C M I

ICROSCOPE, an optical instrument, consisting of lenses, or mirrors, by means of which small objects appear larger than they do to the naked cye. Single microseopes consist of a single lens or mirror; or if more lenses or mirrors be made use of, they only serve to throw light upon the object, but do not contribute to enlarge the image of it. Double or compound microscopes are those in which the image of an object is composed by means of more lenses or mirrors than one.

For the principles on which the construction of microscopes depends, see OPTICS. In the present article, it is intended to describe the finished instrument, with all its varied apparatus, according to the latest improvements; and to illustrate by proper details its uses and importance.

I. Of SINGLE Microscopes.

THE famous microscopes made use of by Mr Leeuwenhoeck, were all, as Mr Baker assures us, of the single kind, and the construction of them was the most simple possible; each consisting only of a single lens set hetween two plates of silver, perforated with a small hole, with a moveable pin before it to place the object on and adjust it to the eye of the beholder. He informs us also, that lenses only, and not globules, were used in every one of these microscopes.

Plate

Micro-

scope.

1. The single microscope now most generally known cccxxxv11. and used is that called Wilson's Pocket Microscope. The Fig. 1. body is made of brass, ivory, or silver, and is represented by AA, BB. CC is a long fine threaded male screw that turns into the body of the microscope; D a convex glass at the end of the serew. Two concave round pieces of thin brass, with holes of different diameters in the middle of them, are placed to eover the above-mentioned glass, and thereby diminish the aperture when the greatest magnifiers are employed. EE, three thin plates of brass within the body of the microscope; one of which is bent semicircularly in the middle, so as to form an arched cavity for the reception of a tube of glass, the use of the other two being to receive and hold the sliders between them. F, a piece of wood or ivory, arched in the manner of the semicircular plate, and cemented to it. G, the other end of the body of the microscope, where a hollow female serew is adapted to receive the different magnifiers. H is a spiral spring of steel, between VOL. XIV. Part I. +

T C M

the end G and the plates of brass, intended to keep Microthe plates in a right position and counteract the long screw CC. I is a small turned handle, for the better holding of the instrument, to serew on or off at pleasure.

To this microscope belong six or seven magnifying glasses : six of them are set in silver, brass, or ivory, as in the figure K; and marked 1, 2, 3, 4, 5, 6, the lowest numbers being the greatest magnifiers. L is the seventh magnifier, set in the manner of a little barrel, to be held in the hand for the viewing of any larger object. M is a flat slip of ivory, called a slider, with four round holes through it, wherein to place objects between two pieces of glass or Muscovy tale, as they appear at d d d d. Six such sliders, and one of brass, are usually sold with this microscope, some with objects placed in them, and others empty for viewing any thing that may offer : but whoever pleases to make a collection, may have as many as he desires. The brass slider is to confine any small object, that it may be viewed without crushing or destroying it. N is a tube of glass contrived to confine living objects, such as frogs, fishes, &c. in order to discover the circulation of the blood. All these are contained in a little neat box of fish-skin or mahogany, very convenient for carrying in the pocket.

When an object is to be viewed, thrust the ivory slider, in which the said object is placed, between the two flat brass plates EE: observing always to put that side of the slider where the brass rings are farthest from the eye. Then serew on the magnifying glass you intend to use, at the end of the instrument G; and looking through it against the light, turn the long screw GC, till your object be brought to suit your eye; which will be known by its appearing perfectly distinct and clear. It is most proper to look at it first through a magnifier that can show the whole at once, and afterwards to inspect the several parts more particularly with one of the greatest magnifiers; for thus you will gain a true idea of the whole, and of all its parts. And though the greatest magnifiers can show but a minute portion of any object at once, such as the claw of a fica, the horn of a louse, or the like ; yet by gently moving the slider which contains the object, the eye may gradually examine it all over.

As objects must be brought very near the glasses when the greatest magnifiers are made use of, be eareful not to serateh them by rubbing the slider against A them

scope

Micro-

scope.

them as you move it in or out. A few turns of the screw CC will easily prevent this mischief, by giving them room enough. You may change the objects in your sliders for any others you think proper, by taking out the brass rings with the point of a penknife; the tales will then fall out, if you but turn the sliders; and after putting what you please between them, by replacing the brass rings you will fasten them as they were before. It is proper to have some sliders furnished with tales, but without any object between them, to be always in readiness for the examination of fluids, salts, sands, powders, the farina of flowers, or any other casual objects of such sort as need only be applied to the outside of the tale.

The circulation of the blood may be easiest seen in the tails or fins of fishes, in the fine membranes between a frog's toes, or best of all in the tail of a water-newt. If your object be a small fish, place it within the tube N, and sprcad its tail or fin along the side thereof : if a frog, choose such a one as can but just be got into your tube; and, with a pen, or small stick, expand the transparent membrane between the toes of the frog's hind foot as much as you can. When your object is so adjusted that no part of it can intercept the light from the place you intend to view, unscrew the long screw CC, and thrust your tube into the arched cavity, quite through the body of the microscope ; then screw it to the true focal distance, and you will see the blood passing along its vessels with a rapid motion, and in a most surprising manner.

The third or fourth magnifiers may be used for frogs or fishes: but for the tails of water-newts, the lifth or sixth will do; because the globules of their blood are twice as large as those of frogs or fish. The first or second magnifier cannot well be employed for this purpose; because the thickness of the tube in which the object lies, will searce admit its being bronght so near as the focal distance of the magnifier.

An apparatus for the purpose of viewing opaque objects generally accompanies this microscope; and which consists of the following parts. A brass arm QR, which is screwed at Q, upon the body of the microscope at G. Into the round hole R, any of the magnificrs suitable to the object to be viewed are to be screwed; and under it, in the same ring, the concave polished silver speculum S. Through a small aperture in the body of the microscope under the brass plates EE, is to slide the long wire with the forceps T: This wire is pointed at one of its ends; and so, that either the points or forceps may be used for the objects as may be necessary. It is easy to conceive, therefore, that the arm at R, which turns by a twofold joint at a and b, may be brought with its magnifier over the object, the light reflected upon it by the application of the speculum, and the true focus obtained by turning of the male screw CC as before directed .- As objects are sometimes not well fixed for view, either by the forceps or point, the small piece shown at V is added, and in such cases answers better : it scrcws over the point of T; it contains a small round piece of ivory, blackened on one side, and left white upon the other as a contrast to coloured objects, and by a small piece of watch-spring fastens down the objects upon the ivory.

2. Single Microscope by reflection. In fig. 2. A is a scroll of brass fixed upright upon a round wooden base B, or a maliogany drawer or case, so as to stand perfectly firm and steady. C is a brass screw, that passes through a hole in the upper limb of the scroll into the side of the microscope D, and screws it fast to the said seroll. E is a concave speculum set in a box of brass, which hangs in the arch G by two small screws ff, that screw into the opposite sides thereof. At the bottom of this arch is a pin of the same metal, exactly fitted to a hole h in the wooden pedestal, made for the reception of the pin. As the arch turns on this pin, and the speculum turns on the end of the arch, it may, by this twofold motion, be easily adjusted in such a manner as to reflect the light of the sun, of the sky, or of a candle, directly upwards through the microscope that is fixed perpendicularly over it; and by so doing may be made to answer many purposes of the large double reflecting microscope. The body of the microscope may also be fixed horizontally, and objects viewed in that position by any light you choose; which is an advantage the common double reflecting microscope has not. It may also be rendered further useful by means of a slip of glass; one end of which being thrust through between the plates where the sliders go, and the other extending to some distance, such objects may be placed thereon as cannot be applied in the sliders : and then, having a limb of brass that may fasten to the body of the microscope, and extend over the projecting glass a hollow ring wherein to screw the magnifiers, all sorts of subjects may be examined with great convenience, if a hole be made in the pedestal, to place the speculum exactly underneath, and thereby throw up the rays of light. The pocket-microscope, thus mounted, says Mr Baker, " is as easy and pleasant in its use; as fit for the most curious examination of the animalcules and salts in fluids, of the farinæ in vegetables, and of the circulation in small animals; in short, is as likely to make considerable discoveries in objects, that have some degree of transparency, as any microscope I have ever seen or heard of."

The brass scroll A is now generally made to unscrew into three parts, and pack with the microscope and apparatus into the drawer of a mahogany pocketcase, upon the lid of which the scroll is made to fix when in use.

The opaque apparatus also, as above described, is applicable this way by reflection. It only consists in turning the arm R (fig. 1.), with the magnifier over the concave speculum below (fig. 2.), or to receive the light as reflected obliquely from it : the silver speculum screwed into R will then reflect the light, which it receives from the glass speculum, strongly upon the object that is applied upon the wire T underneath.

This miscroscope, however, is not upon the most convenient construction, in comparison with others now made: it has been esteemed for many years past from its popular name, and recommendation by its makers. Its portability is certainly a great advantage in its favonr; but in most respects it is superseded by the microscopes hereafter described.

3. Microscope for Opaque Objects, called the Single Fig. 3. Opaque Microscope. This microscope remedies the inconvenience of having the dark side of an object next the

Microscope.

3

M Ι C

scope, screw the speculum, with the magnifier you

Micros SCOUR

Micro- the eye, which formerly was an insurmountable objection to the making observations on opaque objects with any considerable degree of exactness or satisfaetion : for, in all other contrivances commonly known, the nearness of the instrument to the object (when glasses that magnify much are used) unavoidably overshadows it so much, that its appearance is rendered obseure and indistinet. And, notwithstanding ways have been tried to point light upon an object, from the sun or a candle, by a convex glass placed on the side thereof, the rays from either can be thrown upon it in such an acute angle only, that they serve to give a confused glare, but are insufficient to afford a clear and perfect view of the object. But in this microscope, by means of a concave speculum of silver highly polished, in whose centre a magnifying lens is placed, such a strong and direct light is reflected upon the object, that it may be examined with all imaginable ease and pleasure. The several parts of this instrument, made cither of brass or silver, are as follow.

Through the first side A, passes a fine serew B, the other end of which is fastened to the movcable side C. D is a nut applied to this screw, by the turning of which the two sides A and C arc gradually brought together. E is a spring of steel that separates the two sides when the nut is unscrewed. F is a piece of brass, turning round in a soeket, whence proceeds a small spring tube moving upon a rivet ; through which tube there runs a steel wire, one end whereof terminates in a sharp point G, and the other with a pair of pliers H fastened to it. The point and pliers are to thrust into, or take up and hold, any inseet or object; and either of them may be turned upwards, as best suits the purpose. I is a ring of brass, with a female sercw within it, mounted on an upright piece of the same metal; which turns round on a rivet, that it may be set at a due distance when the least magnifiers are employed. This ring receives the screws of all the magnifiers. K is a concave speculum of silver, polished as bright as possible; in the centre of which is placed a double convex lens, with a proper aperture to look through it. On the back of this speculum a male screw L is made to fit the brass ring I, to screw into it at pleasure. There are four of these eoncave speeula of different depths, adapted to four glasses of different magnifying powers, to be used as the objeets to be examined may require. The greatest magwifiers have the least apertures. M is a round objectplate, one side of which is white and the other black : The intention of this is to render objects the more visible, by placing them, if black, on the white side, or, if white, on the black side. A steel spring N turns down on each side to make any object fast; and issuing from the object-plate is a hollow pipe to screw it on the needle's point G. O is a small box of brass, with a glass on each side, contrived to confine any living object, in order to examine it: this also has a pipe to serew upon the end of the needle G. P is a turned handle of wood, to screw into the instrument when it is made use of. Q, a pair of brass pliers to take up any object, or manage it with conveniency. R is a soft hair-brush for cleaning the glasses, &c. S is a small ivory box for tales, to be placed, when wanted, in the small brass box O.

When you would view any object with this micro-

think proper to use, into the brass ring I. Place your object, either on the needle G in the pliers H, on the object-plate M, or in the hollow brass box O, as may be most convenient; then holding up your instrument by the handle P, look against the light through the magnifying lens; and by means of the nut D, together with the motion of the neodle, by managing its lower end, the object may be turned about, raised, or depressed, brought nearer the glass, or removed farther from it, till you find the true focal distance, and the light be seen strongly reflected from the speculum up-on the object, by which means it will be shown in a manner surprisingly distinct and clear; and for this purpose the light of the sky or of a candle will answer very well. Transparent objects may also be viewed by this microscope ; only observing, that when such come under examination, it will not always be proper to throw on them the light reflected from the speculum; for the light transmitted through them, meeting the rcfleeted light, may together produce too great a glare. A little practice, however, will show how to regulate both lights in a proper manner.

4. Ellis's single and Aquatic Microscope. Fig. 4. re- Fig. 4. presents a very convenient and useful microscope, contrived by Mr John Ellis, author of An Essay upon Corallines, &e. To practical botanists, observers of animaleula, &c. it possesses many advantages above those just described. It is portable, simple in its construction, expeditious, and commodious in use. K represents the box containing the whole apparatus : it is generally made of fish-skin; and on the top there is a female screw, for receiving the screw that is at the bottom of the pillar A: this is a pillar of brass, and is screwed on the top of the box. D is a brass pin which fits into the pillar; on the top of this pin is a hollow socket to receive the arm which carries the magnifiers; the pin is to be moved up and down, in order to adjust the lenses to their focal or. proper distance from the object. [N. B. In the representa-tions of this microscope, the pin D is delineated as passing through a socket at one side of the pillar A; whereas it is usual at present to make it pass down a hole bored through the middle of the pillar.] E, the bar which carries the magnifying lens; it fits into the socket X, which is at the top of the pin or pillar D. This arm may be moved backwards and forwards in the socket X, and sideways by the pin D; so that the magnifier, which is serewed into the ring at the end E of this bar, may be easily made to traverse over any part of the object that lies on the stage or plate B. FF is a polished silver speculum, with a magnifying lens placed at the centre thereof, which is perforated for this purpose. The silver speculum serews into the arm E, as at F. G, another speculum, with its lens, which is of a different magnifying power from the former. H, the semicirele which supports the mirror I; the pin R, affixed to the semicircle H, passes through the hole which is towards the bottom of the pillar A. B, the stage, or the plane, on which the objects are to be placed; it fits into the small dove-tailed arm which is at the upper end of the pillar DA. C, a plane glass, with a small piece of black silk stuck on it; this glass is to lay in a groove made in the stage C. M, a hollow glass to be laid oceasionally on the stage in-A 2 stead

M I C

scope.

stead of the planc glass C. L, a pair of nippers. These are fixed to the stage by the pin at bottom; the steel wire of these nippers slides backwards and forwards in the socket, and this socket is moveable upwards and downwards by means of the joint, so that the position of the object may be varied at pleasure. The object may be fixed in the nippers, stuck on the point, or affixed, by a little gum-water, &c. to the ivory cylinder N, which occasionally screws to the point of the nippers.

To use this microscope : Take all the parts of the apparatus out of the box; then begin by screwing the pillar A to the cover thereof; pass the pin R of the semicircle which carries the mirror through the hole that is near the bottom of the pillar A; push the stage into the dove-tail at B, slide the pin into the pillar (see the N. B. above); then pass the bar E through the socket which is at the top of the pin D, and screw one of the magnifying lenses into the ring at F. The microscope is now ready for use : and though the enumeration of the articles may lead the reader to imagine the instrument to be of a complex nature, we can safely affirm that he will find it otherwise. The instrument has this peculiar advantage, that it is difficult to put any of the pieces in a place which is appropriated to another. Let the object be now placed either on the stage or in the nippers L, and in such manner that it may be as nearly as possible over the centre of the stage : bring the speculum F over the part you mean to observe; then throw as much light on the speculum as you can, by means of the mirror I, and the double motion of which it is capable; the light received on the speculum is reflected by it on the object. The distance of the lens F from the object is regulated by moving the pin D up and down, until a distinct view of it is obtained. The best rule is, to place the lens beyond its focal distance from the object, and then gradually to slide it down till the object appears sharp and well defined. The adjustment of the lenses to their focus, and the distribution of the hight on the object, are what require the most attention : on the first the distinctness of the vision depends; the pleasure arising from a clear view of the parts under observation is due to the modification of the light. No precise rule can be given for attaining accurately these points; it is from practice alone that ready habits of obtaining these necessary properties can be acquired, and with the assistance of this no difficulty will be found.

Fig. 5.

Micro-

scope.

5. A very simple and convenient microscope for botanical and other purposes, though inferior in many respects to that of Mr Ellis, was contrived by the ingenious Mr Benjamin Martin, and is represented at fig. 5. where AB represents a small arm supporting two or more magnifiers, one fixed to the upper part as at B, the other to the lower part of the arm at C; these may be used separately or combined together. The arm AB is supported by the square pillar IK, the lower end of which fits into the socket E of the foot FG; the stage DL is made to slide up and down the square pillar; H, a concave mirror for reflecting light on the object .- To use this microscope, place the object on the stage, reflect the light on it from the concave mirror, and regulate it to the focus, by moving the stage nearer to or farther from the lens at B. The ivory sliders pass through the stage; other objects may

be fixed in the nippers MN, and then brought under the Microeye-glasses; or they may be laid on one of the glasses which fit the stage. The apparatus to this instrument consists of three ivory sliders ; a pair of nippers ; a pair of forceps ; a flat glass and a concave ditto, both fitted to the stage.

