; in lat. 80. 12. it was 81° 52'; and in lat. 80. 27. it was 82° 21/2.

Several authors have endeavoured to apply this discovery of the dip to the finding of the latitude; and Mr Bond attempted to apply it to the finding of the longitude also; but for want of observations and experiments he could not make any progress. The affair was farther prosecuted by Mr Whiston, who published a treatise on the longitude, and for some time imagined it was possible to find it exactly by means of the dip of the needle : yet he at last despaired of it, for the following reasons; I. The weakness of the magnetic power. 2. The concussion of the ship, which he found it exceedingly difficult to avoid so much as was necessary for the accuracy of the experiments. 3. The principal objection was an irregularity in the motions of all magnetic needles, both horizontal and dipping,

by which they, within the compass of about a degree, Needle, vary uncertainly backward and forward; even sometimes in a few hours time, without any evident cause. For a particular account of these variations, both of the horizontal and dipping needle, see the article VA-RIATION.

Mr Nairne made a dipping needle in 1772 for the Board of Longitude, which was used in the voyage towards the north pole. This is represented at fig. 2. Fig. 2. The needle AA is 12 inches long, and its axis, the ends BB of which are made of gold, alloyed with copper, rests on friction wheels CCCC, of four inches diamcter, cach end on two friction wheels; which whicels are balanced with great care. The ends of the axis of the friction wheels are likewise of gold alloyed with copper, and moved in small holes made in bell metal; and opposite to the ends of the axes of the ncedle and the friction wheels, arc flat agates, set in at DDD, finely polished. The magnetic needle vibrates within a circle of bell metal, EEE, divided into degrees and half degrees; and a line, passing through the middle of the needle to the ends, points to the divisions. The needle of this instrument was balanced before it was made magnetical; but by means of a cross, the ends of which are FFFF, (contrived by the reverend Mr Mitchell) fixed on the axis of the needle, on the arms of which are cut very fine screws to receive small buttons, that may be screwed nearcr or farther from the axis, the needles may be adjusted both ways to a great nicety, after being made magnetical, by reversing the poles, and changing the sides of the needle. GG are two levels, by which the line of o degrees of the instrument is set horizontal, by means of the four adjusting screws LLLL; H is the perpendicular axis, by which the instrument may be turned, that the divided face of the circle may front the east or west; to this axis may be fixed an index I, which points to an opposite line on the horizontal plate K when the instrument is turned half round; MMMM arc screws which hold the glass cover to keep the needle from being disturbed by the wind. When this needle is constructed for sca, it is suspended by an universal joint on a triangular stand, and adjusted vertically by a plumb line and button above the divided circle and the dovetail work at the upper 90; and the divisions on the circle are adjusted so as to be perpendicular to the horizon by the same plumb line, and an adjoining scrcw; and when it is adjusted, a pointer annexed to a screw, which scrves to move the divided circle, is fixed at the lowest 90. Whenever the instrument is used to find the dip, it must be so placed that the needle may vibrate exactly in the magnetic meridian.

Magnetical NEEDLE, in Navigation, a needle touched with a loadstone, and sustained on a pivot or centre; on which playing at liberty, it directs itself to certain points in or under the horizon; whence the magnetical needle is of two kinds, viz. horizontal or inclinatory. See the article MAGNET.

Horizontal needles are those equally balanced on each side of the pivot that sustains them, and which, playing horizontally with their two extremes, point out the north and south points of the horizon. For their application and use, see the article COMPASS.

In the construction of the horizontal needle, a piece of pure steel is provided; of a length not exceeding six inches,

Needle. inches, lest its weight should impede its volubility; very thin, to take its verticity the better; and not pierced with any holes, or the like, for ornament sake, which prevent the equable diffusion of the magnetic virtue. A perforation is then made, in the middle of its length, and a brass cap or head soldered on, whose inner cavity is conical, so as to play freely on a style or pivot headed with a fine steel point. The north point of the needle in our hemisphere is made a little lighter than the southern; the touch always destroying the balance, if well adjusted before, and rendering the north end heavier than the south, and thus occasioning the needle to dip.

The method of giving the needle its verticity or directive faculty has been shown already under the article MAGNET; but if, after touching, the needle be out of its equilibrium, something must be filed off from the heavier side, till it balance evenly.

Needles in sea compasses are usually made of a rhomboidal or ohlong form; we have given their structure already under the article COMPASS.

The needle is not found to point precisely to the north, except in very few places; but deviates from it more or less in different places, and that too at different times; which deviation is called its declination or variation from the meridian. See the article VARIA-TION.

Surgcons NEEDLES are generally made crooked, and their points triangular; however, they are of different forms and sizes, and bear different names, according to the nurposes they are used for.

The largest are needles for amputation; the next, needles for wounds; the finest, needles for sutures. They have others, very short and flat, for tendons; others, still shorter, and the eye placed in the middle, for tying together of vessels, &c. Needles for couching cataracts are of various kinds; all of which have a small, broad, and sharp point or tongue, and some with a sulcus at the point. Surgeons have sometimes used two needles in this operation; one with a sharp point for perforating the coats of the eye, and another with a more obtuse point for depressing or conching the opaque crystalline lens; but care should be taken in the use of any of these, that they be first well polished with cloth or leather, before they are applied to the eye.

Mr Warner observes, that the blade of the couching needle should be at least a third part larger than those generally used upon this occasion, as great advantages will be found in the depressing of the cataract, by the increased breadth of the blade of that instrument. The handle, also, if made somewhat shorter than usual, will enable the operator to perform with greater steadiness than he can do with a larger handled instrument.

It is to be observed, that needles of silver pierce more easily in stitching arteries after an amputation, than those made of steel.

NEEDLE Fish. See SYNGNATHUS, ICHTHYOLOGY Index.

NEEDLES, sharp pointed rocks north of the isle of Wight. They are situated at the western extremity of the island, which is an acute point of high land, from which they have been disjoined by the washing of the

sea. There were of these lofty white rocks formerly Needle three, but about 14 years ago the tallest of them, called Lot's Wife, which rose 120 feet above low water Negative. mark, and in its shape resembling a needle, being undermined by the constant efforts of the waves, was thrown down, and totally disappeared.

NEEDS, or St NEOTS, six miles from Huntingdon, 58 miles from London, so called from the monument of a saint of that name in it, who was burnt by the Dancs, is a large well built town, having a handsome strong church, with a very fine steeple, and a stone bridge over the Ouse. Its population in 1811 was 1988.

NEEDWOOD FOREST, in Staffordshire, between the Trent, Dove, and Blythe, and near Utoxeter, is said to exceed all the forests in England in the excellence of its soil and the fineness of its turf.

NE EXEAT REGNO, in Law, is a writ to restrain a person from going out of the kingdom with-out the king's license. F. N. B. 85. It may be directed to the sheriff, to make the party find surety that he will not depart the realm, and on refusal to commit him to prison : or it may be directed to the party himself; and if he then goes, he may be fined. And this writ is granted on a suit being commenced against a man in the chancery, when the plaintiff fears the defendant will fly to some other country; and thereby avoid the justice and equity of the court ; which hath been sometimes practised : and when thus granted, the party must give bonds to the master of the rolls, in the penalty of 1000l. or some other large sum, for yielding obedience to it; or satisfy the court, by answer, affidavit, or otherwise, that he hath no design of leaving the kingdom, and give security.

NEFASTI DIES, in Roman antiquity, an appellation given to those days wherein it was not allowed to administer justice, or hold courts. They were so called because non fari licebat, the prætor was not allowed to pronounce the three solemn words or formulas of the law, do, dico, addico, I give, I appoint, I adjudge. These days were distinguished in the calendar by the letter N. for nefastus ; or N. P. Nefastus Primo, when the day was only nefastus in the forenoon, or first part. The days of a mixed kind were called intercisi.

NEGAPATAN, a town of Asia, in the peninsula on this side the Ganges, and on the coast of Coromandel. It was first a colony of the Portuguese, but was taken from them by the Dutch, and now forms part of the British territory. It is situated in E. Long. 79. 10. N. Lat. 11. 15.

NEGATION, in Logic, an act of the mind affirming one thing to be different from another; as that the coul is not matter. Sce LOGIC.

NEGATIVE, in general, something that implies a negation: thus we say, negative quantities, negative powers, negative signs, &c.

NEGATIVE Sign. The use of the negative sign, in algebra, is attended with several consequences that at first sight are admitted with difficulty, and has sometimes given occasion to notions that seem to have no real foundation. This sign implies, that the real value of the quantity represented by the letter to which it is prefixed is to be subtracted ; and it serves, with the positive sign, to keep in view what elements or parts enter into the composition of quantities, and in what

Negative what manner, whether as increments or deciements, (that is, whether by addition or subtraction), which is Signs. of the greatest use in this art.

In consequence of this, it serves to express a quantity of an opposite quality to the positive, as a line in a contrary position; a motion with an opposite direction; or a centrifugal force in opposition to gravity; and thus often saves the trouble of distinguishing and demonstrating separately, the various cases of proportions, and preserves their analogy in view. But as the proportions of lines depend on their magnitude only, without regard to their position, and motions and forces are said to be equal or unequal, in any given ratio, without regard to their directions; and, in general, the proportion of quantity relates to their magnitude only, without determining whether they are to be considered as increments or decrements; so there is no ground to imagine any other proportion of -band +a (or of -1 and 1) than that of the real magnitude of the quantities represented by b and a, whether these quantities arc, in any particular case, to be added or subtracted. It is the same thing to subtract the decrement, as to add an equal increment, or to subtract -b from a-b, as to add +b to it : and because multiplying a quantity by a negative number implies only a repeated subtraction of it, the multiplying -b by -n, is subtracting -b as often as there are units in n; and is therefore equivalent to adding +b so many times, or the same as adding +n b. But if we infer from this, that I is to -n as -b to n b, according to the rule, that unit is to one of the factors as the other factor is to the product, there is no ground to imagine, that there is any mystery in this, or any other meaning than that the real magnitudes represented by \mathbf{I}, n, b , and n b are proportional. For that rule relates only to the magnitude of the factors and product, without determining whether any factor, or the product, is to be added or subtracted. But this likewise must be dctermined in algebraic computations; and this is the proper use of the rules concerning the signs, without which the operation could not proceed. Because a quantity to be subtracted is never produced in composition by any repcated addition of a positive, or repeated subtraction of a negative, a negative square number is never produced by composition from the root. Hence $\sqrt{-1}$, or the square root of a negative, implies an imaginary quantity; and in resolution, is a mark or character of the impossible cases of a problem, unless it is compensated by another imaginary symbol or supposition, when the whole expression may have a real sig-Thus $1 + \sqrt{-1}$, and $1 - \sqrt{-1}$, taken nification. separately, are imaginary, but their sum is 2; as the conditions that separately would render the solution of a problem impossible, in some cases destroy each others effect when conjoined. In the pursuit of general conclusions, and of simple forms representing them, expressions of this kind must sometimes arise where the imaginary symbol is compensated in a manner that is not always so obvious.

By proper substitutions, however, the expression may be transformed into another, wherein each particular term may have a real signification as well as the whole expression. The theorems that are sometimes briefly discovered by the use of this symbol, may be demon-

in the computations by the method of fluxions, its cvidence cannot be said to depend upon arts of this kind. See ALGEBRA and FLUXIONS.

other way; and though such symbols are of some use

NEGINOTH. This term is read before some of the Psalms, as Psalm lxvii. It signifies string instruments of music, to be played on by the fingers, or women musicians; and the titles of these Psalms where this word is found; may be thus translated, A psalm of David to the master of music, who presides over the string instruments.

NEGOMBO, a sea port town of Asia, on the west coast of Ceylon. It has a fort built by the Portuguese, which was taken from them by the Dutch in 1640. E. Long. 80. 25. N. Lat. 17. 0.

NEGRIL POINT, the most westerly promontory of the island of Jamaica.

NEGRO, Homo pelli nigra, a name given to a variety of the human species, who are entirely black, and are found in the torrid zone, especially in that part of Africa which lies within the tropics. In the complexion of Negroes, we meet with many various shades; but they likewise differ far from other men in all the features of their face. Round cheeks, high cheek-bones, a forehead somewhat elevated, a short, broad, flat nose, thick lips, small cars, ugliness, and irregularity of shape, characterize their external appcarance. The negro women have the loins greatly depressed, and very large buttocks, which gives the back the shape of a saddle. Vices the most notorious seem to be the portion of this unhappy race; idleness, treachery, revenge, cruelty, impudence, stealing, lying, profanity, debauchery, nastiness, and intemperance, are said to have extinguished the principles of natural law, and to have silenced the reproofs of conscience. They are strangers to every sentiment of compassion, and are an awful example of the corruption of man when left to himself.

The origin of the negroes, and the cause of their remarkable difference from the rest of the human spccies, has much perplexed the naturalists. Mr Boyle has observed, that it cannot be produced by the heat of the climate : for though the heat of the sun may darken the colour of the skin, yet experience does not show that it is sufficient to produce a new blackness like that of the negroes.

In Africa itself, many nations of Ethiopia are not black; nor were there any blacks originally in the West Indics. In many parts of Asia under the same parallel with the African region inhabited by the blacks, the people are but tawncy. He adds, that there are negrocs in Africa beyond the southern tropic; and that a river sometimes parts nations, one of which is black, and the other only tawney. Dr Barriere alleges that the gall of negroes is black, and being mixed with their blood is deposited between the skin and scarf-skin. However, Dr Mitchell of Virginia, in the Philosophical Transactions, Nº 476, has endeavoured. by many learned arguments to prove, that the influence of the sun in hot countries, and the manner e life of their inhabitants, are the remote causes of the colour of the negroes, Indians, &c. Lord Kamer
Negro. on the other hand, and such philosophers as he, whose genius and imagination are too lively to submit to a dry and painful investigation of facts, have contended that no physical cause is sufficient to change the colour, and what we call the regular features of white men, to the dark hue and deformity of the woollyheaded negro. Their arguments have been examined with much acuteness and ingenuity by Dr Stanhopc Smith of New Jersey, Dr Hunter, and Professor Zimmerman, who have made it in a high degree probable, that the action of the sun is the original and chief cause of the black colour, as well as distorted features of the negro. See AMERICA, Nº 48-51. and COMPLEXION.

True negroes are found in no quarter of the globe where the heat of the climate is not very great. They exist nowhere but in the torrid zone, and only in three regions situated in that zonc, viz. in Senegal, in Guinea, and on the western shores of Africa, in Nubia, and the Papous land, or what is called New Guinea. In all these regions the atmosphere is scorching, and the heat excessive. The inhabitants of the north are whitest ; and as we advance southwards towards the line, and those countries on which the sun's rays fall more perpendicularly, the complexion gradually assumes a darker shade. And the same men, whose colour has been rendered black by the powerful action of the sun, if they remove to the north, gradually become whiter (at least their posterity), and lose their burnt colour. Whites when transported into the burning regions of the torrid zone, are the first subject to fever; the skin of the face, hands, and feet, becomes burnt, hardens. and falls off in scales. Hitherto the colour of negrocs appears to be only local, extrinsic, and accidental, and their short frizzled and sparse hair is to be accounted for in the very same manner.

Climate possesses great and evident influences on the hair, not only of men, but of all other animals. If in. one case these transmutations are acknowledged to be consistent with identity of kind, they ought not in the other to be estecmed criterions of different species. Nature has adapted the pliancy of her work to the situations in which she may require it to be placed. The beaver and sheep removed to the warm latitudes exchange, the one its fur, and the other its wool, for a coarse hair that preserves the animal in a more moderate temperature. The coarse and black shag of the bear is converted, in the arctic regions, into the finest and whitest fur. The colour of the hair is likewise changed by climate. The bcar is white under the arctic circle; and, in high northern latitudes, foxes, hares, and rabbits, arc found white. Similar effects of climate are discernible on mankind. The hair of the Danes is generally rcd; of the English, fair or brown; and of the French, commonly black. The hair of all people of colour is black, and that of the African negroes is likewise sparse and curled in a manner peculiar to themselves; but this peculiarity is analogous to the effect which a warm climatc has on almost every other animal. Cold, by obstructing the perspiration, tends to throw out the perspirable matter accumulated at the skin in an additional coat of hair. A warm climate, by opening the pores, eyaporates this matter before it can be concreted into the substance of hair; and the laxness and aperture of the pores render the hair liable to be easily eradicated by innumerable incidents. Its curl may result Negro. in part from the nature of the secretion by which it is nourished, and in part from external heat. That it depends in some degree on the quality of the secretion is rendered highly probable from its appearance on the chin and other parts of the human body. Climate is as much distinguished by the nature and proportion of the secretions as by the degree of heat. (See PHYSIOLO-GY, sect. 6.). Whatever be the nutriment of the hair, it is evidently combined in the torrid zone of Africa with some fluid of a highly volatile or ardent quality. which produces the rank smell of many African nations. Saline secretions tend to curl and to burn the hair. The evaporation of any volatile spirit would render its surface dry and disposed to contract ; whilst the centre continuing distended by the vital motion, these opposite dilatations and contractions would necessarily produce a curve, and make the hair grow involved. External and violent heat parching the extremitics of the hair, tends likewise to involve it. A hair held near the fire in-stantly coils itself up. Africa is the hottest country on the globe; and the influence of its heat, either external or internal, or both, in giving the peculiar form to the hair of the natives, appears, not only from its sparseness and its curl, but from its colour. It is not of a shining, but of an adust black; and its extremities tend to brown, as if it had been scorched by the fire.

The poculiarities of the negro features and form may likewise be accounted for from the excessive heat of the climate and the state of African society. Being savages, they have no arts to protect them from the rays of a burning sun. The heat and screnity of the sky preserving the lives of the children without much care of the parents, they seem of course to be, in the interior parts of the country, negligent of their offspring. Able themselves to endure the extremes of that ardent climate, they inure their children to it from their most tender age. They suffer them to roll in the dust and sand bcneath the direct rays of a vertical sun. The mother, if she be engaged, lays down the infant on the first spot. she finds, and is seldom at the pains to seek the miserable shelter of a barren shrub, which is all that the interior country affords. When we reflect on the influence of a glare of light upon the eye, and on the contortions of countenance produced by our efforts to repel or prevent it, we need not wonder, that the pliant features of a negro infant should, by constant exposure, acquire that permanent irregularity which we term their characteristic ugliness. But besides the climate, food and clothing and modes of life have prodigious effects. on the human form and features. This is apparent even in polished societies, where the poor and labouring part of the community are much more coarse in their features, and ill formed in their limbs, than persons of better fortune and more liberal means of subsistence. What an immense difference exists in Scotland, for instance, between the chiefs and the commonalty of the Highland clans? If they had been separately found in different countries, they would have been ranged by some philosophers under different species. A similar distinction takes place between the nobility and peasantry of. France, of Spain, of Italy, and of Germany.

That food and clothing, and the different modes of life, have as great an influence upon the shapes and features of the Africans as upon the natives of Europe, is evident

Negro.

evident from the different appearances of the negroes in the southern republics of America according to the stations in which they are employed. "The field slaves (says Dr Smith) are badly fed, clothed, and lodged. They live in small buts on the plantations, where they labour remote from the society and example of their superiors. Living by themselves, they retain many of the customs and manners of their African anecstors. The domestic servants, on the other hand, who are kept near the persons, or employed in the families of their masters, are treated with great lenity ; their service is light; they are fed and elothed like their superiors; they see their manners, adopt their habits, and insensibly receive the same ideas of elegance and beauty. The field slaves are, in consequence, slow in changing the aspect and figure of Africa. The domestic servants have advanced far before them in acquiring the agreeable and regular features, and the expressive countenance of civil society. The former are frequently ill-shaped. They preserve, in a great degree, the African lips, nose, and hair. Their genius is dull, and their coun. tenance sleepy and stupid. The latter are straight and well proportioned ; their hair extended to three, four, and sometimes even to six or eight inches; the size and shape of the mouth handsome, their features regular, their capacity good, and their look animated."

Upon the whole, we hope that the reader, who shall . candidly weigh in his own mind what we have said at present and under the article COMPLEXION, will agree with us, that the black colour in the torrid zone, the sparse crisp hairs of the negroes, and the peculiarities of their features and form, proceed from causes altogether extrinsie; that they depend on local temperature and the state of society; and that they are as accidental as the various shades of colour which characterise the different nations of Europe. If the whites be considered as the stock whence all others have sprung, it is easy to conceive how they have degenerated into negroes. Some have conjectured that the complete change may have taken place at the end of three centuries, whilst others have thought that it could not be effected in less than double that period. Such conjectures can be formed from no certain data; and a much greater length of time is undoubtedly necessary before negroes, when transplanted into our temperate countries, can entirely lose their black colour. By crossing the breed with whites, every taint of the negro colour may be expelled we believe, from the fifth generation (A).

But the most serious charge brought against the poor negroes is, that of the viccs said to be natural

to them. If they be, indeed, such as their enemies Negro. represent them, treacherous, crucl, revengeful, and intemperate, by a necessity of *nature*, they must be a different race from the whites; for though all these vices abound in Europe, it is evident that they proceed not from nature, but from wrong education, which gives to the youthful mind such deep impressions as no future exertions can completely eradicate. Let us inquire coolly if the vices of the negroes may not have a similar origin.

In every part of Africa with which the nations of Europe have any commerce, slavery prevails of the worst kind. Three-fourths of the people are slaves to the rest, and the children are born to no other inheritance. " Most parts of the coast differ in their go- Edwards's vernments ; some are absolute monarchies, whilst others History of draw near to an aristocracy. In both the authority of the West the chief or chiefs is unlimited, extending to life, and it Indies, is exercised as often as criminal cases require, unless vol. ii. death is commuted into slavery ; in which case the offender is sold, and if the shipping will not buy the eriminal, he is immediately put to death. Fathers of free condition have power to sell their children, but this power is very seldom enforced. In Congo, however, a father + will sell a son or daughter, or perhaps both, + Mod. for a piece of cloth, a collar or girdle of coral or beads, Univer. and often for a bottle of wine or brandy. A husband History, may have as many wives as he pleases, and repudiate or vol. xin. even sell them, though with child, at his pleasure. The P. 55wives and concubines, though it be a capital crime for the former to break the conjugal faith, have a way to rid themselves of their husbands, if they have set their affections upon a new gallant, by accusing them of some crime for which the punishment is death. In a word, the bulk of the people in every state of Africa are born slaves to great men, reared as such, held as property, and as propety sold (see SLAVERY). There Edwards's are indeed many circumstances by which a free man History of may become a slave: such as being in debt, and not the West able to pay; and in some of such cases, if the debt be Indics. large, not only the debtor, but his family likewise, become the slaves of his creditor, and may be sold. Adultery is commonly punished in the same manner, both the offending parties being sold, and the purchase-money paid to the injured husband. Obi, or pretended witchcraft (in which all the negroes firmly believe, see WITCHCRAFT), is another, and a very common offence, for which slavery is adjudged the lawful punishment; and it extends to all the family of the offender. There are various other crimes which subject the offender and his

NC

⁽A) I. A white man with a negro woman, or negro man with a white woman, produce a mulatto, half white and half black, or of a yellow-blackish colour, with black, short frizzled hair. 2. A white man with a mulatto woman, or a negro with a mulatto woman, produce a *quadroon*, three-fourths white and one-fourth black, or three-fourths black and one-fourth white, or of a lighter yellow than the former. In America, they give the name of *cabres* to those who are descended from a black man and a mulatto woman, or a mulatto man and a black woman, who are three-fourths black and one-fourth white, and who are not so black as a negro, but blacker than a mulatto. 3. A white man with a quadroon woman, or a negro with a quadroon woman, produce a *mestizo*, seven-eighths white and one-eighth black, or seven-eighths black and one-eighth white. 4. A white man with a mestizo woman, or a negro with a mestizo woman, produce, the one almost a perfect white, the other almost a perfect black, called a *quinteroon*. This is the last gradation, there being no visible difference between the fair quinteroons and the whites : and the children of a white and quinteroon consider themselves as free from all taint of the negro race.

his children to be sold; and it is more than probable. Negro. that if there were no buyers, the poor wretches would be murdered without mercy.

> In such a state of society, what dispositions can be looked for in the people, but cruelty, treachery, and revenge? Even in the civilized nations of Europe, blessed with the lights of law, science, and religion, some of the lower orders of the community consider it as a very trivial crime to defraud their superiors ; whilst almost all look up to them with stupid malevolence or rancorous envy. That a depressed people, when they get power into their hands, are revengeful and cruel, the present age affords a dreadful proof in the conduct of the demagogues of a neighbouring nation; and is it wonderful that the negroes of Africa, unacquainted with moral principles, blinded by the cruellest and most absurd superstitions, and whose customs tend to eradicate from the mind all natural affection, should sometimes display to their lordly masters of Enropean extraction the same snirit that has been so generally displayed by the lower orders of Frenchmen to their ecclesiastics, their nobles, and the family of their murdered sovereign ! When we consider that the majority of the negroes groan under the cruellest slavery, both in their own country, and in every other where they are to be found in considerable numbers, it can excite no surprise that they are in general treacherous, cruel, and vindictive. Such are the caprices of their tyrants at home, that they could not preserve their own lives or the lives of their families for any length of time, but by a perpetual vigilance, which must necessarily degenerate, first into cunning, and afterwards into treachery ; and it is not conceivable that habits formed in Africa should be instantly thrown off in the West Indies, where they are the property of men whom some of them must consider as a different race of beings.

But the truth is, that the ill qualities of the negroes have been greatly exaggerated. Mr Edwards, in his valuable History of the West Indies, assures us that the Mandingo negroes display such gentleness of disposition and demeanor, as would seem the result of early education and discipline, were it not that, generally speaking, they are more prone to theft than any of the African tribes. It has been supposed that this propensity, among other vices, is natural to a state of slavery, which degrades and corrupts the human mind in a deplorable manner; but why the Mandingoes should have become more vicious in this respect than the rest of the natives of Africa in the same condition of life, is a question he cannot answer.

"The circumstances which (according to the same author) distinguish the Koromantyn or Gold Coast negroes from all others, are firmness both of body and mind; a ferociousness of disposition; but withal, activity, courage, and a stubbornness, or what an ancient Roman would have deemed an elevation of soul, which prompts them to enterprises of difficulty and danger, and enables them to meet death, in its most horrid shape, with fortitude or indifference. They sometimes take to labour with great promptitude and alacrity, and have constitutions well adapted for it; for many of them have undoubtedly been slaves in Africa. But as the Gold Coast is inhabited by various tribes, which are engaged in perpetual warfare and hostility with each other, there cannot be a doubt that many of the captives N EG

taken in battle, and sold in the European settlements, Negro. were of free condition in their native country, and perhaps the owners of slaves themselves. It is not wonderful that such men should endeavour, even by means the most desperate, to regain the freedom of which they have been deprived; nor do I conceive that any further circumstances are necessary to prompt them to action, than that of being sold into captivity in a distant country. One cannot surely but lament (says our author) that a people thus naturally intrepid, should be sunk into so deplorable a state of barbarity and superstition; and that their spirits should ever be broken down by the yoke of slavery. Whatever may be alleged concerning their ferociousness and implacability in their present notions of right and wrong, I am persuaded that

serve, cultivation and improvement. " Very different from the Koromantyns are the negroes imported from the Bight of Benin, and known in the West Indies by the name of Eboes. So great is their constitutional timidity and despondency of mind, as to occasion them very frequently to seck, in a voluntary death, a refuge from their own melancholy reflections. They require therefore the gentlest and mildest treatment to reconcile them to their situation ; but if their confidence be once obtained, they manifest as great fidelity, affection, and gratitude, as can reasonably be expected from men in a state of slavery. The females of this nation are better labourers than the men, probably from having been more hardly treated in Africa.

they possess qualities which are capable of, and well de-

" The natives of Whidah, who, in the West Indies, are generally called Papaws, are unquestionably the most docile and best disposed slaves that are imported from any part of Africa. Without the fierce and savage manners of the Koromantyn negroes, they are also happily exempt from the timid and desponding temper of the Eboes. The cheerful acquiescence with which these people apply to the labours of the field, and their constitutional aptitude for such employment, arise, without doubt, from the great attention paid to agriculture in their native country. Bosman speaks with rapture of the improved state of the soil, the number of villages, and the industry, riches, and obliging manners of the natives. He observes, however, that they are much greater thieves than those of the Gold Coast, and very unlike them in another respect, namely, in the dread of pain, and the apprehension of death. They are, say's he, so very apprehensive of death, that they are unwilling to hear it mentioned, for fear that alone should hasten their end; and no man dares to speak of death in the presence of the king, or any great man, under the penalty of suffering it himself, as a punishment for his presumption. He relates further, that they are addicted to gaming beyond any people of Africa. All these propensities arc observable in the character of the Papaws in a state of slavery in the West Indies. That punishment which excites the Koromantyn to rebel, and drives the Ebo negro to suicide, is received by the Papaws as the chastisement of legal authority, to which it is their duty to submit patiently. The case seems to be, that the generality of these people are in a state of absolute slavery in Africa, and, having been habituated to a life of labour, they submit to a change of situation with little reluctance."

5 C

Vol. XIV. Part II.

Having

Ne

Ne

Negro.

Having recited such observations as occurred to him on contemplating the various tribes of negroes from cach other, Mr Edwards thus estimates their general character, influenced as they are by circumstances which soon efface the native and original impressions which distinguish one nation from another when newly imported into the West Indies.

" Notwithstanding what has been related of the firmness and courage of the natives of the Gold Coast, it is certain that the negrocs in general in our islands (such of them at least as have been any length of time in a state of servitude) are of a distrustful and cowardly disposition. So degrading is the nature of slavery, that fortitude of mind is lost as free agency is restrained. To the same cause probably must be imputed their propensity to conceal or violate the truth; which is so general, that the vice of falsehood is one of the most prominent features in their character. If a negro is asked even an indifferent question by his master, he seldom gives an immediate reply; but, affecting not to understand what is said, compels a repetition of the question, that he may have time to consider, not what is the true answer, but what is the most politic one for him to give. The pronencess observable in many of them to the vice of theft has already been noticed; and I am afraid (says our author), that evil communication makes it almost general. It is no easy matter, I confess, to discriminate those circumstances which are the result of proximate causes, from those which are the effects of national customs and early habits in savage life; but I am afraid that cowardice and dissimulation have been the properties of slavery in all ages, and will continue to be so to the end of the world. It is a situation that necessarily suppresses many of the best affections of the human heart .- If it calls forth any latent virtues, they are those of sympathy and compassion towards persons in the same condition of life; and accordingly we find that the negroes in general are strongly attached to their countrymen, but above all, to such of their companions as came in the same ship with them from Africa. This is a striking circumstance : the term shipmate is understood among them as signifying a relationship of the most endcaring nature ; perhaps as recalling the time when the sufferers were cut off together from their common country and kindred, and awakening reciprocal sympathy from the remembrance of mutual affliction. But their benevolence, with a very few exceptions, extends no further. The softer virtues are seldom found in the bosom of the enslaved African. Give him sufficient authority, and he becomes the most remorseless of tyrants. Of all the degrees of wretchedness endured by the sons of men, the greatest, assuredly, is the misery which is felt by those who are unhappily doomed to be the slaves of slaves ; a most unnatural relation, which sometimes takes place in the sugar plantations. The same observation may be made concerning their conduct towards the animal creation. Their treatment of eattle under their direction is brutal beyond belief. Even the useful and social qualities of the dog secure to him no kind usage from an African master. One of the most pleasing traits in their character is the respect and attention which they pay to their aged countrymen. The whole body of negroes on a plantation must be reduced to a deplorable state of wretchedness, if at any time, they suffer their aged

companions to want the common necessaries of life, or Negro, even many of its comforts, as far as they can procure Negroland. them. They seem to be actuated on these occasions by a kind of involuntary impulse, operating as a primitive law of nature, which scorns to wait the cold dictates of reason : among them, it is the exercise of a common duty, which courts no observation, and looks for no applause.⁷⁹

As the colour and features, and moral qualities of the negroes, may be thus easily accounted for by the influence of climate and the modes of savage life, so there is good reason to believe that their intellectual endowments are equal to those of the whites who have been found in the same circumstances. Of these imitative arts in which perfection can be attained only in an improved state of society, it is natural to suppose that they have but little knowledge; but the fabric and colours of the Guinca cloths arc a proof of their native ingenuity. In the West Indies many of them are expert carpenters, some watchmakers, and one or two have successfully practised physic; while others have figured both in Latin and English poetry, so that we cannot doubt but that "God, who made the world, hath made of one blood all nations of men," and animated them with minds equally rational.

NEGROLAND, or NIGRITIA, a country of Africa, lying next to Gninea towards the north, and cxtending from 18° of west to 23° of east longitude, and from 9° to 20° of north latitude. On the north it is bounded by Zaara or the Desert; on the cast, by countries unknown; on the south, by Guinea; and on the west, by the Atlantic ocean; and is watered by the great river Niger or Senegal, which runs through it from cast to west. The Europeans have settlements on the coasts of this country, especially near the mouths of the Niger and Gambia, which last is supposed to be a branch of the former. A great many nations inhabit the banks of the rivers; some Pagans, some Mohammedans, of different languages, and independent of one another. The country is fruitful, especially along the rivers; abounding in rice, Guinea grain, and Indian corn, where it is cultivated; and with cocoa nuts, plantains, pulse, palm trees, and tropieal fruits; nor is it destitute of cattle, and a variety of other animals, particularly such as abound in Guinea. See GUINEA.

Negroland is fertilized by the overflowing of its rivers the Senegal and Gambia, as Egypt is by the Nile. It hath not yet been ascertained whether the Gambia is a branch of the Senegal or not. As far as the Europeans have penetrated up the country, they appear to be distinct; and the Mandingo negroes report that the Gambia has a different origin. The entrance into Senegal river, is narrow and somewhat difficult, by reason of its immoveable bar, and sandy shoals, as well as the several islands at the mouth of it, and the several canals and marshes that clog it : but after sailing up cight or ten leagues, it is found broad and deep, and fit to carry large vessels; and, excepting about five or six leagues on each side above the month, which is sandy and barren ground, the banks are covered with stately trees and villages, and the country in general is fertile and well watered; for, like the Nile, this river overflows its banks for many leagnes, and enriches the land to a great degree,

Negroland gree, though, for want of skill, the inhabitants do not reap the advantages which they might obtain from Negropont, its fertility. The people on both sides of the river live as near to it as they can, and feed great herds of eattle, sowing large and small millet, the former of which is called by us *Turkey wheat*, in great quantities, and with great increase. If the river fails of overflowing at its usual season, a great scarcity ensues in the adjacent country; and, even when it overflows regularly, it breeds such vast flights of grashoppers and insects, as quite darken the air, and frequently devour the whole produce of the soil : in which ease the people kill those insects and cat them; which they do either by pounding in leather bags, and then boiling them in milk, or which is reckoned the more delicions method, by frying or broiling them over a light blaze in a fryingpan full of holes. Thus the legs and wings of the insects are burnt off, and the rest of the body is sufficiently roasted to be eaten as a dainty, which they look upon to be very wholesome and nourishing.

> To the east, north-east, and south-east of the island of Senegal, the country, as far as it is known, is overrun with woods and marshes : the Senegal, Gambia, and Sherhro, passing through it in their way to the Atlantic ocean. The Niger rises near the Senegal, and runs eastward, but its termination is unknown. During the rainy months, which begin in July, and continue to October, they lay the whole country under water; and indeed the sudden rise of these rivers is incredible to such as are not acquainted with the violent rains that fall hetween the tropies. At Galam, 900 miles from the mouth of the Scnegal, the waters rise 1 50 feet perpendicular from the bed of the river. At the island of Senegal, the river rises gradually, during the rainy season, above 20 feet perpendicular over part of that flat coast; which of itself, so freshens the water that ships lying at anchor, at the distance of three leagues from its mouth, generally make use of it, and fill their water there for their voyage home. When the rains are at an end, which soon happens in Octoher, the intense heat of the sun usually dries up those stagnating waters which lie on the higher parts, and the remainder from lakes and marshes, in which are found all sorts of dead animals. At last, those too are quite dried up; and then the effluvia that arise are almost quite insupportable. At this season the winds blow so hot from the land, that they may be compared to the heat proceeding from the mouth of an oven, and they bring with them an intolerable smell. The wolves, tigers, lions, and other wild beasts, then resort to the river, steeping their body under water, and only their snout above it for the sake of breathing. The birds soar to an immense height in the air, and fly a vast way over the sea, where they continue till the wind changes, and comes from the west.

NEGROPONT, anciently Euboa, an island of the Archipelago, stretching along the eastern coast of Achaia or Livadia, from which it is separated by a narrow channel called the Euripus. This strait is so narrow, that the island is joined to the continent by a bridge thrown over it; and here, it is thought, there was formerly an isthmus. The irregularity of the tides

in the Euripus hath from the remotest antiquity been Negroponi, very remarkable, and this irregularity is found to be Nehemiah. connected with the age of the moon. From the three last days of the old moon to the eighth day of the new moon, and from the 14th to the 20th day inclusive, they are regular, but on the other days they are irregular, flowing 12, 13, or 14 times in the space of 24 hours, and ebbing as often. The island is 90 miles long and 25 broad in the widest part; and produces corn, oil, fruit, and cattle, in great abundance. The only place in the island worth notice is the capital, which is also ealled Negropont ; and which is walled, and contains about 15,000 inhabitants; but the Christians are said to be much more numerous than the Turks. The captain bashaw, or admiral of Turkey, who is also governor of the city, the island, and the adjacent continent of Greece, resides here : and the harbour, which is very safe and spacious, is seldom without a fleet of galleys, ready to be put to sea against the pirates and the Maltese. A part of the bridge between the city and the coast of Greece, consists of a draw bridge no longer than just to let a galley pass through.

NEHEMIAH, or NEEMIAS, son of Hachaliah, was born at Babylon during the eaptivity, (Neh. i. 1, 2, &c.). He was, according to some, of the race of the priests, but according to others, of the tribe of Judah and the royal family. Those who maintain the first opinion, support it by a passage in Ezra, (x. 10.) where he is called a priest ; but those who believe that he was of the race of the kings of Judah, say, 1st, That Ne-hemiah having governed the republic of the Jews for a considerable time, there is great probability he was of that tribe of which the kings always were. 2dly, Nehemiah mentions his brethren Hanani, and some other Jews, who coming to Babylon during the captivity, acquainted him with the sad condition of their country. 3dly, The office of cupbearer to the king of Persia, to which Nehemiah was promoted, is a further proof that he was of an illustrious family. 4thly, He excuses himself from entering into the inner part of the temple, probably because he was only a laie, (Neh. vi. 11.) "Should such a man as I flee? And who is there that, being as I am, would go into the temple to save his life ?"

The Scripture (Ezra ii. 63. Nehem. vii. 65.) calls him הרשחא tirshatha, that is to say, " eup-bearer;" for he had this employment at the court of Artaxerxes Longimanus. He had an exceeding great tenderness for the country of his fathers, though he had never seen it; and one day, as some Jews newly come from Jerusalem acquainted him with the miserable estate of that city, that its wall were beat down, its gates burnt, and the Jews were become a reproach among all nations; he was sensibly affected with this relation ; he fasted, prayed, and humbled himself before the Lord, that he would be favourable to the design he had then conceived of asking the king's permission to rebuild Jerusalem. The course of his attendance at court being come, he presented the cup to the king according to custom; but with a countenance sad and dejected; which the king observing, entertained some suspicion, as if he might have had some bad design ; but Nehemiah (ii.) discovering the occasion of his disquiet, Artaxerxes gave him leave to go to Jerusalem, and repair its walls and gates; but, however, upon this condition, that he 5 C 2 should

Yeh

Ne

-

Nehemials, should return to court at a time appointed. Letters were made out, directed to the governors beyond the Euphrates, with orders to furnish Nehemiah with timhers necessary for covering the towers and gates of the city, and the house designed for Nehemiah himself, who was now appointed governor of Judea, in the year of the world 3350.

Nehemiah being arrived at Jerusalem with the king's commission, went round the city; and having viewed the condition of the walls, assembled the chief of the people, produced his commission, and exhorted them to undertake the reparation of the gates and walls of the city. He found every person ready to obey him; The whereupon he immediately began the work. enemies of the Jews observing these works in such forwardness, made use of all the means in their power to deter Nehemiah from this undertaking, and made several attempts to surprise him; but finding that their designs were discovered, and that the Jews kept upon their guard, they had recourse to craft and stratagem, endeavouring to draw him into an ambuscade in the fields, where they pretended they would finish the dispute at an amicable conference : but Nehemiah gave them to understand, that the work he had begun required his personal attendance; and therefore he could not come to them. He seut the same answer to four several messages that they sent one after another on the same subjeet, (Id. iv. and vi.).

Sanballat, the chief of the enemies of the Jews, together with his associates, wrote word, that a report was spread that the Jews were building the walls of Jerusalem only with a design to make it a place of strength, to support them in an intended revolt; that it was said also that Nehemiah had suborned false prophets to fayour his designs, and to encourage the people to choose him king; and to stop the course of these rumours, he advised him to come to him, that they might confer together, and take such resolutions as should be found convenient. Nehemiah gave himself no trouble on this account, but returned for answer, that all those accusations were false and made at random. About the same time he discovered, that a false prophet called Shemaiah, had been corrupted by his enemies, and that some of the chief of the eity were secretly in confederacy with them. Yet all this did not discourage him; he went on with his work, and happily completed it in two and fifty days after it had been begun.

Then he made a dedication of the walls, of the towers, and of the gates of Jerusalem, with the solemnity and magnificence that such a work required. He separated the priests, the Levites, and the princes of the people, into two companies, one of which walked to the south and the other to the north, on the top of the walls. These two companies were to meet at the temnle. The procession was accompanied with music both voeal and instrumental: and when they were all come to the temple, they there read the law, offered sacrifices, and made great rejoicings. And as the feast of tabernacles happened at the same time, it was celebrated with great solemnity, (Id. viii.). Nehemiah observing that the compass of the city was too large for its inhabitants, he ordered that the chief of the nation should fix their dwelling in the city; and eaused them to draw lots, by which a tenth part of the whole people of Justah were to dwell at Jerusalem, (Id. xi.). Then he ap-

plied himself to the reformation of such abuses as had Nehemiah. crept into the administration of the public affairs. He curbed the inhumanity of the great ones, who held in a state of slavery the sons and daughters of those who were poor or unfortunate, keeping their lands in possession, which these poor people had been obliged either to mortgage or to sell to the rich. Another abuse there was, which Ezra had in vain attempted to redress, that they had contracted marriages with strange and idolatrous women. Nehemiah undertook to dissolve these marriages, succeeded in it, and sent away all such women as had been taken against the express command of the law, (Id. ix.). Having likewise observed, that the priests and Levites were obliged to take refuge whereever they could, and so the ministry of the temple was not attended or performed with that deceney it ought, because they did not receive the revenues that the law had appointed for their subsistence; he obliged the people punctually to pay the ministers of the Lord what was due to them, and enjoined the priests and Levites duly to attend on their respective duties, and to discharge their functions, (Id. xiii. 10, 11, &c.). He enforced the observation of the sabbath, which had been much neglected at Jerusalem, and would not permit strangers to come in to buy and sell, but kept the gates of the city shut all that day. And, to perpetuate as much as was possible these good regulations which he had newly established, he engaged the chief men of the nation solemnly to renew the covenant with the Lord. This ceremony was performed in the temple, and an instrument was drawn up, which was signed by the principal men, both priests and people (Id. ix. x.), in the year of the world 3551.

We read in the books of Maccabees (2 Macc. i. 19, 20, 21. &c.), that Nehemiah sent to search for the holy fire, which before the captivity of Babylon the priests had hid in a dry and deep pit; but not finding any fire there, but instead thereof a thick and muddy water, he sprinkled this upon the altar ; whereupon the wood which had been sprinkled with this water took fire presently as soon as the sun began to appear. Which miracle coming to the knowledge of the king of Persia, he caused the place to be encompassed with walls where the fire had been hid, and granted great favours and privileges to the priests. It is recorded in the same books, (2 Mace. ii. 13, 14.), that Nehemiah erected a library, wherein he placed whatever he could find, either of the books of the prophets, of David, or of such princes as had made presents to the temple. Lastly, he returned to Babylon (Id. v. 14. and xiii. 6.) according to the promise he had made to King Artaxerxes, about the thirty-second year of this prince, in the year 3563. From thence he returned again to Jerusalem, where he died in peace, about the year 3580, having governed the people of Judah for about thirty years.

The book which in the English Bible, as also in the Hebrew, has the name of *Nehemiah*, in the Latin Bible is called the book of *Esdras*; and it must be confessed, that though this author speaks in the first person, and though at first reading one would think that he had writ it day by day as the transactions occurred, yet there are some things in this book which could not have been written by Nehemiah himself; for example, memorials are quoted wherein were registered the names of

3

Nehemiah of the priests in the time of Jonathan the son of Eliashib, and even to the times of the high priest Jaddus, Nelson. who met Alexander the Great. These therefore must have been added afterwards.

> It may well be questioned, whether this Nehemiah be the same that is mentioned in Ezra, (ii. 2. and Nch. vii. 7.) as one that returned from the Babylonish captivity under Zerubbabel; since from the first year of Cyrus to the twentieth of Artaxerxes Longimanus, there are no less than nincty-two years intervening; so that Nehemiah must at this time have been a very old man, upon the lowest computation an hundred, consequently utterly incapable of being the king's cup-bearer, of taking a journey from Shushan to Jerusalem, and of behaving there with all the courage and activity that is recorded of him. Upon this presumption, therefore, we may conclude that this was a different person, though of the same name, and that Tirshatha (the other name by which he is called, Ezra ii. 63. and Neh. vii. 65.) denotes the title of his office, and both in the Persian and Chaldcan tongues was the general name given to the king's deputies and governors.

> NEHOW, one of the Sandwich islands, discovered by Captain Cook in his last voyage to the Pacific ocean : these islands are cleven in number, and are situated from 18° 44' to 22° 15' N. Lat. and from 154° 56' to 160° 24' W. Long.

> NEIGHBOUR, I. One who dwells or is seated near to another (2 Kings iv. 3.). 2. Every man to whom we have an opportunity of doing good (Matt. xxii. 39.). 3. A fellow labourer of one and the same people (Acts vii. 27.). 4. A friend (Job. xvi. 21.). At the time of our Saviour, the Pharisecs had restrained the word neighbour to signify those of their own nation only, or their own friends; being of opinion that to hate their enemy was not forbidden by their law. But our Saviour informed them, that the whole world were their neighbours; that they ought not to do to. another what they would not have done to themselves; and that this charity ought to be extended even to their enemies, (Matt. v. 43. Luke x. 29, &c.).

> NEISSE, a town of Silesia, containing 7000 people, and the residence of the bishop of Breslaw, who has a magnificent palace here. The air is very wholesome, and provisions are cheap; the inhabitants carry on a great trade in wine and linen. This place suffered greatly by an inundation and fire in 1729. It was taken by the Prussians in 1741, who augmented the fortifications, and built a citadel to which they gave the name of Prussia. It is seated on a river of the same name, in E. Long. 17. 35. N. Lat. 50. 32.

> NEIUS MONS, in Ancient Geography, at the foot of which stood Ithaca, a town of the island of that name, (Homer).

> NELSON, The Right Honourable VISCOUNT, one of the most celebrated naval commanders, was the son of the reverend Edmund Nelson, and was born at Burnham Thorpe, in Norfolk, where his father was rector, in the year 1758. He received his education at the school of North Walsham; but we are unacquainted with the particulars relative to his childhood, and whether the progress he made in his studies was in any respect extraordinary. It is certain, however, that he discovered 2 strong predilection for the naval profession at a very

early period, and having quitted school at the age of Nelsor. twelve years, went on board the Raisonable of 64 guns, commanded by his mother's brother, Captain Maurice Suekling.

In the month of April 1773, a voyage of discovery to the north pole was undertaken by the honourable Constantine John Phipps, afterwards Lord Mulgrave, in consequence of an application by the Royal Society to Lord Sandwich ; and although the instructions which were issued, prohibited all boys from being received on board, yet the enterprising spirit of Horatio Nelson earnestly solicited to be appointed eockswain to Captain Lutwidge, rather than submit to be left behind; and his unsubdued spirit so forcibly struck the captain, that his wish was complied with.

When the ship returned to England in the month of October 1773, Mr Nelson having received information that a squadron was fitting out for the East Indies, employed all his interest to be appointed to one of the ships. It was not long before he was placed in the Seahorse of 20 guns, commanded by the celebrated Captain Farmer, and stationed in the fore-top to keep watch, but soon after removed to the quarter-deck.

He obtained the professional order of lieutenant on the 8th of April, 1777, and received his commission the next day, as second of the Lowestoffe of 32 guns, Captain William Locker, in which ship he arrived at Jamaica; but feeling that his glowing mind was circumscribed in so small a frigate, he requested the command of a schooner, which acted as tender to the Lowestoffe, thus availing himself of the opportunity of becoming an experienced pilot for every intricate passage through the islands, situated on the northern side of Hispaniola.

When Sir Peter Parker arrived at Jamaica in the year 1778, Lientenant Nelson was nominated by that gallant admiral to be the third of his own flag ship, the Bristol, and by rotation soon became the first. In this ship his services terminated in the rank of a lieutenant.

On the 11th of June, 1779, he obtained the rank of post-captain; and during the nine years he had been in the service he not only became an able officer by his constant attention to every part of his duty, and his keen observation, but he also laid the foundation of being a pilot of distinguished eminence. The first ship to which he was appointed after being made a post captain, was the Hinchinbroke. On the arrival of Count. d'Estaign at Hispaniola, as an attack upon Jamaica was immediately apprehended, Captain Nelson was intrusted with the command of the batteries of Port-Royal, with the concurring approbation of the British admiral and general. In the menth of January 1780, it was resolved on to reduce Fort Juan, on the river St John. in the gulf of Mexico, when Captain Nelson was made choice of to command the naval department, and that of the military was committed to Major Polson. In accomplishing the object of this arduous and interesting undertaking, Nelson's usual intrepidity was again exhibited. Having quitted the ship under his command, he superintended the transporting of the troops in boats, 300 miles up a river, which none but Spaniards had ever navigated since the time of the buccaneers.

His great and vigorous exertions were represented by Major Polson to General Dalling in their true colours, nor

٦

Nelson. nor was his gallantry passed over by that officer in - silence. After storming an out-work belonging to the enemy, he constructed batteries, and fought the Spaniards; and it is to his conduct in the reduction of Fort Jnan that the success of Britain has been justly and chiefly ascribed. He was next appointed to the Janus, at that time stationed at Jamaica; on his arrival at which place every medical assistance was given him which his situation required ; but as his health still eontinued on the decline, he deemed it expedient to return to England in his majesty's ship Lion, the honourable William Cornwallis commander, to whose unremitting care and attention he owed the preservation of his life. He obtained the command of the Albemarle in the month of August 1781, which put his delieate constitution to the severest trial, as he was stationed during the whole of the ensuing winter in the north seas.

He sailed from Quebee in the month of October, 1782, with a convoy to New York, where he had an opportunity of joining the fleet under Sir Samuel Hood ; and in the month following he sailed with him to the West Indies, where he was honourably employed until the termination of hostilities. He soon after received orders to repair to England, being directed to attend in his way, his royal highness Prince William Henry on his visit to the Havannah. When he reached England, the Albemarle was paid off at Portsmouth on the 31st July, 1783. During the autumn of that year he paid a visit to France, where he continued till the spring of the ensuing year, when he received the command of the Borcas frigate of 28 guns, and his destination was the Leeward Islands, where he continued until June 1787, and was then ordered to repair to England. In the month of March the same year he was married to the amiable and accomplished widow of Dr Nesbit, of the island of Nevis. When the Boreas frigate was paid off at Sheerness on the 30th November, 1787, he retired to the parsonage-house of Burnham Thorpe, which had been conferred upon him by his father for a place of residence, there to enjoy the consolations which result from domestic felicity.

He again came forward on the 30th of January 1793, to shine forth more conspicuous as a naval officer than he had ever done before, at which time he received the command of the Agamemuon of 64 guns, being soon placed under the orders of that truly great and illustrious character, Lord Hood, who at that period was destined to command in the Mediterranean. The unlimited confidence reposed in him by this noble and gallant admiral, is an incontestable evidence of the high estimation in which his courage and naval abilities were held. If his superior designed to attack batteries, or cut ships out of the harbours in which they were moored; if troops were to be landed in perilous situations, or passages of extreme difficulty to be explored, the great Nelson took the lead on every such occasion, seconded by the brave officers and crew belonging to the Agamemuon. Toulon, Bastia, and Calvi, witnessed his gallant and intrepid deportment, of which Lord Hood did not fail to make honourable mention. At the siege of Calvi Captain Nelson lost the sight of his right eye, a shot from the battery of the enemy having struck that of which he had the command, and driven some partieles of sand against his face with irresistible impetuosity.

When Lord Hood left his station in the Mediter- Nelson, ranean in the month of October, 1794, the command devolved on Admiral Hotham, who honoured our hero with an equal share of his confidence and esteem. On the 13th and 14th of March, and 13th of July 1795, he again rendered himself conspicuous in the actions which then took place with the French fleet; and soon after he was chosen by Admiral Hotham to cooperate with General De Vins, on the coast of Genoa, in which service he continued so long as Hotham retained the command, who was superseded by Sir John Jervis. This officer so much applauded the conduct of Captain Nelson, that he received the honour of wearing a pendant of distinction ; and in the month of May he was removed from the Agamemnon to the Captain of 74 guns. On the 11th of August he had a captain appointed under him.

From April to October 1795, Commodore Nelson was continually employed in the most active and arduous service, the blockade of Leghorn, the taking of Porto Ferrajo, with the island of Caprea, and finally in the evacuation of Bastia. In Deecmber 1796 he hoisted his broad pendant on board La Minerve frigate, and was dispatched with that ship, and La Blanche, to Porto Ferrajo, to bring the naval stores left there to Gibraltar, which the fleet was in much want of. While on this service in the night of the 17th December, he fell in with two Spanish frigates, one of which he immediately attacked, and ordered the Blanche to bear down to engage the other. About half past ten the commodorc brought his ship to close action, which continued without interruption till half past one, when the Spanish frigate of 40 guns, 28 of which were 18 pounders, struck to La Minerve.

After various other active and important services during the three preceding months, Sir Horatio Nelson, in April 1797, hoisted his flag on board the Captain of 74 guns as rear-admiral of the blue, and in the end of May he shifted his flag from the Captain to the Theseus, when he was appointed to the command of the inner squadron at the blockade of Cadiz. While on this service he exhibited another remarkable proof of his undaunted personal eourage. In the attack on the Spanish gun-boats in July, he was boarded in his barge, which had only the usual complement of 10 men, and the coekswain. The commander of the Spanish gunboats, in a barge with 30 men and officers, made a desperate attack on the admiral and his brave companions. The conflict remained long doubtful, but after 18 of the Spaniards were killed, and almost the whole of the remainder wounded, the rear-admiral and his brave erew succeeded in carrying this superior force.

On the 15th of July the same year, Admiral Nelson was detached with a small squadron to attack the town of Santa Cruz in the island of Tenerifie. A thousand men, including marines, were landed in the course of a dark night, made themselves masters of the town, and retained possession of it for seven hours; but finding it impossible to storm the eitadel, they prepared for their retreat, which the Spaniards allowed them to make unmolested, agreeable to the stipulations which had been entered into. In this unfortunate attack the brave Nelson lost his arm by a eannon shot.

But a more splendid seene of the life of our hero is now opening. On the 13th of April 1798 he was detached

Nelson. tached from Earl St Vincent's fleet, in pursuit of the - French to the coast of Egypt, with 12 sail of the line and one 50 gun ship, while the enemy's fleet consisted of 13 sail of the line and four frigates, protected by the batterics on the shore, and several gun-boats. This memorable action commenced at sunset, and terminated gloriously for the honour of our hero and that of the British navy. Ninc sail of the line fell into the hands of the conqueror, two were burnt, and two effected their escape. The brave Nelson was wounded in the action, believing himself to have been shot through the head; but after his wound was examined by the surgeon, it was happily found not to be mortal, a circumstance which diffused the most lively satisfaction through the whole fleet. To the honour of this great man it ought to be mentioned, that even under the conviction of approaching dissolution, he prepared for the interesting change with calmness and fortitude, desired his chaplain to recommend him to Lady Nelson, appointed the brave Hardy to the rank of post-captain and to the command of a ship, and took an affectionate leave of Captain Louis.

> The French admiral's ship, L'Orient, was blown up during the action. From the mainmast of this ship Captain Hallowell ordered a coffin to be constructed, which was presented to Admiral Nelson, and gratefully accepted by the hero, as a token of affectionate regard. For some months he had it placed upright in his cabin; but in consequence of the entreatics of an old servant, the admiral was at length prevailed on to allow it to he removed. Our readers will not be surprised that Lord Nelson should now be regarded as the great defence of the empire, and the support of her national glory. It is to his gallantry and naval skill that we are indebted for the victory of Copenhagen, and the annihilation of that formidable northern confederacy which menaeed the prosperity, the commerce, the very existence of the rest of Europe.

One of the most important services which Lord Nelson performed, was the pursuit of the combined fleets of France and Spain to the West Indies. This fleet had sailed from Cadiz on the 10th of April, and it was at first conjectured that Egypt was the place of their destination. In consequence of this conjecture, Lord Nelson sailed in pursuit of the enemy for the coast of Egypt ; and, having missed his object, after reconnoitring that coast, he passed the straits of Gibraltar, and anchored in Lagos bay on the 10th of May; soon after which he sailed for the West Indies with ten ships of the line; arrived off Barbadocs on the 4th of June; and having touched at Tobago, Trinidad, and Grenada, at the latter of which places he was informed that the combined fleet had been seen on the 6th off Dominica; he reached Antigua on the 12th, where he received information that the enemy had been seen on the 8th standing to the northward. Lord Nelson, without the loss of a moment, continued the pursuit of the enemy on their return to Europe, where they arrived about the end of July; and after taking in provisions and water at Gibraltar, and reconnoitring the harbour of Cadiz; be returned to England, where he arrived in the Victory, on the 18th of August, after having been engaged for nearly four months in one of the most arduous, and, at the same time, one of the most important and beneficial, although, in its immediate object, unsuccessful enterprises, for which his life was distinguished. Nelson. His lordship had now been absent from England more than two years, on the Mediterranean station.

The concluding scene of this extraordinary man's naval career, kindles emotions of admiration and regret; and at once excites both transport and extreme of sorrow. Perhaps no action, in point of splendour and magnaninity, can equal that which deprived his country of one of the greatest heroes it ever produced. Britons appear to be sensible of its vast importance; yet it is not improbable that posterity will consider it as still more splendid, their love and admiration not being damped by the poignant recollection that they personally saw the man by whose loss it was accomplished. When Lord Nelson perceived that, in consequence of his manœuvres, he had reduced the enenty to the absolute necessity of engaging him, he exclaimed in the presence of Captain Hardy and the other officers who surrounded him on the quarter deck ; " Now they eannot escape us; I think we shall at least make sure of twenty of them .- I shall probably losc a leg, but that will be purchasing a victory cheaply." But alas! amidst the inexpressible satisfaction and delight, which a vietory so splendid could not fail to inspire, he has left us to lament that it was purchased by the loss of a life so incomparably valuable.

His lordship's flag ship fell on board the Redoubtable, by which means he was exposed to the fire of the musketry from the tops; and the insignia of his grandeur and dignity, it is supposed, singled him out to the aims of the enemy, which in the issue were too fatally successful. His secretary was cut in two by his side with a chain shot, and soon after a ball grazed his lordship's shoulder, entered his left breast, and passed through his lungs. He lived about three hours after this tragical event, during which he remained perfectly recollected, and he displayed the same heroic magnanimity in the arms of death, which had so eminently distinguished him through the whole of his carcer. His last words to Captain Hardy were, "I know I am dying. I could have wished to survive to breathe my last upon British ground, but the will of God be donc !" In a few moments he expired. His last signal ought not, and will not be forgotten, which was by telegraph,-" That England expected every man would do his duty." He spoke in raptures concerning the event of the day only a short time before his dissolution, and sent word to Admiral Collingwood, desiring that he would make, his affectionate farewell to all his brother seamen throughout the fleet. In this manner died, in the 47th year of his age, the greatest commander that perhaps ever adorned the British navy, leaving behind him a name dear to Great Britain, and an example of heroism which will inspire his companions in arms to emulate his virtues, that they too may live in the remembrance of a grateful posterity.

His singular plan of attack on this memorable occasion was communicated by his lordship to all his captains, who unanimously gave it as their opinion that it could not possibly fail of success, being concerted with such consummate wisdom; and they even pledged their lives for the favourable result of it. His titles were, Viscount Nelson, and Duke of Bronté .- The united parliament voted him a pension of 3000l. a year, to continue during his own life and his two next heirs; the East

Nelson

1

Games.

East India Company made him a present of 10,0001.; the grand signior gave him a diamond aigrette worth 4000l.; Nemean the emperor of Russia gave him a diamond box worth 2500l.; the king of Naples made him presents to the amount of 5000l. together with the dukedom of Bronté, and an estate of 3000l. per annum. Thus all Europe conspired to testify the estimation in which they held this distinguished hero; and the numerous monuments which have been, and still are erecting to his memory throughout the British empire, will continue lasting evidences of the esteem in which he was held by his grateful country. Parliament also voted a sum for the purchase of an estate for his heirs, and his majesty conferred the title of earl on his immediate successor.

Nor were his talents wholly confined to the knowledge of naval tactics, for it is known that as a senator he was highly respectable, although he enjoyed few opportunities of coming forward in that capacity. When he did, his speeches were heard by their lordships with respect, and the most profound attention. The few specimens we have of his abilities as a politician, afford no mean proof that if he had devoted as much of his time to those studies as he did to his peculiar profession, he would have made a distinguished figure in the house of peers.

NEMAUSIS, or NEMAUSUM, in Ancient Geography, the capital of the Arecomici in Gallia Narbonensis; a colony, (Coin), with the surname of Augusta, (Inscription). In it stands a Roman amphitheatre, which is still almost entire. Now Nismes in Languedoc.

NEMEA (Straho, Livy); a river of Achaia, run-ning between Sicyon and Corinth, the common boundary of both territories, and falling into the Corinthian bay

NEMEA, in Ancient Geography, situated between Cleonæ and Philus in Argolis; whether town, district, or other thing, uncertain ; there a grove stood in which the Argives celebrated the Nemean games, and there happened all the fabulous circumstances of the Nemean lion. The district Nemea is called Bembinadia, (Pliny); a village, Bembina, standing near Nemea, (Strabo). Stephanus places Nemea in Elis; though not in Elis, but on its borders ; Pliny, erroneously in Arcadia. In the adjoining mountain is still shown the den of the lion, distant 15 stadia from the place Nemea, (Pausanias); in which stands a considerable temple of Jupiter Nemæus and Cleonæus, from the vicinity of these two places. This place gave name to the Nemzan games, colebrated every third year.

NEMEAN GAMES, so called from Nemea, a village between the cities of Cleonæ and Philus, where they were celebrated every third year. The exercises were chariot-races, and all the parts of the Pentathlum. These games were instituted in memory of Opheltes or Archemorus the son of Euphetes and Creusa, and who was nursed by Hypsipele; who leaving him in a meadow while she went to show the besiegers of Thebes a fountain, at her return found him dead, and a serpent twined about his neck: whence the fountain, before

Ne

Ne

called Langia, was named Archemorus; and the cap- Nemean tains, to comfort hypsipele, instituted these games .- Games Others ascribe their institution to Hercules, after his Nemesius. victory over the Nemean lion. Others allow, that they were instituted first in henour of Archemorus; but intermitted, and revived again by Hercules. The victors were crowned with parsley, an herb used at funerals, and feigned to have sprung from Archemorus's blood. The Argives presided at these games.

NEMESIANUS, AURELIUS OLYMPIUS, a Latin poet who was born at Carthage, and flourished about the year 281, under the emperor Carns, and his sons Carinus and Numerian: the last of which emperors was so fond of poetry, that he contested the glory with Nemesianus, who had written a poem upon fishing and maritime affairs. We have still remaining a poem of our author called Cynegeticon, and four eclogues : they were published by Paulus Manutius in 1538; by Barthelet in 1613; at Leyden in 1653; with the notes of Janus Vlitias. Giraldi hath preserved a fragment of Nemesianus, which was communicated to him by Sannazarius, to whom we are obliged for our poet's works : for having found them written in Gothic characters, he procured them to be put into the Roman, and then sent them to Paulus Manutius. Although this poem hath acquired some reputation, it is greatly inferior to those of Oppian and Gratian upon the same subject ; yet Nemesianus's style is natural enough, and has some degree of elegance. The world was so much possessed with an opinion of his poem in the eighth century, that it was read among the classics in the public schools, particularly in the time of Charlemagne, as appears from a letter of the celebrated Hincmar bishop of Rheims, to his nephew Hincmar of Laon.

NEMESIS, in Pagan worship, the daughter of Jupiter and Necessity, or, according to others, of Oceanus and Nox, had the care of revenging the crimes which human justice left unpunished. She was also called Adrastæa, because Adrastus king of Argos first raised an altar to her; and Rhamnusia, from her having a magnificent temple at Rhamnus in Attica. She had likewise a temple at Rome in the Capitol. She is represented with a stern countenance, holding a whip in one hand and a pair of scales in the other.

NEMESIUS, a Greek philosopher who embraced Christianity, and was made bishop of Emesa in Phœnicia, where he had his birth ; he flourished in the beginning of the fifth century. There is a work of his extant, entitled De Natura Hominis, in which he refutes the fatality of the Stoics and the errors of the Manichees, the Apollianarists, and the Eunomians; but he espouses the opinion of Origen concerning the pre-existence of souls (A). This treatise was translated by Valla, and printed in 1535. Another version was afterwards made of it by Ellebodius, and printed in 1665; it is also inserted in the Bibliotheca Patrum, in Greek and Latin. Lastly, Another edition was published at Oxford in 1671, folio, with a learned preface, wherein the editor endeavours to prove, from a passage in this book, that the

(A) It is much more probable that he and Origen both brought their opinion with them from the schools of philosophy, than that either of them borrowed it from the other. See METAPHYSICS, Part III. Chap. IV.

NEMINE CONTRADICENTE, " none contradicting it;" a term chiefly used in parliament when any thing is carried without opposition.

NEMOURS, a town in France, in the department of Seine and Marne, containing 3469 inhabitants in 1800. It is seated on the river Loing, in E. Long 2. 45. N. Lat. 48. 15.