The two last microscopes are frequently fitted up with a toothed rack and pinion, for the more ready adjustment of the glasses to their proper focus.

6. Withering's portable Botanic Microscope. Fig. 6. Fig. 6. represents a small botanical microscope contrived by Dr Withering, and described by him in his Botanical Arrangements. It consists of three brass plates, ABC, which are parallel to each other; the wires D and E are rivetted into the upper and lower plates, which are by this means united to each other; the middle plate or stage is moveable on the aforesaid wires by two little sockets which are fixed to it. The two upper plates each contain a magnifying lens, but of different powers; one of these confines and keeps in their places the fine point F, the forceps G, and the small knife H.-To use this instrument, unscrew the upper lens, and take out the point, the knife, and the forceps; then screw the lens on again, place the object on the stage, and then move it up or down till you have gained a distinct view of the object, as one lens is made of a shorter focus than the other; and spare lenses of a still deeper focus may be had if required. This little microscope is the most portable of any. Its principal merit is its simplicity.

7. Botanical Lenses or Magnifiers. The haste with which botanists, &c. have frequently occasion to view objects, renders an extempore pocket-glass indispensably necessary. The most convenient of any yet constructed, appears to be that contrived, in regard to the form of the mounting, by Mr Benjamin Martin; and is what he called a Hand Megalascope, because it is well adapted for viewing all the larger sort of small objects universally, and by only three lenses it has seven different magnifying powers.

Fig. 7. represents the case with the three frames and Fig. 7. lenses, which are usually of 1, 1¹/₂, and 2 inches focus: they all turn over cach other, and shut into the case, and are turned out at pleasure.

The three lenses singly, afford three magnifying powers; and by combining two and two, we make three more: for d with e makes one, d with f another, and e with f a third; which, with the three singly, make six; and lastly, all three combined together make another; so that upon the whole, there are seven powers of magnifying with these glasses only.

When the three lenses are combined, it is better to turn them in, and look through them by the small apertures in the sides of the case. The eye in this case is excluded from extra light; the aberration of the superfluous rays through the glasses is cut off; and the eye coincides more exactly with the common axes of the lenses.

A very useful and easy kind of microscope (describ-ed by Joblot, and which has been long in use), adapted chiefly for viewing, and confining at the same time, any living insects, small animals, &c. is shown at fig. 8. Fig. 8. where A represents a glass tube, about $1\frac{1}{4}$ inch dia-meter, and 2 inches high. B, a case of brass or wood, containing a sliding tube, with two or three magnify-

ing

Microscope.

Fig. 9

ing glasses that may be used either separately or combined. In the inside, at the bottom, is a piece of ivory, black and white on opposite sides, that is occasionally removed, and admits a point to be screwed into the centre. The cap unscrews at D, to admit the placing of the object : the proper distance of the glasses from the object is regulated by pulling up or down the brass tube E at top containing the eye-glasses.

This microscope is particularly useful for exhibiting the well-known curious curculio imperialis, vulgarly called the diamond beetle, to the greatest advantage; for which, as well as for other objects, a glass bottom, and a polished reflector at the top, arc often applied, to condense the light upon the object. In this case, the stand and brass-bottom F, as shown in the figure, are taken away by unscrewing.

9. Mr Lyonct's Single Anatomical Dissecting Microscope .- Fig. 9. represents a curious and extremely useful microscope, invented by that gentleman for the purpose of minute dissections, and microscopic preparations. This instrument must be truly useful to amateurs of the minutiæ of insects, &c. being the best adapted of any for the purposes of dissection. With this instrument Mr Lyonet made his very curious microscopical dissection of the chenille de saule, as related in his Traité Anatomique de la chenille qui ronge le bois de saule, 4to.

AB is the anatomical table, which is supported by a pillar NO; this is screwed on the foot CD. The table AB is prevented from turning round by means of two steady pins. In this table or board there is a hole G, which is exactly over the centre of the mirror EF, that is to reflect the light on the object; the hole G is designed to receive a flat or concave glass, on which the objects for examination are to be placed.

RXZ is an arm formed of several balls and sockets, by which means it may be moved in every possible situation; it is fixed to the board by means of the screw H. The last arm IZ has a female screw, into which a magnifier may be screwed as at Z. By means of the screw II, a small motion may be occasionally given to the arm IZ, for adjusting the lens with accuracy to its focal distance from the object.

Another chain of balls is sometimes used, carrying a lens to throw light upon the object ; the mirror is likewise so mounted, as to be taken from its place at K, and fitted on a clamp, by which it may be fixed to any part of the table AB.

To use the Dissecting Table .- Let the operator sit with his left side near a light window; the instrument being placed on a firm table, the side DH towards the stomach, the observations should be made with the left eye. In dissecting, the two elbows are to be supported by the table on which the instrument rests, the hands resting against the board AB; and in order to give it greater stability (as a small shake, though imperceptible to the naked eye, is very visible in the microscopc), the dissecting instruments are to be held one in each hand, between the thumb and two forefingers.

II. Of DOUBLE Microscopes, commonly called Com-POUND Microscopes.

Double microscopes arc so called, from being a combination of two or more lenses.

The particular and chief advantages which the com- Micropound microscopes have over the single, are, that the scope. objects are represented under a larger field of view, and with a greater amplification of reflected light.

I. Culpeper's Microscope .- The compound microscope. originally contrived by Mr Culpeper, is represented at fig. 10. It consists of a large external brass body A, Fig. to. B, C, D, supported upon three scrolls, which are fixed to the stage EF; the stage is supported by three larger scrolls, that arc screwed to the mahogany pedestal GH. There is a drawer in the pedestal, which holds the apparatus. The concave mirror I is fitted to a. socket in the centre of the pedestal. The lower part LMCD of the body forms an exterior tube, into which the upper part of the body ABLM slides, and may be moved up or down, so as to bring the magnifiers, which arc screwed on at N, nearer to or farther from the object.

To use this microscope: Screw one of the buttons. which contains a magnifying lens, to the end N of the body : place the slider, with the objects, between the plates of the slider-holder. Then, to attain distinct vision, and a pleasing view of the object, adjust the body to the focus of the lens you are using, by moving the upper part gently up and down, and regulate the light by the concave mirror.

For opaque objects, two additional pieces must be used. The first is a cylindrical tube of brass (representcd at L, fig. 11.), which fits on the cylindrical part at Fig. 11. N of the body. The second piece is the concave speculum h; this is to be screwed to the lower end of the aforesaid tube: the upper edge of this tube should be made to coincide with the line which has the same number affixed to it as to the magnifier you are using ; e.g. if you are making use of the magnifier marked 5, slide the tube to the circular line on the tube N that is marked also with Nº 5. The slider-holder should be removed when you are going to view opaque objects, and a plane glass should be placed on the stage in its stead to receive the object; or it may be placed. in the nippers, the pin of which fits into the hole in the stage.

The apparatus belonging to this microscope consists of the following particulars : viz. Five magnifiers, each fitted in a brass button; one of these is seen at N, fig. 10. Six ivory sliders, five of them with objects. A brass tube to hold the concave speculum. The concave speculum in a brass box. A fish pan. A set of glass tubes. A flat glass fitted to the stage. A concave glass fitted to the stage. A pair of forceps. A steel wire, with a pair of nippers at one end and a point at the other. A small ivory cylinder, to fit on the pointed end of the aforesaid nippers. A convex lens, moveable in a brass semicircle; this is affixed to a long brass pin, which fits into a hole on the stage.

The construction of the foregoing microscope is very simple, and it is easy in use; but the advantages of the stage and mirror are too much confined for an extensive application and management of all kinds of objects. Its greatest recommendation is its cheapness; and to those who are desirous of having a compound microscope at" a low price, it may be acceptable.

2. Cuff's Microscope.-The improved microscope next in order is that of Mr Cuff. Besides remedying the disadvantages above mentioned, it contains the addition.

C M T

scopie.

addition of an adjusting screw, which is a considerable improvement, and highly necessary to the examination of objects under the best defined appearance from the glasses. It is represented at fig. II. with the apparatus that usually accompanies it. A, B, C, shows the body of this microscope; which contains an eye-glass at A, a broad lens at B, and a magnifier which is screwed on at C. The body is supported by the arm DE, from which it may be removed at pleasure. The arm DE is fixed on the sliding bar F, and may be raised or depressed to any height within its limits. The main pillar a b is fixed in the box be; and by means of the brass foot d is screwed to the mahogany pedestal XY, in which is a drawer containing all the apparatus. O is a milled-headed serew, to tighten the bar F when the adjusting serew c g is used. p q Is the stage, or plate, which carries the objects; it has a hole at the centre n. G, a concave mirror, that may be turned in any direction, to reflect the light of a eandle, or the sky, upon the object.

To use this microscope: Screw the magnifier you intend to use to the end C of the body; place the slider-holder \mathbf{P} in the hole n, and the slider with the object between the plates of the slider-holder; set the upper edge of the bar DE to coincide with the divisions which correspond to the magnifier you have in use, and pinch it by the milled nut; now reflect a proper quantity of light upon the object, by means of the eoneave mirror G, and regulate the body exactly to the eye and the focus of the glasses by the adjusting screw c g.

To view opaque objects, take away the slider-holder P, and place the object on a flat glass under the centre of the body, or on one end of the jointed nippers o p. Then screw the silver coneave speculum h to the end of the cylinder L, and slide this cylinder on the lower part of the body, so that the upper edge thereof may coincide with the line which has the same mark with the magnifier that is then used : reflect the light from the concave mirror G to the silver speculum, from which it will again be reflected on the object. The glasses are to be adjusted to their focal distance as before directed.

The apparatus eonsists of a convex lens H, to colleet the rays of light from the sun or a candle, and condense them on the object. L a cylindrical tube, open at each side, with a concave speculum screwed to the lower end h. P the slider-holder: this consists of a cylindrieal tube, in which an inner tube is foreed upwards by a spiral spring; it is used to receive an ivory slider K, which is to be slid between the plates h and i. The cylinder P fits the hole n in the stage; and the hollow part at k is designed to receive a glass tuhe. R is a brass conc, to be put under the bottom of the cylinder P, to intercept occasionally some of the rays of light. S, a box containing a concave and a flat glass, between which a small living inseet may be confined: it is to be placed over the hole n. T, a flat glass, to lay any oceasional object upon; there is also a concave one for fluids. O is a long steel wire, with a small pair of pliers at one end, and a point at the other, designed to stick or hold objects : it slips backwards and forwards in the short tube o; the pin p fits into the hole of the stage. W, a little round

ivory box, to hold a supply of tale and rings for the Mirrosliders. V, a small ivory cylinder, that fits on the pointed end of the steel wire : it is designed for opaque objects. Light-coloured ones are to be stuck upon the dark side, and vice versa. M, a fish-pan, whereon to fusten a small fish, to view the circulation of the blood: the tail is to be spread across the oblong hole k at the small end, and ticd fast, by means of a ribband fixed thereto; the knob l is to be shoved through the slit made in the stage, that the tail may be brought under the magnifier.

3. This microscope has received several material improvements from Mr Martin, Mr Adams, &c. By an alteration, or rather an enlargement, of the body of the tube which contains the cye-glasses, and also of the eye-glasses themselves, the field of view is made much larger, the mirror below for reflecting light is made to move upon the same bar with the stage; by which means the distance of it from the stage may be very easily and suitably varied. A condensing glass is applied under the stage in the slider-holder, in order to modify and increase the light that is reflected by the mirrors below from the light of a eandle or lamp. It is furnishcd also with two mirrors in one frame, one concave and the other plane, of glass silvered; and by simply unserewing the body, the instrument, when desired, may be converted into a single microscope. Fig. 12. is a Fig. 12, representation of the instrument thus improved; and the following is the description of it, as given by Mr Adams in his Essays.

AB represents the body of the microscope, containing a double eyc-glass and a body-glass; it is here shown as serewed to the arm CD, from whence it may be occasionally removed, either for the convenience of packing, or when the instrument is to be used as a single microscope.

The eye-glasses and the body-glasses are contained in a tube which fits into the exterior tube AB; by pulling out a little this tube when the microscope is in use, the magnifying power of each lens is increased.

The body AB of the microscope is supported by the arm CD; this arm is fixed to the main pillar CF, which is serewed firmly to the mahogany pedestal GH; there is a drawer to this pedestal, which holds the apparatus.

NIS, the plate or stage which carries the slider-holder KL; this stage is moved up or down the pillar CF, by turning the milled nut M; this nut is fixed to a pinion, that works in a toothed rack eut on one side of the pillar. By means of this pinion, the stage may be gradually raised or depressed, and the object adjusted to the focus of the different lenses.

KL is a slider-holder, which fits into a hole that is in the middle of the stage NIS; it is used to confine and guide either the motion of the sliders which contain the objects, or the glass tubes that are designed to confine small fishes for viewing the circulation of the blood. The sliders are to be passed between the two upper plates, the tubes through the bent plates.

L is a brass tube, to the upper part of which is fixed the condensing lens before spoken of; it fits into the under part of the slider-holder KL, and may be set at different distances from the object, according to its distanee from the mirror or the candle.

O is the frame which holds the two reflecting mirrors,

scope. Fig. II.

Micro-

Plate

fig. 31.

7

Microscope.

rors, one of which is plane, the other concave. These Alicromirrors may be moved in various directions, in order to reflect the light properly, by means of the pivots on which they move, in the semicircle QSR, and the motion of the semicircle itself on the pin S: the coneave mirror generally answers best in the day-time; the plane mirror combines better with the condensing lens, and a lamp or eandle. At D there is a socket for receiving the pin of the arm Q (fig. 31.) to which the eoncave speeulum, for reflecting light on opaque objects, is fixed. At S is a hole and slit for receiving either the CCCXLI. nippers L (fig. 31.) or the fish-pan I; when these are used, the slider-holder must be removed. T, a hole to receive the pin of the convex lens M.

To use this microscope: Take it out of the box. Screw the hody into the round end of the upper part of the arm CD. Place the brass sliders, which contain the magnifiers, into the dove-tailed slit which is on the under side of the aforesaid arm, as seen at E, and slide it forwards until the magnifier you mean to use is under the centre of the body: opposite to each magnifier in this slit there is a noteh, and in the dove-tailed part of the arm CD there is a spring, which falls into the above-mentioned notch, and thus makes each magnifier coincide with the centre of the hody. Pass the ivory slider you intend to use between the upper plates of the slider-holder KL, and then reflect as strong a light as you can on the subject by means of one of the mirrors; after this, adjust the object to the focus of the magnifier and your eyc, by turning the milled serew M, the motion of which raises and depresses the stage NIS. The degree of light necessary for each object, and the accuracy required in the adjustment of the lenses to their proper focal distance from the object, will be easily attained by a little practice.

When opaque objects are to be examined, remove the slider-holder, and place the object on a flat glass, or fix it to the nippers L, the pin of these fit into the hole on the stage; serew the eoneave speculum R into the arm Q (fig, 31.), and then pass the pin of this arm through the soeket D (fig. 12.); the light is now to he reflected from the concave mirror to the silver speculum, and from this down on the object. No exact rule can be given for reflecting the light on the object; we must therefore refer the reader to the mother of all aptness, practice. The speculum must be moved lower or higher, to suit the foeus of the different magnificrs and the nature of the object.

The foregoing directions apply equally to the using of this instrument as a single microscope; with this difference only, that the body AB is then removed, and the eye is applied to the upper surface of the arm CD, exactly over the magnifiers.

This microscope is sometimes made with the following alterations, which are supposed to make it still more convenient and useful. The arm CD that earries the body and magnifiers is made both to turn on a pin, and to slide backwards and forwards in a socket at C; so that, instead of moving the objects below on the stage, and disturbing them, the magnifiers are more conveniently brought over any part of the objects as desired. The condensing glass is made larger, and slides upon the square bar CF quite distinct from the stage, like the mirrors below; and it is thereby made

useful for any other objects that may be applied on glasses fitted to the stage, as well as those put into the slider-holder K. It is thereby not confined to this stage alone as in the preceding. When the body AB is taken away, the arm CD may be slipt away from its bar, with the magnifiers, and the forceps, wire, and joint, applied to it; and it thereby serves the purpose of a small single or opaque hand microscope, for any objeet oecasionally applied to this wire. The magnifiers in the slider E are mounted in a wheel ease, which perhaps prevents its heing in the way so much as the long slider E before described .- This contrivance is represented at X, fig. 12.