NENAGH, a post and fair town of Ireland, in the county of Tippcrary, and province of Munster, 75 miles from Dublin. It is situated on a branch of the river Shannon which runs into Lough-Derg. Here stand the ruins of an old eastle called Nenagh-round. Also those of an hospital founded in the year 1200, for canons following the rule of St Augustin. It was dedicated to St John the Baptist, and was usually called Teachon, or St John's house. In the reign of Henry III. a friary for conventual Franciscans was also founded here, and esteemed the richest foundation of that order in the kingdom. Here is a barrack for two troops of horse. This town was burnt on St Stephen's day, 1348, by the Irish. The fairs held here are four.

NENIA, or NÆNIA, in the ancient poetry, a kind of funeral song sung to the music of flutes at the obsequics of the dead. Authors represent them as sorry compositions, sung by hired women mourners called Prafica. The first rise of these Nenia is ascribed to the physicians. In the heathen antiquity, the goddess of tears and funerals was called Nenia; whom some suppose to have given that name to the funeral song, and others to have taken her name from it.

NEOCESARIA, (Pliny), a town of Pontus on the south or the left side of the Lycus. About the year 342, when Leontius and Sallustius were consuls, it was entirely ruined by a dreadful earthquake, no edifice having withstood the violence of the shock, except the church and the bishop's habitation, who was saved, with the clergy and some other pious persons, while the rest of the inhabitants were buried in its ruins.

NEOMAGUS, (Ptolemy); Noviomagus, (Antonine); a town of the Regni in Britain: now thought to be Guildford in Surry, (Lhuvd); or Croydon, (Talbot). But Camden takes it to be Woodcotc, two miles to the south of Croydon, where traccs of an ancient town are still to be secn.

NEOMAGUS, (Ptolemy); Noviomagus (Antonine); a town of the Treviri on the Mosclle. Now Numagen 14 miles east, below Triers.

NEOMAGUS, (Ptolemy); Noviomagus Lexoviorum, (Antonine); a town of Gallia Celtica. Now Liseux, in Normandy.

NEOMAGUS, (Ptolemy); Noviomagus Nemetum, (Antonine). Now Spire, a city of the Palatinate, on the left or west side of the Rhine.

NEOMAGUS, (Ptolemy); a town of Gallia Narbonensis, on the confines of the Tricastini. Now Nyons in Dauphine.

NEOMENIA, or NOUMENIA, a festival of the ancient Greeks, at the beginning of every lunar month, which, as the name imports, was observed upon the day of the new moon, in honour of all the gods, but especially Apollo, who was called Neomenios, because the sun is the fountain of light; and whatever distinction

Vol. XIV. Part II.

of times and seasons may be taken from other plancts, Ncomenia yet they are all owing to him as the original of those borrowed rays by which they shine. The games and, public entertainments at these festivals were made by the rich, to whose tables the poor flocked in great numbers. The Athenians at these times offered solemn prayers and sacrifices for the prosperity of their country during the ensuing month. See GAMES.

N

E

P

The Jews had also their neomenia, or feast of the new moon, on which peeuliar sacrifices were appointed: and on this day they had a sort of family entertainment and rejoicing. The most celebrated neomenia of all others was that at the beginning of the civil year, or first day of the month Tisri, on which no servile labour was performed : they then offered particular burnt sacrifices, and sounded the trumpets of the temple. The modern Jews keep the neomenia only as a feast of devotion, which any one may observe or not as he pleases.

NEOPHYTES, " new plants ;" a name given by the ancient Christiaus to those heathens who had newly embraced the faith; such persons being considered as regenerated, or born anew by baptism. The term ncophytes has been also used for new priests, or those just admitted into orders, and sometimes for the novices in monasteries. It is still applied to the converts made by the missionaries among the infidels.

NEPA, a genus of insects belonging to the order of hemiptera. See ENTOMOLOGY Index.

NEPAL, a kingdom of India, to the north-east of the city of Patna, inclosed among the secondary branches of the Himmaleh mountains, of great extent from east to west, but scarcely exceeding a degree of latitude in breadth. The height of the country above the sea, as indicated by the barometer, is not less than 4000 feet ; yet Colonel Kirkpatrick found the thermometer on one oceasion at 87°. But the neighbouring mountains afford the inhabitants every variety of elimate, from the heat of Bengal to the cold of Russia. The high grounds are very healthy; in the valleys fever prevails; guttural tumours or goitres are found in both. Iron and copper abound in this country. Though stones are found, the houses are built of brick, eemented with mud. The cattle are similar to those of Bengal, and the honey is excellent. The soil is fertile, and besides wheat, rice, and sugar, yields the Zooral a species of yam, and the Kuraila a kind of wild asparagus, which form a considerable part of the subsistence of the poorer inhabitants.

The inhabitants consist principally of the two superior classes of Hindoos, and a race called Newars, who are probably of Chinese or Tartar origin. The former, who compose the army, engross all situations of trust, and are found dispersed all over the country. The Newars are confined almost entirely to the valley of of Nepal Proper. The latter are divided into several castes or orders. The total population is estimated at about half a million. The Newars are a peaceable and industrious people, of a middle size, with broad shoulders and chests, very stout limbs, round and flat faces, but open and cheerful. The Newar women change their husbands as often as they plcase on the slightest pretences. The religion of the country is the same as the Hinduism of Bengal. The government is despotic. The trade is inconsiderable, being crushed by monopolies.

Khatmandu, the capital, is supposed to contain about

50,000

5 D

Nepal.

NEPENTHES, a genus of plants belonging to the gynandria class; and in the natural method ranking among those of which the order is doubtful. See Bo-TANY Index.

NEPETA, CATMINT, or Nep, a genuis of plants belonging to the didynamia class, and in the natural method ranking under the 42d order, Verticillaia. See BOTANY Index.

NEPHELIUM, a genus of plants belonging to the-

moncecia class. See BotANY Index. NEPHEW, a term relative to uncle and annt, signifying a brother's or sister's son; who, according to the civil law, is in the third degree of consanguinity, but according to the canon in the second.

NEPHRITIC, something that relates to the kidneys. See KIDNEY.

NEPHRITIC Wood, (lignum nephriticum), a wood of a very dense and compact texture, and of a fine grain, brought to us from New Spain in small blocks, in its natural state, and covered with its bark. This wood is said to be a good diuretie; and we are told it is used among the Indians in all diseases of the kidneys and bladder, and in suppression of urine, from whatever cause. It is also recommended in fevers, and in obstructions of the viscera. The way of taking it among the Indians is only an infusion in cold water. These uses are not however properly ascertained. See Gui-LANDINA, BOTANY Index.

NEPHRITIC Stone. See NEPHRITE or Jade, MINE-RALOGY Index.

NEPHRITICS, in Pharmacy, medicines proper for diseases of the kidneys. See MATERIA MEDICA Index.

NEPHRITIS, or inflammation of the kidneys. See MEDICINE Index.

NEPOS, CORNELIUS, a celebrated Latin biographer, who flourished in the time of Julius Cæsar, and lived, according to St Jerome, to the sixth year of Augustus. He was an Italian, if we may credit Catullus, and born at Hostilia, a small town in the territory of Verona, in Cisalpine Gaul. Ausonius, however, will have it that he was born in the Gauls. Leander Alberti thinks Nepos's country was Verona. Cicero and Atticus were friends of our author ; who wrote the lives of the Greek historians, as he himself attests in that of Dion, speaking of Philistns. What he says, also, in the lives of Cato and Hannibal, proves that he had also written the lives of the Latin captains and historians. He wrote some other excellent works which are lost.

All that we have left of his at present is, " The Lives of the illustrious Greek and Roman Captains;" which were a long time ascribed to Æmilius Probus, who published them, as it is said, under his own name, to insinuate himself thereby into the favour of the cmperor Theodosius ; but, in the course of time, the fraud has been discovered, although several learned persons have confounded the two authors. This piece has been translated into French by the Sieur de Claveret, with a dedication to the duke of Longueville, in 1663; and again by M. le Gras, then of the congregation of the Otatory at Paris, 1729, 12mo. We have an excellent translation of it into English, by several hands at Oxford, which has gone through several editions.

NEPTUNE, in Pagan worship, the god of the Neptune. sca, was the son of Saturn and Vesta or Ops, and the brother of Jupiter and Pluto. He assisted Jupiter in his expeditions; on which that god, when he arrived at the supreme power, assigned him the sea and the islands for his empire. He was, however, expelled from heaven with Apollo for conspiring against Jupiter, when they were both employed by Laomedon king of Phrygia in building the walls of Troy; but that prince dismissing Neptune without a reward, he sent a sea monster to lay waste the country, on which he was obliged to expose his daughter Hesione. He is said to have been the first inventor of horsemanship and chariot racing; on which account Mithridates king of Pontns threw chariots drawn by four horses. into the sea in honour of this god; and the Romans instituted horse races in the circus at his festival, during which all other horses left working, and the mules were adorned with wreaths of flowers.

In a contest with Minerva he produced a horse by striking the earth with his trident; and on another occasion, in a trial of skill with Minerva and Vulcan; produced a bull, whence that animal was sacrificed to him. His favourite wife was Amphytrite, whom he long courted in vain, till sending a dolphin to intercede for him, he met with success; on which he rewarded the dolphin by placing him among the stars. He had also two other wives, one of whom was called Salasia from the salt water; the other Venilia from the ebbing and flowing of the tides. He had likewise many concubines, by whom he had a great number of children. He is represented with black hair, with a garment of an azure or sea green : holding his trident in his hand, and seated in a large shell drawn by sea horses : attended by the sea gods Palemon, Glaucus, and Phorcys, and the sea goddesses Thetis, Melita, and Panopæa, and a long train of tritons and sea nymphs.

This deity was known in Egypt by the name of Cenobus or Canopus, and was worshipped as the numen aquarum or spirit of the Nile. His emblem was the figure of certain vases or pitchers, with which the Egyptians filtrated the water of the sacred river, in order to purify and render it fit for use. From the mouth of each of these vases, which were charged with hieroglyphics, arose the head and sometimes the head and hands of a man or woman. Such are the emblems which still remain of the Egyptian Neptune or Canobus; and it was by this emblem that the tutelar god of Egypt vanquished the god of Chaldea in the ridiculous manner mentioned by Ruffinus in his Ecclesiastical History*.

" The Chaldeans (says he) who adored the fire, cap. 26. carried their god into various countries that he might try his strength in contests with other gods. He vanquished, as we may easily conceive, the images made of gold, silver, brass, and wood, &c. by reducing them to ashes; and thus the worship of fire was everywhere established. The priest of Canobus, unwilling, as became him, to admit the superiority of strange gods, contrived to make his god vanquish the god of Chaldæa in a pitched battle. The vases which were worshipped as the emblems of Canobus, being used for filtering the waters of the Nile, were of course perforated on all sides with very small holes. This faithful priest having stopped all the holes in one of these

Nero.

Neptune these with wax, and painted the vase of different colours for a reason which the reader will admit to be a good one, filled it up with water, and fitted to its mouth the head of an idol. This emblem of Canobus was then placed in a small fire brought by the Chaldeans as the emblem of their god ; and thus the gods of Egypt and Chaldea were forced into battle. The contest, however, was of short duration. The heat melting the wax made way for the water to run out, which quickly extinguished the fire; and thus Canobus vanquished the god of the Chaldeans." Ridiculous as this story is, it is perfectly suitable to the genius of Paganism, and the mean artifices of the Pagan priesthood ; but we suspect that the historian laboured under one mistake, and substituted the Chaldeans instead of the Persians. See POLYTHEISM.

NEREIDS, in the Pagan theology, sea nymphs, daughters of Ncreus and Doris .- The Nercids were osteemed very handsome ; insomuch that Cassiopc, the wife of Cepheus king of Ethiopia, having triumphed over all the beauties of the age, and daring to vic with the Nereids, they were so enraged that they sent a prodigious sea monster into the country, and, to appease them, she was commanded by the oracle to expose her daughter Andromeda, bound to a rock, to be devoured by the monster. In ancient monuments, the Nercids are represented riding upon sea horses; sometimes with an entire human form, and at other times with the tail of a fish.

NEREIS, a genus of animals belonging to the order of vermes mollusca. See HELMINTHOLOGY Index.

NEREUS, in fabulous history, a marine deity, was son of Oceanus and Thetis. He settled in the Ægean sca, was considered as a prophet, and had the power of assuming what form he plcased. He married his sister Doris, by whom he had 50 daughters called the Nereids, who constantly attended on Neptune, and when he went abroad surrounded his chariot.

NERI, ANTHONY, a learned writer who published a curious book printed at Florence 1612, in 4to, with this title, Dell' Arte Verraria Libri VII.; or the Art of Glassmaking.

NERIUM, a genus of plants belonging to the pentandria class; and in the natural method ranking under the 30th order, Contortæ. See BOTANY and DYEING Index.

NERO, CLAUDIUS DOMITIUS CÆSAR, a celebrated Roman emperor, son of Caius Domitius Ahenobarbus and Agrippina the daughter of Germanicus. He was adopted by the emperor Claudius, A. D. 50, and four years after he succeeded him on the throne. In the beginning of his reign he showed several marks of the greatest kindness and condescension, affability, complaisance, and popularity. The object of his administration secmed to be the good of his people; and when he was desired to sign his name to a list of malefactors that were to be executed, he exclaimed, Would to heaven I could not write ! He hated flattery; and when the senate had liberally commended the wisdom of his government, he desired them to keep their praises till he deserved them. These promising virtues soon, however, proved to be artificial : Nero soon displayed the real propensities of his nature. He delivered himself from the sway of his mother, and at last ordered her to be murdered. This unnatural act of bar-

barity might astonish some, but Nero had his devoted Nero. adherents; and when he declared that he had taken " away his mother's life to save himself from ruin, the senate applauded his measures, and the people signified their approbation. Many of his courtiers shared her unhappy fate; and Nero sacrificed to his fury or caprice all such as obstructed his pleasure or diverted his inclination. In the night he generally went from his palace to visit the mcanest taverns, and all the scenes of debauchery which Rome contained. In this nocturnal riot he was fond of insulting the people in the streets; and his attempts to offer violence to the wife of a Roman senator nearly cost him his life. He also turned actor, and openly appeared on the Roman stage in the meanest characters. In his attempts to excel in music, and to conquer the disadvantages of a hoarse disagreeable voice, he moderated his meals, and often passed the day without eating. The Olympian games attracted his notice : he went into Greece, and presented himself a candidate for the public honour. He was defeated in wrestling; but the flattery of the spectators adjudged him the victory, and he returned to Rome with all the splendour and pomp of an eastern conqueror, drawn in the chariot of Augustus, and attended by a band of musicians, actors, and stage daneers from every part of the empire. These private and public amuscments of the emperor were indeed innocent; his character only was injured, and not the lives of the people. His conduct, however, soon became more abominable : he disguised himself in the habit of a woman, and was publicly married to one of his eunuchs. This violence to nature and decency was soon exchanged for another : Nero resumed his sex, and celebrated his nuptials with one of his meanest catamites : and it was on this occasion that one of the Romans observed that the world would have been happy if Nero's father had had such a wife. But his cruelty was now displayed in a still higher degree, for he sacrifieed to his wantonness his wife Octavia. Poppæa, and the celebrated writers Seneca, Lucan, Petronius, &c. Nor did the Christians escape his barbarity. He had heard of the burning of Troy; and as he wished to renew that dismal scene, he caused Rome to be set on fire in different places. The conflagration became soon universal, and during nine successive days the fire continued. All was desolation : nothing was heard but the lamentations of mothers whose children had perished in the flames, the groans of the dying, and the continual fall of palaccs and buildings. Nero was the only one who enjoyed the general consternation. He placed himself on the top of a high tower, and he sung on his lyre the destruction of Troy, a dreadful scene which his barbarity had realized before his cyes. He attempted to avert the public odium from his head by a pretended commiseration of the miseries of his subjects. He began to repair the streets and public buildings at his own expence. He built himself a celebrated palace, which he called his golden house. It was liberally adorned with gold, with precious stones, and with every thing rare and exquisite. It contained spacious fields, artificial lakes, woods, gardens, orchards, and whatever exhibited a beautiful scene. The entrance of this edifice could admit a large colossus of the emperor 120 feet high; the galleries were each a mile long, and the whole was covered with gold.

5 D 2

Nero.

gold. The roofs of the dining halls represented the firmament, in motion as well as in figure; and continually turned round night and day, showering down all sorts of perfumes and sweet waters. When this grand edifice, which, according to Pliny, extended all round the city, was finished, Nero said, that now he could lodge like a man. His profusion was not less remarkable in all his other actions. When he went a fishing his nets were of gold and silk. He never appeared twice in the same garment, and when he took a voyage, there were thousands of servants to take care of his wardrobe. This continuation of debauchery and extravagance at last roused the people. Many conspiracies were formed against him; but they were generally discovered, and such as were accessory suffered the severest punishments. The most dangerous conspiracy against Nero's life was that of Piso, from which he was saved by the confession of a slave. The conspiracy of Galba proved more successful, who, when he was informed that his plot was known to Nero, declared himself emperor. The unpopularity of Nero favoured his cause; he was acknowledged by all the Roman empire, and the senate condemned the tyrant to be dragged naked through the streets of Rome, and whipped to death, and afterwards to be thrown down from the Tarpeian rock like the meanest malefactor. This, however, was not executed ; for Nero prevented it by a voluntary death. He killed himself, A. D. 68, in the 32d year of his age, after a reign of of 13 years and eight months. Rome was filled with acclamations on the occasion; and the citizens, more strongly to indicate their joy, wore caps, such as were generally used by slaves who had received their freedom. Their vengeance was not only exercised against the statues of the deceased monster, but many of his friends were the object of the public resentment; and many were crushed to pieces in such a violent manner, that one of the senators, amid the universal joy, said that he was afraid they should soon have cause to wish for Nero. The tyrant, as he expired, requested that his head might not be cut off from his body, and exposed to the insolence of the populace, but that the whole might be burned on the funeral pile. His request was granted by one of Galba's freedmen, and his obsequies were performed with the usual ceremonies. Though his death seemed to be the source of general gladness, yet many of his favourites lamented his fall, and were grieved to see that their pleasures and amusements were stopped by the death of this patron of debauchery and extravagance. Even the king of Parthia sent ambassadors to Rome, to condole with the Romans, and to beg that they would honour and revere the memory of Nero. His statues were also crowned with garlands of flowers; and many imagined that he was not dead, but that he would soon make his appearance and take vengeance on his enemies. It will be sufficient to observe, in finishing the character of this tyrannical monster, that the name of Nero is even now used emphatically to express a barbarous and unfeeling oppressor. Pliny calls him the common enemy and fury of mankind; and so indeed he has been called by all writers, who exhibit Nero as a pattern of the most execrable barbarity and unpardonable wantonness. The same Pliny furnishes us with this singular anecdote of him : " Nero had or-

dered himself to be painted under the figure of a colossus, upon cloth or canvas, 120 feet in height." He adds, "that this preposterous picture, when it was finished, met with its fate from lightning, which consumed it, and involved likewise the most beautiful part of the gardens where it was placed in the conflagration."

NERVA, COCCEIUS, a Roman emperor after Domitian, who was the last of the 12 Cæsars. He was a native of Narnia in Umbria; his family, however, was originally of Crete. Dion Cassius says he was born on the 17th of March, in the 18th year of Tiberius's reign, and of the Christian era the 32d. Nero in the 12th year of his reign made him prætor, and erected a statue for him in the palace on account of his poems (for he was one of the best poets of his age), some of which were inscribed to him. He was consul in 71 with Vespasian, and in 90 with Domitian.

Ancient authors uniformly celebrate him as a prince of a most mild and humane temper, of great moderation and generosity, who looked on his office as emperor, not as if it was for his own advantage, but for that of his people; and whilst he reigned, which was however but for a short time, he made the happiness of his subjects his only end and pursuit. He narrowly escaped death under Domitian; was naturally of a weak and timorous disposition ; and, as some say, addieted to excessive drinking. The Romans unanimously chose him emperor; and they had no cause to repent of their choice, for he was constantly attentive to what could make them happy ; he was generous, merciful, and disinterested. An instance of his great lenity appears in his pardoning Calpurnins Crassus who conspired against him. In short, he omitted nothing that might contribute to the restoring of the empire to its former lustre : recalling those who had been banished for religion, and redressing all grievances that came to his knowledge. He however found his strength failing, and that it would be impossible for him to finish his designs, in consequence of which he adopted Trajan. After his death, which happened in the year 98, he was ranked among the gods. He was the first Roman emperor of foreign extraction.

NERVES, in *Anatomy*, certain white glistening cords, proceeding from the brain and spinal marrow, and dividing into very small branches, which are sent off throughout all parts of the body; and which are found to be the organs of sensation and motion. See ANATOMY *Index*.

NERVOUS FLUID. See ANATOMY Index.

NESSUS, in fabulous history, a celebrated Centaur, son of Ixion and a Cloud. He offered violence to Dejanira, whom Hercules had intrusted to his care, with orders to carry her across the river Evenus. Hercules saw the distress of his wife from the opposite shore of the river, and immediately he let fly one of his poisoned arrows, which struck the Centaur to the heart. Nessus, as he expired, gave the tunic he then wore to Dejanira, assuring her that from the poisoned blood which had flowed from his wounds, it had received the power of calling a husband away from unlawful loves. Dejanira received it with pleasure, and this mournful present caused the death of Hercules.—A river which separates Thrace from Macedonia. It is also called *Nesus*, *Nestos*, and *Nestus*.

Nero || Nessus. Nest, Nestor,

NEST. Sec NIDUS. Eatable Birds NESTS. See BIRDS Nests.

NESTOR, in fabulous history, a son of Neleus and Chloris, nephew to Pelias and grandson to Neptune. He had eleven brothers, who were all killed with his father by Hercules. His tender age detained him at home, and was the cause of his preservation. The conqueror spared his life and placed him upon the throne of Pylos. He married Eurydice the daughter of Clymenus; or, according to others, Anaxibia the daughter of Atrens. He soon distinguished himself in the field of battle ; and was present at the nuptials of Perithous, when a bloody engagement took place between the Lapithæ and Centaurs. As king of Pylos and Messenia he led his subjects to the Trojan war, where he distinguished himself among the rest of the Grecian chiefs, by eloquence, address, wisdom, justice, und uncommon prudence. Homer displays his character as the most perfect of all his heroes ; and Agamemnon exclaims, that if he had 20 generals like Nestor, he should soon see the walls of Troy reduced to ashes. After the Trojan war Nestor retired to Greece, where he enjoyed in the bosom of his family the peace and tranquillity which were due to his wisdom and to his age. The manner and the time of his death are unknown : the ancients are all agreed that he lived three generations of men; which length of time is supposed to be 300 years, though more probably only 90 years, allowing 30 years for each generation. From that circumstance, therefore, it was usual among the Greeks and the Latins, when they wished a long and happy life to their friends, to wish them to see the years of Nestor. He had many children; two daughters, Pisidice, and Polycaste; and seven sons, Perseus, Straticus, Aretus, Echephron, Pisistratus, Antilochus, and Thrasymedes. Nestor was one of the Argonauts, according to Valerius Flaccus, v. 380, &c.-A poet of Lycaonia in the age of the emperor Severus. He was father to Pisander, who under the emperor Alexander wrote some fabulous stories .---- One of the body guards of Alexander.

NESTOR, whose secular name is not known, was a native of Russia, and the earliest historian of the north. He was born in 1056 at Bielozero; and in the 19th year of his age he assumed the monastic habit in the convent of Petcherski at Kiof, and took the name of *Nestor*. He there made a considerable proficiency in the Greek language: but seems to have formed his style and manner rather from the Byzantine historians, Cedrenus, Zonaras, and Syncellus, than from the ancient classics. The time of Nestor's death is not ascertained; but he is supposed to have lived to an advanced age, and to have died about the year 1115.

His great work is his Chronicle, to which he has prefixed an introduction, which after a short sketch of the early state of the world, taken from the Byzantine writers, contains a geographical description of Russia and the adjacent regions; an account of the Sclavonian nations, their manners, their emigrations from the banks of the Danube, their dispersion, and settlement in the several countries wherein their descendants are now established. He then enters upon a chronological series of the Russian annals, from the year 858 to about 1113. His style is simple and unadorned, such as suits a mere recorder of facts; but his chronological exactness, though it renders his narrative dry and tedious, Nestor, contributes to ascertain the era and authenticity of the Nestorians, events which he relates.

It is remarkable (says Mr Coxe, from whom we have taken this narrative), that an author of such importance, whose name frequently occurs in the early Russian books, should have remained in obscurity above 600 years; and been scarcely known to his modern countrymen, the origin and actions of whose ancestors he records with such circumstantial exactness. A copy of his Chronicle was given in 1668 by Prince Radzivil to the library of Konigsburg, where it lay unnoticed till Peter the Great, in his passage through that town, ordered a transcript of it to be sent to Petersburgh. But it still was not known as the performance of Nestor : for when Muller in 1732 published the first part of a German translation, he mentioned it as the work of the abbot Theodosius of Kiof; an error which arose from the following circumstance : The ingenious editor not being at that time sufficiently acquainted with the Sclavonian tongue, employed an interpreter, who, by mistaking a letter in the title, supposed it to have been written by a person whose name was Theodosius. This ridiculous blunder was soon circulated and copied by many foreign writers, even long after it had been candidly acknowledged and corrected by Muller.

NESTORIANS, a sect of ancient Christians, still said to be subsisting in some parts of the Levant; whose distinguishing tenet is, that Mary is not the mother of God. They take their name from Nestorius bishop of Constantinople, whose doctrines were spread with much zeal through Syria, Egypt, and Persia.

One of the chief promoters of the Nestorian cause was Barsumas, created bishop of Nisibis, A. D. 435. Such was his zeal and success, that the Nestorians, who still remain in Chaldca, Persia, Assyria, and the adjacent countries, consider him alone as their parent and founder. By him Pherozes the Persian monarch was persuaded to expel those Christians who adopted the opinions of the Greeks, and to admit the Nestorians in their place, putting them in possession of the principal seat of ecclesiastical authority in Persia, the see of Selencia, which the patriarch of the Nestorians has always filled even down to our time .- Barsumas also erected a school at Nisibis, from which proceeded those . Nestorian doctors who in the fifth and sixth centuries sprcad abroad their tenets through Egypt, Syria, Arabia, India, Tartary, and China.

He differed considerably from Nestorius, holding that there arc two persons in Jesus Christ, as well as that the Virgin was not his mother, as God, but only as man.

The abettors of this doctrine refuse the title Nestorians; alleging that it had been handed down from the earliest times of the Christian church.

In the tenth century, the Nestorians in Chaldea, whence they are sometimes called *Chaldeans*, extended their spiritual conquests beyond Mount Imaus, and introduced the Christian religion into Tartary properly so called, and especially into that country called *Karit*, bordering on the northern part of China. The prince of that country, whom the Nestorians converted to the Christian faith, assumed, according to the vulgar tradition, the name of *John* after his baptism, to which he added

To this spiritual motive he added one, that, though Nestorius. carnal, he possibly judged of equal force :--- " Join with me (said he) in war against them, and I will assist you against the Persians." Although the wiser and better part of his audience were amazed to see a man, before he had tasted (as the historian * expresses him-* Socrates, sclf) the water of his city, declarc that he would persecute all who were not of his opinion; yet the majority of the people approved of this discourse, and encouraged him to execute his purpose. Accordingly, five days after his consecration, he attempted to demolish the church in which the Arians secretly held their assemblies; and he succeeded so far in his design, that these people, growing desperate, set it on fire themselves, and consumed with it some of the neighbouring houses. This fire excited great commotions in the city, and Nestorius was ever afterwards called an incendiary.

From the Arians he turned his persecution against the Novatians, but was stopped in his career by the interposition of the emperor. He then let loose his fury upon those Christians of Asia, Lydia, and Caria, who celebrated the feast of Easter upon the 14th day of the moon ; and for this unimportant deviation from the Catholic practice, many of those people were murdered by his agents both at Miletum and Sardis .- One cannot be sorry that such a relentless persecutor should himself be afterwards condemned as a heretic, for holding an opinion which no man who speaks or thinks with philosophic accuracy will now venture to controvert. This obnoxious tenet, which produced a schism in the church, and was condemned by a general council, was nothing more than that "the Virgin Mary cannot with propriety be called the mother of God." The people being accustomed to hear this expression, were much inflamed against their bishop, imagining that he had revived the error of Paulus Samosetenus and Photinus, who taught that Jesus Christ was a mere man. The monks declared openly against him, and, with some of the most considerable men of Constantinople, separated themselves from his communion. Several bishops wrote to him earnest persuasives to acknowledge that Mary was the mother of God; and when he would not comply, they procured his condemnation in the council of Ephesus, which deprived him of his see. He then retired to his ancient monastery at Antioch, whence he was taken four years afterwards by the emperor's order, and banished in 435 to Tarsus. That city being taken and destroyed by the Barbarians, he was removed to Panopolis, a city of Thebais; where he was not suffered to remain long, but was compelled to go from place to place, till, being in one of his journeys mortally bruised by a fall, death relieved him from the fury of his persecutors.

If we examine such of his writings as remain, we shall find that he was very unjustly condemned. It appears that he rejected the errors of Ebion, Paulus Samosetenus, and Photinus; that he maintained in express terms, that the divine Word was united to the human nature in Jesus Christ in the most strict and intimate sense possible ; that these two natures, in this state of union, make but one Christ and one person; that the properties of the Divine and human natures may both be attributed to this person; and that Jesus Christ may be said to have been born of a virgin, to have suffered and

Nestorians, added the surname of Presbyter, from a principle of

Nestorius. modesty; whence it is said his successors were each of them called Prester John until the time of Gengis Khan. But Mosheim observes, that the famous Prester John did not begin to reign in that part of Asia before the conclusion of the 11th century. The Nestorians formed so considerable a body of Christians, that the missionaries of Rome were industrious in their endeavours to reduce them under the papul yoke. Inno-cent IV. in 1246, and Nicolas IV. in 1278, used their utmost efforts for this purpose, but without success. Till the time of Pope Julius III. the Nestorians acknowledged but one patriarch, who resided first at Bagdad, and afterwards at Mousul; but a division arising among them, in 1551 the patriarchate became divided, at least for a time, and a new patriarch was consecrated by that pope, whose successors fixed their residence in the city of Ormus in the mountainous part of Persia, where they still continue, distinguished by the name of Simcon; and so far down as the last century, these patriarchs persevered in their communion with the church of Rome, but seem at present to have withdrawn themselves from it. The great Nestorian pontiffs, who form the opposite party, and look with a hostile eye on this little patriarch, have since the year 1559 been distinguished by the general denomination of Elias, and reside constantly in the city of Mousul. Their spiritual dominion is very extensive, takes in a great part of Asia, and comprehends also within its circuit the Arabian Nestorians, and also the Christians of St Thomas, who dwell along the coast of Malabar. It is observed, to the lasting honour of the Nestorians, that of all the Christian societies established in the East, they have been the most careful and successful in avoiding a multitude of superstitious opinions and practices that have infected the Greek and Latin churches. About the middle of the 17th century, the Romish missionaries gained over to their communion a small number of Nestorians, whom they formed into a congregation or church; the patriarchs or bishops of which reside in the city of Amida, or Diarbekir, and all assume the denomination of Joseph. Nevertheless the Nestorians in general persevcre to our own times in their refusal to enter into the communion of the Romish church, notwithstanding the earnest entreaties and alluring offers that have been made by the pope's legate to conquer their inflexible constancy.

NESTORIUS, from whom the sect of Nestorian Christians derive their name, was born in Germanica a city of Syria. He received his education at Antioch, where he was likewise baptized ; and soon after his baptism he withdrew himself to a monastery in the suburbs sof that city. Upon his being admitted to the order of priesthood, he quickly acquired so great reputation by the eloquence of his preaching, and the regularity of his life, that by the emperor Theodosius he was deemed a fit person to fill the second see in the Christian church, and was accordingly consecrated bishop of Constantinople in the year 429.

In one of his first sermons after his promotion, he publicly declared his intention to make war upon heretics; and with that intolerant spirit which has so often disgraced the preachers of the mild religion of Jesus, he scalled upon the emperor to free the earth from heretics, promising to give him heaven as a reward for his zeal.

ll Net.

Sports-

honary.

NESTUS, or NESSUS, a river which separates Thrace from Macedonia. It falls into the Ægean sea ncar the island Thasos. It is sometimes called Nesus and Nessus.

NET, a device for catching fish and fowl. See the article FISHERY.

The taking fowls by nets is the readiest and most advantageous of all others, where numbers are to be taken. The making the nets is very easy, and what every true sportsman ought to be able to do for himself. All the necessary tools are wooden needles, of which. there should be several of different sizes, some round and others flat; a pair of round pointed and flat scissars; and a wheel to wind off the thread. The packthread is to be of different strength and thickness, according to the sort of birds to be taken; and the general size of the meshes, if not for very small birds, is two inches from point to point. The nets should neither be made too deep nor too long, for they are then difficult to manage; and they must be verged on each side with twisted thread. The natural colour of the thread is too bright and pale, and is therefore in many cases to be altered. The most usual colour is the russet; which is to be obtained by plunging the net, after it is made, into a tanners pit, and letting it lie there till it be sufficiently tinged : this is of a double service to the net, since it preserves the thread as well as alters the colour. The green colour is given by chopping some green wheat and boiling it in water, and then soaking the net in this green tineture. The yellow colour is given in the same manner with the decoction of celandine; which gives a pale straw-colour, which is the colour of stubble in the harvest-time. The brown nets are to be used on ploughed lands, the green on grass grounds, and the yellow on stubble lands.

Day-NET, among fowlers, a net generally used for taking such small birds as play in the air, and will stoop either to prey, gig, or the like ; as larks, linnets, buntings, &c. The time of the year for using this net nan's Dic- is from August to November; and the best time is very early in the morning: and it is to be observed, that the milder the air, and the brighter the sun is, the better will be the sport, and of longer continuance. The place where this net should be laid, ought to be plain champaign, either on short stubbles, green leas, or flat meadows, near corn fields, and somewhat remote from towns and villages : you must be sure to let your net lie close to the ground, that the birds ereep not out and make their escape.-The nct is made of a fine packthread with a small mesh, not exceeding half an inch square; it must be three fathoms long, and but one broad : it must be verged about with a small but strong cord; and the two ends extended upon two small long poles, suitable to the breadth of the net,

-

with four stakes, tail-strings, and drawing-lines .- This net is composed of two, which must be exactly alike ; and are to be laid opposite to one another, so even and close, that when they are drawn and pulled over, the sides must meet and touch each other. You must stake this net down with strong stakes, very stiff on their lines, so that you may with a nimble touch cast them to and fro at pleasure ; then fasten your drawing-cord or hand-lines (of which there must be a dozen at least, and each two yards long) to the upper end of the foremost staves: and so extend them of such a straitness, that with a little strength they may rise up in the nets and cast them over.

Your nets being thus laid, place your gigs, or playing-wantons, about 20 or 30 paces beyond, and as much on this side your nets : the gigs must be fastened to the tops of long poles, and turned into the wind, se as they may play to make a noise therein. These gigs are a sort of toys made of long goose-feathers, like shuttle-cocks, and with little small tunnels of wood running in broad and flat swan-quills, made round like a small hoop; and so, with longer strings fastened to a pole, will, with any small wind or air, move after such a manner, that birds will come in great flocks to play about them.

When you have placed your gigs, then place your stale; which is a small stake of wood, to prick down into the earth, having in it a mortice-hole, in which a small and slender piece of wood, about two feet long, is fastened, so as it may move up and down at pleasure : and fasten to this longer stick a small line, which, running through a hole in the stick above-mentioned, and so coming up to the place where you are to sit, you may, by drawing the line up and down withyour right hand, raise up the longer stick as you see occasion.

Fasten a live lark, or such like bird, to this longer stick, which, with the line making it to stir up and down by your pulling, will entice the birds to come to, your net.

There is another stale, or enticement, to draw on. these birds, called a looking-glass; which is a round stake of wood, as big as a man's arm, made very sharp at the end, to thrust it into the ground : they make it. very hollow in the upper part, above five fingers deep; into which hollow they place a three-square piece of wood about a foot long, and each two inches broad, lying upon the top of the stake, and going with a foot into the hollowness : which foot must have a great knob at the top, and another at the bottom, with a deep. slenderness between; to which slenderness you are to fasten a small packthread, which, running through a hole in the side of the stake, must come up to the place where you sit. The three square piece of wood which lies on the top of the stake, must be of such a poise and evenness, and the foot of the socket so smooth and round, that it may whirl and turn round upon the least touch; winding the packthread so many times about it, which being suddenly drawn, and as suddenly let. go, will keep the engine in a constant rotatory motion: then fasten with glue on the uppermost flat, squares of the three-square piece, about 20 small pieces of looking-glass, and paint all the square wood between them of a light and lively red; which, in the

Net.

the continual motion, will give such a reflection, that Nether- the birds will play about to admiration until they are taken.

Both this and the other stale are to be placed in the middle between the two nets, about two or three fect distance from each other; so that in the falling of the nets, the chords may not touch or annoy them : neither must they stand one before or after another; the glass being kept in a continual motion, and the bird very often fluttering. Having placed your nets in this manner, as also your gigs and stales, go to the further end of your long drawing lines and stale lines; and having placed yourself, lay the main drawing line across your thigh, and, with your left, pull the stale line to show the birds; and when you perceive them to play ncar and about your nets and stales, then pull the net over with both hands, with a quick but not too hasty motion; for otherwise your sport will be spoiled.

Plate

See Plate CCCLXIX. where A shows the bodies of CCCLXIX. the main net, and how they ought to be laid. B, the tail lines, or the hinder lines, staked to the ground. C, the fore lines staked also to the ground. D, the bird stale. E, the looking-glass stale. G, the line which draws the bird stale. H, the line that draws the glass stale. I, the drawing double lines of the nets, which pulls them over. K, the stakes which stake down the four nether points of the nets and the two tail lines. L, the stakes that stake down the fore lines. M, the single line, with the wooden button to pull the net over with. N, the stake that stakes down the single line, and where the man should sit; and O, the gig.

NET, Neat, in commerce, something pure, and unadulterated with any foreign mixture.

Thus wines are said to be net when not falsified or balderdashed; and coffee, rice, pepper, &c. are net when the filth and ordures are separated from them. See NEAT.

A diamond is said to be net when it has no stains or flaws ; a crystal, when transparent throughout.

NET is also used for what remains after the tare has been taken out of the weight of any merchandise, i. e. when it is weighed clear of all package. See TARE.

Thus we say, a barrel of cochineal weighs 450 pounds; the tare is 50 pounds, and there remain net 400 pounds.

NET Produce, a term used to express what any commodity has yielded, all tare and charges deducted.

. The merchants sometimes use the Italian words netto proceduto, for net produce.

NETHERLANDS, anciently called Belgia, but since denominated Low Countries or Netherlands, from their low situation, are situated between 2° and 7° of east longitude, and between 50° and 53° 30' of north latitude: and are bounded by the German sea on the north, Germany on the east, by Lorrain and France on the south, and by another part of France and the British seas on the west; extending near 300 miles in length from north to south, and 200 miles in breadth from east to west. They consist of 17 provinces; 10 of which were called the Austrian and French Netherlands, and the other seven the United Provinces. The whole united were crected into a kingdom at the peace of Paris in 1814.

The greatest part of the Netherlands was conquered

-7

by the Romans; and that part which lies towards Nether. Gaul continued in their subjection till the decline of lands. that empire; after which the Franks became masters of it; and under the French monarchy, it was part of the kingdom of Metz or Austrasia.

Towards the end of the 15th century Maximilian of Austria, son of the emperor Ferdinand III. acquired, by marrying the only daughter of the dukc of Burgundy, the duchies of Brabant, Limburg, and Luxemburg; the counties of Flanders, Burgundy, Hainault, Holland, Zcaland, and Namur; and the lordship of Friesland. Philip of Austria, son to Maximilian and Mary, married Jane the daughter of Ferdinand king of Arragon and of Isabella queen of Castile ; by which means their son Charles inherited not only almost all Spain and the great countries then lately discovered in America, but also those noble provinces of the Netherlands, and was chosen emperor under the name of Charles V. Towards the latter end of the 1527, he added to his dominions the temporalities of the bishoprick of Utrecht on both sides of the Yssel; and Henry of Bavaria, being distressed through war with the duke of Guelderland, and tired with the continued rebellion of his own subjects, surrendered to the emperor the temporalities of his dioccse, which was confirmed by the pope, and the states of the country. In 1536, Charles V. bought of Charles of Egmond the reversion of the duchy of Guelderland and of the county of Zutphen, in case that prince should die without issue. The same year the city of Groningen took the oath of allegiance, and submitted to Charles V. and in 1543 he put a garrison into the city of Cambray, and built a citadel there. Having thus united the 17 provinces, as it were in one body, he ordered that they should continue for ever under the same prince, without being ever separated or dismembered; for which purpose he published in November 1549, with the consent and at the request of the states of all the provinces, a perpetual and irrevocable edict or law, by which it was enacted, that in order to keep all those provinces together under one and the same prince, the right of representation, with regard to the succession of a prince or princess, should take place for ever both in a direct and collateral line, notwithstanding the common laws of some provinces to the contrary. Charles had even a mind to incorporate these provinces with the Germanic body, and to make of them a circle of the empire, under the title of the circle of Burgundy, in order thereby to engage the princes of the empire to concern themselves for the preservation of those provinces. But the Netherlands, always jealous of their liberty, did not seem to like that incorporation; and when they were demanded to pay their share towards the expences of the empire, they refused it : whercupon the princes of Germany refused, in their turn, to take any part in the wars in Flanders, and looked upon those provinces as by no means belonging to the Germanic body.

Philip of Austria and his son Charles, who were born in the Netherlands, had for these provinces that natural affection which men use to have for their native country; and, knowing how jealous the inhabitants were of their liberty, and of the privileges granted to them by their former princes, they took great care to preserve them and suffered willingly that the states, who were the guardians of the people's liberty and privileges, should

lands.

Innds

Nether- should in a manner share the supreme authority with them. Philip II. son to the emperor Charles V. had not the same affection for the Netherlands, nor those generous sentiments which his father had endeavoured to inspire him with. Being born in Spain of a Portuguese woman, he had no regard but for his native country; and, when he removed out of the Netherlands, he left them to the weak government of a woman, to the proud and haughty spirit of Cardinal de Grenville, and to the wild ambition of some lords of these provinces, who availing themselves of the imprudent conduct and continual blunders of the council of Spain, found their private interest in the disturbances they could not fail to produce. Philip II. also, instead of the mild and moderate measures which his predecessors had successfully employed on many oceasions, as best suiting the genius and temper of the people, had recourse to the most violent and ernel proceedings; which, far from curing the evil, served only to exasperate it the more and render it incurable. The Spaniards, whom he sent thither, being born and educated in an absolute monarchy, jealous of the liberties and envious of the riches of the people, broke through all their privileges, and used them almost after the same manner as they had done the inhabitants of their new and ill-gotten dominions in America. This treatment oceasioned a general insurrection. The counts Hoorn, Egmont, and the prince of Orange, appeared at the head of it, and Luther's reformation gaining ground about the same time in the Netherlands, his disciples joined the malecontents: whereupon King Philip introduced a kind of inquisition in order to suppress them, and many thousands were put to death by that court, besides those that perished by the sword; for these persecutions and encroachments had occasioned a civil war, in which several battles were fought. The counts Hoorn and Egmont were taken and beheaded : but the prince of Orange, retiring into Holland, with the assistance of England and France, preserved Holland and some of the adjacent provinces, which entered into a treaty for their mutual defence at Utrecht in 1 579. and they have ever since been styled the United Provinces; but the other provinces were reduced to the ohedience of Spain by the duke of Alva and other Spanish generals. However, their ancient privileges were in a great measure restored ; every province was allowed its great council or parliament, whose concurrence was required to the making of laws, and raising money for the government, though these assemblies were too often obliged to follow the dictates of the court.

The empcror Joseph II. endcavoured to deprive them even of the form of their free constitution; and he might very probably have succeeded, had he not attempted at the same time a reformation of the church. The Austrian Netherlands are wholly Catholie, and so bigotted to the Romish superstition, that though they had tamely submitted to many encroachments of the archducal house on their civil rights, no sooner did the monarch encroach upon the property of the holy mother church than they resisted his authority, and elaimed all their aneient privileges political and religious.

The Spaniards continued possessed of almost eight of these provinces, until the dake of Marlborough, general of the allies, gained the memorable victory of

Vol. XIV. Part II.

Ramillies. After which Brussels the capital, and great Nether. part of these provinces, acknowledged Charles VI. (afterwards emperor) their sovereign; and his daughter, Nettings. the late empress queen, remained possessed of them till, the war that followed the death of her father, when the French made an entire conquest of them, except part of the province of Luxemburg ; but they were restored by the peace of Aix-la-Chapelle in 1748, and the French retained only Artois, the Cambresis, part of Flanders, part of Hainault, and part of Luxemburg.

These provinces were overrun by the French in 1794, and formally ceded to them by the treaty of Campo Formio in 1797. They kept possession of them till 1814, when they were separated from France, and along with the seven Dutch provinces, formed into a kingdom under the prince of Orange, who assumed the title of king of the Netherlands. By the new constitution promulgated in 1815, the people of the two countries were to be represented in an assembly called the States-General, whose sittings were to be held alternately in a town in Holland and a town in Belgium. The States consist of two chambers; the deliberations of the lower are public, those of the upper private. The constitution guarantees the liberty of the press, the right of petitioning, and the independence of the judges.

The soil is generally fruitful, but differs in the several parts. The climate also differs in the several provinces; in those towards the south it does not differ much from that of England, though the seasons are more regular. In the northern provinces the winter is generally very sharp, and the summer sultry het; but the extreme cold and excessive heat seldom continue above five or six weeks. The air is reckoned very wholesome, but is subject to thick fogs in winter, through the moistness of the country, which would be very noxious, were it not for the dry easterly winds, which, blowing off a long continent for two or three months in the year, clear the air, and occasion very sharp frosts in January and February; during which, the ports, rivers, and canals are commonly shut up. The face of the country is low and flat; for, exeept some small hills and a few rising grounds in Utrecht and Guelderland, and in the parts lying towards Gcrmany, there is no hill to be seen in the whole 17 provinces. This is the reason why they have been called the Low Countries. French Flanders abounds in grain, vegetables, flax and eattle, but is in want of wood.

For the Dutch Netherlands, sec UNITED Provinces. NETHINIMS, among the Jews, the posterity of the Gibeonites, who were condemned by Joshna to be hewers of wood and drawers of water for the house of God.

NETOPION, a name given by the ancients to a very fragrant and costly ointment, consisting of a great number of the finest spicy ingredients. Hippocrates, in his Treatise on the Discases of Women, frequently prescribes the netopion in diseases of the uterus ; and in other places he speaks of its being poured into the ear as a remedy for dcafness; these compositions, by their attenuating qualities, dividing the viscous and thick humours. The word netopion is also sometimes used to express the unguentum Egyptiacum, and sometimes simply for oil of almonds.

NETTINGS, in a ship, a sort of grates made of small ropes seized together with rope yarn or twine, and fixed 5E

Neva.

Nettings fixed on the quarters and in the tops ; they are sometimes stretched upon the ledges from the waste trees to the roof trees, from the top of the forecastle to the poop, and sometimes are laid in the waste of a ship to serve instead of gratings.

NETTUNO, a handsome town of Italy, in the Campagna di Roma. It is but thinly peopled, though scated in a fertile soil. The inhabitants are almost all hunters. E. Long. 12. 57. N. Lat. 41. 30.

NEVA, a river at Petersburgh, in Russia. The views upon the banks exhibit the grandest and most lively scenes. The river is in most places broader than the Thames at London. It is deep, rapid, and transparent as crystal, and its banks are lined on each side with a continued range of handsome buildings. On the north side the fortress, the academy of sciences and that of art are the most striking objects; on the opposite side are the imperial palace, the admiralty, the mansions of many Russian nobles, and the English line, so called because (a few houses excepted) the whole row is occupied by the English merchants. In front of these buildings, on the south side, is the quay, which stretches for three miles, except where it is interrupted by the admiralty; and the Neva, during the whole of that space, has been lately embanked at the expence of the empress, by a wall, parapet, and pavement of hewn granite; a most elegant and durable monument of imperial magnificence. There is a communication between the opposite sides of the river by a bridge of pontoons, which, when any thing is apprehended from the force of ice rushing down the stream, can be, and is generally indeed, removed. The great depth of the river, it appears, prevents the building of a stone bridge; and, if it could be built, there is no reason to suppose it could possibly resist the force of those vast shoals of ice which in the beginning of winter come down this rapid river. An attempt, however, has been made to remedy this inconvenience; and a Russian peasant has actually projected the plan of throwing a wooden bridge of one arch across it, which, in its narrowest part, is 980 feet in breadth. As we think this is a matter of very considerable importance, as well as of curiosity, we shall give the following copious account of the plan and its author, in Mr Coxe's own words; who tells us that the artist had then executed a model 98 feet in length, which he saw and examined with considerable attention.

"The bridge is upon the same principle with that of Shaffhausen, excepting that the mechanism is more complicated, and that the road is not so level. I shall attempt to describe it by supposing it finished, as that will convey the best idea of the plan. The bridge is roofed at the top, and covered at the sides ; it is formed by four frames of timber, two on each side, composed of various heams or trusses, which support the whole machine. The road is not, as is usual, carried over the top of the arch, but is suspended in the middle.

" The following proportions I noted down with the greatest exactness at the time when they were explained to me by the artist.

658 feet Length of the abutment on the north end, 080 Span of the arch, Length of the abutment on the south end, 658 Length of the whole structure, including the 2296 abutments, The plane of the road upon its first ascent makes an angle of five degrees with the ordinary surface of the river. Mean level of the river to the top of the 168 bridge in the centre, -----Ditto to the bottom of the bridge in the 126 centre, Height of the bridge from the bottom to the top in the centre, 42 Height from the bottom of the bridge in the ÷., centre to the road, 7 Height from the bottom of ditto to the - - -84 water, Height from the water to the spring of the 56 arch,

So that there is a difference of 35 feet between the road at the spring of the arch and the road at the centre; in other words, an ascent of 35 feet in half. 980, or in the space of 490 feet, which is little more than eight-tenths of an inch to a foot. The bridge is broadest towards the sides, and diminishes towards the centre.

In the broadest part it is		-	168 feet
In the centre or narrowest	-		42
The breadth of the road is		-	28

"The artist informed me, that to complete the bridge would require 49,650 iron nails, 12,908 large trees, 5500 heams to strengthen them: and that it would cost 300,000 rubles or 60,000l. He speaks of this bold project with the usual warmth of genius; and is perfectly convinced that it would be practicable. I must own that I am of the same opinion, though 1 hazard it with great diffidence. What a noble effect would be produced by a bridge striking across the Neva, with an arch 980 feet wide, and towering 168 feet from the surface of the water ! The description of such a bridge seems almost chimerical; and yet upon inspection of the model we become reconciled to the idea. But whether the execution of this stupendous work may be deemed possible or not, the model itself is worthy of attention, and reflects the highest honour on the inventive faculties of that unimproved genius. It is so compactly constructed, and of such uniform solidity, that it has supported 3540 pood, or 127,440 pounds, without having in the least swerved from its direction, which I am told is far more, in proportion to its size, than the bridge if completed would have occasion to sustain from the pressure of the carriages added to its own weight.

" The person who projected this plan is a common Russian peasant. This extraordinary genius was apprentice to a shopkceper at Nishnei Novogorod : opposite to his dwelling was a wooden clock, which ex-cited his curiosity. By repeated examination he comprehended the internal structure, and without any assistance formed one exactly similar in its proportion and materials. His success in this first essay urged him to undertake the construction of metal clocks and watches.

Neva.

Ne

Veno

~

watches. The empress, hearing of these wonderful exertions of his native genius, took him under her pro-Neuchat- tection, and sent him to England ; from whence, on account of the difficulties attending his ignorance of the language, he soon returned to Russia. I saw a repeating watch of his workmanship at the Academy of Sciences : it is about the bigness of an egg; in the inside is represented the tomb of our Saviour, with the stone at the entrance, and the centinels upon duty : suddenly the stone is removed, the centinels fall down, the angels appear, the women enter the sepulehre, and the same chant is heard which is performed on Eastereve. These are triffing, although curious peformances ; but the very planning of the bridge was a most sublime conception. This person, whose name is Kulibin, bears the appearance of a Russian peasant : he has a long beard, and wears the common dress of the country. He receives a pension from the empress, and is encouraged to follow the bent of his mechanical genius (A).

NEVEL, or NEBEL, in the Jewish antiquities, a kind of musical intrument. See NABLUM. NEVERS, a town of France, in the department of

Nievre, and situated in E. Long. 3. 14. N. Lat. 46. 59. on the river Loire, which here receives the rivulet Nievre. It contained 10,1 50 inhabitants in 1800. It. is a place of great antiquity, supposed to be Cæsar's Noviodunum in Æduis, where he erected magažines for his armies. Francis 1. made it a dueby and peerage in 1 521, in favour of Francis of Cleves, to whom it came by marriage. It devolved afterwards to the house of Mantua, and then to the Palatine family, who in 1651 sold it to Cardinal Mazarine. The cardinal obtained a title of duke and peer for his nephew Philip Maneini, in whose family it continued till the late revolution. The town is fortified with walls, defended with many high towers and deep ditches, and is the seat of a bishoprie, suffragan of Sens, as likewise of a bailiwie and chamber of accounts. There was a stone bridge on the Loire, which was carried away by the ice, and has been replaced by a wooden one. This town is famous for its manufacture of glass, earthen ware, cloth, and cutlery. In the centre of Nevers, on the summit of a hill, is built the palace of the ancient dukes. It appears to have been constructed in the sixteenth century, and exhibits a model of the beauty and delicacy of Gothic architecture. The apartments are hung with tapestry of 200 years old, which have an air of grotesque and rude magnificence.

NEUCHATTEL, a town of Swisserland, capital of a county of the same name. There are several ancient ruins near it, which show its former extent ; and there are two large churches, besides a eastle where the governor resides. The town contains about 3000 in-

NE Ü

habitants. It is situated partly on a small plain, be- Neuchattween Mount Jura and the lake of Neuchattel, which is 17 miles long and five broad; the side of the harbour is the usual walk of the inhabitants. Part of it too is built upon the side of the mountain; whence some of its streets are very steep. In this small place several public works have lately been executed, which Mr Coxe thinks are far beyond the revenues, or even the wants, of such a little state. Among these he instances a superb causeway and a town-house " built (says he) of such solid materials, as if it was intended to survive to the most distant posterity, and to rival the duration of the much-famed Roman capitol." At the beginning of the 18th century, commerce was very little followed in this town, owing to an absurd opinion which prevailed among the inhabitants, of its being disgraceful; but this prejudice is now extinguished, and the town in a much more flourishing situation than before. The chief article of exportation is wine. which is much esteemed; and manufactures of printed linens and eottons have been established with considerable success. The flourishing state of Neuchattel is principally owing to the benefactions of Mr David Pury, late banker of the court at Lisbon. He was born at Neuchattel in 1709; but having received his education there; he quitted it in great poverty, and repaired to Geneva, where he served his apprenticeship, but in what line is not mentioned. From Geneva he went to London, where he aeted as clerk to a dealer in precious stones, and acquired great reputation by estimating the value of diamonds at sight. After a long residence in England he went to Lisbon, where he carried on a very extensive commerce; and having been appointed court-banker, his fortune rapidly increased. His generosity, however, kept pace with his wealth; and he not only remitted large sums to Neuchattel while living, but left his country his heir when he died. His contributions in all are estimated by Mr Coxe at 200,000l.; a considerable part of which has been employed in constructing the public works already mentioned. Neuehattel has a grand and little eouneil : the first is composed of 40 persons, with two masters of the keys; the little council consists of 24 members, comprehending the mayor, who is president. These two councils assemble regularly every month. The ecclesiastics likewise assemble every month, to consult on affairs belonging to the church, and to fal up the places of ministers that dic. They choose a dean every year, who is president of the general assemblies, which are called classes; and sometimes he is confirmed in this dignity. E. Long. 7. 10. N. Lat. 47. 5. NEUCHATTEL, & sovereign county of Swisserland,

bounded on the west by the Franche Compte, on the north by the bishoprie of Basle, and on the east and 5 E 2 south

(A) We have given the detail in Mr Coxe's own words, as it appears to us to deserve attention on account of the greatness of the project, which would have excited admiration had it been attempted by one enlightened by science and liberal arts, much more when it comes through the humble medium of a Russian peasant. It was never executed, as we are just informed by a gentleman who left St Petersburgh about the beginning of June 1793; but the model remains, and is still shown. The same gentleman (we quote his own words) adds, " that every mechanic thinks it practicable; and that the general belief is, that the empress would have built it, had she not found use for all her money in carrying on her warlike and diplomatic transactions with other courts."

Neva

Nevis

Ncuchattel south by the cantons of Berne and Friburg. This principality of Neuchattel and Vallengin extend from the lake of Neuchattel to the borders of Franche Compte, being in length about 12 leagues, and six in breadth. The plain with the lower part of the mountains is occupied by the district of Neuchattel, but Vallengin is totally enclosed by Jura. Parallel chains of these mountains run from east to west, forming scveral valleys in the most elevated parts. The lower grounds of this chain consist of arable lands and vineyards; the higher of large tracts of forest, which in many parts have been cleared and converted into pasture grounds, intermixed with fields of barley and oats. The inhabitants are numerous, and remarkable for their genius, politeness, and active industry. It contains three cities, one town, 90 villages, and about 300 houses dispersed in the mountains. The inhabitants are all Protestants, except two Roman eatholic villages: and in 1529 they entered into a strict alliance with the cantons of Berne, Friburg, Soleure, and Lucern. The air is healthy and temperate, but the soil not everywhere equally fertile: however, there are large vincyards, which produce white and red wine, which last is excellent. The pastures on the mountains feed a great number of cattle; there are plenty of deer in the forests; the lakes and rivers abound with fish. The mildness of the government, and agreeable situation of the inhabitants in general in these districts is evident from the great increase of population in the space of 32 years. In 1752 they contained only 28,017 subjects and 4318 aliens: but in 1784 the number was augmented to 31,576 subjects and 9704 aliens; being an increase of near a fourth part in that time. The facility with which the burghership of Neuehattel is acquired, may also be accounted one of the means of augmenting its population; for between the years 1760 and 1770, the magistrates admitted 41 persons to this privilege; from 1770 to 1780, 46; from 1780 to 1785, 51; in all 138; many of whom had children before they purchased their burghership, and 38 of them were foreigners, either German, French, or Dutch. This country has experienced similar changes with the rest of Switzerland during the usurpation of the French.

NEUFCHATTEAU, a commercial town of France, in the department of the Vosges, containing 2700 inhabitants. It formerly had an abbey of the nuns of St Clair, a commandery of Malta, and several convents of monks and nuns. It is seated in a fertile soil, which produces eorn, wine, and all the necessaries of life, on the river Mouzon. E. Long. 5. 45. N. Lat. 48. 20.

NEVIS, one of the Caribbee islands, lying about seven leagues north of Montserrat, and separated from St Christopher's by a narrow channel. It makes a beautiful appearance from the sea, being a large conical mountain covered with fine trees, of an easy ascent on every side, and entirely cultivated. The circumference is about 21 miles, with a considerable tract of level ground all around. The climate in the lower part is reckoned to be warmer than Barbadoes, but it is more temperate towards the summit. The soil is very fine in the lower part, but grows coarser as we ascend. The productions are nearly the same with those of St Christopher's. There are three pretty good roads er hays, with small towns in their vicinity; Charles Town, Moreton bay, and Newcastle. This

pleasant island was settled under the auspices of Sir Nevis Thomas Warner from St Christopher's. His successor, Governor Lake, was considered as the Solon of Neuter. this little country, in which he disposed of every thing with such prudence, wisdom, and justice, as procured him a high reputation with the French as well as English. In the Dutch war they met with some disturbance from the French; but by being eovered by an English squadron, the enemy were obliged to desist from their intended invasion, after a smart engagement in sight of the island. Sir William Stapleton sometimes resided here, and Sir Nathaniel Johnson constantly, at which time the inhabitants of Nevis were computed at 30,000. In the war immediately after the Revolution, they excrted themselves gallantly, and had two regiments of 300 men each. In that of Qucen Anne they behaved equally well, though they were less fortunate; for the French landing with a superior force, and having inveigled most of their slaves, they were forced to capitulate. About 4000 of these slaves the French earried away and sold to the Spaniards, to work in their mines. The parliament, after making due inquiry into the losses they had sustained, voted them about a third part of the sum in which they had suffered. These losses by war, an epidemic disease, and repeated hurrieanes, exceedingly diminished the number of the people. They are now thought not to exceed 2000 or 3000 whites, and 6000 blacks. There is here a lieutenant governor, with a council, and an assembly, which is composed of three members from each of the five parishes into which the island is divided. The commodities are eotton and sugar; and about 20 sail of ships are annually employed in this trade.

NEURADA, in Botany, a genus of plants belonging to the decandria class, and in the natural method ranking under the 13th order, Succulentæ. See Bo-TANY Index.

NEUROGRAPHY, significs a description of the nerves. See ANATOMY.

NEUROPTERA, the name of one of the orders into which the elass of insects is divided according to the Linnæan classification. See ENTOMOLOGY Index.

NEUTER, a person indifferent, who has espoused neither party, and is neither friend nor foe.

A judge ought to be neuter in the eauses he judges; in questions, where reason appears neuter, a man should ever ineline to the side of the unhappy.

NEUTER, in Grammar, denotes a sort of gender of nouns, which are neither masculine nor feminine. See GENDER.

The Latins have three kinds of genders, masculine, feminine, and neuter. In English, and other modern tongues, there is no such thing as neuter nouns. See NOUN.

Verbs NEUTER, by some grammarians called intransitive verbs, are those which govern nothing, and that are neither active nor passive. See VERB.

When the action expressed by the verb has no object to fall upon, but the verb alone supplies the whole idea of the action ; the verb is said to be neuter : as, I sleep, thou yawnest, he sneezes, we walk, ye run, they stand still.

Some divide verbs nenter into, I. Such as do not signify any action, but a quality; as albet, "it is white;" or

Neuter or a situation, as sedet, " he sits;" or have some relation to place; as adest, "he is present;" or to some other Newark. state or attribute, as regnat, " he rules," &e. And, 2. Those that do signify actions, though those such as do not pass into any subject different from the actor ; as to dine, to sup, to play, &c.

But this latter kind sometimes eease to be neuter, and commence active; especially in Greek and Latin, when a subject is given them; as, vivere vitam, ambu-lare viam, pugnare pugnam. Thus the old French poets say, Soupirer son tourment ; the English, to sigh his woes, &e.

But this is observed only to obtain where something particular is to be expressed, not contained in the verb: as, vivere vitam beatam, to live a happy life; pugnare bonam pugnam, to fight a good fight, &c.

According to the abbot de Dangeau, verbs neuter may be divided into active and passive; the first, those that form their tenses in English, by the auxiliary verb to have ; in French, by avoir. The second, those that form them in English with the verb to be; in French étre .- Thus, to sleep, to yawn, dormir and eternuer, are neuters active .- To come, and to arrive, are neuters passive.

NEUTRAL Salts, in Chemistry, compounded of an acid with any other substance capable of uniting with it and destroying its aeidity, as sulphurie aeid and soda, or Glauber's salt, muriatie acid and soda, or common salt.

NEUTRALITY, the state of a person or thing that is neuter, or that takes part with neither side.

NEW-ABBEY, situated near Kilcullen bridge in the county of Kildare, and province of Leinster in Ireland. It was founded by Rowland Eustace, of a great and ancient family in this county ; the tower is still standing, and some part of the abbey; the ruins of the rest have contributed to build several dwellings near it. In the inside Rowland Eustace and his lady lie buried; their figures, clothed in armour, are to be seen there. Near this is a handsome seat of the Carter family, on the opposite side of the river Liffey.

NEWARK upon Trent, in the county of Nottingham, is a great thoroughfare in the York road, 124 miles from London. It has bridges over the Trent, which forms an island here, by dividing itself into two streams two miles above the town, which meet again two miles below it. A magnificent castle was built here in the reign of King Stephen, which held out stoutly in the barons wars for King John, who died here. October 10. 1216; and it also stood out for King Charles I. to the last ; but after he had put himself into the hands of the Scots army then before it, the governor by his order surrendered it, after which it was demolished .- It was situated near the river ; the walls of the towers are very thick, and of a very great height; and were there no historical testimony, these remains are sufficient evidence that it was formerly of great importance. In the court before these ruins is a very fine bowling green. The town being subject to inundations from the river Trent, and often from that circumstance made impassable, a turnpike road, at the instigation of a publican, was made about twenty years ago, so high as to be passed with safety in the greatest floods, by arehes of brick being made in several places to earry off the water, constructed by Mr Smeaton, at the expense of 12,000l. Near the town there is a bridge

constructed for the same purpose, made mostly upon Newark dry land, consisting of nine arches. Its church, which is reckoned one of the finest in the kingdom, was built Newcastle by Henry VI. and has a lofty spire. The population on Tyne. in 1811 was 7236.

NEWBOROUGH, or NEWBURGH, in the isle of Anglescy, North Wales, distant from London 254 miles, though but a small town, situated over against Caernarvon in North Wales, about 17 miles southwest from Beaumaris, is governed by a mayor, two bailiffs and a recorder. Its Welsh name is Rhossir, or Rhosvair.

NEWBURG, the name of several towns of Germany, two of which are the chief towns of duchies of the same name; one in Bavaria, and the other in the Palatinate.

NEWBURY, a town in the county of Berks in England, 16 miles from Reading, and 56 from London, arose on the decay of Spinham-Land. Notwithstanding its name signifies New-Borough, it is as old almost as the Conquest. It made so much broad. eloth formerly, that in the reign of Henry VIII. here flourished John Winscomb, commonly called Jack of Newbury, one of the greatest clothiers that ever was in England, who kept 100 looms in his house; and in the expedition to Flowden Field against the Seots, marched with 100 of his own men, all armed and elothed at his own expense; and he built all the west part of the church. Also Mr Kenric, the son of a clothier here, though afterwards a merchant in London, left 4000l. to the town, as well as 7500l. to Reading, to encourage the woollen manufactory. It makes a great quantity of shalloons and druggets, but not near so much broad cloth now as formerly; yet it. is a flourishing town, with spacious streets, and a large market place, in which is the guild-hall. In the neighbourhood, on the banks of the Kennet, there is a stratum of petrified wood dug out for firing, where they frequently find trunks of large oaks yet undecayed, with petrified hazel nuts, fir concs, &c. with the bones and horns of stags, antclopes, &c. tusks of boars, and heads of beavers. The river Kennet, which abounds with excellent trout, eels, and cray-fish, runs through the town. It was made a corporation by Queen Elizabeth, and is governed by a mayor, high steward, aldermen, &c. The population in 1811 was 4898.