4. Martin's New Universal Compound Microscope .---This instrument was originally constructed by Mr B. Martin, and intended to comprise all the uses and advantages of the single, compound, opaque, and aquatic microscopes. The following is a description of it.

Fig. 13. is a representation of the instrument plaeed np for use. ABCD is the body of the miero-cccxxxiz.. scope : which consists of four parts, viz. AB the eyepiece, or that containing the eye-glasses, and is serewed into C, which is a moveable or sliding tube on the top; this inner tube contains the body-glass screwed into its lower part. D is the exterior tube or ease, in which the other slides up and down in an easy and steady manner. This motion of the tube C is useful to increase and decrease the magnifying power of the body-glass when thought necessary, as before mentioned. E is a pipe or snout serewed on to the body of the microscope D, and at its lower part, over the several magnifying lenses hereafter described. FGHI is the square stem of the microscope, upon which the stage R moves in an horizontal position, npwards or downward, by means of the fine rack work of teeth and pinion. KL is a strong solid joint and pillar, by which the position of the instrument is readily altered from a verticalone to an oblique or to a perfectly horizontal one as may be required : it is thus well adapted to the ease of the observer either sitting or standing ; and as it is very often convenient to view objects by direct unreflected light, when the square stem FI is placed in a horizontal position for this purpose, the mirror T is then to be taken off in order to prevent the obstruction of the rays. M is a circular piece of brass, serving as a base to the pillar. NOP, the tripod or foot by which the whole body of the microscope is steadily supported; it folds up when packed into the case. W is a brass frame, that contains the condensing lens, and acts in conjunction with the large coneave and plane mirrors below at T; the reflected rays from which, either of the common light or of that of a candle or lamp, it agreeably modifies, and makes steady in the field of view.

The particulars of the apparatus to this microscope are as follow: Q is a circular brass box, containing six magnifiers or object lenses, numbered 1, 2, 3, 4, 5, 6; the digits 'of which appear severally through a small round hole in the upper plate of it. To the upper side is fixed a small eircle of brass, by which it is connected with, and serewed into, the round end of the arm a b c d; which is a long piece of brass, and moves through either by teeth or pinion, or not, as may be desired, in ef; which is a socket on the upper part of the pillar, and admits, with a motion both easy and steady, the brass

Plate fig. 13. brass arm. R is a fixed stage, upon which the objects to be viewed arc to be placed : it is firmly fastened to the square pillar, which is moved by the rack-work. In the middle is a large circular hole, for receiving concave glasses, with fluids, &c. ; it has also a sliding spring frame to fasten down slips of glass or other things: at abc are three small sockets or holes, intended to receive several parts of the apparatus. S is the refractor, or illuminating lens, for converging the sun's rays upon opaque objects laid upon the stage R. To this purpose it moves on a semicircle upon a long shank g, in a spring socket h, in the arm i; this arm moving every way by a stout pin k in the socket a of the stage. In this manner it is easily adjusted to any position of the sun, candle, &c .- T, the reflecting-glass frame, containing a concave and plane speculum, which is moved upon the square pillar by the hand. The use of it is to illuminate all transparent objects that are applied to the stage above.

Fig. 14.

Micro-

scope.

Fig. 14. Nº 1. is an auxiliary moveable stage ; which by means of a piu k is placed in the hole a of the stage R, and can be moved in a horizontal direction over the whole field of the stage. In this stage, there are three circular holes with shouldered bottoms; a large one in the middle, and on each side a small one, for the reception of the three following necessary articles : Nº 2. a watch-glass to be placed in the large hole, to hold fluids containing animalcules, &cc.; a circular piece of ivory, Nº 3. one side of which is black, the other white, to support opaque objects of different coutrasted colours; and circular plane and concave glasses, Nº 4. for extemporancoustransparent objects .- The same use is made of the other small hole as of the large one, only in a lesser degree, to receive small concave glasses, plates, &c.

Nº 5. is the silvered speculum, called a liberkhun, which makes the single opaque microscope, by being screwed to the slider abc d (fig. 13.) in room of the box of lenses Q, and the body AE above it. The chief use of this is to view very small objects strongly illuminated near the compounded focus of the mirror T (fig. 13.). Nº 6. is the forceps or pliers, for holding such kind of objects, and by which they can he applied very readily to the focus of the lens in the liberkhun. They have a motion all ways by means of the spring socket a, the joint b, and the shank c: they are placed in the socket c of the fixed stage R (fig. 13.). Nº 7. is a small piece of ivory, to be placed upon the pointed end of the pliers : it is black upon one side, and white upon the other, to receive opaque objects.

 N° .8. is a liberkhun of a larger size than that first mentioned, with a hole in its centre: this is screwed into N° 9. the hole *a* of a brass ring, fastened to a long wire *b*; which moves up and down in the spring socket *b* of the stage R, in which it also moves sideways; and thus, with the body AE above, forms an *aquatic* compound microscope for showing all sorts of objects in water and other fluids placed under it in the watch-glass N° 2. on the stage.

 N° 11. is a cone, with a proper aperture *a* to exclude superfluous light, that would disturb a critical observation of a curious object; it is placed on the under side of the fixed stage R.

Nº 12. is what is usually called a bug-box, consist-

2

ing of a concave glass with a plane one screwed over Microit; by means of which a bug, louse, flea, &c. may be secured and viewed alive. It is to be placed on either of the stages \mathbb{R} (fig. 13.), or \mathbb{N}° 1. (fig. 14.).

N° 13. is the fish pan. In the long concave body a b, a fish may be so confined by the ribband c, that the transparent tail may be in part over the slit or hole at a. In this state, it is placed on the stage R, with the pin d in the hole c of the stage, and moves freely and horizontally for viewing the circulation of the blood, &c.

N^o 14. is the slider-holder that is placed on the stage R: it receives the sliders and tubes when filled with transparent objects, to be viewed either by the compound or single microscope.

Nº 15. represents the ivory slider, to hold the objects between the tales as usual.

Nº 16. is a useful auxiliary slider framed in brass. In this slider small concave glasses are cemented; and a slip of plane glass slides over them; by which any small living object, as mites, &c. may be confined without injury, and deliberately viewed.

 \mathbb{N}^{\bullet} 17. represents a set of glass tubes, three in number, one within another; they are useful for small tadpoles, water newts, cels, &c. when the circulation of the blood is to be viewed. There is a small hole at one end of each tube, that serves to admit the air; for when they are filled with water, the other end is stopped with a cork.

Nº 18. is a small ivory box, containing spare tales and wires, to supply the sliders with occasionally.

 N° 19. a brass cell or button, containing a very small lens, properly set between two small plates of brass, that it may be brought very near to the object when viewed therewith as a single microscope. This magnifier is screwed into the same hole as the wheel of six magnifiers Q are (fig. 13.).

N° 20. is a lens, adapted to view and examine objects, by magnifying them sufficiently, so as to be able to apply them to the microscope for inspection : on this account it is called the *explorator*.

The preceding are the chief articles of the apparatus: which, on account of their being somewhat different from what is applied to other microscopes, we have been thus particular in describing. In using the microscope, and while viewing objects by either the single or compound instrument, the focal distances of the magnifiers are made perfectly exact by turning of the pinion at the nut *av*, in one way or the other, very gently in the teeth of the rack-work at X (fig. 13.).

It is necessary that the centres of the object-lenses or magnifiers, the stage, and the mirrors at bottom, should all be in a right line in the axis of the microscope, when opaque objects are to be viewed, that are placed upon the ivory piece N° 7. or the forceps N° 6. and all other such sort of objects which are placed in the centre of the stage R, or slider-holder N° 14: But when aquatic or living objects, which require a great space to move in, are to be viewed, then the horizontal motion at ef (fig. 13.) is made use of, and the view may be extended laterally over the whole of the diameter of the object or field of view; and by putting the arm a b c d forward or backward in its socket ef, the view is extended in the contrary direction

direction equally well; and in this manner the whole of the objects may be viewed without the least disturbance

As the brass arms a b c d may be brought to the height of three or four inches above the stage R; so, by means of the rack-work motion of the stage, a lens of a greater focal distance than the greatest in the wheel Q may be occasionally applied in place of the wheel, and thereby the larger kind of objects be viewed; the instrument becoming, in this case, what is called a megalascope.

In viewing moving living objects, or even fixed ones, when nice motions are requisite, a rack-work and pinion is often applied to the arm $a \ b \ c \ d$: the arm is cut out with teeth; and the pinion, as shown at Y, is applied to work it. This acts but in one direction ; and, in order to produce an equally necessary motion perpendicular to this, rack-work and pinion is applied tangent-wise to the stage, which is then jointed.

What has been related above respects the construction of those denominated parlour microscopes, in contradistinction to those which are portable: their dimensions, however, have been considerably reduced by opticians, in order to render them fit for the pocket; and as they are for the most part constructed on nearly the same principles as those which have been already described, what has been said will sufficiently instruct our readers in using any pocket microscope whatever. Only it may be observed, that in those reduced instruments, both the field of view and the magnifying power are proportionably diminished.

We shall conclude the account of this sort of microscope with descriptions of a very portable pocket apparatus of microscopic instruments, and of a new microscopic pocket telescope, both invented by the late Mr B. Martin, and since made by most instrumentmakers in London.

The former is represented at fig. 15. It consists of two parts, viz. the body a b, and the pedestal i k, which is joined by a screw at the part between b and i. It consists of three cylindric tubes, viz. (1.) the exterior tube, or case, ab; (2.) a middle tube cb; and (3.) the interior tube fg. The middle tube c d is the adjuster; and is connected with the outer tube by the rack-work of teeth and pinion, as shown at e: by which means it is moved up and down at pleasure through the smallest space, and carries with it the internal tube fg. The interior tube fg receives on its lower part at b the several capsules or boxes 2, 3, 4, 5, (fig. 16.) which contain the object lenses or

magnifiers. The method of using this compound microscope in the perpendicular position, is as follows: The stage N° I. is put within the exterior tube at b. Under the springs are applied the four ivory sliders, which contain a variety of transparent objects; then move the interior tube fg up and down with the hand, till you discern the object in the slider, and there let it rest. After this, turn the pinion at e very tenderly one way or the other, till you obtain a perfect view of the transparent objects properly illuminated, from a mirror contained in the pedestal or stand i k, suspended upon, and moveable about, the points of Vol. XIV. Part I. two screws (11). Nº 6. (fig. 16.) represents a-move- Microable stage, which is placed in the spring socket m. It contains a concave glass, for the reception of animal-cules in fluids; and has the advantage of bringing any Fig. 16. part into view by moving the handle at n. If living and moving objects are required to be shown, they must be confined in the concave, by putting a glass cover, Nº 7. upon the stage; and then a small spider, a louse, a flea, bug, &c. may be seen, and the motion or circulation of the blood, &c. observed with surprising distinctness.

To view the circulation of the blood in the most eminent degree, it must be done by placing small frogs, tadpoles, water-newts, fishes, &c. in a tube as represented Nº 8. (fig. 17.); which tube is placed in the Fig. 17. holes o in the opposite sides of the case a b, fig. 15. in the lower part .- Nº 9. (fig. 16.) is a pair of pincers or pliers d, for holding any object; the other end of the steel wire is pointed to receive a piece of ivory b, with one end black, and the other white, on which you, stick objects of different hue: this also, when used, is placed in the spring socket m.

To use this instrument as a compound opaque, you screw off the body part a b, and screw to it the handle r (fig. 16.); by this means you may hold the microscope in a horizontal position, as shown in the figure. The silver dish or speculum (which is contained in the bottom or base k, fig. 15.), is then screwed on at b. Nº 9. is placed in the spring socket m, and adjusted. backward and forward in m, till the reflected light from the speculum falls in a proper manuer on the opaque object. Either of the four magnifiers, 2, 3, 4, 5, may be used, and brought to a proper focus, as before describcd by the tooth and pinion e (fig. 15.). If you take off the opaque apparatus, and apply the stage Nº 1. (fig. 16.) with an ivory slider, and at the end b screw in either of the two lenses, Nº 10. (which are distinguished by the name of illuminators), the microscope being held up to the light (and properly adjusted), the whole field of view will be strongly illuminated, and present a most pleasing appearance of any transparent object. These two convex lenses are of different focuses, and are to be used singly or together ; Nº 2. being the greatest magnifier, will require the object to be strongly illuminated, and of course both the lenses must be used together. By candle-light, this method of viewing transparent objects will prove very entertaining; by screwing the handle r into the part s of Nº 10. it becomes a delightful hand megalascope for viewing flowers, fossils, shells, &c,; and each lens, as before mentioned, having a different focus, produces two magnifying powers used singly, and when combined a third.

The manner of using this instrument as a single microscope (like Wilson's) is represented in fig. 17. where the button or magnifier at each is to be screwed off, and the circular piece Nº 11. is screwed in its place. This piece has a spring socket made to receive the slider-holder Nº 12. Nº 13. is a circular piece of brass, with a long shank and spring, and is introduced through the outside tube a b at t. N° 2, 3, 4, 5, are screwed occasionally in the centre of this piece, and used as single lenses with ivory sliders, &c. Nº 14. contains a lens of a great magnifying power, for viewing very minute objects : to render this instrument the most complete single opaque microscope, you have only to screw into Nº 13. the

Eig. 15.

Micro

scope.

There. the silver speculum Nº 15, which has a small lens set in its centre. The slider-holder Nº 12. is taken out of Nº 11, and the pincers or nippers d b, being detached from the other part of Nº 9. arc passed through the long spring socket Nº 11. and ready to receive any opaque hody in the pincers, or on the black and white piece of ivory. To the large screw of Nº 13. are applied the two lenses Nº 10. which make it the completest megalascope that can be desired.

The handle r contains the four ivory sliders with objects.

The shagreen case which contains this universal microscope and its apparatus, is six inches long, three inches wide, two inches decp; and weighs together 16 ounces. "Thus (says Mr Martin) so small, so light, so portable, and yet so universally complete, is this pocket microscopic apparatus, that you find nothing material in the large three-pillared microscope, the epaque microscope, Wilson's single microscope, and the aquatic microscope, all, together, which you have not in this; besides some very considerable advantages in regard to the field of view, &c. which they have not (A)."

This inventive artist having contrived a construction of the compound microscope so small as to admit of being packed in a common walking cane, thought next of introducing the same instrument into the inside of what he called his Pocket Three-brass drawer Achromatic Telescope. The same eye glasses that serve the purpose of a telescope, answer as the compound magnifier, for viewing transparent and opaque objects in a microscope.

Fig. 18, 19, 20, represent the telescope separated by unscrewing it at m, in order that the whole of the necessary parts in use may be exhibited. Fig. 19. represents the exterior tube, which is of mahogany, and its rims of brass. It is detached from the rest of the telescope, as not making any part of the microscope. The brass cover k l, that shuts up the objectglass of the telescope, is also the box which contains the two-wheel object frames, and a small plain reflecting mirror.

In fig. 20. A is the cover taken off, by unscrewing the top part : The mirror B is taken out; and also, by unscrewing the bottom part, the two circular wheels, with the objects shown in C and D.

Fig. 18. is a representation of the three internal brass sliding tubes of the telescope, which form the microscopic part. The tubes are to be drawn out as shown in this figure; then, at the lower end of the large tube in the inside, is to be pulled out a short tube b c, that serves as a kind of stage to hold the wheels, with objects, and support the reflecting mirror. This tube is to be partly drawn out, and turned so that the circular hole that is pierced in it may coincide with a similar hole that is cut in the exterior tube. This tube is represented as drawn out in the figure;

and the mirror B placed therein, and the wheel with Mierotransparent objects. C (fig. 20.) represents the wheel scope. with transparent objects, and D the wheel with opaque They are both made of ivory; and turn objects. round upon a centre brass pin slit upon the top, which fits upon the cdge of the tube; which tubc is then to be pushed up into the telescope tuhe, so that its lower end may rest upon the upper cdge of the wheel aecording to its view at a, fig. 18.

In viewing the objects, the second brass tube of the tclescope must be pushed down, till its milled edge at top falls upon that of the exterior tube; taking care that the circular hole is duly placed to the exterior one. These circular holes are not seen in fig. 18. being supposed in the opposite side, where the wheel is fixed. The adjustment for the focus is now only necessary; which is obtained by pushing downwards or upwards the proper tube, till the object appear quite distinct. In viewing transparent objects, the instrument may be used in two positions ; one vertical, when the light is to be reflected upon the object by the mirror; the other, by looking up directly against the light of a candle, common light, &c.; in which case the mirror must be taken away. In viewing opaque objects, the mirror is not used; but as much common light as possible must be admitted through the circular holes in the sides of the tubes.

There is a spare hole in the transparent wheel, and also one in the opaque, to receive any occasional object that is to be viewed. Any sort of object whatsoever may be viewed, by only pushing up the microscope tube into its exterior, and bringing the first eye-tube to its focal distance from the object.

The brass tubes are so contrived, that they stop when drawn out to the full length : so that by applying one hand to the outside tube, and the other to the end of the smallest tube, the telescope at one pull may be drawn out; then any of the tubes (that next to the eye is best) may be pushed in gradually, till the most distinct view of the object be obtained.

The tubes all slide through short brass spring tubes, any of which may be unscrewed from the ends of the sliding tubes by means of the milled edges which project above the tubes, taken from each other, and the springs set clear if required.

III. Of SOLAR Microscopes.

This instrument, in its principle, is composed of a tube, a looking-glass or mirror, a convex lens, and Wilson's single microscope before described. The sun's rays being reflected through the tube by means of the mirror upon the object, the image or picture of the object is thrown distinctly and beautifully upon a screen of white paper or a white linen sheet, placed at a proper distance to receive the same ; and may be magnified

(A) Notwithstanding the properties that have been ascribed to the above instrument, and the praises bestowed upon it by some, which induced us to admit so minute a description, we must apprise our readers, that it has been omitted in Mr Adams's cnumeration; and upon inquiry we learn, that it has fallen into neglect among the most judicious opticians, being found too imperfect to serve the purposes of science, and too complicated for the use of persons who seek only entertainment.

scope.

Microscope.

Plate

CCCXL.

fig. 21.

magnified to a size not to be conceived by those who have not seen it: for the farther the screen is removed, the larger will the object appear; insomuch, that a louse may thus be magnified to the length of five or six feet, or even a great deal more; though it is more distinct when not enlarged to above half that size.

The different forms in which the Solar Microscope is constructed, are as follow.

I. The old construction is represented in fig. 21. A is a square wooden frame, through which pass two long screws assisted by a couple of nuts I, I. By these it is fastened firmly to a window shutter, wherein a hole is made for its reception ; the two nuts being let into the shutter, and made fast thereto. A circular hole is made in the middle of this frame to receive the piece of wood B, of a circular figure; whose cdge, that projects a little beyond the frame, composes a shallow groove 2, wherein runs a catgut 3; which, by twisting round, and then crossing over a brass pulley 4, (the handle whereof 5, passes through the frame), affords an easy motion for turning round the circular piece of wood B, with all the parts affixed to it. C is a brass tube, which, screwing into the middle of the eircular piece of wood, becomes a ease for the uneovered brass tube D to be drawn backwards or forwards in. E is a smaller tube, of about one inch in length, comented to the end of the larger tube D. F is another brass tube, made to slide over the above described tube E; and to the end of this the microscope must be serewed, when we come to use it. 5. A convex lens, whose focus is about 12 inches, designed to collect the sun's rays, and throw them more strongly upon the object. G is a looking-glass of an oblong figure, set in a wooden frame, fastened by hinges in the circular piece of wood B, and turning about therewith by means of the above-mentioned eatgut. H is a jointed wire, partly brass and partly iron; the brass part whereof 6, which is flat, being fastened to the mirror, and the iron part 7, which is round, passing through the wooden frame, enable the observer, by putting it backwards or forwards, to elevate or depress the mirror according to the sun's altitude. There is a brass ring at the end of the jointed wire 8, whereby to manage it with the greater ease. The extremities of the catgut are fastened to a brass pin, by turning of which it may be braced up, if at any time it becomes too slack.

When this microscope is employed, the room must be rendered as dark as possible; for on the darkness of the room, and the brightness of the sunshine, depend the sharpness and perfection of your image. Then putting the looking-glass G through the hole in your window shutter, fasten the square frame A to the shutter by its two screws and nuts 1, 1. This done, adjust your looking-glass to the elevation and situation of the sun, by means of the jointed wire H, together with the catgut and pulley, 3, 4. For the first of these raising or lowering the glass, and the other inelining it to either side, there results a twofold motion, which may casily be so managed as to bring the glass to a right position, that is, to make it reflect the sun's rays directly through the lens 5, upon the paper screen, and form thereon a spot of light exactly round. But though the obtaining a perfect circular spot of

light upon the screen before you apply the micro- Microscope, is a certain proof that your mirror is adjusted scope. right, that proof must not always be expected : for the sun is so low in winter, that if it shine in a direct line against the window, it cannot then afford a spot of light exactly round; but if it be on either side, a round spot may be obtained, even in December. As soon as this appears, screw the tube D into the brass collar provided for it in the middle of your wood-work, taking care not to alter your looking-glass: then screwing the magnifier you choose to employ to the end of your microscope in the usual manner, take away the lens at the other end thereof, and place a slider, containing the objects to be examined, between the thin brass plates, as in the other ways of using the microscope.

Things being thus prepared, screw the body of the microscope over the small end E of the brass tube F; which slip over the small end E of the tube D, and pull out the said tube D less or more as your object is capable of enduring the sun's heat. Dead objects may be brought within about an inch of the focus of the convex lens 5; but the distance must be shortened for living creatures, or they will soon be killed.

If the light fall not exactly right, you may easily, by a gentle motion of the jointed wire and pulley, direct it through the axis of the microscopie lens. The short tube F, to which the microscope is serewed, renders it easy, by sliding it backwards or forwards on the other tube E, to bring the objects to their focal distance; which will be known by the sharpness and clearness of their appearance: they may also be turned round by the same means without being in the least disordered.

The magnifiers most useful in the solar microscope are in general, the fourth, fifth, or sixth. The sereen on which the representations of the objects are thrown, is usually composed of a sheet of the largest elephant paper, strained on a frame which slides up or down, or turns about at pleasure on a round wooden pillar, after the manner of some fire sereens. Larger sereens may also be made of several sheets of the same paper pasted together on cloth, and let down from the eeiling with a roller like a large map.

" This microscope (says Mr Baker) is the most entertaining of any; and perhaps the most capable of making discoveries in objects that are not too opaque : as it shows them much larger than can be done any other way. There are also several conveniences attending it, which no other microscope can have : for the weakest eyes may use it without the least straining or fatigue : numbers of people together may view any object at the same time; and by pointing to the particular parts thereof, and discoursing on what lies before them, may be able better to understand one another, and more likely to find ont the truth, than in other microscopes, where they must peep one after another, and perhaps see the object neither in the same light nor in the same position. Those also, who have no skill in drawing, may, by this contrivance, easily sketch out the exact figure of any object they have a mind to preserve a picture of; since they need only fasten a paper on the screen, and tracc it out thereon either with a pen or pencil, as it appears before them. It is worth B 2 the

Microscope.

Fig. 22.

the while of those who are desirous of taking many draughts in this way, to get a frame, wherein a sheet of paper may be put in or taken out at pleasure ; for if the paper be single, the image of an object will be seen almost as plainly on the back as on the fore side; and, by standing behind the screen, the shade of the hand will not obstruct the light in drawing, as it must in some degree when one stands before it." This construction, however, has now become rather obsolete, and is superseded by the following.

II. The improved Solar Mieroscope, as used with the improved single Microscope, with teeth and pinion. Fig. 22. represents the whole form of the single microscope; the parts of which are as follows : ABCD the external tube; GHIK the internal moveable one; QM part of another tube within the last, at one end of which is fixed a plate of brass hollowed in the middle, for receiving the glass tubes; there is also a moveable flat plate, between which, and the fixed end of the second tube, the ivory sliders are to be placed. L, a part of the microscope, containing a wire spiral spring, keeping the tube QM with its plates firm against the fixed part IK of the second tube.

EF is the small rack-work of teeth and pinion, by which the tube IG is moved gradually to or from the end AB, for adjusting the objects exactly to the focus of different lengths. NO is a brass slider, with six magnifiers ; any one of which may easily be placed before the object. It is known when either of the glasses is in the centre of the eye-hole, by a small spring falling into a noteli in the side of the slider, made against cach of the glasses. Those parts of the apparatus, cccxxxxix. fig. 14. marked Nº 15, 16, 17, 18, 19, 20, 21, and 22. are made use of here to this microscope. GH is a brass cell, which holds an illuminating glass for converging the sun's beams or the light of a candle strongly upon the objects. The aperture of the glass is made greater or less, by two circular pieces of brass, with holes of different sizes, that are screwed separately over the said lens. But at times objects appear best when the microscope is held up to the common light only, without this glass. It is also taken away when the microscope is applied to the apparatus now to be described.

Fig. 23. represents the apparatus, with the single microscope screwed to it, which constitutes the Solar Microscope. AB is the inner moveable tube, to which the single microscope is serewed. CD is the external tube, containing a condensing convex glass at the end D, and is serewed into the plate EF, which is cut with teeth at its circumference, and moved by the pinion I, that is fixed with the plate GH. This plate is screwed fast against the window-shutter, or board fitted to a convenient window of a darkened room, when the instrument is used. KL is a long frame, fixed to the circular plate EF; containing a lookingglass or mirror for reflecting the solar rays through the lens in the body of the tube D. O is a brass milled head, fastened to a worm or endless screw; which on the outside turns a small wheel, by which the reflecting mirror M is moved upwards and downwards.

In using this microscope, the square frame GH is first to be screwed to the window shutter, and the room well darkened: which is best done by cutting a round hole of the size of the moveable plate EF,

that carries the reflector, in the window-shutter or Microboard; and, by means of two brass nuts a a, let in- scope. to the shutter to receive the screws PP, when placed through the holes in the square frame GII, at the two holes QQ: which will firmly fasten the microscope to the shutter, and is easily taken away by only unscrewing the screws PP.

The white paper screen, or white cloth, to receive the images, is to be placed several feet distant from the window : which will make the representations the larger in proportion to the distance. The usual distances arc from 6 to 16 feet.

The frame KL, with its mirror M, is to be moved by turning the pinion I, one way or the other, till the beams of the sun's light come through the hole into the room : then, by turning of the worm at O, the mirror must be raised or depressed till the rays become perfectly horizontal, and go straight across the room to the screen. The tube CD, with its lens at D, is now to be screwed into the hole of the circular plate EF: by this glass the rays will be converged to a focus; and from thence proceed diverging to the screen, and there make a large circle of light. The single microscope, fig. 22. is to be screwed on to the end AB (fig. 23.) of the inner tube; and the slider NO, with either of the lenses marked 1, 2, 3, 4, 5, or 6, in the centre of the hole at the end AB. This will occasion a circle of light upon the screen much larger than before. The slider or glass-tube, with the objects to be viewed, is to be placed between the plates at IK against the small magnifier, and moved at pleasurc. By shifting the tube AB in or out, you may place the object in such a part of the condensed rays as shall be sufficient to illuminate it, and not scorch or burn it; which will generally require the glass to be about one inch distant from the focus. It now remains only to adjust the object, or to bring it so near to the magnifier that its image formed upon the screen shall be the most distinct or perfect : and it is effected by gently turning the pinion F, fig. 22. a small matter one way or the other. If the object be rather large in size, the least magnifiers are generally used, and vice versa.

Nº 1. is the greatest magnifier, and Nº 6. the least, in the brass slider NO. But, if desired, single lenses of greater magnifying powers are made : and they are applied, by being screwed to the end AB, fig. 22. and the brass slider NO is then taken away.

The same object may be variously magnified, by the lenses severally applied to it; and the degree of magnifying power is easily known by this rule: As the di-stance of the object is to that of its image from the magnificr; so is the length or breadth of the object to that of the image.

Instead of the brass sliders with the lenses NO, there is sometimes screwed a lens of a large size, and longer focal distance : the instrument is then converted into a megalascope; and is adapted for viewing the larger kind of objects contained in large sliders, such as is represented at R. And, in the same manner, small objects of entertainment, painted upon glass like the sliders of a magic lanthorn, are much magnified, and represented npon the same screen.

The solar microscopes just described are capable only of magnifying transparent objects; for which purpose

4

Fig. 23.

Micro- pose the last instrument is extremely well adapted. But as opaque objects form the most considerable part of the curious collections in the works of art as well as nature, a solar microscope for this purpose was a long time wanted .- For several years previous to 1774, Mr Martin made several essays towards the construction of such an instrument; and at last completed one about the time just mentioned, which he named,

III. The Opaque Solar Microscope. With this instrument (to use his own words) " all opaque objects, whether of the animal, vegetable, or mineral kingdom, may be exhibited in great perfection, in all their native beauty; the lights and shades, the prominences and eavities, and all the varieties of different hues, tints, and colours; heightened by reflection of the solar rays condensed upon them .- Transparent objects are also shown with greater perfection than by the common solar microscope."

Fig. 24. represents the solar opaque microscope, mounted for exhibiting opaque objects.

Fig. 25. is the single tooth and pinion microscope, as before, which is used for showing transparent objeets; the cylindrical tube Y thereof being made to fit into the tube FE of the solar microscope.

ABCDEF, (fig. 24.) represents the body of the solar microscope; one part thereof, ABCD, is coni-cal; the other, CDEF, is cylindrical. The cylindrieal part receives the tube G of the opaque box, or the tube Y of the single microscope. At the large end AB of the conical part, there is a lens to receive the rays from the mirror, and refract them towards the box HIKL. NOP is a brass frame; which is fixed to the moveable circular plate a b c : in this frame there is a plane mirror, to reflect the solar rays on the afore-mentioned lens. This mirror may be moved into the most convenient position for reflecting the light, by means of the nuts Q and R. By the nut Q it may be moved from east to west; and it may be elevated or depressed by the nut R. de, Two serews to fasten the microscope to a window shutter. The box for opaque objects is represented at HIKL: it contains a plane mirror M, for reflecting the light which it receives from the large lens to the object, and thereby illuminating it; S is a serew to adjust this mirror, or place it at a proper angle for reflecting the light. VX, two tubes of brass, one sliding within the other, the exterior one in the box HIKL ; these carry the magnifying lenses : the interior tube is sometimes taken out, and the cxterior one is then used by itself. Part of this tube may be seen in the plate within the box HIKL. At H there is a brass plate, the back part of which is fixed to the hollow tube h, in which there is a spiral wire, which keeps the plate always bearing against the side H of the brass box HIKL. The sliders, with the opaque objects, pass between this plate and the side of the box; to put them there, the plate is to be drawn back hy means of the nut g: i k is a door to one side of the opaque box. The foregoing pieces constitute the several parts necessary for viewing opaque objects. We shall now proceed to describe the single microscope, which is used for transparent objects: but in order to examine these, the box HIKL must be first removed, and in its place we must insert the tube Y of the single microscope that we are now going to describe.

Fig. 25. represents a large tooth and pinion micro- Microscope: at m, within the body of this microscope, are scope two thin plates, that are to be separated in order to Fig. 25 let the ivory sliders pass between them; they are presscd together by a spiral spring, which bears up the under plate, and forces it against the upper one.

The slider S (under fig. 4.), which contains the magnifiers, fits into the hole n; and any of the magnifiers may be placed before the object, by moving the aforesaid slider : when the magnifier is at the centre of the hole P, a small spring falls into one of the notehes which is on the side of the slider.

Under the plate m are placed two lenses, for enlarging the field of view on the screen : the smaller of the two is fixed in a piece of brass, and is nearest the plate m; this is to be taken out when the magnifiers, Nº 4, 5, or 6, are used, or when the megalascope lens T (fig. 24.) is used; but is to be replaced for N° 1, 2, 3.

This microscope is adjusted to the foeus by turning the milled nut O.

To use the solar microscope :- Make a round hole in the window shutter, a little larger than the circle a b c; pass the mirror ONP through this hole, and apply the square plate to the shutter ; then mark with a pencil the places which correspond to the two holes through which the screw is to pass; take away the microscope, and bore two holes at the marked places, sufficiently large to let the milled screws d e pass through them.

The screws are to pass from the outside of the shutter, to go through it : and being then screwed into their respective holes in the square plate, they will, when screwed home, hold it fast against the inside of the shutter, and thus support the microscope.

Screw the conical tube ABCD to the circle a b c, and then slide the tube G of the opaque box into the cylindrical part CDEF of the body, if opaque objects are to be examined; but if they be transparent objects you mean to show, then place the tube Y within the tube CDEF.

The room is to be darkened as much as possible, that no light may enter but what passes through the body of the microscope; for, on this circumstance, together with the brightness of the sunshine, the perfection and distinctness of the image in a great measure depend.

When the microscope is to be used for opaque objects, I. Adjust the mirror NOP, so as to receive the solar rays, by means of the two finger screws or nuts, QR; the first, Q, turns the mirror to the right or left; the second, R, raises or depresses it: this you are to do till you have reflected the sun's light through the lens at AB strongly upon a screen of white paper placed at some distance from the window, and formed thereon a round spot of light. An unexperienced observer will find it more convenient to obtain the light by forming this spot before he puts on either the opaque box or the tooth and pinion microscope.

Now put in the opaque box, and place the object between the plates at II; open the door i k, and adjust the mirror M till you have illuminated the object strongly. If you cannot effect this by the serew S, you must move the screws Q, R, in order to get the light reflected strongly from the mirror NOP, or the mirror

Fig. 24.

scope.

Micro- mirror M, without which the latter cannot illuminate the object. scope.