NEWCASTLE-under-Line, a town in England, in the county of Stafford, on a branch of the Trent, is 15 miles north of Stafford, 33 south south-east of Warrington, and 149 from London : had a castle, now in ruins; and is so called from an older castle, which formerly stood two miles off, at Chesterton-under-Line. It was incorporated by King Henry I. and again by Queen Elizabeth and King Charles II. and is governed by a mayor, two justices, two bailiffs, and 24 eommon council. The population in 1811 was 6175. The clothing trade flourishes here; but its ehief manufactory is hats, here being an incorporated company of felt-makers. A great quantity of stone ware is made near this place.

NEWCASTLE on Type, the capital of the county of Northumberland in England, 15 miles north of Durham, 94 north of York, 63 south by cast of Berwick, 60 cast of Carlisle, and 271 from London, stands at the end of the Picts wall, on the north side of the Tyne, over

01

the county, and makes no part of the liberties .- It is Newcastle now the county prison, and in the great hall the judges on Tyne. hold the assizes. Here Baliol king of Scotland did homage to King Edward I. in 1292 : as did Edward Baliol in 1334 to King Edward III. Here is a magnificent exchange and a customhouse; and a very fine quay. There is a handsome mansion house for the mayor, who is allowed 1000l. a-year, for his table, besides a coach and barge. The old bridge was carried away in a flood, and the present was creeted about 1775, of nine noble elliptic arches. With the old bridge 22 houses were thrown down, and six lives lost. It was originally built of wood; but having been destroyed by fire in 1248, was rebuilt of stone, and consisted of 12 arches, three of which on the north side were closed up, and served for cellars: this was again rebuilt about 1450; and was crowded with wooden buildings; but near the middle was a tower with an iron gate, used as a town prison. A strong building crossed the bridge, which was used as a magazine. On the south front was a statue of King Charles II. The water which destroycd this bridge, on November 11. 1771, was upwards of 12 feet above high water mark in spring tides .- On removing the foundations of the piers of the old bridge to crect the present, by observations made, and medals found, part of it is supposed to have existed from the time of the Romans. It is computed that above 6000 keelmen are employed here, who have formed themselves into a friendly society; and by their own contributions, built a noble hospital containing 50 chambers, for such of their fraternity as are poor, disabled, or past their labour 3 and it is supported by the contribution of those that are in health. The town is extremely populous; and, notwithstanding the multitude of those employed in and about the coal pits, with which the town is in a manner surrounded, has abundance of poor; but it has also many wealthy inhabitants, and it is said they pay above 4000l. a-year to their relief. It is observed, that this town has the greatest public revenue in its own right as a corporation, of any town in England, it being computed at no less than 8000l. a-year. In 1774, the receipts of the corporation were 20,360l. 9s. 8d.; and their disburse-ments about 19,445l. The number of inhabitants in 1811 was 27,587, exclusive of a number of scamen who cannot he accurately estimated. Here are four churches or chapels. That of St Nicholas is the mother church, a curious fabric, built cathedral-wise by David king of Scots, 240 feet long, 75 broad, and proportionably high, with a tower steeple 194 feet in height, of Gothic architecture; also St Andrew's, St John's, and All Saints, lately rebuilt on the site of the old structure, of a circular form. Here are also several meeting houses, and four charity schools for 300 children; a fine hall for the surgeons, and a large prison called Newgate ; also an hospital for lunatics, another for the lying-in of married women, as well as a fund raised for the relief of those who are delivered at their own houses. Here is a well endowed and large infirmary, and an assembly room that attracts attention, containing every useful apartment, and a ball room 93 feet by 40 : The front is ornamented with six Ionic pillars, &c. In another part of the town is a new theatre. Here is a very neat set of baths. A free grammar school was granted by James I. from an old foundation of

Newcastle over which it has a stately bridge into the bishopric on Tyne. of Durham, in which its suburb called Gateside is situated; for the liberties of Newcastle extend no farther than the great iron gate upon the bridge, which has the arms of the bishop of Durham carved on the east side and those of Newcastle on the west side. W. Long. 1. 27. N. Lat. 55. 5. It is admitted to have been a Roman station, though no evidence at present appears, except at Pandon-gate, whose superstructure is of different workmanship and model from any others of the town, the arches heing circular. The Carpenter's tower is also of Roman original. In the Saxons time it was called Moncaster, from the monks here, who all fled when it was depopulated by the Danes ; and afterwards Newcastle, from a castle built here by William the Conqueror's son, Robert, in 1080, to defend the country against the Scots, whose kings had this town before the Norman conquest, and sometimes resided here. -Several monasteries and houses were huilt here soon after the castle; and it was greatly enlarged and enriched by a good trade to the coasts of Germany, and by the sale of its coal to other parts of England; for which, and for other merchandise, it is become the great emporium of the north of England, it being the neatest and largest town in those parts, next to York. In the reign of Edward I. it was burnt by the Scots ; hut a very rich burgher, who was taken prisoner, soon ransomed himself for a good sum of money, and began the first fortifications of the place, which he extended from Sandgate to Pampedon, and thence to the Austin friars gate; which the townsmen finished, and encompassed with stout walls, which extended two miles, wherein are seven gates and many turrets, with several casemates bomb-proof. To which two other gates were added in more modern times, viz. Bridgegate and Sand-gate : the wall between them was afterwards removed to open the quay. Edward III, granted the corporation the duties and customs of the town for seven years, to enable them to complete the fortification. It is a borough at least as ancient as King Richard II. who granted that a sword should be carried before the mayor ; and King Henry VI. made it a town and county incorporate of itself, independent of Northumherland. Henry VII. built a monastery here for the Franciscans. Besides which, it had several religious foundations, several of which structures have been converted to companies halls and private residences. In the reign of Henry VIII. this place is said to have exceeded in the strength and magnificence of its works all the cities of England, and most places in Europe. The town is governed by a mayor, 12 aldermen, a recorder, sheriff, town clerk, a clerk of the chambers, two coroners, eight chamherlains, a sword-bearer, a water bailiff, and seven scriptants at mace. Its situation, especially the most busy part of it towards the river, is very uneven, it being built on the declivity of a steep hill, and the houses very close. The castle overlooks the whole town. That part built by Robert was of great strength, and square, and surrounded by two walls; the square was 62 feet by 54, and the walls 13 feet thick, within which was a chapel. The outward fortifications are now defaced, and their site crowded with buildings. The tower remains

> cipal entrance is to the south. This castle belongs to 3

> entire, and situated on a lofty eminence, and its prin-

castle states at 41,000l. is now very considerably up- Newcastle n Tyne.

wards of 70,0001. The coals carried out of it annually (on an average Newcastle. from 1785 to 1791) were nearly 448,000 Newcastle chaldrons; the weight of which is 1,187,200 tons. The following are the exports of coals from the Tyne for the years annexed.

Years.	Coastways,	Over sea.	Plantation
1802	494,488	41,157	2844
1803	505,137	42,808	1516
1804	579,929	48,737	3852
1805	552,827	47,213	2360

The number of persons employed in the coal trade ofthe rivers Tyne and Wear in 1792 exceeded 64,000.

The manufacture of earthen ware is greatly increased, and carried on to great perfection in its neighbourhood, in seven potterics; and their produce exported hence to foreign parts, as well as to the different ports of this kingdom; some of which potteries constantly employ upwards of 100 persons, men, women, and children.

New works of considerable extent for the manufacture of iron have been established; as also a very capital manufactory for white lead, milled lead, &c. Independent of red and white lead, the quantity of lead exported from the river Tyne during four years was as follows.

Years.	Tons.	Cwt.
1802	8609	18.
1803	6364	6
1804	10352	2
1805	9163	3

The trade with the West India islands is increasing, and may in time become very considerable; as the port has great advantages, in being able to supply on the cheapest terms many articles wanted in those islands; such as coals, grindstones, lime, bricks, tiles, iron wares, &c.; and is most advantageously situated for the re-exportation of the West India produce to the ports on the Baltic, to Germany, the United Provinces, Flanders, and part of France; and moreover, the risk of navigation, and the rate of insurance, not being greater than between those islands and Liverpool, and some other ports on the western coast of this kingdom.

The population of Newcastle in 1811 was 27,587, and it is daily increasing in inhabitants and opulence. It has long been noted for hospitality and good living. Great improvements have been made in the town, by opening new streets, and paving the principal ones, in the same manner as in London. To the list of public edifices of modern erection, and mentioned above, viz. the grand assembly rooms, and the elegant theatre, which were built by subscription, and the superb parish church of All Saints, built at a very great expence by the parishioners, may be added a commodious riding house, built also by subscription.

NEWCASTLE, a borough town of Ircland, in the county of Dublin, and province of Leinster, which formerly returned two members to parliament, and holds two fairs, 9th of May and 8th of October.

NEWCASTLE is also the name of a handsome town in .

on Tyne. chapel is the election of the officers of the corporation. "There were formerly several palaces in this city, viz. Pampedon hall, Lumley place, Earl's Place, Northumber-land house, Westmoreland place, &c. The free masons have lately erected an elegant hall, richly ornamented, to hold their lodge in, near High friar chair, capable of holding above 4000 of that ancient fraternity. Here is an hospital for 39 decayed freemen and their widows ; and another for three elergymen's widows and three merchants widows. The Maidens hospital, built in 1753, is endowed with 2400l. for six maiden women and six poor men. Dr Thomlin, a prebendary of St Paul's, and rector of Whicham in the bishopric of Durham, gave a library of above 6000 valuable books to the corporation, and settled a rent charge of 51. a-year for ever for buying new ones; and Sir Walter Blacket, formerly one of its representatives in parliament, built a neat repository for them, and settled 25l. a-year for ever on a librarian. The upper or north part of the town, inhabited by the politer sort of people, is much pleasanter than that part next the river, and has three level, well built, and spacious streets. The river all the way up from Shields to Newcastle is broad, the channel safe, and the tide flows with a strong current to the town, and far beyond it. In the beginning of the civil wars, this town was taken and plundered by the Scotch fanatics, who here sold their king, Charles I. for 200,000l. in hand, and security for as much more. The glass works are very curious, and have more business of the finc sort than most other places : the duty on this article drawn by government is said to amount to 200,000l. annually. Besides, it has a considerable manufacture of broad and narrow cloths, and several soap boileries; and this place is famous for grindstones, for which there is such a demand, that scarce a ship stirs without them ; from whence came the proverb, " That a Scotsman and a-Newcastle grindstone travel all the world over." Ships fit for the coal trade are built here to perfection, with great strength. Here is a considerable manufactory of hardware and wrought iron, after the manner of that at Sheffield.-Its markets are on Tuesdays and Saturdays. Its fairs in August, which last nine days, and October 29th, which last nine days. By an act of Queen Mary, the price of the carriage of goods hither from London by waggons was settled at 2d. per lib. London alone. is said to consume at least 766,887 chaldrons of its coal every year; but as for the fish vended in that city by the name of Newcastle salmon, it is more properly called Berwick salmon, the fresh salmon being taken near 50 miles farther, as far as the Tweed, and brought on the backs of horses to Shields, where it is cured, pickled, and sent on board for London. It is worth remembering, that at the assizes here in 1743, two old men were subpœna'd hither as witnesses from a neighbouring village, viz. one 135 years of age, and his son 95, both hearty, and having their sight and hearing; and that in 1744, one Adam Turnbull died in this town aged 112, who had had four wives, the

> years old. The annual amount of the revenue of customs at this port, which Mr Brand in his History of New-

> last of whom he had married when he was near 100

Newcastle in the county of Limerick and province of Munster, on the high road to Kerry, 114 miles from Dublin. New Fo- Here was a religions house possessed by the knights templars. It is said, they used some barbarous customs rest. which greatly disgusted the Irish, who, watching a favourable opportunity, attacked a number of the knights riding out together and put them to death ; the place is still remembered where their remains were interred. This order was suppressed in the famous council of Vienna, 22d of March 1312. Newcastle consists of a large square where markets and fairs are held; on the northern side stands a market house, with an assembly room; on the south side is the church, which is the neatest in the county : it was finished in 1777 at the sole expense of Lord Courtenay. It stands close to the walls and fortifications of the knights templars, of which one of the castles is fitted up for Lord Courtenay's agent.

NEWCASTLE, a town in America, 35 miles below Philadelphia, on the west bank of Delaware river. It was first settled by the Swedes about the year 1627, and called Stockholm. It was afterwards taken by the Dutch, and called New Amsterdam. When it fell into the hands of the English, it was called by its present name. It contained 2438 inhabitants in 1800, including 235 slaves, and was formerly the seat of go-vernment. This is the first town that was settled on Delaware river.

NEWCASTLE, Duke of. See CAVENDISH. New England. See ENGLAND, New.

New Forest of Hampshire in England, is a tract of at least 40 miles in compass, which had many populous towns and villages, and 36 mother churches, till it was destroyed and turned into a forest by William the Conqueror. There are nine walks in it; and to every one a keeper, under a lord warden, besides two rangers, and a bow-bearer. As this large tract lay many ages open and exposed to invasions from foreigners, King Henry VIII. built some castles in it : and it has now several pretty towns and villages. It is situated in that part of Hampshire which is bounded on the east hy Southampton river, and on the south by the British channel. It possesses advantages of situation, with respect to the convenience of water carriage and nearness to the dock yards, superior to every other forest, having in its neighbourhood several ports and places of shelter for shipping timber, among which Lymington is at the distance of only two miles, Bewley about half a mile, and Redbridge three or four miles from the forest; and the navigation to Portsmouth, the most considerable dock yard in this kingdom, is only about 30 miles from the nearest of those places. This is the only forest belonging to the crown of which the origin is known. Doomsdaybook contains the most distinct account of its afforestation by William the Conqueror : the contents of every field, farm, or estate afforested, in hides, earucates, or virgates, by which the extent of land was then computed, together with the names of the hundreds and villages, and of the former proprietors (which are for the most part Saxon), the rent or yearly value of each possession, and the tax which had been paid for it to the crown during the reign of Edward the Confessor, before the inhabitants were expelled, and that part of the country laid waste, are all to be

found in that most curious and venerable record. New Fo-Wishing to discover the original extent of the forest, rest. we extracted, for our own information, all that relates to it in that ancient survey. The extract is far too voluminous for insertion. The names of many of the places having been changed since that time, it is difficult to ascertain with precision what were then the limits of the forest. The oldest perambulation we have met with is among the Pleas of the Forest, in the eighth year of King Edward I. preserved in the Chapter-house at Westminster. The boundaries there described include all the country from Southampton river on the east to the Avon on the west, following the sea coast as far as the southern boundary between those rivers, and extending northwards as far as North Chadeford, or North Charford, on the west, and to Wade and Orebrugg, or Owerbridge, on the cast; and the greatest part, if not the whole, of that extensive district, is mentioned in Doomsday book to be the forest belonging to the crown. Another perambulation was however made in the 29th of the same king, which leaves out a great part of the country contained within the former. This perambulation, which is preserved in the Tower of London, confines the forest to limits which, as far as we can trace them, appear to have been followed in the 22d year of Charles II. when the forest was again perambulated. By the Charta de Foresta, all lands not belonging to the crown which had been afforested by Henry II. Richard I. or King John, were to he disafforested; but as no provision was made for the reduction of the more ancient afforestations, it is easy to account for the great diminution of this forest in the reign of Edward I. who was not a prince likely to submit to any encreachment on his rights. The perambulation of the 22d of Charles II. is the last which we find on record : it contains the present legal bounds of the forest, and was given to the surveyors as their guide, in taking the plan which they have made lately by direction. From that plan, with the approbation of the lords commissioners of his majesty's treasury, an engraving was made. According to the last-mentioned perambulation and the plan, the forest extends from Godshill on the northwest to the sea on the south-east, about 20 miles; and from Hardley on the east to Ringwood on the west, about 15 miles; and contains within those limits about 92,365 acres statute measure. The whole of that quantity, however, is not forest land, or now the property of the crown: there are several manors and other considerable freehold estates within the perambulation, belonging to individuals, to the amount of about 24,797 acres; about 625 acres are copyhold or customary lands belonging to his majesty's manor of Lyndhurst; about 1004 acres are lease-hold under the crown, granted for certain terms of years, and forming part of the demised land revenue, under the management of the surveyor-general of crown lands; about 901 acres are purprestures or encroachments on the forest; about 1193 acres more are enclosed lands held by the master-keepers and groom-keepers, with their respective lodges; and the remainder, being about 63,845 acres, are woods and waste lands of the forest. To perpetuate the spot where William Rufus was killed by the glance of an arrow shot at a stag, a triangular stone was erected in 1745. George III. visited

New Fo. siled this spot in 1789. In August 1782, a curious ancient golden cross was found here by a labouring Newfound- man digging turf. It weighed above an ennce of gold, and had on one side an engraving of our Saviour, and on the other, the ladder, spear, nails, and other emblems

of his sufferings.

New Years Gifts, presents made on the first day of the new year. Nonins Marcellus refers the origin of this custom among the Romans to Tatius king of the Sabines, who reigned at Rome conjointly with Romulus, and who having considered as a good omen a present of some branches cut in a wood consecrated to Strenia, the goddess of strength, which he received on the first day of the new year, authorized this custom afterwards, and gave to these presents the name of strenæ. However this may be, the Romans on that day celebrated a festival in honour of Janus, and paid their respects at the same time to Juno; but they did not pass it in idleness, lest they should become indolent during the rest of the year. They sent presents to one another of figs, dates, honey, &c. to show their friends that they wished for a happy and agreeable. life. Clients, that is to say, those who were under the protection of the great, carried presents of this kind to their patrons, adding to them a small piece of silver. Under Augustus, the senate, the knights, and the people, presented such gifts to him, and in his absence deposited them in the capitol. Of the succeeding princes some adopted this custom and others abolished it; but it always continued among the people. The carly Christians condemned it, because it appeared to be a relick of Paganism and a species of superstition; but when it began to have no other object than that of being a mark of veneration and esteem, the church ceased to disapprove it.

NEWEL, in architecture, is the upright post which a pair of winding stairs turn about; this is properly a cylinder of stone, which bears on the ground, and is formed by the end of the steps of the winding stairs.

NEWFIDLER-SEA, a lake in Hungary, 17 miles in length and 6 in breadth.

NEWFOUNDLAND, a large island of North America, belonging to Great Britain, lying between 46. 50. and 51. 30. N. Lat. and between 53. 30. and 58. 20. W. Long. from London. The form is that of an irregular triangle, the base or south side being 80 leagues in extent; the east side is the longest; and the whole circumference about 1 50 leagues. It is bounded on the north by the straits of Belleisle, which separate it from Labrador; on the east and south it hath the Atlantic ocean, and on the west the gulf of St Lawrence. The climate is rather severe ; and the soil, at least on the sea coast, which is all that we know of it, is poor and barren.' A few kitchen vegetables, with strawberries and raspberries, are all its produce. The country within land is mountainous, and abounds with timber; there are several rivers which are plentifully stored with various sorts of fish, abundance of deep bays, and many good ports. St John's and Placentia are the two principal settlements, and at each of these there is a fort; the number of people who remain here in the VOL. XIV. Part II.

winter hath been computed at 4000. The French, by Newfoundthe treaty of Utrecht, were permitted to fish from Cape Bonavista on the east side round the north of the island to Point Rich on the west; and by the treaty of Paris, they are allowed the isles of St Pierre and Miquelon, upon which they are to dry their fish, but not to creet fortifications of any kind.

The great importance of this place arises from its fishery, which is in part carried on by the inhabitants at the several harbours, which are about 20 in number, who take vast quantities of cod near the coast, which they bring in and cure at their leisure, in order to have it ready for the ships when they arrive. But the great and extensive fishery is on the banks at some distance from the island. The great hank lies 20 leagues from the nearest point of land, from the latitude 41° to 49°, stretching 300 miles in length and 75 in breadth .---To the east of this lies the False Bank ; the next is styled Vert, or the Green Bank, about 240 miles long, and 120 over; then Banquero, about the same size; the shoals of Sand Island, Whale Bank, and the Bank of St Peter's, with several others of less note, all abounding with fish.

The cod are caught only by a hook; an expert fisher will take from 1 50 to 300 and upwards in a day; for the fish never bite in the night: the labour is very great. The season is from May to October, in the height of which there are from 500 to 700 sail upon the banks at a time. The fish caught in the spring months are best; they are cured in very different ways. Some are styled white fish, others mud fish, which are stowed and salted in the hold, and will not keep long; but the best and most valuable are the dried cod. The quantity taken is prodigious : yet in some seasons and in different places varies considerably, as the fish frequently change their stations. The fishing ships, as they are called, lie upon the banks, with the help of their boats take and cure their own fish, and as soon as they are full sail for a market. The sack ships proceed directly to the island, where they purchase fish from the inhabitants either by barter or bills of ex-The principal markets for cod are Spain, change. Portugal, Italy, and the West Indies. The value of this fishery is computed at some hundred thousand pounds annually; employing, besides several hundred ships, some thousands of seamen, and affording a maintenance to a number of tradesmen of different occupations, by which many large towns on the west side of England accumulate much wealth, and at the same time contribute in many respects to the benefit of the public.

The great utility of this fishery was very early seen, and very vigorously pursued; for in the heginning of the reign of King James I. we had two hundred and fifty sail employed therein. It is computed, that three quintals of wet fish make one quintal of dried cod. Besides, the livers of every hundred quintals make a hogshead of oil; and exclusive of these there are many lesser advantages that go in diminution of the expence. The fishery, as we have said above, produces differently in different seasons; but it is judged to be a very good one when it produces 300,000 quintals of fish and 3000 barrels of oil, both equally saleable and valuable commodities. As every ship carries twelve, and each of their boats eight men, and as these return home in six months, there cannot be a more noble nursery for 5 F seamen.

land.

land.

Newfound- seamen. The artificers and traders employed in building, vietualling, and repairing these vessels, are very numerous in the respective ports from which they sail. These eircumstances justify the particular attention paid by government to this branch of the public service; in respect to which that they may be well informed, an annual and very distinct account, by which the whole is seen at one view, is delivered by the proper officer to the governor of Newfoundland, that is, to the commodore of his majesty's squadron. Mr Pennant, in the appendix to his Aretie Zoology, gives us, from what appears to be very good authority, the following account of this island.

"Within the eircuit of 60 miles of the southern part, the country is hilly, but not mountainous. The hills increase in height as they recede from the sea; their course is irregular, not forming a chain of hills, but rising and falling abruptly. The coasts are high, and the shores most remarkably bold. The same may he said of almost every part of this vast island. The country is much wooded, and the hills (such as have not flat tops to admit the rain to stagnate on them) are clothed with birch, with hazel, spruce, fir, and pine, all small ; which is chiefly owing to the inhabitants taking off the bark to cover the fish stages. This peninsula is so indented by the fine and deep bays of Placentia, St Mary, Conception, and Trinity, that it may be penetrated in all parts, which is done for the sake of fowling, or the procuring of spars for masts, oars, &c. The island is on all sides pierced with deep bays, which peninsulate it in many places by isthmuses most remarkably narrow .- The mountains on the south-west side, near the sea, are very high, and terminate in lofty headlands; such are Chapeau Ronge, a most remarkably high promontory, Cape St Mary's, and Cape le Hune. Such in general is the formation of the island; on the northeast, most of the hills in the interior part of the country terminate pyramidically, but form no chain. The interior parts of the country consist chiefly of morasses, or dry barren hummocks, or level land, with frequent lakes or ponds, and in some places covered with stunted black spruce. The rivers of Newfoundiand are unfit for navigation, but they are of use in floating cown the wood with the summer floods. Still the rivers and the brooks are excellent guides for the hunters of beavers and other animals, to penetrate up the country, which as yet has never been done deeper than 30 miles. Near the brooks it is that timber is commonly met with, but seldom above three or four miles inland, and in valleys; the hills in the northern district being naked and barren.

" In some parts of Newfoundland there is timber sufficiently large for the building of merchant ships : the hulk is made of juniper, and the pine furnishes masts and yards; but as yet none has been found large enough for a mast for a large cutter. The fishery is divided into two seasons; that on the shore, or the shore season, commences about the 20th of April, and ends about the 10th of October ; the boats fish in from four to 20 fathoms of water. The most important, the bank fishing season, begins the 10th of May, and continues till the last of September, and is carried on in 30 to 45 fatlioms deep of water. Banking vessels have sailed from St John's to the bank as early as the 12th of April. At first they use pork or birds for a bait;

but as they catch fish, they supply themselves with a shell Newfoundfish called clams, which is found in the belly of the cod. The next bait is the lobster ; after that the herring and the launce, which last till June, when the capelan comes on the coast, and is another bait. In August the squid comes into use, and finally the herring again. The greatest number of eod fish taken by a single fisherman in the season has been 12,000, but the average is 7000. The largest fish which has been taken was four feet three inches long, and weighed 46 pounds. A hanking vessel of 10,000 fish ought to be filled in three weeks, and so in proportion; and 80 quintals (1121b. each) for a boat in the same time.

" In 1785, 541 English vessels fished on the bank, a number exceeding that of the French. A heap of dried fish, 20 feet long and ten wide, and four deep, contains 300 quintals. Such a heap settles, in the course of 48 hours after it is made, about $\frac{1}{12}$. An extraordinary splitter will split five quintals of fish in an hour. The average in that time is two. There is no fishing during winter, on account of the inclemency of the season. It is supposed that the fish in a great measure quit the banks before that time, as in general they are very scarce when the fishing vessels go upon the banks early in the spring.

" There are a few small towns on the coasts, which have gardens sown with English pulse; but many of the inhabitants quit the country in winter.

" An admiral or some sca officer is generally governor of Newfoundland."

NEWMARKET, in Cambridgeshire, 13 miles from Cambridge, 13 from St Edmundsbury, and 60 from London, is a town with one long street, the north side in Suffolk, the south side in Cambridgeshire. It is a healthy place, and a great thoroughfare in the road from London to Norfolk; but stands mostly by the horse races every year in April and October, here being the finest course in England; on which there is a house for the king when he comes to the races, which was built by Charles II. The king gives a plate or two every year, besides those given by the nobility; and wagers are laid upon the horses, which are seldom under 500l. and often above 1000l. Here are two coffeehouses, at which, every night and morning during the races, there is gaming, as there is also at the houses of the nobility and gentry. Here are also cock matches. Here is a little chapel, which is a chapel of ease to the mother church at Ditton; and another in the Suffolk side, which is parochial. The town was burnt in 1683, but soon rebuilt; and in 1811 contained 1917 inhabitants.

NEWROSS, a horough town in the county of Wexford, and province of Leinster in Ireland, 67 miles from Dublin. This town was formerly walled, and some of the gates still remain. It lies on the river Barrow, which is here very deep, and ships of burden can come up to the quay even when the tide is out. The church is large, but the customhouse and quay are both small, and sometimes overflooded many feet, It is one of the staple ports for exporting wool, yet its trade is but inconsiderable; beef and butter are the principal articles exported. Here is a barrack for a troop of horse, and a good ferry into the county of Kilkenny. Near this town is a charter school. It is also a post town, and gives title of carl to the family of Gore. It was formerly fortified, and adorned with

land Newross. Newross

with many religious houses, among which was a Crouched friary, built on the summit of a hill in the town; Newton. but one of the friars having killed a principal inhabitant, the whole body of the people arose, put the friars to death, and totally destroyed the friary; on the site of which the monastery of St Saviour, for conventual Franciscans, was afterwards crected by Sir John Devereux ; and the east end of this last building is now the parish church. A friary for Eremites, following the rule of St Augustine, was also founded here in the reign of Edward 111.

NEWSPAPERS, periodical publications, daily, weekly, &cc. for the purpose of communicating to the world every thing of importance, whether political or literary, &c. which is going on. They have tended much to the dissemination of learning, and have served many other valuable purposes; and while they are carried on with candour, impartiality, and ability, they are unquestionably a great national benefit. When this, however, is not the case, and it often happens, they disgrace their authors, and are highly injurious to the public. They were first published in England, August 22. 1642. Journal de Sçavans, a French paper, was first published in 1665, though one was printed in England, under the title of the Public Intelligencer, by Sir Roger L'Estrange, 1663, which he dropped, on the publication of the first London Gazette. Newspapers and pamphlets were prohibited by royal proclamation 1680. Though at the Revolution prohibitions of this kind were done away, and the press set at liberty, yet newspapers were afterwards made objects of taxation, and for this purpose were first stamped in 1713. The number of them, however, gradually increased; and there were printed in the whole kingdom during the years 1775, 12,680,000; 1776, 12,830,000; 1777, 13,150,642; 1778, 13,240,059; 1779, 14,106,842; 1780, 14,217,371; 1781, 14,397,620; 1782, 15,272,519. They are now still more numerous. The average number of newspapers printed in England at the close of the reign of George II. was 9,464,790. The number in 1790, was 14,035,639; in 1792, it was 15,005,760. Chalmers' Life of Ruddiman, p. 442.

NEW STYLE, first used in England in 1753, was introduced into the western world by Pope Gregory XIII. See CHRONOLOGY, Nº 24.

NEWT, or EFT, the common lizard. See LACER-TA, ERPETOLOGY Index.

NEWTON, SIR ISAAC, one of the greatest philosophers and mathematicians the world has ever produced, was the only child of Mr John Newton of Colesworth, not far from Grantham in Lincolnshire, who had an estate of about 120l. per abnum, which he kept in his own hands. He was born at that place on Christmas day 1642. His father dying when he was young, his mother's brother, a clergyman of the name of Ayscough, or Askew, who lived near her, and directed all her affairs after the death of Mr Newton, put her son to school at Grantham. When he had finished his school learning, his mother took him home, intending, as she had no other child, to have the pleasure of his company; and that he, as his father had done, should occupy his own estate. But his uncle happening to find him in a hay loft at Grantham working a mathematical problem, and having otherwise observed the boy's mind to be uncommonly bent upon learning,

he prevailed upon her to part with him; and she sent Newton. him to Trinity College in Cambridge, where her brother, having himself been a member of it, had still many friends. Isaac was soon taken notice of by Dr Isaac Barrow; who, observing his bright genius, contracted a great friendship for him. M. de Fontenelle tells us. " That in learning mathematics he did not study Euclid, who seemed to him too plain and simple, and unworthy of taking up his time. He understood him almost before he read him ; and a cast of his eye upon the contents of his theorems was sufficient to make him master of them. He advanced at once to the geometry of Des Cartes, Kepler's Optics, &c. It is certain that he had made his great discoveries in geometry, and laid the foundation of his two famous works, the Principia and Optics, by the time he was 24 years of age."

In 1664, he took the degree of bachclor of arts; and in 1668 that of master, being elected the year before, fellow of his college. He had before this time discovered the method of fluxions; and in 1669 he was chosen professor of mathematics in the university of Cambridge, upon the resignation of Mr Barrow. The same year, and the two following, he read a course of optical lectures in Latin, in the public schools of the university; an English translation of which was printed at London in 1728, in 8vo, as was the Latin original the next year in 4to. From the year 1671 to 1679, he held a correspondence by letters with Mr Henry Oldenburg secretary of the Royal Society, and Mr John Collins fellow of that society ; which letters contain a variety of curious observations.

Concerning the origin of his discoveries, we are told that as he sat alone in a garden, the falling of some apples from a tree led him into a speculation on the power of gravity; that as this power is not diminished at the remotest distance from the centre of the earth to which we can rise, it appeared to him reasonable to conclude, that it must extend much farther than was usually thought; and pursuing this speculation, by comparing the periods of the several planets with their distances from the sun, he found, that if any power like gravity held them in their courses, its strength must decrease in the duplicate proportion of the increase of distance. This inquiry was dropped ; but resumed again, and gave rise to his writing the treatise which he published in 1687, under the name of Mathematical Principles of Natural Philosophy; a work looked upon as the production of a celestial intelligence rather than of a man. The very same year in which this great work was published, the university of Cambridge was attacked by King James II. when Mr Newton was one of its most zealous defenders, and was accordingly nominated one of the delegates of that university to the high-commission court; and the next. year he was chosen one of their members for the convention parliament, in which he sat till it was dissolved. In 1696, Mr Montague, then chancellor of the exchequer, and afterwards earl of Halifax, obtained for him of the king the office of warden of the mint; in which employment he was of signal service, when the money was called in to be recoined. Three years after, he was appointed master of the mint; a place of very considerable profit, which he held till his death. In 1699, he was elected one of the members of the Royal Aca-, demy of Sciences at Paris. In 1701, he was a second 5 F 2 time

NEW

Newton time chosen member of parliament for the university of Cambridge. In 1704, he published his Optics ; which is a piece of philosophy so new, that the science may be considered as entirely indebted to our author. In 1705, he was knighted by Queen Anne. In 1707, he pub-lished his Arithmetica Universalis. In 1711, his Analysis per Quantitatum Series, Fluxiones et Differentias, Sce. was published by William Jones, Esq. In 1712, several letters of his were published in the Commercium Epistolicum. In the reign of George I. he was better known at court than before. The princess of Walcs, afterwards queen consort of England, used frequently to propose questions to him, and to declare that she thought herself happy to live at the same time with him, and have the pleasure and advantages of his conversation. He had written a treatise of ancient chronology, which he did not think of publishing ; but the princess desired an abstract, which she would never part with. However, a copy of it stole abroad, and was carried into France, where it was translated and printed, with some observations, which were afterwards answered by Sir Isaac. But, in 1728, the Chronology itself was published at London in quarto; and was attacked by several persons, and as zealonsly defended by Sir Isaac's friends. The main design of it was to find out, from some tracts of the most aneient Greek astronomy, what was the position of the colures with respect to the fixed stars, in the time of Chiron the centaur. As it is now known that these stars have a motion in longitude of one degree in 72 years, if it be once known through what fixed stars the colure passed in Chiron's time, by taking the distance of these stars from those through which it now passes, we might determine what number of years has elapsed since Chiron's time. As Chiron was one of the Argonauts, this would fix the time of that famous expedition, and consequently that of the Trojan war; the two great events upon which all aneient chronology depends. Sir Isaac places them

> nologers have done. This great man had all along enjoyed a settled and equal state of health to the age of 80, when he began to he afflicted with an incontinence of urine. However, for the five following years, he had great intervals of case, which he procured by the observance of a strict regimen. It was then believed that he certainly had the stone; and when the paroxysms were so violent, that large drops of sweat ran down his face, he never uttered the least complaint, or expressed the smallest degree of impatience; but, as soon as he had a moment's ease, would smile and talk with his usual cheerfulness. Till then he always read and wrote several hours in a day. He had the perfect use of all his senses and understanding till the day before he died, which was on the 20th of March 1726-7, in the 85th year of his age. He lay in state in the Jerusalem chamber at Westminster, and on the 28th of March his body was conveyed into Westminster abbey; the pall being supported by the lord chancellor, the dukes of Montrose and Roxburgh, and the carls of Pembroke, Sussex, and Macelcsfield. The bishop of Rochester read the funeral service, being attended by all the clergy of the church. The corpse was interred just at the entrance into the choir, where a noble monument is creeted to his memory.