The object being strongly illuminated, shut the door ik, and a distinct view of the object will soon be obtained on your screen, by adjusting the tubes VX, which is cifeeted by moving them backwards or forwards.

A round spot of light cannot always be procured in northern latitudes, the altitude of the sun being often too low; neither can it be obtained when the sun is directly perpendicular to the front of the room.

As the sun is continually changing its place, it will be necessary, in order to keep his rays full upon the object, to keep them continually directed through the axis of the instrument, by the two screws Q and R.

To view transparent objects, remove the opaque box, and insert the tube Y, fig. 25. in its place; put the slider S into its place at n, and the slider with the objects between the plates at m; then adjust the mirror NOP, as before directed by the serews Q, R, so that the light may pass through the object; regulate the focus of the magnifier by the screw O. The most pleasing magnifiers in use arc the fourth and fifth.

The size of the object may be increased or diminished, by altering the distance of the screen from the microscope : five or six feet is a convenient distance.

To examine transparent objects of a larger size, or to render the instrument what is usually ealled a megalascope, take out the slider S from its place at n, and screw the button T (fig. 24.) into the hole at P, fig. 25. and remove the glass which is under the plate at m, and regulate the light and focus agreeable to the foregoing directions.

N. B. At the end of the tube G there is a lens for increasing the density of the rays, for the purpose of burning or melting any combustible or fusible substance: this lens must be removed in most cases, lest the objects should be burnt. The intensity of the light is also varied by moving this tube backwards or forwards.

Apparatus of the Opaque Solar Microscope .- The large square plate and mirror ; the body of the microscope; the opaque box and its tube; the tooth and pinion microscope; the slider with the magnifiers; the megalascope magnifier; the two screws d and e; some ivory sliders; some sliders with opaque objects; a brass frame, with a bottom of soft deal to stick any object on; a brass cylinder K (fig. 31.), for confining opaque

Plate CCCXLL objects.

IV. The CAMERA OBSCURA, or LUCERNAL, Microscope.

The great faeility with which objects can be represented on paper or a rough glass in the camera obscura, and copies drawn from them by any person though unskilled in drawing, evidently suggested the application of the microscope to this instrument. The greatest number of experiments that appear to have been made with this view, were by Mr Martin and Mr Adams; the former of whom frequently applied the microscope to the portable camera, and with much effect and entertainment. But these instruments being found to answer only with the assistance of the sun, Mr Adams directed his experiments to the construction of an instrument of more extended utility, which could be equally employed in the day-time and by

night. He accordingly succeeded so far as to pro- Microduce, by candle-light, the images of objects refracted ______scope. from a single magnifier upon one or two large convex lenses (of about five inches or upwards in diameter), at the end of a pyramidal shaped box, in a very pleasing and magnified appearance, so as to give opaque objects as well as transparent ones the utmost distinctness of representation; but still the light of a eandle or lamp was found generally insufficient to throw the requisite degree of illumination upon the objects. The invention of what is ealled Argand's lamp, within these few years, offered a complete remedy for this defect, by the intensity and steadiness of its light. This did not escape Mr Adams (son of the former), who inimediately applied it; and who had likewise so altered and improved his father's instrument, both in construction and form, as to render it altogether a different one, and far more perfect and useful.

The advantages and properties of this excellently conceived instrument are numerous and important. " As the far greater part of the objects which surround us are opaque (says our author), and very few are sufficiently transparent to be examined by the common microscopes, an instrument that could be readily applied to the examination of opaque objects has always been a desideratum. Even in the examination of transparent objects, many of the finc and more curious portions are lost, and drowned, as it were, in the light which must be transmitted through them; while different parts of the same object appear only as dark lines or spots, because they are so opaque as not to permit any light to pass through them. These difficulties, as well as many more, arc obviated in the luecrnal microscope; by which opaque objects of various sizes may be seen with ease and distinctness : the beautiful colours with which most of them are adorned, are rendered more brilliant, without changing in the least the real tint of the colour; and the concave and convex parts retain also their proper form .- The facility with which all opaque objects arc applied to this instrument, is another considerable advantage, and almost peculiar to itself; as the texture and configuration of the more tender parts are often hurt by prcvious preparation, every object may be examined by this instrument, first as opaque, and afterwards (if the texture will admit of it) as transparent .- The lucernal microscope does not in the least fatigue the eye; the object appears like nature itself, giving ease to the sight and pleasure to the mind : there is also, in the use of this instrument, no occasion to shut the eve which is not directed to the object. A further advantage peculiar to this microscope is, that by it the outlines of every object may be taken, even by those who are not accustomed to draw; while those who can draw well will receive great assistance, and execute their work with more accuracy and in less time than they would otherwise have been able to have performed it. Transparent objects as well as opaque may be copied in the same manner. The instrument may be used at any time of the day, but the best effect is by night; in which respect it has a superiority over the solar microscope, as that instrument ean only be used when the sun shines.

Transparent objects may be examined with the lucernal microscope in three or four different modes, from My

CCI

Fig

MIC

Plate CCCXLI.

fig. 26.

from a blaze of light almost too great for the eye to bear, to that which is perfectly easy to it: And by the addition of a tin lanthorn to the apparatus, may be thrown on a screen, and exhibited at one view to a large company, as by the solar microscope.

We shall now proceed to the description of the instrument and apparatus as given by Mr Adams.

Fig. 26. represents the improved Lucernal Microscope, mounted to view opaque objects. ABCD is a large mahogany pyramidal box, which forms the body of the microscope; it is supported firmly on the brass pillar FG, by means of the socket H and the curved piece 1K.

LMN is a guide for the eye, in order to direct it in the axis of the lenses; it consists of two brass tubes, one sliding within the other, and a vertical flat piece, at the top of which is the hole for the eye. The outer tube is seen at MN, the vertical piece is represented at LM. The inner tube may be pulled out, or pushed in, to adjust it to the focus of the glasses. The vertical piece may be raised or depressed, that the hole, through which the object is to be viewed, may coincide with the centre in the field of view; it is fixed by a milled screw from M, which could not be shown in this figure.

At N is a dove-tailed piece of brass, made to receive the dove-tail at the end of the tubes MN, by which it is affixed to the wooden box ABCDE. The tubes MN may be removed from this box occasionally, for the convenience of packing it up in a less compass.

OP, a small tube which earries the magnifiers.

O, one of the magnifiers; it is sercewed into the end of a tube, which slides within the tube P; the tube P may be unscrewed occasionally from the wooden body.

QRSTVX, a long square bar, which passes through the sockets YZ, and earries the stage or frame that holds the objects; this bar may be moved backward or forward, in order to adjust it to the focus by means of the pinion which is at a.

b, A handle furnished with an universal joint, for more conveniently turning the pinion. When the handle is removed, the nut (fig. 27.) may be used in its stead.

de, A brass bar, to support the curved piece KI, and keep the body AB firm and steady.

fghi, The stage for opaque objects: it fits upon the bar QRST by means of the socket hi, and is brought nearer to or removed farther from the magnifying lens by turning the pinion a: the objects are placed in the front side of the stage (which cannot be seen in this figure) between four small brass plates; the edges of two of these are seen at kl. The two upper pieces of brass are moveable; they are fixed to a plate, which is acted on by a spiral spring, that presses them down, and confines the slider with the objects: this plate, and the two upper pieces of brass, are lifted up by the small nut m.

At the lower part of the stage, there is a semicircular lump of glass *n*, which is designed to receive the light from the lamp, fig. 29. and to collect and throw it on the concave mirror *o*, whence it is to be reflected on the object.

The upper part fg hs (fig. 26.) of the opaque stage

takes out, that the stage for transparent objects may Microbe inserted in its place.

Fig. 28. represents the stage for transparent objects; Fig. 28. the two legs 5 and 6 fit into the top of the under part Fig. 28. r s h i o f the stage for opaque objects; 7 is the part which confines or holds the sliders, and through which they are to be moved; 9 and 10, a brass tube, which contains the lenses for condensing the light, and throwing it upon the object; there is a second tube within that, marked 9 and 10, which may be placed at different distances from the object by the pin 11.

When this stage is used as a single microscope, without any reference to the lucernal, the magnifiers or object lenses, are to be serewed into the hole 12, and to be adjusted to a proper focus by the nut 13.

N. B. At the end AB (fig. 26.) of the wooden body there is a slidor, which is represented as partly drawn out at A: when quite taken out, three grooves will be perceived; one of which contains a board that forms the end of the box; the next contains a frame with a grayed glass; and the third, or that farthest from the end AB, two large convex lenses.

Fig. 29. represents one of Argand's lamps, which Fig. 29. are most suitable for microscopic purposes, on account of the clearness, the intensity, and the steadiness of the light. The following account of the method of managing them, with other observations, is copied from an account given by Mr Parker with those he sells.

The principle on which the lamp acts, consists in disposing the wick in thin parts, so that the air may come in contact with all the burning fuel; by which means, together with an increase of the current of air occasioned by rarefaction in the glass tube, the whole of the fuel is converted into flame.

The wicks are circular; and, the more readily to regulate the quantity of light, are fixed on a brass collar, with a wire handle, by means of which they are raised or depressed at pleasure.

To fix the wick on, a wooden mandril is contrived, which is tapered at one end, and has a groove turned at the other.

The wick has a sclvage at one end, which is to be put foremost on the mandril, and moved up to the groove; then putting the groove into the collar of the wick-holder, the wick is easily pushed forward upon it.

The wick-holder and wiek being put quite down in their place, the spare part of the wick should, while dry, be set a-light, and suffered to burn to the edge of the tubes; this will leave it more even than by cutting, and, being black by burning, will be much easier lighted : for this reason, the black should never be quite cut off.

The lamp should be filled an hour or two before it is wanted, that the cotton may imbibe the oil and draw the better.

The lamps which have a reservoir and valve, need no other direction for filling than to do it with a proper trimming pot, carefully observing when they are full; then pulling up the valve by the point, the reservoir, being turned with the other hand, may be replaced without spilling a drop.

Those lamps which fill in the front like a bird-fountain, must be reclined on the back to fill; and this should

Fig. 27.

Micro- should be done gently, that the oil in the burner may return into the hody when so placed and filled : if, by being too full, and oil appears above the guard, only move the lamp a little, and the oil will disappear; the lamp may then be placed erect, and the oil will flow to its proper level.

The oil must be of the spermaceti kind, commonly called chamber oil, which may generally be distinguished by its paleness, transparency, and inoffensive scent : all those oils which are of a red and brown colour, and of an offensive scent, should be carefully avoided, as their glutinous parts clog the lamp, and the impurities in such oil, not being inflammable, will accumulate and remain in the form of a crust on the wick. Scal oil is nearly as pale and sweet as chamber oil; but being of a heavy sluggish quality, is not proper for lamps with fine wicks.

Whenever bad oil has been used, on charging it, the wick must also be changed ; because, after having imbibed the coarse particles in its capillary tubes, it will not draw up the fine oil.

To obtain the greatest degree of light, the wick should be trimmed exactly even, the flame will then be completely equal.

There will be a great advantage in keeping the lamp clean, especially the burner and air tubes ; the neglect of cleanliness in lamps is too common: a candlestick is generally cleaned every time it is used, so should a lamp; and if a candlestick is not to be objected to because it does not give light after the candle is exhausted, so a lamp should not be thought ill of, if it does not give light when it wants oil or cotton : but this last has often happened, because the deficiency is less visible.

The glass tubes arc best cleaned with a piece of wash leather.

If a fountain lamp is left partly filled with oil, it may be liable to overflow : this happens by the contraction of the air when cold, and its expansion by the warmth of a room, the rays of the sun, or the heat of the lamp when re-lighted : this accident may be effectually prevented by keeping the reservoir filled, the oil not being subject to expansion like air. On this account, those with a common reservoir are best adapted for microscopic purposes.

To examine Opaque Objects, with the Lucernal Mi. croscope. 'To render the use of this instrument easy, it is usually packed with as many of the parts together as possible : it occupies on this account rather more room, but is much less embarrassing to the observer, who has only three parts to put on after it is taken out of its box, namely, the guide for the eye, the stage, and the tube with its magnifier.

But to be more particular : Take out the wooden slider A (fig. 26.), then lift out the cover and the gray glass, from their respective grooves under the slider A.

Put the end N of the guide for the cye LMN into its place, so that it may stand in the position which is represented in this figure.

Place the socket which is at the bottom of the opaque stage, on the bar QXT, so that the concave mirror o may be next the end DE of the wooden body.

Screw the tubes PO into the end DE. The mag- Micronifier you intend to use is to be screwed on the end O scope of these tubes.

The handle G b, or the milled nut, fig. 27. must be placed on the square end of the pinion a.

Place the lamp lighted before the glass lamp n, and the object you intend to examine between the spring plates of the stage; and the instrument is ready for use.

In all microscopes there are two circumstances which must be particularly attended to: first, the modification of the light, or the proper quantity to illuminate the object; secondly, the adjustment of the instrument to the focus of the glass and eye of the observer. In the use of the lucernal microscope there is a third circumstance, which is, the regulation of the guide for the eye.

1. To throw the light upon the object. The flame of the lamp is to be placed rather below the centre of the glass lump n, and as near it as possible; the concave mirror a must be so inclined and turned as to receive the light from the glass lump, and reflect it thence upon the object; the best situation of the concave mirror and the flame of the lamp depends on a combination of circumstances, which a little practice will discover.

2. To regulate the guide for the eye, or to place the centre of the eye-piece L so that it may coincide with the focal point of the lenses and the axis of vision : Lengthen and shorten the tubes MN, by drawing out or pushing in the inner tube, and raising or depressing the eye-piece ML, till you find the large lens (which is placed at the end AB of the wooden body) filled by an uniform field of light, without any prismatic colours round the edge; for till this piece is properly fixed, the circle of light will be very small, and only occupy a part of the lens; the cye must be kept at the centre of the eye-piece L, during the whole of the operation; which may be rendered somewhat easier to the observer, on the first use of the instrument, if he hold a piece of white paper parallel to the large lens, removing it from or bringing it nearer to them till he find the place where a lucid circle, which he will perceive on the paper, is brightest and most distinct ; then he is to fix the centre of the eye-piece to coincide with that spot; after which a very small adjustment will set it perfectly right.

3. To adjust the lenses to their focal distance. This is effected by turning the pinion a, the eye being at the same time at the eye-piece L. The gray glass is often placed before the large lenses, while regulating the guide for the eye, and adjusting for the focal distance.

If the observer, in the process of his examination of an object, advance rapidly from a shallow to a deep magnifier, he will save himself some labour by pulling out the internal tube at O.

The upper part f g r s of the stage is to be raised or lowered oceasionally, in order to make the centre of the object coincide with the centre of the lens at O.

To delineate objects, the gray glass must be placed before the large lenses; the picture of the object will be formed on this glass, and the outline may be accurately taken by going over the pieture with a pencil.

The

To use the Lucernal Microscope in the examination of Transparent Objects.—The instrument is to remain as before: the upper part fgs of the opaque stage must be removed, and the stage for transparent objects, represented at fig. 28. put in its place; the end 9 10 to be next the lamp.

Place the grayed glass in its groove at the end AB, and the objects in the slider-holder at the front of the stage; then transmit as strong a light as you are able on the object, which you will easily do by raising or lowering the lamp.

The object will be beautifully depicted on the gray glass; it must be regulated to the focus of the magnificr, by turning the pinion a.

The object may be viewed either with or without the guide for the eye. A single observer will see an object to the greatest advantage by using this guide, which is to be adjusted as we have described above. If two or three wish to examine the object at the same time, the guide for the eye must be laid aside.

Take the large lens out of the groove, and receive the image on the gray glass; in this case, the guide for the eye is of no use: if the gray glass be taken away, the image of the object may be received on a paper screen.

Take out the gray glass, replace the large lenses, and use the guide for the eye; attend to the foregoing directions, and adjust the object to its proper focus. You will then see the object in a blaze of light almost too great for the eye, a eircumstance that will be found very useful in the examination of particular objects. The edges of the object in this mode will be somewhat coloured: but as it is only used in this full light for occasional purposes, it has been thought bctter to leave this small imperfection, than, by remedying it, to sacrifice greater advantages; the more so, as this fault is easily corrected, a new and interesting view of the object is obtained, by turning the instrument out of the direct rays of light, and permitting them to pass through only in an oblique direction, by which the upper surface is in some degree illuminated, and the object is seen partly as opaque, partly as transparent. It has been already observed, that the transparent objects might be placed between the slider-holders of the stage for opaque objects, and then be examined as if opaque.

Some transparent objects appear to the greatest advantage when the lens at 9 10 is taken away; as, by giving too great a quantity of light, it renders the edges less sharp.

The variety of views which may be taken of every object by means of the improved lucernal microscope, will be found to be of great use to an accurate observer: it will give him an opportunity of correcting or Vol. XIV. Part I. +

scope.

confirming his discoveries, and investigating those parts Microin one mode which are invisible in another.

To throw the image of transparent objects on a screen as in the solar microscope .- It has been long a microseopical desideratum, to have an instrument by which the image of transparent objects might be thrown on a screen, as in the common solar microscope: and this not only because the sun is so uncertain in this climate, and the use of the solar microscope requires confinement in the finest part of the day, when time seldom hangs heavy on the mind; but as it also affords an increase of pleasure, by displaying its wonders to several persons at the same instant, without the least fatigue to the eye.

This purpose is now effectually answered, by affixing the transparent stage of the lucernal to a lanthorn, with one of Argand's lamps .- The lamp is placed within the lanthorn, and the end 9 10 of the transparent stage is serewed into a female serew, which is rivetted in the sliding part of the front of the lanthorn; the magnifying lenses are to be screwed into the hole represented at 12, and they are adjusted by turning the milled nut. The quantity of light is to be regulated by raising and lowering the sliding-plate or the lamp,

Apparatus which usually accompanies the improved Lucernal Microscope .- The stage for opaque objects, with its semicircular lump of glass, and coneave mirror. The stage for transparent objects, which fits on the upper part of the foregoing stage. The sliding tube, to which the magnifiers arc to be affixed : one end of these is to be sercied on the end D of the wooden body; the magnifier in use is to be screwed to the other end of the inner tube. Eight magnifying lenses: these are so constructed that they may be combined together, and thus produce a very great variety of magnifying powers. A fish-pan, such as is represented at I. A steel wire L, with a pair of nippers at one end, and a small cylinder of ivory / at the other. A slider of brass N, containing a flat glass slider, and a brass slider into which are fitted some small concave glasses. A pair of forceps. Six large and six small ivory sliders, with transparent objects. Fourteen wooden sliders, with four opaque objects in each slider; and two spare sliders. Some capillary tubes for viewing small animalcula.

Ingenious men seldom content themselves with an instrument under one form; hence such a variety of microscopes, hence many alterations in the Lucernal Microscope. Mr Adams himself, we understand, has fitted up this last in a great many different ways; and it is reasonable to think that no person was more likely to give it every improvement of which it is susceptible. Of the alterations by other hands we shall only particularize one, made by Mr Jones of Holborn (B), whose description is as follows :

A (fig. 30.) represents a portion of the top of the ma-Fig 30. C hogany

(B) We trust the reader will never consider any paragraph wherein the name of an instrument-maker or other artist is inserted, as a recommendation of those artists by the editors of this work. In the course of a pretty extensive correspondence, they have been favoured with vcry liberal communications from various artists, for which they are greatly indebted to them: the inserting their names in this work is therefore to be considered

29

Micro- Rogany box in which it packs, to preserve it steady ; it slides in a dove-tail groove withinside, a similar groove to which is cut in the top of the box Λ ; so that when the instrument is to be used, it is slipt out of the box withinside, and then slipt into the groove at top ready for use, almost instantly, as shown in the figure. The adjustment of the objects is at the stage E; for the right foeal distance is readily and conveniently made by turning the long serew-rod BB, which goes through the two pillars supporting the box, and works in the base of the brass stage E; which base is also dovetailed, so as to have a regular and steady motion in another brass basis that supports it. In this instrument, therefore, the pyramidical box does not move; but the stage part only, which, from its small weight, moves in the most agreeable and steady manner. While observing the image of the object upon the glass through the sight-hole at G, the object may be moved or changed by only turning the rack-work and pinion applied to the stage by means of the handle D, for that purpose. By this contrivance you have no oceasion to change your position during the view of the objects upon one of the sliders. This motion changes

the objects horizontally only; and as they are generally placed exactly in one line, it answers all the purposes for which this motion is intended very well. But it may sometimes happen that the observer would wish to alter the vertical position of the object; to perform which there is another plain rod at F, that acts simply as a lever for this purpose, and moves the sliding part of the stage E vertically either upwards or downwards.

Thus, without altering his position, the observer may investigate all parts of the objects in the most satisfactory manner. Rack-work and pinion might be applied to the stage for the vertical motion also; but as it would materially enhance the expense, it is soldom applied. The brass work at the handle of D contains a Hooke's universal joint.

The brilliancy of the images of the objects shown upon the large lenses at the end of the box, being very frequently so great as to dazzle the eyes, Mr Jones applies a slight tinge of blue, green, and other coloured glass, to the sight-hole at G, which softens this glare, and casts an agreeable hue upon the objects.

Description of those Parts of a Microscopical Apparatus, common to most Instruments, which are delineated at fig. 31.

A and B represent the brass cells which contain the magnifiers belonging to the different kinds of compound microscopes. The magnifiers are sometimes contained in a slider like that which is delineated at S (fig. 24.). The lenses of A and B are confined by a small cap; on unscrewing this, the small lens may be taken out and eleaned. The magnifiers A of the lucernal microscope are so contrived, that any two of

them may be serewed together, by which means a con-Mierosiderable variety of magnifying powers is obtained.

To get at the lenses in the slider S (fig. 24.) take out the two serews which hold on the cover.

C represents the general form of the slider-holder. It consists of a cylindrical tube, in which an inner tube is forced up by a spring. It is used to receive the ivory or any other slider, in which the transparent objects are placed; these are to be slid between the two upper plates: the hollow part in one of the plates is designed for the glass tubes.

D, the condensing lens and its tube, which fits into the slider-holder C, and may be moved up and down in it. When this piece is pushed up as far as it will go, it condenses the light of a eandle, which is reflected on it by the plain mirror of the compound microscope, and spreads it uniformly over the object; in this ease it is best adapted to the shallowest magnifiers. If the deeper lenses arc used, it should be drawn down, or rather removed further from the object, that it may concentrate the light in a small compass, and thus render it more dense. The condensing lens is sometimes fitted up differently; but the principle being the same, it will be easy to apply it to use notwithstanding some variations in the mechanism.

E, a brass conc. It fixes under the slider-holder, and is used to lessen occasionally the quantity of light which comes from the mirror to any object.

F, a box with two flat glasses, which may be placed at different distances from each other in order to confine a small living insect.

G, a small brass box to hold the silver speeulum H.

H, a small silver concave speeulum, designed to reflect the light from the mirror on opaque objects; it should only be used with the shallow magnifiers. It is applied in different ways to the compound microscope ; sometimes to a tube similar to that represented at X, which slides on the lower part of the body; sometimes it is screwed into the ring of the piece Q; the pin of this generally fits into one of the holes in the stage. When this speeulum is used, the slider-holder should be removed.

I, a fish-pan, whereon a small fish may be fastened, in order to view the circulation of the blood : its tail is to be spread across the oblong hole at the smallest end, and tied fast by means of the ribbon fixed thereto, by shoving the knob which is on the back of it through the slit made in the stage; the tail of the fish may be brought under the lens which is in use.

K, a cylindrieal piece, intended for the solar opaque microscope ; by pulling back the spiral spring, smaller or larger objects may be confined in it.

k, A pair of triangular nippers for taking hold of and confining a large object.

L, a long steel wire, with a small pair of plicrs at one end and a steel point at the other: the wire slips backwards or forwards in a spring tube, which is affixed to a joint, at the bottom of which is a pin to fit one

as a grateful acknowledgment from the editors for favours conferred on them,-not as a testimonial of their opinion of the abilities of an individual, or as designed to insinuate any preference over others in the same line, where such preference has not been already bestowed by the public.

scope.

one of the holes in the stage ; this piece is used to con-Microfine small objects. sope.

1, A small ivor & cylinder that fits on the pointed end of the steel wire L; it is designed to receive opaque objects. Light-coloured ones are to be stuck on the dark side, and vice versa.

M, a convex lens, which fits to the stage by means of the long pin adhering to it. This piece is designed to collect the light from the sun or a candle, and to throw them on any object placed on the stage; but it is very little used at present.

N, a brass slider, into which is fitted a flat piece of glass, and a brass slider containing four small glasses, one or two of them concave, the others flat; it is designed to confine small living objects, and when used is to be placed between the two upper plates of the sliderholder.

O, a glass tube to receive a small fish, &c.

P, represents one of the ivory sliders, wherein objects are placed between two pieces of talc, and confined by a brass ring.

Q, a piece to hold the speculum H : this piece is generally fitted to the microscope represented at fig. 12.

R, a pair of forceps, to take up any occasional object.

S, a camel's hair pencil to brush the dust off the glasses; the upper part of the quill is scooped out, to take np a drop of any fluid, and place it on either of the glasses for examination.

T, an instrument for cutting thin transverse sections of wood. It consists of a wooden base, which supports four brass pillars; on the top of the pillars is placed a flat piece of brass, near the middle of which there is a triangular hole.

A sharp knife, which moves in a diagonal direction, is fixed on the upper side of the afore-mentioned plate, and in such a manner that the edge always coincides with the surface thereof.

The knife is moved backwards and forwards by means of the handle a. The piece of wood is placed in the triangular trough which is under the brass plate, and is to be kept steady therein by a milled screw which is fitted to the trough; the wood is to be pressed forward for cutting by the micrometer screw b.

The pieces of wood should be applied to this instrument immediately on being taken out of the ground, or else they should be soaked for some time in water, to soften them so that they may not hurt the edge of the knife.

When the edge of the knife is brought in contact with the piece of wood, a small quantity of spirits of wine should be poured on the surface of the wood, to prevent its curling up; it will also make it adhere to the knife, from which it may be removed by pressing a piece of blotting paper on it.

y, An appendage to the cutting engine, which is to be used instead of the micrometer screw, being preferred to it by some. It is placed over the triangular hole, and kept flat down upon the surface of the brass plate, while the piece of wood is pressed against a circular piece of brass which is on the under side of it. This circular piece of brass is fixed to the screw, by which its distance from the flat plate on which the knife moves may be regulated.

z, An ivory box, containing at one end spare tale Microfor the ivory slider, and at the other spare rings for pressing the tales together and confining them to the slider.

Fluid microscopes have been also proposed; the first, it would appear, was suggested by Mr Grey. This was formed of water, and an account of it will be found in Nº 221, 223, Phil. Trans. An improved microscope, on a similar principle, has been invented by Mr Brewster, of which the following is a description, taken from a note by the translator of Hauy's Natural Philosophy.

" A vertical bar (says Mr Gregory), is fixed upon a horizontal pedestal; and from the top of this bar proceeds a horizontal arm, which supports a circular case containing the lenses; below this another horizontal arm slides up and down, capable of adjustment by means of a screw, and carrying the usual sliders to hold the object which it is proposed to examine; and upon the pedestal is fixed the frame of a mirror, which has both an inclined and a horizontal motion, in order to illuminate any object upon the slider. The upper circular case is hollow, and contains four or more planoconvex lenses, which are constituted each of a drop of very pure and viscid turpentine varnish, taken up by the point of a piece of wood, and dropped upon a picee of very thin and well polished glass. The lenses thus formed may be made of any focal length by taking up a greater or a less quantity of fluid. The lower surface of the glass having been first smoked with a candle, the black pigment immediately below the lenses is then to be removed, so that no light may pass but through the lenses. The piece of glass is then perforated at its centre, and surrounded by a toothed wheel, which, when the wheel is put in the upper circular screw, may be turned by a common endless sercw, so that the fluid lenses shall be brought severally under an eye-aperture properly disposed, and any object be successfully examined with a variety of magnifying powers." Note, p. 365. See also Ferguson's Lectures by Brewster, vol. ii.

AFTER what has been related of microscopes, they cannot be said to be complete without the valuable addition of a *micrometer*; for the use and advantages of which, see the article MICROMETER.

HAVING presented our readers with descriptions of the various microscopes generally used, we think it our duty to point out to them those which we conceive to be best calculated to answer the purposes of science. The first which presents itself to our mind is that of Ellis : It is better adapted than any other portable microscope, to the purpose of general observation; simple in its construction, and general in its application. To those who prefer a double microscope, we should recom-mend that figured in Plate CCCXXXVIII. fig. 12. If opaque objects, as insects, &c. be subjects of investigation, the Lucernal Microscope claims the preference; but if amusement alone guides the choice, the Solar Microscope must be fixed upon.

WE shall now proceed to explain some necessary particulars respecting the method of using microscopes; after which, we shall subjoin an enumeration of the prin-C 2 cipal

Miero

scope.

scope.

Me

cipal objects discovered or elucidated by their mcans. On this subject Mr Adams, in his Essay on the Microscope, has been very copious; with a view, as he informs us, to remove the common complaint made by Mr Baker, " that many of those who purchase microscopes are so little acquainted with their general and extensive usefulness, and so much at a loss for objects to examine by them, that after diverting their friends some few times with what they find in the sliders which generally accompany the instrument, or perhaps with two or three common objects, the microscope is laid aside as of little further value : whereas no instrument has yet appeared in the world capable of affording so constant, various, and satisfactory an entertainment to the mind."

I. In using the microscope, there are three things necessary to be considered. (1.) The preparation and adjustment of the instrument itself. (2.) The proper quantity of light, and the best method of directing it to the object. (3.) The method of preparing the objects, so that their texture may be properly understood.

1. With regard to the microscope itself, the first thing necessary to be examined is, whether the glasses be clean or not : if they are not so, they must be wipcd with a piece of soft leather, taking care not to soil them afterwards with the fingers; and, in replacing them, care must be taken not to place them in an oblique situation. We must likewise be careful not to let the breath fall upon the glasses, nor to hold that part of the body of the instrument where the glasses are placed with a warm hand; because thus the moisture expelled by the heat from the metal will condense upon the glass, and prevent the object from being distinctly seen. The object should be brought as near the centre of the field of view as possible; for there only it will be exhibited in the greatest perfection. The eye should be moved up and down from the eye-glass, of a compound microscope, till the situation is found where the largest field and most distinct view of the object are to be had : but every person ought to adjust the microscope to his own eye, and not to depend upon the situation it was placed in by another. A small magnifying power should always be begun with ; by which means the observer will best obtain an exact idea of the situation and connexion of the whole; and will of consequence be less liable to form any erroneous opinion when the parts arc viewed separately by a lens of greater power. Objects should also be examined first in their most natural position : for if this be not attended to, we shall be apt to form very inadequate ideas of the structure of the whole, as well as of the connexion and use of the parts. A living animal ought to be as little hurt or discomposed as possible.

From viewing an object properly, we may acquire a knowledge of its nature : but this cannot be done without an extensive knowledge of the subject, much patience, and many experiments; as in a great number of cases the images will resemble cach other, though derived from very different substances. Mr Baker therefore advises us not to form an opinion too suddenly after viewing a microscopical object; nor to draw our inferences till after repeated experiments and examinations of the object in many different lights and positions; to pass no judgment upon things extended by force, or

contracted by dryness, or in any manner out of a na- Microtural state, without making suitable allowances. The true colour of objects cannot be properly determined by very great magnifiers; for as the pores and interstices of an object are enlarged according to the magnifying power of the glasses made use of, the component particles of its substance will appear separated many thousand times farther asunder than they do to the naked eye : hence the reflection of the light from these particles will be very different, and exhibit different colours. It is likewise somewhat difficult to observe opaque objects; and as the apertures of the larger magnifiers are but small, they are not proper for the purpose. If an object be so very opaque, that no light will pass through it, as much as possible must be thrown upon the upper surface of it. Some consideration is likewise necessary in forming a judgment of the motion of living creatures, or even of fluids, when seen through the microscope; for as the moving body, and the space wherein it moves, are magnified, the motion will also be increased.

2. On the management of the light depends in a great measure the distinctness of the vision : and as, in order to have this in the greatest perfection, we must adapt the quantity of light to the nature of the object. and the focus of the magnifier, it is therefore necessary to view it in various degrees of light. In some objects, it is difficult to distinguish between a prominence and a depression, a shadow or a black stain : or between a reflection of light and whiteness, which is particularly observable in the eye of the libellula and other flies : all of these appearing very different in one position from what they do in another. The brightness of an object likewise depends on the quantity of light, the distinctness of vision, and on regulating the quantity to the object; for some will be in a manner lost in a quantity of light scarcely sufficient to render another visible.