500 years nearer the birth of Christ than other chro-

Sir Isaac was of a middling stature, and in the latter

part of his life somewhat inclined to be fat. His coun- Newton tenance was pleasing, and at the same time venerable. He never made use of spectacles, and lost but one tooth during his whole life.

His temper is said to have been so equal and mild, that no accident could disturb it. Of this the following remarkable instance is related. Sir Isaac had a favourite little dog, which he called Diamond; and being one day called out of his study into the next room, Diamond was left behind. When Sir Isaac returned, having been absent but a few minutes, he had the mortification to find, that Diamond having thrown down a lighted eandle among some papers, the nearly finished labour of many years was in flames, and almost consumed to ashes. This loss, as Sir Isaac was then very far advanced in years, was irretrievable; yet without once striking the dog, he only rebuked him with this exclamation, " Oh ! Diamond ! Diamond ! thou little knowest the mischief thou hast done !"

He was a great lover of peace, and would rather have chosen to remain in obseurity than to have the calm of life ruffled by those storms and disputes which genius and learning always draw upon those that are peculiarly eminent for them. In contemplating his genius it presently becomes a doubt, which of these endowments had the greatest share, sagacity, penetration, strength or diligence : and after all, the mark that seems most to distingnish it is, that he himself made the justest estimation of it, dectaring, that, if he had done the world any service, it was due to nothing but industry and patient thought; that he kept the subject under consideration constantly before him. and waited till the first dawning opened gradually, by little and little, into a full and clear light. It is said, that when he had any mathematical problems or solutions in his mind, he would never quit the subject on any account. Dinner has been often three hours ready for him before he could be brought to table : and his man often said, when he has been getting up in a morning, he has sometimes begun to dress, and with one leg in his breeches sat down again on the hed, where he has remained for hours before he got his elothes on. From his love of peace, no doubt, arose that unusual kind of horror which he had for all disputes; a steady unbroken attention, free from those frequent recoilings inseparably incident to others, was his peculiar felicity; he knew it, and he knew the value of it. No wonder then that controversy was looked on as his bane. When some objections, hastily made to his discoveries concerning light and colours, induced him to lay aside the design he had of publishing his optic lectures, we find him reflecting on that dispute, into which he was unavoidably drawn thereby, in these terms : " I blamed my own imprudence for parting with so real a blessing as my quiet, to run after a shadow." It is true this shadow (as Mr Fontenelle observes) did not escape him afterwards, nor did it cost him that quiet which he so much valued, but proved as much a real happiness to him as his quiet itself; yet this was a happiness of his own making : he took a resolution, from these disputes, not to publish any more about that theory till he had put it above the reach of controversy, by the exactest experiments and the strictest demonstrations; and accordingly it has never been called in question since. In the same temper, after

Newtor, ter he had sent the manuscript of his Principia to the Royal Saciety, with his consent to the printing of it by them, upon Mr Hook's injuriously insisting that himself had demonstrated Kepler's problem before our author, he determined, rather than be involved again in a controversy, to suppress the third book, and was very hardly prevailed upon to alter that resolution. It is true, the public was thereby a gainer ; that book. which is indeed no more than a corollary of some propositions in the first, being originally drawn up in the popular way, with the design to publish it in that form; whereas he was now convinced that it would be best not to let it go abroad without a strict demonstration.

After all, notwithstanding his anxious care to avoid every occasion of breaking his intense application to study, he was at a great distance from being steeped in philosophy: on the contrary, he could lay aside his thoughts, though engaged in the most intricate researches, when his other affairs required his attendance; and as soon as he had leisure, resume the subject at the point where he had left off. This he seems to have done not so much by any extraordinary strength of memory, as by the force of his inventive faculty, to which every thing opened itself again with ease, if nothing intervened to ruffle him. The readiness of his invention made him not think of putting his memory much to trial: but this was the offspring of a vigorous intenseness of thought, out of which he was but a common man. He spent therefore, the prime of his age in those abstruse researches, when his situation in a college gave him leisure, and even while study was his proper profession. But as soon as he was removed to the mint, he applied himself chiefly to the business of that office; and so far quitted mathematics and philosophy, as not to engage in any pursuits of either kind afterwards.

The amiable quality of modesty is represented as standing foremost in the character of this great man's mind and manners. It was in reality greater than can be easily imagined, or will be readily believed ; yet it always continued so without any alteration, though the whole world, says Fontenelle, conspired against it; and let ns add, though he was thereby robbed of his invention of fluxions. Nicholas Mercator publishing his Logarithmotechnia in 1668, where he gave the quadrature of the hyperbola by an infinite series, which was the first appearance in the learned world of a series of this sort drawn from the particular nature of the eurve, and that in a manner very new and abstracted ; Dr Barrow, then at Cambridge, where Mr Newton, at that time about 26 years of age, resided, recollected that he had met with the same thing in the writings of that young gentleman; and there not confined to the hyperbola only, but extended, by general forms, to all sorts of curves, even such as are mechanical; to their quadratures, their rectifications, and their eentres of gravity; to the solids formed by their rotations, and to the superficies of those solids; so that, when their determinations were possible, the series stopped at a certain point, or at least their sums were given by stated rules: and, if the absolute determinations were impossible, they could yet be infinitely approximated; which is the happiest and most refined method, says Mr Fontenelle, of snpplying the defects of human knowledge that man's imagination could possibly invent. To be

master of so fruitful and general a theory was a mine of Newton. gold to a geometrician; but it was a greater glory to have been the discoverer of so surprising and ingenious a system. So that Mr Newton finding, by Mercator's book, that he was in the way to it, and that others might follow in his track, should naturally have been forward to open his treasures, and secure the property, which consisted in making the discovery; but he contented himself with his treasure which he had found, without regarding the glory. What an idea does it give us of his unparalleled modesty, when we see him declaring, that he thought Mereator had entirely discovered his secret, or that others would, before he was of a proper age for writing? His MS. upon infinite series was communicated to none but Mr John Collins and the lord Brounker; and even that had not been complied with, but for Dr Barrow, who would not suffer him to indulge his modesty so much as he desired.

It is further observed, concerning this part of his. character, that he never talked either of himself or others, nor ever behaved in such a manner as to give the most malicious consurers the least oceasion even to suspect him of vanity. He was candid and affable, and always put himself upon a level with his company. He never thought either his merit or his reputation suffieient to excuse him from any of the common offices of social life ; no singularities, either natural or affected, distinguished him from other men. Though he was firmly attached to the church of England, he was averse to the persecution of the non-conformists. He judged of men by their manners; and the true schismatics, in his opinion, were the vicious and the wicked. Not that he confined his principles to natural religion, for he was thoroughly persuaded of the truth of revelation; and amidst the great variety of books which he had constantly before him, that which he studied with the greatest application was the Bible: and he understood the nature and force of moral certainty as well as he did that of a strict demonstration.

Sir Isaac did not neglect the opportunities of doing good, when the revenues of his patrimony, and a profitable employment, improved by a prudent economy, ... put it in his power. We have two remarkable instances of his bounty and generosity; one to Mr M'Laurin, professor of mathematics at Edinburgh, to whom he offered 201. per annum, and the other to his niece Barton, on whom he settled an annuity of 100l. When decency upon any occasion required expence and show, he was magnificent without grudging it, and with a very good grace; at all other times, that pomp which seems great to low minds only, was utterly retrenched, and the expence reserved for better uses. He never married, and perhaps he never had leisure to think of it. Being immersed in profound studies during the prime of his age, and afterwards engaged in an employment of great importance, and even quite taken up with the company which his merit drew to him, he was not sensible of any vaeancy in life, or of the want of a companion at home. He left 32,000l. at his death; but made no will, which Mr Fontenelle tells us was because he thought a legacy was no gift. As to his works, besides what were published in his lifetime, there were found after his death, among his papers, several discourses upon subjects of antiquity, history, divinity, chemistry.

sophy is

founded.

The term Newtonian Philosophy is applied very differently; whence divers confused notions relating concerning thereto. Some authors under this philosophy include all the corpuscular philosophy, considered as it now stands corrected and reformed by the discoveries and improvements made in several parts thereof by Sir Isaac Newton. In which sense it is that Gravesande calls his elements of physics, Introductio ad Philosophiam Newtonianam. And in this sense the Newtonian is the same with the new philesophy ; and stands contradistinguished from the Cartesian, the Peripatetic, and the ancient Corpuscular.

Others, by Newtonian philosophy, mean the method or order which Sir Isaac Newton observes in philosophizing; viz. the reasoning and drawing of conclusions directly from phenomena, exclusive of all previous hypotheses; the beginning from simple principles; deducing the first powers and laws of nature from a few select phenomena, and then applying those laws, &c. to account for other things. And in this sense the Newtonian philosophy is the same with the experimental philosophy, and stands opposed to the ancient corpuscular

Others, by Newtonian philosophy, mean that wherein physical bodies are considered mathematically, and where geometry and mechanics are applied to the solution of the appearances of nature. In which sense the Newtonian is the same with the mechanical and mathematical philosophy.

Others again, by Newtonian philosophy, understand that part of physical knowledge which Sir Isaac Newton has handled, improved, and demonstrated, in his Principia.

Others, lastly, by Newtonian philosophy, mean the new principles which Sir Isaac Newton has brought into philosophy; the new system founded thereon; and the new solutions of phenomena thence deduced; or that which characterizes and distinguishes his philosophy from all others .- Which is the sense wherein we shall chiefly consider it.

As to the history of this philosophy, we have nothing to add to what has been given in the preceding article. It was first made public in the year 1687, by the author, then a fellow of Trinity College, Cambridge, and in the year 1713, republished with considerable improvements .- Several authors have since attempted to make it plainer; by setting aside many of the more sublime mathematical researches, and substituting either more obvious reasonings or experiments in lieu thereof; particularly Whiston in his Prælect. Phys. Mathemat. Gravesande in Element. et Instit. and Dr Pemberton in his View.

The whole of the Newtonian philosophy, as delivered by the author, is contained in his Principia or Mathematical Principles of Natural Philosophy. He founds his Definitions system on the following definitions :

on which 1. The quantity of matter is the measure of the same, arising from its density and bulk conjunctly .--Thus air of a double density, in a double space, is

quantity, &c. 2. The quantity of motion is the measure of the same, arising from the velocity and quantity of mat-

ter conjunctly. This is evident, because the motion of the whole is the motion of all its parts; and therefore in a body double in quantity, with equal velocity, the motion is double, &c.

3. The vis insita, or innate force of matter, is a Vis insita power of resisting, by which every body, as much as defined and in it lies, endeavours to persevere in its present state, objected to, whether it be of rest, or moving uniformly forward in a right line .- This definition is proved to be just, only by the difficulty we find in moving any thing out of its place; and this difficulty is by some reckoned to proceed only from gravity. They contend, that in those cases where we can prevent the force of gravity from acting upon bodies, this power of resistance becomes insensible, and the greatest quantities of matter may be put in motion by the very least force. Thus there have been balances formed so exact, that when loaded with 200 weight in each scale, they would turn by the addition of a single drachm. In this case 400lb. of matter was put in motion by a single drachm, i. e. by 3 x 200 part of its own quantity : and even this small weight, they say, is only necessary on account of the inaccuracy of the machine : so that we have no reason to suppose, that, if the friction could be entirely removed, it would take more force to move a tun weight than a grain of sand. This objection, however, is not taken notice of by Sir Isaac : and he bestows on the resisting power above mentioned the name of vis inertiæ; a phrase which is perhaps not well chosen, and with which inferior writers have endeavoured to make their readers merry at the expence of Newton. A force of inactivity, it has been said, is a forceless force; and analogous to a black white, a cold heat, and a tempestuons calm.

But objections of more importance have been made to the whole of this doctrine than those which merely respect the term vis inertiæ. " An endeavour to remain at rest (we are told *) is unnecessary, whilst no- * Young's thing attempts to disturb the rest. It is likewise im- Examinat possible to be conceived, as it implies a contradiction. tion of the third and A man, by opposing force to force, may endeavour fourth Denot to be moved ; but this opposition is an endeavour finitions of to move, not with a design to move, but by counter-the first acting another force to prevent being moved. An Book of the endeavour not to move therefore cannot exist in bo- &c. dies, because it is absurd ; and if we appeal to fact, we shall find every body in an actual and constant endeavour to move." It has been likewise observed, and we think justly, that " if bodies could continue to move by any innate force, they might also begin to move by that force. For the same cause which can mové a body with a given velocity at one time, could do it, if present, at any other time; and therefore if the force by which bodies continue in motion were innate and essential to them, they would begin to move of themselves, which is not true." Newton indeed says that this innate force is the cause of motion under certain circumstances only, or when the body is acted upon by a force impressed ab extra. But if this impressed force do not continue as well 89 5

spaces round it.

Newtonian as begin the motion, if it cease the instant that

* Young's

tion, &c.

Examina-

Philosophy. the impression is over, and the body continue to move by its vis incrtiæ, why is the body ever stopped? " If in the beginning of the motion the body, by its innate force, overcomes a certain resistance of friction and air, in any following times, the force being undiminished, it will overcome the same resistance for ever. These resistances, therefore, could never change the state of a moving body, because they cannot change the quantity of its motive force. But this is contrary to universal experience." For these reasons we are inclined to think that bodies are wholly passive; that they endeavour nothing; and that they continue in motion not by any innate force or vis insita, but by that force, whatever it be, which begins the motion, and which, whilst it remains with the moving body, is gradually diminished, and at last overcome by opposite forces, when the body of course ceases to move.

> 4. An impressed force is an action exerted upon a body, in order to change its state, cither of rest or of moving uniformly forward in a right line .- This force consists in the action only; and remains no longer in the body when the action is over. For a body maintains every new state it acquires by its vis inertiæ only.

> It is here implied, and indeed fully expressed, that motion is not continued by the same power that produced it. Now there are two grounds on which the truth of this doctrine may be supposed to rest.

> " First, On a direct proof that the impressed force does not remain in the body, either by showing the nature of the force to be transitory and incapable of more than its first action; or that it acts only on the surface, and that the body escapes from it; or that the force is somewhere else, and not remaining in the body. But none of these direct proofs are offered.

> " Secondly, It may rest on an indirect proof, that there is in the nature of body a sufficient cause for the continuance of every new state acquired; and that therefore any adventitions force to continue motion, though necessary for its production, is superfluous and inadmissible. As this is the very ground on which the supposition stands, it ought to have been indubitably certain that the innate force of the body is sufficient to perpetuate the motion it has once acquired, before the other agent, by which the motion was communicated, had been dismissed from the office. But the innate force of body has been shown not to be that which continues its motion; and therefore the proof, that the impressed force does not remain in the body, fails. Nor indeed is it in this case desirable to support the proof, because we should then be left without any reason for the continuance of motion*." When we mention an impressed force, we mean such a force as is communicated either at the surface of the body or by being diffused through the

and motive. 6. The absolute quantity of a centrifugal force is the measure of the same, proportional to the efficacy of the

cause that propagates it from the centre, through the Newtonian Philosophy.

7. The accelerative quantity of a centripetal force is the measure of the same, proportional to the velocity which it generates in a given time.

8. The motive quantity of a centripetal force is a measure of the same, proportional to the motion which it generates in a given time. This is always known by the quantity of a force equal and contrary to it, that is just sufficient to hinder the descent of the body.

SCHOLIA.

I. Absolute, true, and mathematical time, of itself, of time. and from its own nature, flows equably, without regard to any thing external, and, by another name, is called duration. Relative, apparent, and common time, is some sensible and external measure of duration, whether accurate or not, which is commonly used instead of true time; such as an hour, a day, a month, a year, &c.

II. Absolute space, in its own nature, without re-space. gard to any thing external, remains always similar and immoveable. Relative space is some moveable dimension or measure of the absolute spaces; and which is vulgarly taken for immoveable space. Such is the dimension of a subterraneous, an acrial, or eelestial space, determined by its position to bodies, and which is vulgarly taken for immoveable space; as the distance of a subterraneous, an aerial, or celestial space, determined by its position in respect of the carth. Absolute and relative space are the same in figure and magnitude; but they do not remain always numerically the same. For if the earth, for instance, moves, a space of our air which, relatively and in respect of the earth, remains always the same, will at one time be one part of the absolute space into which the earth passes ; at another time it will be another part of the same; and so, absolutely understood, it will be perpetually mutable.

III. Place is a part of space which a body takes Place deup; and is, according to the space, either absolute or fined. relative. Our author says it is part of space ; not the situation, nor the external surface of the body. For the places of equal solids are always equal; but their superficies, by reason of their dissimilar figures, are often unequal. Positions properly have no quantity, nor are they so much the places themselves as the properties of places. The motion of the whole is the same thing with the sum of the motions of the parts; that is, the translation of the whole out of its place is the same thing with the sum of the translations of the partsout of their places : and therefore the place of the. whole is the same thing with the sum of the places of the parts; and for that reason it is internal, and in the whole body.

IV. Absolute motion is the translation of a body of Motion. from one absolute place into another, and relative motion the translation from one relative place into another. Thus, in a ship under sail, the relative place of a body is that part of the ship which the body possesses, or that part of its cavity which the body fills, and which therefore moves together with the ship; and relative rest is the continuance of the body in the same part of the ship, or of its cavity. But real absolute

Newtonian absolute rest is the continuance of the body in the Philosophy same part of that immoveable space in which the ship itself, its cavity, and all that it contains, is moved.

Wherefore, if the earth is really at rest, the body which relatively rests in the ship will really and absolutely move with the same velocity which the ship has on the earth. But if the earth also moves, the true and absolute motion of the body will arise, partly from the true motion of the earth in immoveable space; partly from the relative motion of the ship on the earth : and if the body moves also relatively in the ship, its true motion will arise partly from the true motion of the earth in immovcable space, and partly from the relative motions as well of the ship on the earth as of the body in the ship; and from these relative motions will arise the relative motion of the body on the earth. As if that part of the earth where the ship is, was trnly moved towards the cast, with a velocity of 10010 parts; while the ship itself with a fresh gale is carried towards the west, with a velocity expressed by 10 of these parts; but a sailor walks in the ship towards the cast with one part of the said velocity : then the sailor will be moved truly and absolutely in immoveable space towards the east with a velocity of 1001 parts: and relatively on the earth towards the west, with a velocity of 9 of those parts.

Absolute time, in astronomy, is distinguished from relative, by the equation or correction of the vulgar time. For the natural days are truly unequal, though "they are commonly considered as equal, and used for a measure of time : astronomers correct this inequality for their more accurate deducing of the celestial motions. It may be that there is no such thing as an equable motion whereby time may be accurately measured. All motions may be accelerated or retarded; but the true or equable progress of absolute time is liable to no change. The duration or perseverance of the existence of things remains the same, whether the motions are swift or slow, or none at all; and therefore ought to be distinguished from what are only sensible measures thereof, and out of which we collect it by means of the astronomical equation. The necessity of which equation for determining the times of a phenomenon is evinced, as well from the experiments of the pendulum clock as by eclipses of the satellites of Jupiter.

8 Immutabi-

As the order of the parts of time is immutable, so lity of time also is the order of the parts of space. Suppose those and space. parts to be moved out of their places, and they will be moved (if we may be allowed the expression) out of themselves. For times and spaces are, as it were, the places of themselves as of all other things. All things are placed in time as to order of succession; and in space as to order of situation. It is from their essence or nature that they arc places; and that the primary places of things should be moveable is absurd. These are therefore the absolute places; and transla-+ tions out of those places are the only absolute motions.

But because the parts of space cannot be seen, or distinguished from one another by the senses, therefore in their stead we use sensible measures of them. For, from the positions and distances of things from any body, considered as immovcable, we define all place ; and then with respect to such places, we estimate all NE W

motions, considering bodies as transferred from some Newtonian of those places into others. And so, instead of abso-Philosophy. lute places and motions, we use relative ones; and that without any inconvenience in common affairs : but in philosophical disquisitions we ought to abstract from our senses, and consider things themselves distinct from what arc only sensible measures of them. For it may be, that there is no body really at rest, to which the places and motions of others may be referred.

But we may distinguish rest and motion, absolute and relative, one from the other, by their properties, causes, and effects. It is a property of rest, that bodies really at rest do rest in respect of each other. And therefore, as it is possible, that in the remote regions of the fixed stars, or perhaps far beyond them, there may be some body absolutely at rest, though it be impossible to know from the position of bodies to one another in our regions, whether any of these do keep the same position to that remote body ; it follows, that absolute rest cannot be determined from the position of bodics in our regions.

It is a property of motion, that the parts which Of the morctain given positions to their wholes do partake of the tion of difmotion of their wholes. For all parts of revolving ferent bobodies endcavour to recede from the axis of motion ; respect to and the impetus of bodies moving forwards arises from one anothe joint impetus of all the parts. Therefore if sur-ther. rounding bodies are moved, those that are relatively at rest within them will partake of their motion. Upon which account the true and absolute motion of a body cannot be determined by the translation of it from those only which seem to rest; for the external bodies ought not only to appear at rest, but to be really at rest. For otherwise all included bodies, beside their translation from near the surrounding ones, partake likewise of their true motions; and though that translation was not made, they would not really be at rest, but only seem to be so. For the surrounding bodies stand in the like relation to the surrounded, as the exterior part of a whole does to the interior, or as the shell does to the kernel; but if the shell moves, the kernel will also move, as being part of the whole, without any removal from near the shell.

A property near akin to the preceding is, that if a place is moved, whatever is placed therein moves along with it; and therefore a body which is moved from a place in motion, partakes also of the motion of its place. Upon which account all motions from places in motion, are no other than parts of entire and absolute motions; and every entire motion is composed of the motion of the body out of its first place, and the motion of this place out of its place; and so on, until we come to some immoveable place, as in the above-mentioned example of the sailor. Wherefore entire and absolute motions can be no otherwise determined than by immoveable places. Now, no other places are immoveable but those that from infinity to infinity do all retain the same given positions one to another; and upon this account must ever remain unmoved, and do thereby constitute what we call immoveable space.

The causes by which true and relative motions are distinguished one from the other, are the forces inipressed Ph

At an

tiv

dis

1

785 Newtonian pressed upon bodies to generate motion. True mo-Philosophy. tion is neither generated nor altered, but by some force impressed upon the body moved : but relative motion may be generated or altered without any force impressed upon the body. For it is sufficient only to impress some force on other bodies with which the former is compared, that by their giving way, that relation may be changed, in which the relative rest or motion of the other body did consist. Again, True motion suffers always some change from any force impressed upon the moving body ; but relative motion does not necessarily undergo any changes by such force. For if the same forces are likewise impressed on those other bodies with which the comparison is made, that the relative position may be preserved; then that condition will be preserved, in which the relative motion consists. And therefore any relative motion may be changed when the true motion remains unaltered, and the relative may be preserved when the true motion suffers some change. Upon which account true motion does by no means consist in such relations.

The effects which distinguish absolute from relative motion are, the forces of receding from the axis of tive motion circular motion. For there are no such forces in a circular motion purely relative; but in a true and absolute circular motion, they are greater or less according to the quantity of the motion. If a vessel hung by a long cord, is so often turned about that the cord is strongly twisted, then filled with water, and let go, it will be whirled about the contrary way; and while the cord is untwisting itself, the surface of the water will at first be plain, as before the vessel began to move ; but the vessel, by gradually communicating its motion to the water, will make it begin sensibly to revolve. and recede by little and little from the middle, and ascend to the sides of the vessel, forming itself into a concave figure ; and the swifter the motion becomes, the higher will the water rise, till at last, performing its revolutions in the same times with the vessel, it becomes relatively at rest in it. This ascent of the water shows its endeavour to recede from the axis of its motion; and the true and absolute circular motion of the water, which is here directly contrary to the relative, discovers itself, and may be measured by this endeavour. At first, when the relative motion in the water was greatest, it produced no endeavour to recede from the axis; the water showed no tendency to the circumference, nor any ascent towards the sides of the vessel, but remained of a plane surface ; and therefore its true circular motion had not yet begun. But afterwards, when the relative motion of the water had decreased, the ascent thereof towards the sides of the vessel proved its endeavour to recede from the axis; and this endeavour showed the real circular motion of the water perpetually increasing, till it had acquired its greatest quantity, when the water rested relatively in the vessel. And therefore this endeavour does not depend upon any translation of the water in repect of the ambient bodies; nor can true circular motion be defined by such translations. There is only one real circular motion of any one revolving body, corresponding to only one power of endeavouring to recede from its axis of motion, as its proper and adequate effect; but relative motions in one and the same body are innumerable, according to the various relations it bears to ex-VOL. XIV. Part II.

N E W

ternal bodies; and, like other relations, are altogether Newtonian destitute of any real effect, otherwise than they may Philosophy. perhaps participate of that only true motion. And therefore, in the system which supposes that our heavens, revolving below the sphere of the fixed stars, carry the plancts along with them, the several parts of those heavens and the planets, which are indeed relatively at rest in their heavens, do yet really move. For they change their position one to another, which never happens to bodies truly at rest; and being carried together with the heavens, participate of their motions, and, as parts of revolving wholes, endeavour to recede from the axis of their motion.

Wherefore relative quantities are not the quantities themselves whose mames they bear, but those sensible measures of them, either accurate or inaccurate, which are commonly used instead of the measured quantities themselves. And then, if the meaning of words be determined by their use, by the names time, space, place, and motion, their measures are properly to be understood; and the expression will be unusual and purely mathematical, if the measured quantities themselves are meant.

It is indeed a matter of great difficulty to discover, and effectually to distinguish, the true motions of particular bodies from those that are only apparent: because the parts of that immoveable space in which those motions are performed, do by no means come under the observation of our senses. Yet we have some things to direct us in this intricate affair; and these arise partly from the apparent motions which are the difference of the true motions, partly from the forces which are the causes and effects of the true motions. For instance, if two globes kept at a given distance one from the other by means of a cord that connects them, were revolved about their common centre of gravity; we might, from the tension of the cord, discover the endeavour of the globes to recede from the axis of motion, and from thence we might compute the quantity of their circular motions. And then, if any equal forces should be impressed at once on the alternate faces of the globes to augment or diminish their circular motions, from the increase or decrease of the tension of the cord we might infer the inerement or decrement of their motions; and thence would be found on what faces those forees ought to be impressed, that the motions of the globes might be most augmented; that is, we might discover their hindermost faces, or those which follow in the circular motion. But the faces which follow being known, and consequently the opposite ones that precede, we should likewise know the determination of their motions. And thus we might find both the quantity and determination of this circular motion, even in an immense vacuum, where there was nothing external or sensible with which the globes might be compared. But now, if in that space some remote bodies were placed that kept always a given position one to another, as the fixed stars do in our regions; we could not indeed determine from the relative translation of the globes among those bodies, whether the motion did belong to the globes or to the bodies. But if we observed the cord, and found that its tension was that very tension which the motions of the globes required, we might conclade the motion to be in the globes, and the bodies to 5 G be

10 Absolute and rela-

cd.

p

Newtonian be at rest; and then, lastly, from the translation of the Philosophy. globes among the bodies, we should find the determination of their motions.

Having thus explained himself, Sir Isaac proposes to show how we are to collect the true motions from their causes, effects, and apparent differences; and vice versa, how from the motion, cither true or apparent, we may come to the knowledge of their causes and effects. In order to this, he lays down the following axioms or laws of motion.

J.aws of motion.

law.

I. EVERY BODY PERSEVERES IN ITS STATE OF REST, OR OF UNIFORM MOTION IN A RIGHT LINE, UN-LESS IT IS COMPELLED TO CHANGE THAT STATE BY FORCES IMPRESSED UPON IT .- Sir Isaac's proof of this axiom is as follows: " Projectiles persevere in their motions, so far as they are not retarded by the resistance of the air, or impelled downwards by the force of gravity. A top, whose parts, by their cohesion, are perpetually drawn aside from rectilinear motion, does not cease its rotation otherwise than as it is retarded by the air. The greater bodies of the planets and comets, meeting with less resistance in more free spaces, preserve their motions, both progressive and circular, for a much Objections longer time."-Notwithstanding this demonstration, to the first however, the axiom hath been violently disputed. It hath been argued, that bodies continue in their state of motion because they are subjected to the continual impulse of an invisible and subtile fluid, which always pours in from behind, and of which all places are full. It hath been affirmed, that motion is as natural to this fluid as rest is to all other matter. It is said, moreover, that it is impossible we can know in what manner a body would be influenced by moving forces if it was entirely destitute of gravity. According to what we can observe, the momentum of a body, or its tendency to move, depends very much on its gravity. A heavy cannonball will fly to a much greater distance than a light one, though both are actuated by an equal force. It is by no means clear, therefore, that a body totally destitute of gravity would have any proper momentum of its own; and if it had no momentum, it could not continue its motion for the smallest space of time after the moving power was withdrawn. Some have imagined that matter was capable of beginning motion of itself, and consequently that the axiom was false; because we see plainly that matter in some cases hath a tendency to change from a state of motion to a state of rest, and from a state of rest to a state of motion. A paper appeared on this subject in the first volume of the Edinburgh Physical and Literary Essays; but the hypothesis never gained any ground.

2. THE ALTERATION OF MOTION IS EVER PROPOR-TIONAL TO THE MOTIVE FORCE IMPRESSED; AND IS MADE IN THE DIRECTION OF THE RIGHT LINE IN WHICH THAT FORCE IS IMPRESSED .- Thus, if any force generates a certain quantity of motion, double

force will generate a double quantity, whether that Newtonian force be impressed all at once, or in successive moments. Philosophy. To this law no objection of consequence has ever been made. It is founded on this self-evident truth, that every effect must be proportional to its cause. Mr Young, who seems to be very ambitious of detecting the errors of Newton, finds fault indeed with the expressions in which the law is stated ; but he owns, that if thus expressed, The alteration of motion is proportional to the actions or resistance which produces it, and is in the direction in which the actions or resistances are made, it would be unexceptionable.

3. TO EVERY ACTION THERE ALWAYS IS OPPOSED AN EQUAL RE-ACTION : OR, THE MUTUAL ACTION OF TWO BODIES UPON EACH OTHER IS ALWAYS EQUAL, AND DIRECTED TO CONTRARY PARTS .- This axiom is Objections also disputed by many. In the above-mentioned paper to the third in the Physical Essays, the author endeavours to make law. a distinction between re-action and resistance; and the same attempt has been made by Mr Young. "When an action generates no motion (says he) it is certain that its effects have been destroyed by a contrary and equal action. When an action generates two contrary and equal motions, it is also evident that mutual actions were exerted, equal and contrary to each other. All cases where one of these conditions is not found, are exceptions to the truth of the law. If a finger presses against a stone, the stone, if it does not yield to the pressure, presses as much upon the finger; but if the stone yields, it re-acts less than the finger acts ; and if it should yield with all the momentum that the force of the pressure ought to generate, which it would do if it were not impeded by friction, or a medium, it would not re-act at all. So if the stone drawn by a horse, follows after the horse, it does not re-act so much as the horse acts; but only so much as the velocity of the stone is diminished by friction, and it is the re-action of friction only, not of the stone. The stone does not re-act, because it does not act; it resists, but resistance is not action.

" In the loss of motion from a striking body, equal to the gain in the body struck, there is a plain solution without requiring any re-action. The motion lost is identically that which is found in the other body; this supposition accounts for the whole phenomenon in the most simple manner. If it be not admitted, but the solution by rc-action is insisted upon, it will be incumbent on the party to account for the whole effect of communication of motion : otherwise he will lie under the imputation of rejecting a solution which is simple, obvious, and perfect; for one complex, unnatural, and incomplete. However this may be determined, it will be allowed, that the circumstances mentioned, afford no ground for the inference, that action and re-action are equal, since appearances may be explained in another way." (A.)