There are various ways in which a strong light may be thrown upon objects; as by means of the sun and a convex lens. For this purpose, the microscope is to be placed about three feet from a southern window; then take a deep convex lens, mounted on a semicircle and stand, so that its position may easily be varied : . place this lens between the object and the window, so that it may collect a considerable number of solar rays, and refract them on the object or the mirror of the microscope. If the light thus collected from the sun be too powerful, it may be lessened by placing a piece of oiled paper, or a piece of glass lightly grayed, be-tween the object and lens. Thus a proper degree of light may be obtained, and diffused equally all over the surface of an object : a circumstance which ought to be particularly attended to; for if the light be thrown irregularly upon it, no distinct view can be obtained. If we mean to make use of the solar light, it will be found convenient to darken the room, and to reflect the rays of the sun on the above-mentioned lens by means of the mirror of a solar microscope fixed to the window-shutter: for thus the observer will be enabled to preserve the light on his subject, notwithstanding the motion of the sun. But by reason of this motion, and the variable state of the atmosphere, solar observations are rendered both tedious and iuconvenient : whence it will be proper for the observer to

he

Micro-

scope.

be furnished with a large tin lanthorn, formed something like the common magic lanthorn, capable of containing one of Argand's lamps. This, however, ought not to be of the fountain kind, lest the rarefaction of the air in the lanthorn should force the oil over. There ought to be an aperture in the front of the lanthorn, which may be moved up and down, and be capable of holding a lens; by which means a pleasant and uniform as well as strong light may easily be procured. The lamp should likewise move on a rod, so that it may be easily raised or depressed. This lanthorn may likewise be used for many other purposes; as viewing of pictures, exhibiting microscopic objects on a sereen, &c. A weak light, however, is best for viewing many transparent objects : among which we may reckon the prepared eyes of flies, as well as the animaleules in fluids. The quantity of light from a lamp or candle may be lessened by removing the microscope to a greater distance from them, or by diminishing the strength of the light which falls upon the objects. This may very conveniently be done hy pieces of black paper with circular apertures of different sizes, and placing a larger or smaller one upon the reflecting mirror, as oceasion may require. There is an oblique situation of the mirrors, which makes likewise an oblique reflection of the light easily discovered by practice, (but for which no general rule can be given in theory); and which will exhibit an object more distinctly than any other position, showing the surface, as well as those parts through which the light is transmitted. The light of a lamp or candle is generally better for viewing microscopie objects than day light; it being more easy to modify the former than the latter, and to throw it upon the objects with different degrees of density.

3. Swammerdam has excelled in the preparation of objects almost all other investigators. Neither difficulty nor disappointment could make him abandon the pursuit of any object until he had obtained a satisfactory idea of it. But unhappily the methods he used in preparing his objects for the microscope are now entirely unknown. Boerhaave examined with the strictest attention all the letters and manuscripts of Swammerdam which he could find ; but his researches were far from being successful. The following are all the particulars, which have thus come to the knowledge of the public.

For dissecting small insects, Swammerdam had a brass table made by S. Muschenbroeek, to which were affixed two brass arms moveable at pleasure to any part of it. The upper part of these vertical arms was constructed in such a manner as to have a slow vertical motion; by which means the operator could readily alter their height as he saw convenient. Onc of these arms was to hold the minute objects, and the other to apply the microscope.

The lenses of Swammerdam's microscopes were of various sizes as well as foci: but all of them the best that could be procured, both for the transparency of the glass and the fineness of the workmanship. His observations were always begun with the smallest magnifiers, from which he proceeded to the greatest; but in the use of them, he was so exceedingly dexterous, that he made every observation subservient to that which succeeded it, and all of them to the confirmation of

each other, and to the completing of the description. Micro-His chief art seems to have been in constructing scissars of an exquisite fineness, and making them very sharp. Thus he was enabled to cut very minute objects to much more advantage than could be done by knives and lancets; for these, though ever so sharp and fine, are apt to disorder delicate substances by displacing some of the filaments, and drawing them after them as they pass through the bodies; but the seissars cut them all equally. The knives, lancets, and styles he made use of in his dissections, were so fine that he could not see to sharpen them without the assistance of a magnifying glass; but with these he could dissect the intestines of bees with the same accuracy that the best anatomists can do those of large animals. He made use also of very small glass tubes no thicker than a bristle, and drawn to a very fine point at one end, but thicker at the other. These were for the purpose of blowing up, and thus rendering visible, the smallest vessels which could be discovered by the microscope ; to trace their courses and communications, or sometimes to inject them with coloured liquors.

Swammerdam sometimes made use of spirit of wine, water, or oil of turpentine, for suffocating the insects he wished to examine ; and would preserve them for a time in these liquids. Thus he kept the parts from putrefying, and gave them besides such additional strength and firmness, as rendered the dissections much more easy than they would otherwise have been. Having then divided the body transversely with the seissars, and made what observations he could without farther dissection, he proceeded to extract the intestines carefully with very fine instruments, to wash away the fat in the like careful manner; and thus to put the parts into such a state as would best expose them to view; but these operations are best performed while the insects are in their nympha state.

Sometimes the delicate viscera of the insects, after having been sufficiented as above mentioned, were put into water : after which, having shaken them gently, he procured an opportunity of examining them, especially the air vessels, which last he could thus separate entire from all the other parts, to the admiration of all who beheld them : as these vessels cannot be distinetly seen in any other manner, or indeed in any way whatever, without injuring them. Frequently also he injected water with a syringe to cleanse the parts thoroughly, after which he blew them up with air and dried them; thus rendering them durable, and fit for examination at a proper opportunity. Sometimes he made very important discoveries, by examining insects which he had preserved for several years in balsam. Other inseets he punctured with a very fine needle; and after squeezing out all their moisture through the holes made in this manner, he filled them with air, by means of very slender glass tubes; then dried them in the shade; and lastly, anointed them with oil of spike in which a little rosin had been dissolved; and by which means they for a long time retained their proper forms. He was likewise in possession of a singular secret, by which he could preserve the limbs of insects as limber and perspicuous as ever they had been. He used to make a small puncture or incision in the tails of worms;

Micro-

scope.

worms; and after having with great caution squeezed out all the humours, as well as great part of the viscera, he injected them with a work a great part of the sizera.

he injected them with wax in such a manner as to give them the appearance of living creatures in perfect heath. He found that the fat of all insects was entirely dissolvable in oil of turpentine; by which means he was enabled plainly to discern the viscera; though, after this dissolution, it was necessary to cleanse and wash them frequently in clean water. In this manner he would frequently have spent whole days in the preparation of a single caterpillar, and cleansing it from its fat, in order to discover the true situation of the insect's heart. He had a singular dexterity in stripping off the skins of caterpillars that were on the point of spinning This was done by letting them drop by their cones. their threads into scalding water, and then suddenly withdrawing them. Thus the epidermis peeled off very casily; and, when this was done, he put them into distilled vinegar and spirit of wine mixed together in equal proportions; which, by giving a due degree of firmness to the parts, gave him an opportunity of separating them with very little trouble from the exuviæ, without any danger to the internal parts. Thus the nympha could be shown to be wrapped up in the catcrpillar and the butterfly in the nympha; and there is little doubt that those who look into the works of Swammerdam, will be amply recompensed, whether they consider the unexampled labour or the piety of the author.

M. Lyonet, an eminent naturalist, usually drowned the insects he designed to examine; by which means he was enabled to preserve both the softness and transparency of the parts. According to him, the insect, if very small, viz. one-tenth of an inch, or little more, in length, should be dissected on a glass somewhat concave. If it should be suspected that the insect will putrefy by keeping for a few days, spirit of wine diluted with water must be substituted instead of pure water. The insect must be suffered to dry; after which it may be fastened by a piece of soft wax, and again covered with water.-Larger objects should be placed in a trough of thin wood; and for this purpose the bottom of a common chip box will answer very well; only surrounding the edge of it with soft wax, to keep in the water or other fluid employed in preserving the insect. The body is then to be opened : and if the parts are soft like those of a caterpillar, they should be turned back, and fixed to the trough by small pins, which ought to be set by a small pair of nippers. At the same time, the skin being stretched by another pair of finer forceps, the insect must be put into water, and dissected therein, occasionally covering it with spirit of wine. Thus the subject will be preserved in perfection, so that its parts may be gradually unfolded, no other change being perceived than that the soft elastic parts become stiff and opaque, while some others lose their colour.

The following instruments were made use of by M. Lyonet in his dissection of the *Chenille de Saule*. A pair of scissars as small as could be made, with long and fine arms: A pair of forceps, with their ends so nicely adjusted, that they could easily lay hold of a spider's thread, or a grain of sand : Two fine steel needles fixed in wooden handles, about two inches and three quarters

in length; which were the most generally useful instruments he employed.

Dr Hooke, who likewise made many microscopic observations, takes notice, that the common ant or pismire is much more troublesome to draw than other insects, as it is extremely difficult to get the body in a quiet natural posture. If its feet be fettered with wax or glue, while the animal remains alive, it so twists its body, that there is no possibility of gaining a proper view of it; and if it be killed before any observation is made, the shape is often spoiled before it can be exa-The bodies of many minute insects, when their mined. life is destroyed, instantly shrivel up; and this is observable even in plants as well as insects, the surface of these small bodies being affected by the least change of air; which is particularly the case with the ant. this creature, however, be dropped into rectified spirit of wine, it will instantly be killed; and when it is taken out, the spirit of wine evaporates, leaving the animal dry, and in its natural posture, or at least in such a state, that it may easily be placed in whatever posture we please.

Parts of Insects. The wings, in many insects, are so transparent, that they require no previous preparation : but some of those that are folded up under elytra or cases, require a considerable share of dexterity to unfold them; for these wings are naturally endowed with such a spring, that they immediately fold themselves again, unless care be taken to prevent them. The wing of the carwig, when expanded, is of a tolerable size, yet is folded up under a case not one-eighth part of its bulk; and the texture of this wing renders it difficult to be unfolded. This is done with the least trouble immediately after the insect is killed. Holding then the creature by the thorax, between the finger and the thumb, with a blunt-pointed pin endeavour gently to open it, by spreading it over the forefinger, and at the same time gradually sliding the thumb over it. When the wing is sufficiently expanded, separate it from the insect by a sharp knife or a pair of scissars. The wing should be pressed for some time between the thumb and finger before it be removed; it should then be placed between two pieces of paper, and again pressed for at least an hour, after which time, as there will be no danger of its folding up any more, it may be put between the talcs, and applied to the microscope. Similar care is requisite in displaying the wings of the notonecta and other water insects, as well as most kinds of grylli.

The minute scales or feathers, which cover the wings of moths or butterflies, afford very beautiful objects for the microscope. Those from one part of the wing frequently differ in shape from such as are taken from other parts; and near the thorax, shoulder, and on the fringes of the wings, we generally meet with hair instead of scales. The whole may be brushed off the wing, upon a piece of paper, by means of a camel's hair pencil; after which the hairs can be separated with the assistance of a common magnifying glass.

It is likewise a matter of considerable difficulty to dissect properly the *proboscis* of insects, such as the gnat, tabanus, &c. and the experiment must be repeated a great number of times before the structure and situation

Micrescope. Micro.

scope.

tuation of the parts can be thoroughly investigated, as the observer will frequently discover in one what he could not in another. The collector of the bee, which forms a very curious object, ought to be first carefully washed in spirit of turpentine; by which means it will be freed from the unctuous matter adhering to it: when dry, it is again to be washed with a camel's hair pencil to disengage and bring forward the small hairs which form part of this microscopic beauty. The best method of managing the stings of insects, which are in danger of being broken by reason of their hardness, is to soak the case and the rest of the apparatus for some time in spirit of wine or turpentine ; then lay them on a piece of paper, and with a blunt knife draw out the sting, holding the sheath with the nail of the finger or any blunt instrument; but great care is necessary to preserve the feelers, which when cleaned add much to the beauty of the object. The beard of the lepas anatifera is to be soaked in clean soft water, frequently brushing it while wet with a camel's hair pencil: after it is dried, the brushing must be repeated with a dry pencil to disengage and separate the hairs, which are apt to adhere together.

To view to advantage the fat, brains, and other similar substances, Dr Hooke advises to render the surface smooth, by pressing it between two plates of thin glass, by which mean's the matter will be rendered much thinner and more transparent : without this precaution, it appears confused, by reason of the parts lying too thick upon one another. For muscular fibres, take a piece of the flesh, thin and dry; moisten it with warm water, and after this is evaporated the vessels will appear more plain and distinct; and by repeated macerations they appear still more so. The exuviæ of insects afford a pleasing object, and require but little preparation. If bent or curled up, they will become so relaxed by being kept a few hours in a moist atmosphere, that you may easily extend them to their natural positions; or the steam of warm water will answer the purpose very well.

The-eyes of insects in general form very curious and beautiful objects. Those of the libellula and other flies, as well as of the lobster, &c. must first be cleaned from the blood, &c. after which they should be soaked in water for some days : one or two skins are then to be separated from the eye, which would be otherwise too opaque and confused; but some care is requisite in this operation; for if the skin be rendered too thin, it is impossible to form a proper idea of the organization of the part. In some substances, however, the organization is such, that by altering the texture of the part, we destroy the objects which we wish to observe. Of this sort are the nerves, tendons, muscular fibres, many of which are viewed to most advantage when floating in some transparent fluid. Thus very few of the muscular fibres can be discovered when we attempt to view them in the open air, though great numbers may be seen if they be placed in water or oil. By viewing the thread of a ligament in this manner, we find it composed of a vast number of smooth round threads lying close together. Elastic objects should be pulled or stretched out while they are under the microscope, that the texture and nature of those parts, the figure of which is altered by being thus pulled out, may be more fully discovered.

Other objects. To examine bones by the microscope, they should first be viewed as opaque objects: but afterwards, by procuring thin slices of them, they may be viewed as transparent. The sections should be ent in all directions, and be well washed and cleaned; and in some cases maceration will be useful, or the bones may be heated red hot in a clear fire, and then taken out; by which means the bony cells will appear more conspicuous. The pores of the skin may be examined by cutting off a thin slice of the upper skin with a razor, and then a second from the same place; applying the latter to the microscope. The lizard, guana, &c. have two skins, one very transparent, the other thicker and more opaque; and, separating these two, you obtain very beautiful objects.

To view the scales of fish to advantage, they ought to be soaked in water for a few days, and then carcfully rubbed to clean them from the skin and dirt which may adhere to them. The scales of the eel are a great curiosity; and the more so, as this creature was not known to have any scales till they were discovered by the microscope. The method of discovering them is this. Take a piece of the skin of an eel from off its side, and spread it while moist on a piece of glass, that it may dry very smooth: when thus dried, the surface will appear all over dimpled or pitted by the scales, which lie under a sort of cuticle or thin skin; which may be raised with the sharp point of a penknife, together with the scales, which will then easily slip out; and thus we may procure as many as we please.

The leaves of many trees, as well as of some plants, when dissected, form a very agreeable object. In order to dissect them, take a few of the most perfect leaves you can find, and place them in a pan with clean water. Let them remain there three weeks, or a month, without changing the water: then take them up; and if they feel very soft, and almost rotten, they are sufficiently soaked. They must then be laid on a flat board, and holding them by the stalk, draw the edge of a knife over the upper side of the leaf, which will take off most of the skin. Then turn the leaf, and do the same with the under side ; and when the skin is taken off on both sides, wash out the pulpy matter, and the fibres will be exhibited in a very beautiful manner. The leaf may be slit into two parts, by splitting the stalk; and the skins peeled from the fibres will also make a good object. This operation is best performed in the antumn; the fibres of the leaves are much stronger at that season, and less liable to be broken .- The internal structure of shells may be observed by grinding them down on a hone: and all ores and minerals should be carefully washed and brushed with a small brush, to remove any sordes that may adhere to them.

To view the circulation of the blood, we must observe living animals of the most transparent kind.— A small cel is sometimes used for this purpose; in which case it must be cleansed from the slime naturally adhering to it; after which it may be put into a tube filled with water, were it can be viewed in a satisfactory manner. The tail of any other small fish may be viewed in the same manner, or put upon a slip of flat glass, and thus laid before the microscope. By filling the tube with water when an cel is made use of,

Microscope.

scope.

Micro- we prevent in a great measure the sliminess of the animal from soiling the glass.

The particles of the blood form a very curious object, and have been carefully viewed by different philosophers; who, neverthelcss, differ from one another very much in their accounts of them. The best method of viewing these is to take a small drop of blood when warm, and spread it as thin as possible upon a flat piece of glass. By diluting it a little with warm water, some of the large globules will be scparated from the smaller, and many of them subdivided; or a small drop of blood may be put into a capillary glass tube, and then placed before the microscope. Mr Baker advises warm milk as proper to be mixed with the blood; but Mr Hewson diluted the blood with its own serum : and by this method hc could preserve the small particles entire, and view them distinctly; and thus he found that they were not globular, as had been imagined by other anatomists, but flat. Having shaken a piece of the crassamentum of the blood in serum till the latter became a little coloured, he spread it with a soft hair pencil on a piece of thin glass, which he placed under the microscope, in such a manner as not to be quite horizontal, but rather higher at one end than the other. Thus the serum flows from the higher to the lower part; and, as it flows, some of the particles will be found to swim on their flat sides, and will appear to have a dark spot in the middle; while others will turn over from one side to the other as they roll down the glass. Many cruel experiments have been tried in order to observe the circulation of the blood in living creatures, and an apparatus had been invented for viewing the circulation in the mesentery of a frog; but as this can answer no useful purpose, and will never be put in practice by persons of humanity, we forbear to mention it.

II. Besides the objects for the microscope already mentioned, there are innumerable others, some hardly visible, and others totally invisible, to the naked eye; and which therefore, in a more peculiar sense, are denominated.