Others

(A) If there be a perfect reciprocity betwixt an impinging body and a body at rest sustaining its impulse, may we not at our pleasure consider either body as the agent, and the other as the resistant? Let a moving body, A, pass from north to south, an equal body B at rest, which receives the stroke of A, act upon A from south to north, and A resist in a contrary direction, both inelastic : let the motion reciprocally communicated be called six. Then B at rest communicates to A six degrees of motion towards the north, and receives six degrees towards the south. B having no other motion than the six degrees it communicated, will, by its equal
line.

Newtonian Others grant that Sir Isaac's axiom is very true in Philosophy respect to terrestrial substances ; but they affirm, that,

⁷ in these, both action and re-action are the effects of gravity. Substances void of gravity would have no momentum; and without this they could not act; they should be moved by the least force, and therefore could not resist or re-act. If therefore there is any fluid which is the cause of gravity, though such fluid could act upon terrestrial substances, yet these could not re-act npon it; because they have no force of their own, but depend entirely upon it for their momentum. In this manner, say they, we may conceive that the planets circulate, and all the operations of nature are carried on by means of a subtile fluid; which being perfectly active, and the rest of matter altogether passive, there is neither resistance nor loss of motion. See MO-TION.

From the preceding axiom Sir Isaac draws the following corollaries.

I. A body by two forces conjoined will describe the diagonal of a parallelogram in the same time that it would describe the sides by those forces apart.

2. Hence we may explain the composition of any one direct force out of any two oblique ones, viz. by making the two oblique forces the sides of a parallelogram, and the direct one the diagonal.

3. The quantity of motion, which is collected by taking the sum of the motions directed towards the same parts, and the difference of those that are directed to contrary parts, suffers no change from the action of bodies among themselves : because the motion which one body loses is communicated to another ; and if we suppose friction and the resistance of the air to be absent, the motion of a number of bodies which mutually impelled one another would be perpetual, and its quantity always equal. 4. The common centre of gravity of two or more Newtonian bodies do not alter its state of motion or rest by the Philosophy. actions of the bodies among themselves; and therefore the common centre of gravity of all bodies acting upon each other (excluding outward actions and impediments) is either at rest, or moves uniformly in a right

5. The motions of bodies included in a given space are the same among themselves, whether that space is at rest, or moves uniformly forward in a right line without any circular motion. The truth of this is evidently shown by the experiment of a ship; where all motions happen after the same manner, whether the ship is at rest, or proceeds uniformly forward in a straight line.

6. If bodies, anyhow moved among themselves, are urged in the direction of parallel lines by equal accelerative forces, they will all continue to move among themselves, after the same manner as if they had been urged by no such forces.

The whole of the mathematical part of the Newtonian philosophy depends on the following lemmas; of which the first is the principal.

LEM. I. Quantities, and the ratios of quantities, which in any finite time converge continually to equality, and before that time approach nearer the one to the other than by any given difference, become ultimately equal. If you deny it; suppose them to be ultimately unequal, and let D be their ultimate difference. Therefore they cannot approach nearer to equality than by that given difference D; which is against the supposition.

Concerning the meaning of this lemma philosophers Objections are not agreed; and unhappily it is the very fundamen- to the first tal position on which the whole of the system rests, lemma, Many objections have been raised to it by people who

5 G 2 supposed

equal and contrary loss and gain, remain in equilibrio. Let the original motion of A have been twelve, then A having received a contrary action equal to six, six degrees of its motion will be destroyed or in equilibrio; consequently, a motive force as six will remain to A towards the south, and B will be in equilibrio, or at rest. A will then endeavour to move with six degrees, or half its original motion, and B will remain at rest as before. A and B being equal masses, by the laws of communication three degrees of motion will be communicated to B, or A with its six degrees will act with three, and B will re-act also with three. B then will act on A from south to north equal to three, while it is acted upon or resisted by A from north to south, equal also to three, and B will remain at rest as before; A will also have its six degrees of motion reduced to one half by the contrary action of B, and only three degrees of motion will remain to A, with which it will yet endeavour to move; and finding B still at rest, the same process will be repeated till the whole motion of A is reduced to an infinitely small quantity, B all the while remaining at rest, and there will be no communication of motion from A to B, which is contrary to experience.

Let a body, A, whose mass is twelve, at rest, be impinged upon first by B, having a mass as twelve, and a velocity as four, making a momentum of 48; and secondly by C, whose mass is six, and velocity eight, making a momentum of 48 equal to B, the three bodies heing inelastic. In the first case, A will become possessed of a momentum of 24, and 24 will remain to B; and, in the second case, A will become possessed of a momentum of 32, and 16 will remain to C, both bodies moving with equal velocities after the shock, in both cases, by the laws of percussion. It is required to know, if in both cases A resists equally, and if B and C act equally? if the actions and resistances are equal, how does A in one case destroy 24 parts of B's motion, and in the other case 32 parts of C's motion, by an equal resistance? And how does B communicate in one case 24 degrees of motion, and C 32, by equal actions? If the actions and resistances are unequal, it is asked how the same mass can resist differently to bodies impinging upon it with equal momenta, and how bodies possessed of equal momenta can exert different actions, it being admitted that bodies resist proportional to their masses, and that their power of overcoming resistance is proportional to their momenta?

It is incumbent on those who maintain the doctrine of universal re-action, to free it from these difficulties and apparent contradictions.

Newtonian supposed themselves capable of understanding it. They Philosophy. say, that it is impossible we can come to an end of any

infinite series, and therefore that the word ultimate can in this case have no meaning. In some cases the lemma is evidently false. Thus, suppose there are two quantities of matter A and B, the one containing half a pound, and the other a third part of one. Let both be continually divided by 2; and though their ratio, or the proportion of the one to the other, doth not vary, yet the difference between them perpetually becomes less, as well as the quantitics themselves, until both the difference and quantities themselves become less than any assignable quantity : yet the difference will never totally vanish, nor the quantities become equal, as is evident from the two following series :

$\begin{array}{c} \frac{1}{2} & \frac{7}{4} & \frac{1}{8} & \frac{7}{10} & \frac{7}{10} & \frac{7}{64} & \frac{7}{108} & \frac{7}{216} & \frac{7}{515} & \frac{7}{1024}, \&e.\\ \frac{1}{3} & \frac{7}{6} & \frac{7}{12} & \frac{7}{24} & \frac{7}{48} & \frac{7}{96} & \frac{7}{192} & \frac{7}{384} & \frac{7}{68} & \frac{7}{1356}, \&c.\\ \text{Diff.} & \frac{7}{6} & \frac{7}{12} & \frac{7}{24} & \frac{7}{48} & \frac{7}{96} & \frac{7}{192} & \frac{7}{384} & \frac{7}{168} & \frac{7}{1316} & \frac{7}{1072}, \&c. \end{array}$

Thus we see, that though the difference is continually diminishing, and that in a very large proportion, there is no hope of its vanishing, or the quantitics becoming equal. In like manner, let us take the proportions or ratios of quantities, and we shall be equally unsuccessful. Suppose two quantities of matter, one containing 8 and the other 10 pounds; these quantities already have to each other the ratio of 8 to 10, or of 4 to 5; but let us add 2 continually to each of them, and though the ratios continually come nearer to that of equality, it is in vain to hope for a perfect coincidenee. Thus,

	8	10	12	14	16	18	20	22	24,	&c.	
	10	12	14	16	18	20	22	24	26,	&c.	
Ratio	4	5	67	7	8	20	IO	13	12	&c.	

15

answered.

For this and his other lemmas Sir Isaac makes the following apology : " These lemmas are premised, to avoid the tediousness of deducing perplexed demonstrations ad absurdum, according to the method of ancient geometers. For demonstrations are more contracted by the method of indivisibles : but because the hypothesis of indivisibles seems somewhat harsh, and therefore that method is reckoned less geometrical, I chose rather to reduce the demonstrations of the following propositions to the first and last sums and ratios of nascent and evaneseent quantities, that is, to the limits of those sums and ratios; and so to premise, as short as I could, the demonstrations of those limits. For hereby the same thing is performed as by the method of indivisibles; and now those principles being demonstrated, we may use them with more safety .- Therefore, if hereafter I should happen to consider quantities as made of particles, or should use little curve lines for right ones; I would not be understood to mean indivisibles, but cvanescent divisible quantities ; not the sums and ratios of determinate parts, but always the limits of sums and ratios; and that the force of such demonstrations always depends on the method laid down in the foregoing lemmas.

" Perhaps it may be objected, that there is no ultimate proportion of evanescent quantities, because the proportion, before the quantities have vanished, is not the ultimate, and, when they are vanished, is none .---But by the same argument it may be alleged, that a body arriving at a certain place, and there stopping,

has no ultimate velocity; because the velocity before Newtonian the body comes to the place is not its ultimate veloci- Philosophy. ty; when it is arrived, it has none. But the answer is ' easy : for by the ultimate velocity is meant that with which the body is moved, neither before it arrives at its place and the motion ceases, nor after; but at the very instant it arrives, that is, that velocity with which the body arrives at its last place, and with which the motion ceases. And in like manner, by the ultimate ratio of evanescent quantities is to be understood the ratio of the quantities, not before they vanish, nor afterwards, but with which they vanish. In like manner, the first ratio of nascent quantities is that with which they begin to be. And the first or last sum is that with which they begin and cease to be (or to be augmented and diminished). There is a limit which the velocity at the end of the motion may attain, but not exceed; and this is the ultimate velocity. And there is the like limit in all quantities and proportions that begin and eease to be. And, since such limits are eertain and definite, to determine the same is a problem strictly geometrical. But whatever is geometrical we may be allowed to make use of in determining and demonstrating any other thing that is likewise geometrical.

" It may also be objected, that if the ultimate ratios of evanescent quantities are given, their ultimate magnitudes will be also given; and so all quantities will consist of indivisibles, which is contrary to what Euclid has demonstrated concerning incommensurables, in the 10th book of his Elements. But this objection is founded on a false supposition. For those ultimate ratios with which quantities vanish are not truly the ratios of ultimate quantities, but limits towards which the ratios of quantities decreasing continually approach."

LEM. II. If in any figure A a c E terminated Plate by the right line A a, A E, and the curve a c E, CCLXIX, for the second secon there be inseribed any number of parallelograms A b, B c, C d, & c. comprehended under equal bases AB, BC, CD, & c. and the sides B b, C c, D d, & e. parallel to one side A a of the figure; and the parallelograms a K b l; b L c m, c M d n, &c. are completed .--- Then if the breadth of those parallelograms be supposed to be diminished, and their number augmented in infinitum; the ultimate ratios which the inscribed figure AK b L c M d D, the circumscribed hgure AalbmendoE, and curvilineal figure AabedE, will have to one another, are ratios of equality .- For the difference of the inscribed and eircumscribed figures is the sum of the parallelograms K l, L m, M n, D o; that is (from the equality of all their bases), the rectangle under one of their bases K b, and the sum of their altitudes Λa , that is, the rectangle AB l a. -But this rectangle, because its breadth AB is supposed diminished in infinitum, becomes less than any given space. And therefore by Lem. I. the figures inscribed and circumscribed become ultimately equal the onc to the other; and much more will the intermediate curvilineal figure be ultimately equal to either.

LEM. III. The same ultimate ratios are also ratios of equality, when the breadths AB, BC, CD, &c. of the parallelograms are unequal, and are all diminished in infinitum .- The demonstration of this differs but little from that of the former.

Phil

Fig.

1

Newtonian

In his succeeding lemmas, Sir Isaac goes on to prove. Philosophy. in a manner similar to the above, that the ultimate ratios of the sinc, chord, and tangent of arcs infinitely diminished, are ratios of equality, and therefore that in all our reasonings about these we may safely use the one for the other :--- that the ultimate form of evancscent triangles made by the arc, chord, and tangent, is that of similitude, and their ultimate ratio is that of equality; and hence, in reasonings about ultimate ratios, we may safely use these triangles for each other, whether made with the sine, the arc, or the tangent .---He then shows some properties of the ordinates of curvilincar figures; and proves that the spaces which a body describes by any finite force urging it, whether that force is determinate and immutable, or is continually augmented or continually diminished, are, in the very beginning of the motion, one to the other in the duplicate ratio of the powers. And, lastly, Having added some demonstrations concerning the evanescence of angles of contact, he proceeds to lay down the mathematical part of his system, and which depends on the following theorems :

Fig. 2.

THEOR. I. The areas which revolving bodies describe by radii drawn to an immoveable centre of force, lie in the same immoveable planes, and are proportional to the times in which they are described .- For, suppose the time to be divided into equal parts, and in the first part of that time, let the body by its innate force describe the right line AB (fig. 2.); in the second part of that time, the same would, by LAW 1. if not hindered, proceed directly to c along the line B c = AB; so that by the radii AS, BS, cS, drawn to the centre, the equal areas ASB, BS c, would be described. But, when the body is arrived at B, suppose the centripetal force acts at once with a great impulse, and turning aside the body from the right line B c, compels it afterwards to continue its motion along the right line BC. Draw c C parallel to BS, meeting BC in C; and at the end of the second part of the time, the body, by Cor. 1. of the Laws, will be found in C, in the same plane with the triangle ASB. Join SC; and because SB and c C are parallel, the triangle SBC will be equal to the triangle SBC, and therefore also to the triangle SAB. By the like argument, if the centripetal force acts successively in C, D, E, &c. and makes the body in each single particle of time to describe the right lines CD, DE, EF, &c. they will all lie in the same plane; and the triangle SCD will be equal to the triangle SBC, and SDE to SCD, and SEF to SDE. And therefore, in equal times, equal arcas are described in one immoveable plane; and, by composition, any sums SADS, SAFS, of those areas are, one to the other, as the times in which they are described. Now, let the number of those triangles be augmented, and their size diminished in infinitum; and then, by the preceding lemmas, their ultimate perimeter ADF will be a curve line : and therefore the centripetal force by which the body is perpetually drawn back from the tangent of this curve will act continually; and any described areas SADS, SAFS, which are always proportional to the times of description, will, in this case also, be proportional to those times. Q. E. D.

COR. 1. The velocity of a body attracted towards an immoveable centre, in spaces void of resistance, is reciprocally as the perpendicular let fall from that centre on the right line which touches the orbit. For the ve- Newtonianlocities in these places, A, B, C, D, E, are as the Philosophy. bases AB, BC, DE, EF, of equal triangles; and these bases are reciprocally as the perpendiculars let fall upon them.

COR. 2. If the chords AB, BC, of two arcs, successively described in equal times by the same body, in spaces void of resistance, are completed into a parallelogram ABCV, and the diagonal BV of this parallelogram, in the position which it ultimately acquires when those arcs are diminished in infinitum, is produced both ways, it will pass through the centre of force.

COR. 3. If the chords AB, BC, and DE, EF, of arcs described in equal times, in spaces void of resistance, are completed into the parallelograms ABCV, DEFZ, the forces in B and E are one to the other in the ultimate ratio of the diagonals BV, EZ, when those arcs are diminished in infinitum. For the motions BC and EF of the body (by Cor. 1. of the Laws), are compounded of the motions Bc, BV and Ef, EZ; but BV and EZ, which are equal to Cc and Ff, in the demonstration of this proposition, were generated by the impulses of the centripetal force in B and E, and are therefore proportional to those impulses.

COR. 4. The forces by which bodies, in spaces void of resistance, are drawn back from rectilinear motions, and turned into curvilinear orbits, are one to another as the versed sines of arcs described in equal times; which versed sines tend to the centre of force, and bisect the chords when these arcs are diminished to infinity. For such versed sines are the halfs of the diagonals mentioned in Cor. 3.

COR. 5. And therefore those forces arc to the force of gravity, as the said versed sines to the versed sines perpendicular to the horizon of those parabolic arcs. which projectiles describe in the same time.

Con. 6. And the same things do all hold good (by Cor. 5. of the laws) when the planes in which the bodies are moved, together with the centres of force, which are placed in those planes, are not at rest, but move uniformly forward in right lines.

THEOR. II. Every body that moves in any curve line described in a plane, and, by a radius drawn to a point either immoveable or moving forward with an uniform rectilinear motion, describes about that point areas proportional to the times, is urged by a contripetal force directed to that point.

CASE I. For every body that moves in a curve line is (by Law I.) turned aside from its rectilinear course by the action of some force that impels it; and that force by which the body is turned off from its rectilinear course, and made to describe in equal times the least equal triangles SAB, SBC, SCD, &c. about the immoveable point S, (by Prop. 40. E. I. and Law 2.) acts in the place B according to the direction of a line parallel to C; that is, in the direction of the line BS; and in the place C according to the direction of a line parallel to d D, that is, in the direction of the line CS, &c.; and therefore acts always in the direction of lines tending to the immoveable point S. Q. E. D.

CASE II. And (by Cor. 5. of the laws) it is indifferent whether the superficies in which a body describes a curvilinear figure be quiescent, or moves together with the body, the figure described, and its point S, uniformly forward in right lines.

COR.

NOP

COR. 1. In non-resisting spaces or mediums, if the Philosophy. areas are not proportional to the times, the forces are not directed to the point in which the radii meet; but diviate therefrom in consequentia, or towards the parts

to which the motion is directed, if the description of the areas is accelerated; but in antecedentia if retarded.

COR. 2. And even in resisting mediums, if the description of the arcas is accelerated, the directions of the forces deviate from the point in which the radii meet, towards the parts to which the motion tends.

SCHOLIUM.

 Λ body may be urged by a contripetal force compounded of several forces. In which case the meaning of the proposition is, that the force which results out of all tends to the point S. But if any force acts perpetually in the direction of lines perpendicular to the described surface, this force will make the body to deviate from the plane of its motion, but will neither augment nor diminish the quantity of the described surfacc; and is therefore not to be neglected in the composition of forces.

THEOR. III. Every body that, by a radius drawn to the centre of another body, howsoever moved, describes areas about that centre proportional to the times, is urged by a force compounded of the centripetal forces tending to that other body, and of all the accelerative force by which that other body is impelled .- The demonstration of this is a natural consequence of the theorem immediately preceding.

Hence, if the one body L, by a radius drawn to the other body T, describes areas proportional to the times, and from the whole force by which the first body L is urged, (whether that force is simple, or, according to Cor. 2. of the laws, compounded of several forces), we subduct that whole accelerative force by which the other body is urged; the whole remaining force by which the first body is urged will tend to the other body T, as its centre.

And vice versa, if the remaining force tends nearly to the other body T, those areas will be nearly proportional to the times.

If the body L, by a radius drawn to the other body T, describes areas, which, compared with the times, are very unequal, and that other body T be cither at rest, or moves uniformly forward in a right line, the action of the centripetal force tending to that other body T is either none at all, or it is mixed and combined with very powerful actions of other forces; and the whole force compounded of them all, if they arc many, is directed to another (immoveable or moveable) centre. The same thing obtains when the other body is actuated by any other motion whatever; provided that centripetal force is taken which remains after subducting that whole force acting upon that other body Т.

SCHOLIUM.

Because the equable description of areas indicates that a centre is respected by that force with which the body is most affected, and by which it is drawn back from its rectilinear motion, and retained in its orbit, we may always be allowed to use the equable description of

areas as an indication of a centre about which all cir- Newtonian Philosophy. lar motion is performed in free spaces.

THEOR. IV. The centripetal forces of bodies which by equable motions describe different circles, tend to the centres of the same circles; and are one to the other as the squares of the arcs described in equal times applied to the radii of circles .- For these forces tend to the centres of the circles, (by Theor. 2. and Cor. 2. Theor. 1.) and are to one another as the versed sines of the least arcs described in equal times (by Cor. 4. Theor 1.), that is, as the squares of the same arcs applied to the diameters of the circles, by one of the lemmas ; and therefore, since those arcs are as arcs described in any equal times, and the diameters are as the radii, the forces will be as the squares of any arcs describcd in the same time, applied to the radii of the circles. Q. E. D.

COR. 1. Therefore, since those ares are as the velocities of the bodies, the centripetal forces are in a ratio compounded of the duplicate ratio of the velocities directly, and of the simple ratio of the radii inversely.

Cor. 2. And since the periodic times are in a ratio compounded of the ratio of the radii directly, and the ratio of the velocities inversely; the centripetal forces are in a ratio compounded of the ratio of the radii directly, and the duplicate ratio of the periodic times inversely.

COR. 3. Whence, if the periodic times are equal, and the velocities therefore as the radii, the centripetal forces will be equal among themselves ; and the contrary.

COR. 4. If the periodic times and the velocities are both in the subduplicate ratio of the radii, the centripetal forces will be equal among themselves; and the contrary.

COR. 5. If the periodic times are as the radii, and therefore the velocities equal, the centripetal forces will be reciprocally as the radii; and the contrary.

COR. 6. If the periodic times are in the sesquiplicate ratio of the radii, and therefore the velocities reciprocally in the subduplicate ratio of the radii, the centripetal forces will be in the duplicate ratio of the radii inversely; and the contrary.

COR. 7. And universally, if the periodic time is as any power Rn of the radius R, and therefore the velocicity reciprocally as the power Rn-r of the radius, the centripetal force will be reciprocally as the power Ran-a of the radius; and the contrary.

COR. 8. The same things all hold concerning the times, the velocities, and forces, by which bodies describe the similar parts of any similar figures, that have their centres in a similar position within those figures, as appears by applying the demonstrations of the preceding cases to those. And the application is easy, by only substituting the equable description of areas in the place of equable motion, and using the distances of the bodies from the centres instead of the radii.

COR. 9. From the same demonstration it likewise follows, that the are which a body uniformly revolving in a circle by means of a given centripetal force describes in any time, is a mean proportional between the diameter of the circle, and the space which the same body, falling by the same given force, would descend through in the same given time.

· By

ral philosophy.

he lays down the following rules for reasoning in natu- Newtonian Philosophy.

" By means of the preceding proposition and its co-Philosophy. rollaries (says Sir Isaac), we may discover the proportion of a centripetal force to any other known force, such as that of gravity. For if a body by means of its gravity revolves in a circle concentric to the earth, this gravity is the centripetal force of that body. But from the descent of heavy bodies, the time of one entire revolution, as well as the arc described in any given time, is given (by Cor. 9. of this theorem). And by such propositions Mr Huygens, in his excellent book De Horologio Oscillatorio, has compared the force of gravity with the centrifugal forces of revolving bodies.

The preceding proposition may also be demonstrated in the following manner. In any circle suppose a polygon to be inscribed of any number of sides. And if a body, moved with a given velocity along the sides of the polygon, is reflected from the circle at the several angular points; the force with which, at every reflection it strikes the circle, will be as its velocity : and therefore the sum of the forces, in a given time, will be as that velocity and the number of reflections conjunctly; that is (if the species of the polygon be given), as the length described in that given time, and increased or diminished in the ratio of the same length to the radius of the circle; that is, as the square of that length applied to the radius; and therefore, if the polygon. by having its sides diminished in infinitum, coincides with the circle, as the square of the arc described in a given time applied to the radius. This is the centrifugal force, with which the body impels the circle; and to which the contrary force, wherewith the circle continually repels the body towards the centre, is equal.

On these principles hangs the whole of Sir Isaac Newton's mathematical philosophy. He now shows how to find the centre to which the forces impelling any body are directed, having the velocity of the body given : and finds the centrifugal force to be always as the versed sine of the nascent arc directly, and as the square of the time inversely; or directly as the square of the velocity, and inversely as the chord of the nascent arc. From these premises he deduces the method of finding the centripetal force directed to any given point when the body revolves in a circle; and this whether the central point is near or at an immense distance; so that all the lines drawn from it may be taken for parallels. The same thing he shows with regard to bodies revolving in spirals, ellipses, hyperbolas, or parabolas .- Having the figures of the orbits given, he shows also how to find the velocities and moving powers; and, in short, solves all the most difficult problems relating to the celestial bodies with an astonishing degree of mathematical skill. These problems and demonstrations are all contained in the first book of the Principia: but to give an account of them here would far exceed our limits; neither would many of them be intelligible, excepting to first-rate mathematicians.

In the second book, Sir Isaac treats of the properties of fluids, and their powers of resistance : and here Rules for he lays down such principles as entirely overthrow the philosophidoctrine of Des Cartes's vortices, which was the facal reasonshionable system in his time. In the third book, he begins particularly to treat of the natural phenomena, and apply them to the mathematical principles formerly demonstrated; and, as a necessary preliminary to this part,

1. We are to admit no more causes of natural things than such as are both true and sufficient to explain their natural appearances.

2. Therefore to the same natural effects we must always assign, as far as possible, the same causes.

3. The qualities of bodies which admit neither intension or remission of degrees, and which are found to belong to all bodies within the reach of our experiments, are to be esteemed the universal qualities of allbodies whatsoever.

4. In experimental philosophy, we are to look upon propositions collected by general induction from phenomena as accurately or very nearly true, notwithstanding any contrary hypotheses that may be imagined, till such time as other phenomena occur, by which they may either be made more accurate, or liable to exceptions.

The phenomena first considered are, I. That the satellites of Jupiter, by radii drawn to the centre of their primary, describe areas proportional to the times of their description; and that their periodic times, the fixed stars being at rest, are in the sesquiplicate ratio of. their distances from its centre. 2. The same thing is likewise observed of the phenomena of Saturn. 3. The five primary planets, Mercury, Venus, Mars, Jupiter, and Saturn, with their several orbits encompass the sun. 4. The fixed stars being supposed at rest, the periodic times of the five primary planets, and of the earth, about the sun, are in the sesquiplicate proportion of their mean distances from the sun. 5. The primary planets, by radii drawn to the earth, describe areas no ways proportionable to the times : but the areas which they describe by radii drawn to the sun are proportional to the times of description. 6. The moon, by a radius drawn to the centre of the earth, describes an area proportional to the time of description. All these phenomena are undeniable from astronomical observations, and are explained at large under the article ASTRONOMY. The mathematical demonstrations are next applied by Sir Isaac Newton in the following propositions:

PROP. I. The forces by which the satellites of Jupiter are continually drawn off from rectilinear motions. and retained in their proper orbits, tend to the centre of that planet; and are reciprocally as the squares of the distances of those satellites from that centre. The former part of this proposition appears from Theor. 2. or 3. and the latter from Cor. 6. of Theor. 5.; and the same thing we are to understand of the satellites of Saturn.

PROP. II. The forces hy which the primary planets are continually drawn off from rectilinear motions, and retained in their proper orbits, tend to the sun ; and are reciprocally as the squares of the distances from the sun's centre. The former part of this proposition is manifest from Phenomenon 5. just mentioned, and from Theor. 2.; the latter from Phenomenon 4. and Car. 6. of Theor. 4. But this part of the proposition is with great accuracy deducible from the quiescence of the aphelion points. For a very small aberration from the reciprocal duplicate proportion would produce a motion of the apsides, sensible in every single revolution, and in many of them enormously great.

PROP. III. The force by which the moon is retained in

16

ing.

Newtonian

Newtonian in its orbit, tends towards the earth; and is reciprocally

Philosophy as the square of the distance of its place from the centre of the earth. The former part of this proposition is evident from Phenom. 5. and Theor. 2.; the latter from Phenom. 6. and Theor. 2. or 3. It is also evident from the very slow motion of the moon's apogee ; which, in every single revolution, amounting but to 3° 3' in consequentia, may be neglected : and this more fully appears from the next proposition.

PROP. IV. The moon gravitates towards the earth, and by the force of gravity is continually drawn off from a rectilinear motion, and retained in its orbit .--The mean distance from the moon to the earth in the syzigics, in semidiameters of the latter, is about 607. Let us assume the mean distance of 60 semidiameters in the syzigies; and suppose one revolution of the moon in respect of the fixed stars to be completed in 27d 7h 43', as astronomers have determined ; and the circumference of the earth to amount to 123,249,600 Paris fect. Now, if we imagine the moon, deprived of all motion, to be let go, so as to descend towards the earth with the impulse of all that force by which it is retained in its orbit, it will, in the space of one minute of time, describe in its fall 154 Paris feet. For the versed sine of that arc which the moon, in the space of one minute of time, describes by its mean motion at the distance of 60 semidiameters of the earth, is nearly 15T Paris feet; or more accurately, 15 feet one inch and one line 4. Wherefore since that force, in approaching to the earth, increases in the reciprocal duplicate proportion of the distance; and, upon that account, at the surface of the earth, is 60 \times 60 times greater than that at the moon; a body in our regions, falling with that force, ought, in the space of one minute of time, to describe 60 × 60 × 1512 Paris feet; and in the space of one second of time to describe $15\frac{1}{12}$ of those feet; or, more accurately, 15 feet I inch I line 4. And with this very force we actually find that bodies here on earth do really descend. -For a pendulum oscillating seconds in the latitude of Paris, will be three Paris feet and 87 lines in length, as Mr Huygens has observed. And the space which a heavy body describes by falling one second of time, is to half the length of the pendulum in the duplicate ratio of the circumference of the circle to its diameter; and is therefore 15 Paris feet 1 inch 1 line 7. And therefore the force by which the moon is retained in its orbit, becomes at the very surface of the earth, equal to the force of gravity which we observe in heavy bodies there. And therefore (by Rule 1. and 2.) the force by which the moon is retained in its orbit is that very same force which we commonly call gravity. For were gravity another force different from that, then bodies descending to the earth with the joint impulse of both forces would fall with a double velocity, and, in the space of one second of time, would describe 305 Paris feet ; altogether against experience.

The demonstration of this proposition may be more diffusely explained after the following manner : Suppose several moons to revolve about the earth, as in the system of Jupiter or Saturn, the periodic times of those moons would (by the argument of induction) observe the same law which Kepler found to obtain among the planets; and therefore their centripetal forces would be reciprocally as the squares of the distan-

4

ces from the centre of the earth, by Prop. I. Now, if Newtonian the lowest of these were very small, and were so near Philosophy. the earth as almost to touch the tops of the highest mountains, the centripetal force thereof, retaining it in its orbit, would be very nearly equal to the weights of any terrestrial bodies that should be found upon the tops of these mountains; as may be known from the foregoing calculation. Therefore, if the same little moon should be deserted by its centrifugal force that carries it through its orhit, it would descend to the earth; and that with the same velocity as heavy bodies do actually descend with upon the tops of those very mountains, because of the equality of forces that oblige them both to descend. And if the force by which that lowest moon would descend were different from that of gravity, and if that moon were to gravitate towards the earth, as we find terrestrial bodies do on the tops of mountains, it would then descend with twice the velocity, as being impelled by both these forces conspiring together. Therefore, since both these forces, that is, the gravity of heavy bodies, and the centripetal forces of the moons, respect the centre of the earth, and are similar and equal between themselves, they will (by Rule 1. and 2.) have the same cause. And therefore the force which retains the moon in its orbit, is that very force which we commonly call gravity; because otherwise, this little moon at the top of a mountain must either be without gravity, or fall twice as swiftly as heavy bodies use to do.

Having thus demonstrated that the moon is retained in its orbit by its gravitation towards the earth, it is easy to apply the same demonstration to the motions of the other secondary planets, and of the primary planets round the sun, and thus to show that gravitation prevails throughout the whole creation ; after which, Sir Isaac proceeds to show from the same principles that the heavenly bodies' gravitate towards each other, and contain different quantities of matter, or have different densitics in proportion to their bulks.

PROB. V. All bodies gravitate towards every planet; and the weights of bodies towards the same planet, at equal distances from its centre, are proportional to the quantities of matter they contain.

It has been confirmed by many experiments, that all sorts of heavy bodies (allowance being made for the inequality of retardation by some small resistance of the air), descend to the earth from equal heights in equal times; and that equality of times we may distinguish to a great accuracy by the help of pendulums. Sir Isaac Newton tried the thing in gold, silver, lead, glass, sand, common salt, wood, water, and wheat. He provided two wooden boxes, round and equal, filled the one with wood, and suspended an equal weight of gold in the centre of oscillation of the other. The boxes hanging by equal threads of II feet, made a couple of pendulums, perfectly equal in weight and figure, and equally receiving the resistance of the air. And placing the one by the other, he observed them to play together forwards and backward, for a long time, with equal vibrations. And therefore the quantity of matter in the gold was to the quantity of matter in the wood, as the action of the motive force (or vis motrix) upon all the gold, to the action of the same upon all the wood ; that is, as the weight

Newtonian weight of the one to the weight of the other. And Philosophy. the like happened in the other bodies. By these experiments, in bodies of the same weight, he could manifestly have discovered a difference of matter less than the thousandth part of the whole, had any such been. But without all doubt, the nature of gravity towards the planets, is the same as towards the earth. For should we imagine our terrestrial bodies removed to the orb of the moon, and there, together with the moon, deprived of all motion, to be let go, so as to fall together towards the earth; it is certain from what we have demonstrated before, that in equal times, they would describe equal spaces with the moon, and of consequence are to the moon in quantity of matter, as their weights to its weight. Moreover, since the satellites of Jupiter perform their revolutions in times which observe the sesquiplicate proportion of their distances from Jupiter's centre, their accelerative gravities towards Jupiter will be reciprocally as the squares of their distances from Jupiter's centre; that is, equal at equal distances. And therefore, these satellites, if supposed to fall towards Jupiter from equal heights, would describe equal spaces in equal times, in like manner as heavy bodies do on our earth. And by the same argument if the circumsolar plancts were supposed to be let fall at equal distances from the sun, they would, in their descent towards the sun, describe equal spaces in equal times. But forces, which equally accelerate unequal bodies, must be as those bodies : that is to say, the weights of the planets towards the sun must be as their quantities of matter. Further, That the weights of Jupiter and his satellites towards the sun arc proportional to the several quantities of their matter, appears from the exceeding regular motions of the satellites. For if some of the bodies were more strongly attracted to the sun in proportion to their quantity of matter than others, the motions of the satellites would be disturbed by that inequality of attraction. If, at equal distances from the sun, any satellite, in proportion to the quantity of its matter, did gravitate towards the sun, with a force greater than Jupiter in proportion to his, according to any given proportion, suppose d to c; then the distance between the centres of the sun and of the satellite's orbit would be always greater than the distance between the centres of the sun and of Jupiter nearly in the subduplicate of that proportion. And if the satellite gravitated towards the sun with a force less in the proportion of e to d, the distance of the centre of the satellite's orb from the sun would be less than the distance of the centre of Jupiter's from the sun in the subduplicate of the same proportion. Therefore, if, at equal distances from the sun, the accelerative gravity of any satellite towards the sun were greater or less than the accelerating gravity of Jupiter towards the sun hnt by $\frac{1}{1000}$ part of the whole gravity; the distance of the centre of the satellite's orbit from the sun would be greater or less than the distance of Jupiter from the sun by $\frac{1}{2000}$ part of the whole distance; that is, by a fifth part of the distance of the utmost satellite from the centre of Jupiter; an eccentricity of the orbit which would be very sensible. But the orbits of the satellites are concentric to Jupiter ; therefore the accelerative gravitics of Jupiter, and of all its satellites, towards the sun, are equal among themselves. And by the same argument, the weight of Saturn and of his sa-

tellites towards the sun, at equal distances from the sun, Newtonian are as their several quantities of matter; and the Philosophy. weights of the moon and of the earth towards the sun, are either none, or accurately proportional to the masses of matter which they contain.

But further, the weights of all the parts of every planet towards any other planet are one to another as the matter in the several parts. For if some parts gravitated more, others less, than in proportion to the quantity of their matter; then the whole planet, according to the sort of parts with which it most abounds, would gravitate more or less than in proportion to the quantity of matter in the whole. Nor is it of any moment whether these parts are external or internal. For if, as an instance, we should imagine the terrestrial bodies with ns to be raised up to the orb of the moon, to be there compared with its body ; if the weights of such bodies were to the weights of the external parts of the moon as the quantities of matter in the one and in the other respectively, but to the weights of the internal parts in a greater or less proportion; then likewise the weights of those bodics would be to the weight of the whole moon in a greater or less proportion; against what we have showed above.

Con. 1. Hence the weights of bodies do not depend upon their forms and textures. For if the weights could be altered with the forms, they would be greatcr or less, according to the variety of forms in equal matter; altogether against experience.

Con. 2. Universally, all bodies about the earth gravitate towards the carth; and the weights of all, at equal distances from the earth's centre, arc as the quantities of matter which they severally contain. This is the quality of all bodies within the reach of our experiments; and therefore (by Rule 3.) to be affirmed of all bodies whatsoever. If ether, or any other body, were either altogether void of gravity, or were to gravitate less in proportion to its quantity of matter; then, because (according to Aristotle, Des Cartes, and others) there is no difference betwixt that and ether bodies, but in merc form of matter, by a successive change from form to form, it might be changed at last into a body of the same condition with those which gravitate most in proportion to their quantity of matter; and, on the other hand, the heaviest bodies, acquiring the first form of that body, might by degrees quite lose their gravity. And therefore the weights would depend upon the forms of bodies, and with those forms might be changed, contrary to what was proved in the preceding corollary.

COR. 3. All spaces are not equally full. For if all spaces were equally full, then the specific gravity of the fluid which fills the region of the air, on account of the extreme density of the matter, would fall nothing short of the specific gravity of quicksilver or gold, or any other the most dense body, and therefore, neither gold, nor any other body, could descend in air. For hodies do not descend in fluids, unless they are specifically heavier than the fluids. And if the quantity of matter in a given space can by any rarefaction be diminished, what should hinder a diminution to infinity?

COR. 4. If all the solid particles of all bodies are of the same density, nor can be rarefied without pores, a void space or vacuum must be granted. [By bodics ςH of

Vol. XIV. Part II.

L

Newtonian of the same density, our author means those whose vires Philosophy.inertice are in the proportion of their bulks.]

PROB. VI. That there is a power of gravity tending to all bodies, proportional to the several quantities of matter which they contain.

That all the planets mutually gravitate one towards another, we have proved before: as well as that the force of gravity towards every one of them, considered apart, is reciprocally as the square of the distance of places from the centre of the planet. And thence it follows that the gravity tending towards all the planets is proportional to the matter which they contain.

Moreover, since all the parts of any planet A gravitate towards any other planet B, and the gravity of every part is to the gravity of the whole as the matter of the part to the matter of the whole; and (by Law 3.) to every action corresponds an equal re-action : therefore the planet B will, on the other hand, gravitate towards all the parts of the planet A; and its gravitytowards any one part will be to the gravity towards the whole, as the matter of the part to the matter of the whole. Q. E. D.

COR. I. Therefore the force of gravity towards any whole planet, arises from, and is compounded of, the forces of gravity towards all its parts. Magnetic and electric attractions afford us examples of this. For all attraction towards the whole arises from the attractions towards the several parts. The thing may be easily understood in gravity, if we consider a greater planet as formed of a number of lesser planets, meeting together in one globe. For hence it would appear that the force of the whole must arise from the forces of the component parts. If it be objected, that, according to this law, all bodies with us must mutually gravitate one towards another, whereas no such gravitation anywhere appears; it is answered, that, since the gravitation towards these bodies is to the gravitation towards the whole earth, as these bodies are to the whole earth, the gravitation towards them must be far less than to fall under the observation of our senses. ['The experiments with regard to the attraction of mountains, however, have now further elucidated this point.]

COR. 2. The force of gravity towards the several equal particles of any body, is reciprocally as the square of the distance of places from the particles.

PROB. VII. In two spheres mutually gravitating each towards the other, if the matter, in places on all sides round about and equidistant from the centres, is similar; the weight of either sphere towards the other will be reciprocally as the square of the distance between their centres.

For the demonstration of this, see the Principia, Book I. Prop. lxxv. and lxxvi.

COR. 1. Hence we may find and compare together the weights of bodies towards different planets. For the weights of bodies revolving in circles about planets are as the diameters of the circles directly, and the squares of their periodic times reciprocally; and their weights at the surfaces of the planets, or at any other distances from their centres, are (by this prop.) greater or less, in the reciprocal duplicate proportion of the distances. Thus from the periodic times of Venus, revolving about the sun, in 224d. $16\frac{3}{4}h$.; of the sutmost circumjovial satellite revolving about Jupiter, in

16d. 16 % h.; of the Huygenian satellite about Saturn Newtonian in 15d. 222h.; and of the moon about the earth in Philosophy. 27d. 7h. 43'; compared with the mean distance of Venus from the sun, and with the greatest heliocentric elongations of the outmost eircumjovial satellite from Jupiter's centre, 8' 16"; of the Huygenian satellite from the centre of Saturn, 3' 4"; and of the moon from the earth, 10' 33"; by computation our author found, that the weight of equal bodies, at equal distances from the centres of the sun, of Jupiter, of Saturn, and of the earth, towards the sun, Jupiter, Saturn, and the earth, were one to another as TOGT, JO21, and TG9282 respectively. Then, because as the distances are increased or diminished, the weights are diminished or increased in a duplicate ratio; the weights of equal bodies to wards the sun, Jupiter, Saturn, and the earth, at the distances 10000, 997, 791, and 109, from their centres, that is, at their very superficies, will be as 10000, 943, 529, and 435 respectively.

COR. 2. Hence likewise we discover the quantity of matter in the several planets. For their quantities of matter are as the forces of gravity at eqnal distances from their centres, that is, in the sun, Jupiter, Saturn, and the earth, as 1, $\frac{1}{1007}$, $\frac{1}{3021}$, and $\frac{1}{100282}$, respectively. If the parallax of the sun be taken greater or less than 10" 30", the quantity of matter in the earth must be augmented or diminished in the triplicate of that proportion.

COR. 3. Hence also we find the densities of the planets. For (by Prop. lxxii. Bock I.) the weights of equal and similar bodies towards similar spheres, are, at the surfaces of those spheres, as the diameters of the spheres. And therefore the densities of dissimilar spheres are as those weights applied to the diameters of the spheres. But the true diameters of the sun, Jupiter, Saturn, and the earth, were one to another as 10000, 997, 791, and 109; and the weights towards the same, as 10000, 943, 529, and 435 respectively; and therefore their densities are as 1 20, 942, 67, and 400. The density of the earth, which comes out by this computation, does not depend upon the parallax. of the sun, but it is determined by the parallax of the moon, and therefore is here truly defined. The sun therefore is a little denser than Jupiter, and Jupiter than Saturn, and the earth four times denser than the sun; for the sun, by its great heat, is kept in a sort of a rarefied state. The moon also is denser than the earth.

COR. 4. The smaller the planets are, they are cateris paribus, of so much the greater density. For so the powers of gravity on their several surfaces come nearer to equality. They are likewise, cæteris paribus, of the greater density as they are nearer to the sun. So Jupiter is more dense than Saturn, and the earth than Jupiter. For the planets were placed at different distances from the sun, that, according to their degrees of density, they might enjoy a greater or less proportion of the sun's heat. Our water, if it were removed as far as the orb of Saturn, would be converted into ice, and in the orb of Mereury would quickly fly away in vapour. For the light of the sun, to which its heat is proportional, is seven times denser in the orb of Mercury than with us: and by the thermometer Sir Isaae found, that a sevenfold heat of our summer sun will make water boil. Nor are we to doubt,

that

Newtmian that the matter of Mercury is adapted to its heat, and Philosophy, is therefore more dense than the matter of our earth ; Newton. since, in a denser matter, the operations of nature re-

quire a stronger heat.

It is shown in the scholium of Prop. xxii. Book II. of the Principia, that, at the height of 200 miles above the earth, the air is more rare than it is at the superficies of the earth, in the ratio of 30 to 0,000000000003998, or as 75,0000000000 to I nearly. And hence the planet Jupiter, revolving in a medium of the same density with that superior air, would not lose by the resistance of the medium the 1000000th part of its motion in 1000000 years. In the spaces near the earth, the resistance is produced only by the air, exhalations, and vapours. When these are carefully exhausted by the air pump from under the receiver, heavy bodies fall within the receiver with perfect freedom, and without the least sensible resistance; gold itself, and the lightest down, let fall together, will descend with equal velocity; and though they fall through a space of four, six, and eight feet, they will come to the bottom at the same time; as appears from experiments that have often been made. And therefore the celestial regions being perfectly void of air and exhalations, the planets and comets meeting no sensible resistance in those spaces, will continue their motions through them for an immense space of time.

NEWTON, Thomas, lord bishop of Bristol and dean of St Paul's London, was born on the first of January 1704. His father, John Newton, was a considerable brandy and cyder merchant, who, by his industry and integrity, having acquired what he thought a competent fortune, left off trade several years before he died.

He received the first part of his education in the free school of Litchfield; a school which, the bishop observes with some kind of exultation, had at all times sent forth several persons of note and eminence; from Bishop Smaldridge and Mr Wollaston, to Dr Johnson and Mr Garrick

From Litchfield he was removed to Westminster school, in 1717, under the care of Dr Freind and Dr Nicoll.

During the time he was at Westminster, there were, he observes, more young men who made a distinguished figure afterwards in the world, than perhaps at any other period, either before or since. He particularly mentions William Murray, the late earl of Mansfield, with whom he lived on terms of the highest friendship to the last.

He continued six years at Westminster school, five of which he passed in the eollege. He afterwards went to Cambridge, and entered at Trinity college. Here he constantly resided eight months at least in every year, till he had taken his Baehelor of Arts degree. Being chosen fellow of his college, he came afterwards to settle in London. As it had been his inclination from a child, and as he was also designed for holy orders, he had sufficient time to prepare himself, and composed some sermons, that he might have a stock in hand when he entered on the ministry. His title for orders was his fellowship; and he was ordained deacon in December 1729, and priest in February following, by Bishop Gibson.

At his first setting out in his office, he was curate at

N E W

St George's Hanover-square; and continued for seve- Newton. ral years assistant preacher to Dr Trebeck. His first preferment was that of reader and afternoon preacher at Grosvenor Chapel, in South Audley street.

This introduced him to the family of Lord Tyreonnel, to whose son he became tutor. He continued in this situation for many years, very much at his ease, and on terms of great intimacy and friendship with Lord and Lady Tyrconnel, " without so much (says he) as an unkind word or a cool look intervening."

In the spring of 1744, he was, through the interest of the earl of Bath (who was his great friend and patron, and whose friendship and patronage were returned by grateful acknowledgements and the warmest encomiums), presented to the rectory of St Mary Le Bow; so that he was 40 years old before he obtained any living.

At the commencement of 1745, he took his doctor's degree. In the spring of 1747 he was chosen lecturer of St George's, Hanover-square, by a must respectable vestry of noblemen and gentlemen of high distinction. In August following he married his first wife, the eldest daughter of Dr Trebeck ; an unaffected, modest, deeent young woman, with whom he lived very happy in mutual love and harmony for near seven years.

In 1749 he published his edition of Milton's Paradise Lost, which, (says he, very modestly) it is hoped hath not been ill received by the public, having, in 1775, gone through eight editions. After the Paradise Lost, it was judged (says he) proper that Dr Newton should also publish the Paradise Regained, and other poems of Milton; but these things he thought detained him from other more material studies, though he had the good fortune to gain by them more than Milton did by all his works put together. But his greatest gain (he says) was their first introducing him to the friendship and intimacy of two such men as Bishop Warburton and Dr Jortin, whose works will speak for them better than any private commendation.

In 1754 he lost his father at the age of 83; and within a few days his wife, at the age of 38. This was the severest trial he ever underwent, and almost overwhelmed him. At that time he was engaged in writing his Dissertations on the Prophecies; and hap. py it was for him : for in any affliction he never found a better or more effectual remedy than plunging deep into study, and fixing his thoughts as intensely as he possibly could upon other subjects. The first volume was published the following winter; but the other did not appear till three years afterwards ; and as a reward for his past and an incitement to future labours, he was appointed, in the mean time, to preach Boyle's lecture. The bishop informs us, that 1250 copies of the Dissertations were taken at the first impression, and 1000 at every other edition : and " though (says he) some things have been since published upon the same subjects, yet, they still hold up their head above water, and having gone through five editions, are again prepared for another. Abroad, too, their reception hath not been unfavourable, if accounts from thence may be depended upon." They were translated into the German and Danish languages; and received the warmest encomiums from persons of learning and rank.

In the spring of 1757, he was made prebendary of Westminster, in the room of Dr Green, and promoted 5H2 to

Newton || Nexi. to the deancry of Salishury. In October following, he was made sub-almoner to his majesty. This he owed to Bishop Gilbert. He married a second wife in September 1761. She was the widow of the Rev. Mr Hand, and daughter of John Lord Viscount Lisburn. In the same month he kissed his majesty's hand for his bishopric.

In the winter of 1764, Dr Stone, the primate of Ireland, died. Mr Grenville sent for Bishop Newton, and in the most obliging manner desired his acceptance of the primacy. Having maturely weighed the matter in his mind, he declined the offer.

In 1768 he was made dean of St Paul's. His ambition was now fully satisfied; and he firmly resolved never to ask for any thing more.

From this time to his death, ill health was almost his constant companion. It was wonderful that such a poor, weak, and slender thread as the bishop's life, should be spun out to such an amazing length as it really was. In the autumn of 1781 (usually the most favourable part of the year to him) he laboured under repeated illnesses : and on Saturday the 9th of February 1782, he began to find his breath much affected by the frost. His complaints grew worse and worse till the Thursday following. He got up at five o'clock, and was placed in a chair by the fire; complained to his wife how much he had suffered in bcd, and repeated to himself that portion of the Psalms, " O my God, I cry unto thee in the day time," &c. &c. About six o'clock he was left by his apothecary in a quiet sleep. Between seven and eight he awoke, and appeared rather more casy, and took a little refreshment. He continued dozing till near nine, when he ordered his servant to come and dress him, and help him down stairs. As soon as he was dressed, he inquired the hour, and bid his servant open the shutter and look at the dial of St Paul's. The servant answered, it was upon the stroke of ninc. The bishop made an effort to take out his watch; with an intent to set it; but sunk down in his chair, and expired without a sigh or the least visible emotion, his countenance still retaining the same placid appearance which was so peculiar to him when alive. Of his numerous works, his Disscritations on the Prophecies are by much the most valuable. His learning was undoubtedly very considerable; but he seldom exhibits evidence of a very vigorous mind. On one occasion, indeed, he appears to have thought with freedom; for we believe he was the first dignitary of the church of England who avowed his belief of the final restitution of all things to harmony and happiness.

NEWTYA, a port little known, on the coast between Goa the capital of the Portuguese settlements in India, and the English settlement of Bombay. Mr Rennel conjectures it to be the *Nitrias* of Pliny; near which the pirates cruized for the Roman ship. Thesame writer places it near to $15^{\circ} 52' 30''$ north latitude, and $73^{\circ} 16' 30''$ east longitude.

NEXI, among the Romans, persons free born, who for debt were reduced to a state of slavery. By the laws of the twelve tables it was ordained, that insolvent debtors should be given up to their creditors to be bound in fetters and cords, whence they were called *Nexi*; and though they did not entirely lose the rights of freemen, yet they were often treated more harshly

5

than the slaves themselves. If any one was indebted to several persons, and could not within 60 days find a cautioner, his body according to some, but according to others his effects, might be cut in pieces, and divided among his creditors. The latter opinion seems by much the most probable, as Livy mentions a law by which creditors had a right to attach the goods but not the persons of their debtors.

NEYTRECHT, a town of Upper Hungary, capital of a county of the same name, with a bishop's see; seated on the river *Neitra*, 40 miles north-east of Presburg. F. Long. 17. 49. N. Lat. 48. 28.

burg. E. Long. 17. 49. N. Lat. 48. 28. NGAN-KING-FOU, a city of China, and capital of the western part of the province of Kiang-uan. It is governed by a particular viceroy, who keeps a large garrison in a fort built on the banks of the river Yang-tsc-kiang. Its situation is delightful; its commerce and riches render it very considerable; and every thing that goes from the southern part of China to Nan-king must pass through it. All the country belonging to it is level, pleasant, and fertile. It has under its jurisdiction only six cities of the third class.

NGÖ-KIA, a Chinese drug, of which the composition will no doubt appear as singular as the numerous properties ascribed to it. In the province Chang-tong, near Ngo-hien, a city of the third class, is a well formed by nature, which is reckoned to be seventy feet in depth, and which has a communication, as the Chinese say, with some subterranean lake, or other large reservoir. The water drawn from it is exceedingly clear, and much heavier than common; and if it be mixed with muddy water, it purifies it and renders it limpid, by precipitating all its impurities to the bottom of the vessel. This water is employed in making the ngo-kia, which is nothing else but a kind of glue procured from the skin of a black ass.

The animal is killed and flayed, and the skin is steeped for five days in water drawn from this well. At the end of that time, it is taken out to be scraped and cleaned; it is afterwards cut into small pieces, which are boiled over a slow fire, in the same kind of water, until it is reduced to a jelly, which is strained, while warm, through a cloth, to free it from all the gross matter which could not be melted. When this glue is cool, and has acquired a consistence, it is formed into square cakes, upon which the Chinese imprint characters and coats of arms, or the signs of their shops.

This well is the only one of the kind in China ; it is always shut, and sealed by the governor of the place with his own seal, until the customary day of making the emperor's glue. This operation generally lasts from the autunnal harvest till the month of March. During that time, the neighbouring people and merchants treat for the purchase of the glue with those who guard the well, and with the people who make The latter manufacture as much of it as they it. can, on their own account, with this difference, that it is not so pure, and that they are less scrupulous in examining whether the ass be fat, or of a very black colour: however, all the glue made here is as much estcemed at Peking as that which the mandarins who are on the spot transmit to court and to their friends.

As this drug is in the greatest request, and as the quantity of it made at Ngo-hien is not sufficient to supply

Nexi || Ngo-kia.

N

Ngo-kia, supply the whole empire, there are not wanting people Niagara. who counterfeit it elsewhere, and who manufacture a spurious kind from the skins of mules, horses, and camels, and sometimes even from old boots; it is, however, very easy to distinguish that which is genuine; it has neither a bad smell nor a disagreeable taste when applied to the mouth; it is brittle and friable, and always of a deep black colour, sometimes inelining to red. The qualities of the counterfeit kind arc entirely different; both its taste and smell arc disagreeable, and it is viscous and flabby even when made of the skin of a hog, which is that which imitates the truc kind the best.

The Chinese attribute a great number of virtues to this drug. They assure us that it dissolves phlegm, facilitates the play and clasticity of the lungs, gives a free respiration to those who breathe with difficulty; that it comforts the breast, increases the blood, stops dysenterics, provokes urine, and strengthens ehildren in the womb. Without warranting the truth of all these properties, it appears, at least, certain, by the testimony of the missionaries, that this drug is serviceable in all discases of the lungs. It is taken with a decoction of simples, and sometimes in powder, but very seldom.

NIAGARA, a fort of North America, which was taken from the French in 1759. According to the treaty of 1794, it was delivered up by Britain to the United States in 1796. It is situated on a small peninsula formed by the river Niagara as it flows into the lake Ontario. About six leagues from the fort is the greatest cataract in the world, known by the name of the Waterfall of Niagara. The river at this fall runs from SSE to NNW; and the rock of the fall crosses it not in a right line, but forms a kind of figure like a hollow semicircle or horse shoe. Above the fall, in the middle of the river, is an island about 800 or 1000 feet long; the lower end of which is just at the perpendicular edge of the fall. On hoth sides of this island runs all the water that comes from the lakes of Canada; viz. Lake Superior, Lake Michigan, Lake Huron, and Lake Erie, which have some large rivers that open themselves into them. Before the water comes to this island, it runs but slowly compared with its motion afterwards, when it grows the most rapid in the world, running with a surprising swiftness before it comes to the fall. It is perfectly white, and in many places is thrown high up into the air. The water that runs down on the west side is more rapid, in greater abundance, and whiter, than that on the east side; and seems almost to outfly an arrow in swiftness. When you are at the fall, and look up the river, you may see that the water is everywhere exceedingly steep, almost like the side of a hill; but when you come to look at the fall itself, it is impossible to express the amazement it oceasions. The height of it, as measured by mathematical instruments, is found to be exactly 137 feet; and when the water is come to the bottom, it jumps back to a very great height in the air. The noise may be heard at the distance of 45 miles, but seldom further; nor ean it be heard even at Fort Niagara, which is only six leagues distant, unless Lake Ontario is calm. At that fart it is observed, that when they hear the noise of the fall more loud than ordinary, they are sure that a north-east wind will follow; which is the more surprising, as the fort lies south-west from the fall. At Niagara. some times the fall makes a much greater noise than at 4 others; and this is held for an infallible sign of approaching rain or other bad weather.

From the place where the water falls there arises abundance of vapour like very thick smoke, insomuchthat when viewed at a distance you would think that the Indians had set the forests on fire. These vapours rise high in the air when it is calm, but are dispersed by the wind when it blows hard. If you go into this vapour or fog, or if the wind blows it on you, it is so penetrating, that in a few moments you will be as wet as if you had been under water. Some are of opinion that when birds come flying into this fog or smoke of the fall, they drop down and perish in the water ; either because their wings are become wet, or that the noise of the fall, astonishes them, and they know not where to go in the darkness : but others think that seldom or never any bird perishes there in that manner; bccause among the abundance of birds found dead below the fall, there are no other sorts than such as live and swim frequently in the water ; as swans, geese, dueks, water hens, teal, and the like. And very often great floeks of them are seen going to destruetion in this manner : they swim in the river above the fall, and so are carried down lower and lower by the water ; and as water fowl commonly take great delight in being earried with the stream, they indulge themselves in enjoying this pleasure so long, till the swiftness of the water becomes so great, that it is no longer possible for them to rise, hut they are driven down the precipiee and perish. They are observed, when they draw nigh the fall, to endeavour with all their might to take wing and leave the water; but they eannot. In the months of September and October such abundant quantities of dead water fowl are found every morning below the fall, on the shore, that the garrison of the fort for a long time live chiefly upon them. Besides the fowl, they find also several sorts of dead. fish, also deer, bears and other animals which have tried to eross the water above the fall; the larger animals are generally found broken to pieces. Just below, a little way from the fall, the water is not ra-pid, but goes all in circles, and whirls like a boiling pot; which however does not hinder the Indians going upon it in small eanocs a-fishing; but a little further, and lower, the other smaller falls begin. When you are above the fall, and look down, your head begins to turn ; even such as have been herc numberless times, will seldom venture to look down, without at the same time keeping fast hold of some tree with onehand.

It was formerly thought impossible for anybody living to come at the island that is in the middle of the fall; but an accident that happened about 50 years ago made it appear otherwise. The history is this: Two Indians of the Six Nations went out from Niagara fort to hunt upon an island that is in the middle of the river, or strait, above the great fall, on. which there used to be abundance of deer. They took. some French brandy with them from the fort, which they tasted several times as they were going over the carrying place; and when they were in their canoe, they took now and then a dram, and so went along up the strait towards the island where they proposed, to:

NIA

Niagara, to hunt; but growing sleepy, they laid themselves - down in the canoe, which getting loose drove back with the stream, farther and farther down, till it came nigh that island that is in the middle of the fall. Here one of them, awakened by the noise of the fall, cries out to the other, that they were gone : Yet they tried if possible to save life. This island was nighest, and with much working they got on shore there. At first they were glad; but when they had considered every thing, they thought themselves hardly in a better state than if they had gone down the fall, since they had now no other choice, than either to throw themselves down the same, or perish with hunger. But hard necessity put them on invention. At the lower end of the island the rock is perpendicular, and no water is running there. The island has plenty of wood; they went to work then, and made a ladder or shrouds of the bark of the lind tree (which is very tough and strong) so long till they could with it reach the water below; one end of this bark ladder they tied fast to a great tree that grew at the side of the rock above the fall, and let the other end down to the water. So they went down along their new invented stairs, and when they eame to the bottom in the middle of the fall they rested a little; and as the water next below the fall is not rapid, as before mentioned, they threw themselves out into it, thinking to swim on shore. We have said before, that one part of the fall is on one side of the island, the other on the other side. Hence it is, that the waters of the two cataraets running against each other, turn back against the rock that is just under the island. Therefore, hardly had the Indians begun to swim, before the waves of the eddy threw them back with violence against the rock from whence they eamc. They tried it several times, but at last grew weary; and by being often thrown against the rock they were much bruised, and the skin torn off their bodies in many places. So they were obliged to elimb up stairs again to the island, not knowing what to do. After some time they perceived Indians on the shore, to whom they eried out. These saw and pitied them, but gave them little hope or help: yet they made haste down to the fort, and told the commandant where two of their brothers were. He persuaded them to try all possible means of relicving the two poor Indians; and it was done in the following manner :

The water that runs on the east side of this island is shallow, especially a little above the island towards the eastern shore. The commandant caused poles to be made and pointed with iron; two Indians took upon them to walk to this island by the help of these poles, to save the other poor creatures, or perish themselves. They took leave of all their friends, as if they were going to death. Each had two such poles in his hands, to set to the bottom of the stream, to keep them steady : and in this manuer reached the island : and having given poles to the two poor Indians there, they all returned safely to the main land. These two Indians (who in the above-mentioned manner were first brought to this island) were nine days on the island, and almost ready to starve to death. Now since the road to this island has been found, the Indians go there often to kill deer, which have tried to cross the river above the fall, and are driven upon it by the stream. On

the west side of this island are some small islands or Niagora. rocks, of no consequence. The cast side of the river is almost perpendicular, the west side more sloping. In former times, a part of the rock at the fall which is on the west side of the island, hung over in such a manner, that the water which fell perpendicularly from it, left a vacancy below, so that people could go under between the rock and the water; but the prominent part some years since broke off and fell down. The breadth of the fall, as it runs in a semicirele, is rec-koned to be about 300 feet. The island is in the middle of the fall, and from it the water on each side is almost the same breadth; the breadth of the island at its lower end is about 100 fect. Below the fall, in the holes of the rocks, are great plenty of eels, which the Indians and French catch with their hands without any other means. Every day when the sun shines, you see here from ten o'elock in the morning to two in the afternoon, below the fall, and under you, where you stand at the side of the fall, a glorions rainbow, and sometimes two, one within the other. The more vapours, the brighter and elearer is the rainbow. When the wind earries the vapours from that place, the rainbow is gone, but appears again as soon as new vapours come. From the fall to the landing above it, where the eanoes from Lake Erie put ashore (or from the fall to the upper end of the earrying place), is half a mile. Lower the canoes dare not come, lest they should be obliged to try the fate of the two Indians, and perhaps with less success. They have often found below the fall pieces of human bodies, perhaps drunken Indians, that have unhappily come down to the fall. The French say, that they have often thrown whole great trees into the water above, to see them tumble down the fall: they went down with surprising swiftness, but could never be seen afterwards; whence it was thought there was a bottomless deep or abyss just under the fall. The rock of the fall consists of a gray limestone. For an interesting account of this eelebrated fall, the reader is referred to Volney's or Hall's Travels in America.

Having mentioned the Six Nations which live on the banks of the Niagara, we shall here add a few partienlars relative to those nations which, as they seem not to be well understood even in America, are probably still less known in Europe. The information which we have to give was communicated to the Royal Society of London by Mr Richard McCausland surgeon to the 8th regiment of foot, who, writing from the best authority, informs us, that each nation is divided into three tribes, of which the principal are called the *turtle tribe*, the *wolf tribe*, and the *bear tribe*.

Each tribe has two, three, or more chiefs, called sachems; and this distinction is always hereditary in the family, but descends along the female line: for instance, if a chief dies, one of his sister's sons, or one of his own brothers, will be appointed to succeed him. Among these no preference is given to proxinity or primogeniture; but the sachent, during his lifetime, pitches upon one whom he supposes to have more abilities than the rest; and in this choice he frequently, though not always, consults the principal men of the tribe. If the successor happens to be a child, the offices of the post are performed by some of Nis

Niagara, of his friends until he is of sufficient age to act himself.

Each of these posts of sachem has a name which is peculiar to it, and which never changes, as it is always adopted by the successor: nor does the order of precedency of each of these names or titles ever vary. Nevertheless, any sachem, by abilities and activity, may acquire greater power and influence in the nation than those who rank before him in point of precedency; but this is merely temporary, and dies with him.

Each tribe has one or two chief warriors; which dignity is also hereditary, and has a peculiar name attached to it.

These are the only titles of distinction which are fixed and permanent in the nation; for although any Indian may by superior talents, either as a counsellor or as a warrior, acquire influence in the nation, yet it is not in his power to transmit this to his family.

The Indians have also their great women as well as their great men, to whose opinions they pay great deference : and this distinction is also hereditary in families. They do not sit in council with the sachems, but have separate ones of their own .- When war is declared, the sachems and great women generally give up the management of public affairs into the hands of the warriors. It may however so happen, that a sachem may at the same time be also a chief warrior.

Friendship seems to have been instituted with a view towards strengthening the union between the several nations of the confederacy; and hence friends are called the sinews of the Six Nations. An Indian has therefore generally one or more friends in each nation. Besides the attachment which subsists during the lifetime of the two friends, whenever one of them happens to be killed, it is incumbent on the survivor to replace him, by presenting to his family either a scalp, a prisoner, or a belt consisting of some thousands of wampum; and this ceremony is performed by every friend of the deceased.

The purpose and foundation of war parties, therefore, is in general to procure a prisoner or scalp to replace NIC

the friend or relation of the Indian who is the head Niagara, of the party. An Indian who wishes to replace a Nicara. friend or relation presents a belt to his acquaintance; and as many as choose to follow him accept this belt, and become his party. After this, it is of no consequence whether he goes on the expedition or remains at home (as it often happens that he is a child ;) he is still considered as the head of the party. The belt he presented to his party is returned fixed to the scalp or prisoner, and passes along with them to the friends of the person he replaces. Hence it happens, that a war party, returning with more scalps or prisoners than the original intention of the party required, will often give one of these supernumerary scalps. or prisoners to another war party whom they meet going out; upon which this party, having fulfilled the purpose of their expedition, will sometimes return without going to war.

NICÆA, in Ancient Geography, the metropolis of Bithynia; situated on the lake Ascanius, in a large and fertile plain ; in compass 16 stadia : first built by Antigonus, the son of Philip, and thence called Antigonea; afterwards completed by Lysimachus, who called it Nicaa, after his consort the daughter of Antipater. According to Stephanus, it was originally a colony of the Bottizi, a people of Thrace, and called *Ancore*; and afterwards called *Niccea*. Now *Nice* in Asia the Less *. Famous for the first general council .- A se- * See Nice. cond Nicaa, (Diodorus Siculus), of Corsica .- A third, of the Hither India, (Arrian); situated on the west side of the Hydaspes, opposite to Bucephale, on the east side .- A fourth Nicaa, a town of Liguria, at the Maritime Alps, on the east side of the river Paulon, near its mouth, which runs between the Varus and Nicara, (Mela). A colony of the Massilians, (Stephanus); the last town of Italy to the west. Now Nizza or Nice, capital of the county of that name, on the Mediterranean .- A fifth, of Locris, (Strabo); a town near Thermopylæ; one of the keys of that pass. It stood on the Sinus Maliacus.