Microscopic Animals. They are the animalcules or moving bodics in water, in which certain substances have been infused; and of which there arc a great many different kinds. These animalcula are sometimes found in water which we would call pure, did not the microscope discover its minute inhabitants; but not equally in all kinds of water, or even in all parts of the same kind of it. The surfaces of infusions are generally covered with a scum which is easily broken, but acquires thickness by standing. In this scum the greatest number of animalcules are usually found. Sometimes it is necessary to dilute the infusions; but this ought always to be done with water, not only distilled, but viewed through a microscope, lest it should also have animalcules in it, and thus prove a source of deception. It is, however, most proper to observe those minute objects after the water is a little evaporated; the attention being less diverted by a few objects than when they appear in great number. One or two of the animalcules may be separated from the rest by placing a small drop of water on the glass near that of the infusion; join them together by making a small connexion between them with a pin; and as

soon as you perceive that an animalcule has entered the Microclear drop, cut off the connexion again.

Eels in paste arc obtained by boiling a little flour and water into the consistence of bookbinders paste; then exposing it to the air in an open vessel, and beating it frequently together to keep the surface from growing mouldy or hard. In a few days it will be found peopled with myriads of little animals visible to the naked eye, which are the eels in question. They may be preserved for a whole year by keeping the pastc moistened with water; and while this is done, the motion of the animals will keep the surface from growing mouldy. Mr Baker directs a drop or two of vinegar to be put into the paste now and then. When they are applied to the microscope, the paste must be diluted in a piece of water for them to swim in.

Numberless animalcules are observed by the microscope in infusions of pepper. To make an infusion for this purpose, bruise as much common black pepper as will cover the bottom of an open jar, and lay it thereon about half an inch thick : pour as much soft water into the vessel as will rise about an inch above the pepper. Shake the whole well together : after which they must not be stirred, but be left exposed to the air for a few days; in which time a thin pellicle will be formed on the surface, in which innumerable animals are to be observed by the microscope.

The microscopic animals are so different from those of the larger kinds, that scarce any sort of analogy seems to exist between them; and one would almost be tempted to think that they lived in consequence of laws directly opposite to those which preserve ourselves and other visible animals in existence. They have been systematically arranged by O. F. Muller; though it is by no means probable that all the different classes have yet been discovered. Such as have been observed, however, are by this author divided in the following manner:

I. Such as have no external organs.

- 1. Monas: Punctiforme. A mere point.
- 2. Proteus : Mutabilis. Mutable.
- 3. Volvox : Sphæricum. Spherical.
- 4. Enchelis: Cylindracea. Cylindrical.
- 5. Vibrio: Elongatum. Long.

* Membranaceous.

- 6. Cyclidium : Ovale. Oval.
- 7. Paramecium: Oblongum. Oblong.
- 8. Kolpoda : Sinuatum. Sinuous.
- 9. Gonium : Angulatum. With angles.
- 10. Bursaria. Hollow like a purse.

II. Those that have external organs.

- * Naked, or not enclosed in a shell.
- 1. Cercaria : Caudatum. With a tail.
- 2. Trichoda : Crinitum. Hairy.
- 3. Kerona : Corniculatum. With horns.
- 4. Himantopus : Cirratum. Cirrated.
- 5. Lencophra : Ciliatum undique. Every part ciliated.
- 6. Vorticella : Ciliatum apice. The apex ciliated. * Covered with a shell.

7. Brachionus : Ciliatum apice. The apex ciliated.

M I

scope

In the treatise on HELMINTHOLOGY under the fifth order of the class vermes, viz. Infusoria, the genera here enumerated have already been noticed according to an arrangement somewhat different, and a few of the species have been described. For the sake of those who wish to prosecute microscopical inquiries, we shall introduce descriptions of a few more, and particularly those whose habitats arc known.

I. Monas.

This is by our author defined to be "an invisible (to the naked eye), pellucid, simple, punctiform worm;" but of which, small as it is, there are several species.

The monas terma or gelatinosa, is a small jellylike point, which can be but imperfectly seen by the single microscope, and not at all by the compound one. In a full light they totally disappear, by reason of their transparency. Some infusions are so full of them that scarce the least empty space can be perceived; the water itself appearing composed of innumerable globular points, in which a motion may be perceived somewhat similar to that which is observed when the sun's rays shine on the water ; the whole multitude of animals appearing in commotion like a hive of bees. This animal is very common in ditch-water, and in almost all infusions either of animal or vegetable substances.

Monas atomus or albida; white monas with a variable point. This appears like a white point, which through a high magnifier appears somewhat egg-shaped. The smaller end is generally marked with a black point, the situation of which is variable; sometimes it appears on the large end, and sometimes there are two black spots in the middle. This species was found in sea water, which had been kept through the whole winter, but was not very fetid. No other kind of animalcule was found in it.

II. The Proteus.

An invisible, very simple, pellucid worm, of a variable form.

The tenax, running out into a fine point. This is a pellucid gelatinous body, stored with black molecules, and likewise changing its figure, but in a more regular order than the former. It first extends itself in a straight line, the lower part terminating in a bright acute point. It appears to have no intestines; and when the globules are all collected in the upper part, it next draws the pointed end up toward the middle of the body, which assumes a round form. It goes through a number of different shapes, part of which are described under the article ANIMALCULE. It is found in some kinds of river water, and appears confined almost entirely to one place, only bending sidewise.

III. Volvox.

An invisible, very simple, pellucid, spherical worm.

The punctum; of a black colour, with a lucid point. This is a small globule, with one hemisphere opaque and black, the other having a crystalline appearance; and a vehement motion is observed in the black part. + VOL. XIV. Part I.

It moves as on an axis, frequently passing through the Microdrop in this manner. Many are often scen joined together in their passage through the water ; sometimes moving as in a little whirlpool, and then separating. They arc found in great numbers on the surface of fctid sea water.

The globulus, with the hinder part somewhat obscure, sometimes verges a little towards the oval in its shape, having a slow fluttering kind of motion, but more quick when disturbed. The intestines are but just visible. It is found in most vegetable infusions, and is ten times large than the monas lens.

The lunula, with lunular molecules, is a small roundish transparent body, consisting of an innumerable multitude of homogeneous molecules of the shape of a crescent, without any common margin. It moves continually in a twofold manner, viz. of the molecules among one another, and the whole mass turning slowly round. It is found in marshy places in the beginning of spring.

IV. Enchelis.

A simple, invisible, cylindric worm.

The viridis, or green enchelis, has an obtuse tail, the fore part terminating in an acute truncated angle; the intestines are obscure and indistinct. It continually varies its motion, turning from right to left.

The punctifera, having the fore part obtuse, the hinder part pointed. It is opaque, and of a green colour, with a small pellucid spot in the fore part, in which two black points may be seen; and a kind of double band crosses the middle of the body. The hinder part is pellucid and pointed, with an incision supposed to be the mouth, at the apex of the fore part. It is found in marshes.

The pupula, with the fore part papillary, is found in dunghill water in November and December : it has a rotatory motion on a longitudinal axis, and moves in an oblique direction through the water. Both ends are obtuse; and the hinder part is marked with a transparent circle, or circular aperture.

V. Vibrio.

A very simple, invisible, round, and rather long worm.

The lineola is found in most vegetable infusions in such numbers, that it seems to fill up almost the whole of their substance. It is so small, that with the best magnifiers we can discorn little more than an obscure tremulous motion among them. It is more slender than the monas terma.

The serpens, with obtuse windings or flexures, is found in river water, but seldom. It is slender and gelatinous, resembling a serpentine line, with an intestine down the middle.

The spirillum is exceedingly minute, and twisted in a spiral form, which seems to be its natural shape, as it never untwists itself, but moves forward in a straight line, vibrating the hind and fore parts. It was found in 1782 in an infusion of the sonchus arvensis.

The vermiculus has a milky appearance, with an obtusc apex, and a languid undulatory motion, like that of the common worm. It is found in marshy water in D November,

Microscope.

Microscope.

November, but seldom. It is thought to be the animal Micromentioned by Lecuwenhoeck as found in the dung of the frog and spawn of the male libellula.

The sagitta, with a setaccous tail, has a long and flexible body; broadest about the middle, and filled there also with gray molecules; the fore part being drawn out into a thin and transparent neck, and the upper end thick and black. It is found in salt water, and seems to move by contracting and extending its neck.

VI. Cyclidium.

A simple, invisible, flat, pellucid, orbicular or oval worm.

The bulla, or orbicular bright cyclidium. This is found occasionally in an infusion of hay. It is very pellucid and white, but the edges somewhat darker than the rest. It moves slowly, and in a semicircular direction.

The millium is very pellucid, and splendid like crystal; and of an elliptical figure, with a line through the whole length of it. The motion is swift, interrupted, and fluttering.

VII. Paramæcium.

An invisible, membranaceous, flat, and pellucid worm.

The chrysalis is found in salt water, and differs very little from the former, only the ends are more obtuse, and the margins are filled with black globules.

The versutum is found in ditches, and has an oblong, green, and gelatinous body, filled with molecules; the lower part thicker than the other; and both ends obtuse. It propagates by division.

VIII. Kolpoda.

An invisible, pellucid, flat, and crooked worm.

The lamella is very seldom met with. It resembles a long, narrow, and pellucid membrane, with the hind part obtuse, narrower, and curved towards the top. It has a vacillatory and very singular motion; going upon the sharp edge, not on the flat side as is usual with microscopic animals.

The gallinula is found in fetid salt water; and has the apex somewhat bent, the belly oval, convex, and striated.

The rostrum is found, though seldom, in water where the lemna grows; and has a slow and horizontal motion. The fore part is bent into a kind of hook; the hind part obtuse, and quite filled with black molccules.

The triquetra was found in salt water, and appears to consist of two membranes; the upper side flattened, the lower convex, with the apex bent into a kind of shoulder.

The assimilis is found on the sea-coast, and has an elliptic mass in the middle, but is not folded like the former. The margin of the fore part is notched from the top to the middle; the lower part swells out, and contracts again into a small point.

The cucullulus is found in an infusion of the sonchus arvensis. It is very pellucid and crystalline, with se-

veral globules, and has an oblique incision a little below the apex.

The ren, or crassa, is found in an infusion of hay, commonly about 13 hours after the infusion is made, and has a quick and vacillatory motion. Its body is yellow, thick, and somewhat opaque; curved a little in the middle, so that it resembles a kidney; and full of molecules. When the water in which it swims is about to fail, it takes an oval form, is compressed, and at last bursts.

IX. Gonium.

An invisible, simple, smooth, and angular worm.

The pulvinatum is found in dunghills; and appears like a little quadrangular membrane, plain on both sides; but with a large magnifier it appears like a bolster formed of three or four cylindric pillows sunk here and there.

The corrugatum is found in various kinds of infusions; and is somewhat of a square shape, very small, and in some positions appears as streaked.

The truncatum is found chiefly in pure water, and then but seldom. It has a languid motion, and is much larger than the foregoing. The fore part is a straight linc, with which the sides form obtuse angles, the end of the sides being united by a curved line. The internal molecules are of a dark green, and there are two little bright vesicles in the middle.

X. Bursaria.

A very simple, hollow, membranaceous worm.

The truncatella is visible to the naked eye; white, oval, and truncated at the top, where there is a large aperture descending towards the base. Most of them have four or five yellow eggs, at the bottom. They move from left to right, and from right to left; ascending to the surface in a straight line, and sometimes rolling about while they descend.

The bulling is pellucid and crystalline, having splendid globules of different sizes swimming about with it. The under side is convex, the upper hollow, with the fore part forming a kind of lip.

The hirundinella has two small projecting wings, which give it somewhat of the appearance of a bird: and it moves something like a swallow. It is invisible to the naked eye; but by the microscope appears a pellucid hollow membrane.

The duplella was found among duckweed, and appcars like a crystalline membrane folded up, without any visible intestines except a small congerics of points under one of the folds.

XI. Cercaria.

An invisible transparent worm with a tail.

The gyrinus greatly resembles the spermatic animal-It has a white gelatinous body; the fore part culcs. somewhat globular; the hind part round, long, and pointed. Sometimes it appears a little compressed on each side. When swimming it keeps its tail in conti- . nual vibration like a tadpole.

The gibba is found in the infusions of hay and other vegetables;
The inquieta is found in salt water, and is remarkable for changing the shape of its body: sometimes it appears spherical, sometimes like a long cylinder, and sometimes oval. It is white and gelatinous, the tail filiform and flexible, the upper part vibrating violently. A pellucid globule may be observed at the base, and two very small black points near the top.

The turbo, with a tail like a bristle, is found among duckweed. It is of a talcy appearance, partly oval and partly spherical; and seems to be composed of two globular bodies, the lowermost of which is the smallest, and it has two little black points like eyes on the upper part. The tail is sometimes straight, sometimes turned back on the body.

The poduria is found in November and December, in marshy places covered with lemma. It is pellucid ; and seems to eonsist of a head, trunk, and tail : the head resembles that of a herring ; the trunk is ventricose and full of intestines, of a spiral form and black colour. The tail most commonly appears to be divided into two bristles. The intestines are in a continual motion when the body moves, and by reason of their various shades make it appear very rough. There are likewise some hairs to be perceived. It turns round as upon an axis when it moves.

The viridis is found in the spring in ditches of standing water; and in some of its states has a considerable resemblance to the last, but has a much greater power of changing its shape. It is naturally cylindrical, the lower end sharp, and divided into two parts ; but sometimes contracts the head and tail so as to assume a spherical figure.

The setifera is found in salt water, but seldom. It is small, the body rather opaque, and of a round figure. The upper part is bright, and smaller than the rest: the trunk is more opaque; the tail sharp, and near it a little row of short hairs. It has a slow rotatory motion.

The hirta was likewise found in salt water. It is opaque and cylindrical; and when in motion, the body appears to be surrounded with rows of small hairs separated from each other.

The pleuronectes is found in water which has been kept for several months. It is mcmbranaceous, roundish, and white, with two blackish points in the fore part, the hinder part being furnished with a slender sharp tail. It has orbicular intestines of different sizes in the middle; the larger of them bright. The motion is vacillatory; and in swimming it keeps one edge of the lateral membrane upwards, the other folded down ...

The tripos is flat, pellucid, triangular, having each angle of the base or fore part bent down into two linear arms, the apex of the triangle prolonged into a tail. It is found in salt water.

XII. Leucophra.

An invisible, pellucid, and ciliated worm.

The mamilla is of a dark colour, and filled with globular molecules; short hairs are curved inwards; and it occasionally projects and draws in a little white protuberance. It is pretty common in marshy water.

The virescens is a large, pear-shaped, greenish-co- Miereloured animalcule, filled with opaque molecules, and co- scope. vered with short hairs; generally moving in a straight line. It is found in salt water.

The bursata is found in salt water, and is similar in many respects to the former. It is of a long oval shape. bulging in the middle, and filled with green molecules, everywhere ciliated except at the apex, which is truncated and shaped somewhat like a purse; the hairs are sometimes collected into little fascicles.

The posthuma is globular, and covered as it were with a pellucid net; is found in fetid salt water.

The signata is common in salt water in the months of November and Dccember. It is oblong and subdepressed, with a black margin filled with little molecules, but more particularly distinguished by a curved line in the middle somewhat in the shape of the letter S; one end of which is sometimes bent into the form of a small spiral.

XIII. Trichoda.

An invisible, pellucid, hairy worm.

The gyrinus is one of the smallest of this genus, and is found in salt water. It is smooth and free from hairs, except at the fore part, where there are a few.

The nigra was found in salt water, and has an opaque body; but when at rest one side appears pellucid. When in violent motion, it seems entirely black.

The pubes is found in water where duckweed grows, chiefly in the month of December. It has a bunch above the hind part marked with black spots, depressed towards the top, a little folded, and somewhat convex on the under part. The apex is furnished with hairs, but they are seldom visible till the creature is in the agonies of death, when it extends and moves them vehemently, and attempting as it were to draw in the very last drop of water.

The patens is found in salt water ; and is of a long cylindrical shape, filled with molecules, the fore part bright and clear, with a long opening near the top which tapers to a point, and is beset with hairs.

The striata is found in the month of December in river water. It is a beautiful animalcule, of a fox colour. It is of an oblong shape, the lower end somewhat larger than the other. It has a set of streaks running from one end to the other, and at the abdomen a double row of little eggs lying in a transverse direction.

The uvula is found in the infusion of hay and other vegetables. It is six times longer than broad, round, flexuous, of an equal size, the greater part filled with obscure molecules; the fore part rather empty, with an alimentary canal and lucid globules near the middle. The margin of the fore part is covered with short hairs.

The linter is found in an infusion of old grass. It is egg-shaped, oblong, with both extremities raised so that the bottom becomes convex, and the upper part depressed like a boat : it is of different shapes at different ages, and sometimes has a rotatory motion.

The paxillus is found in salt water; and is long, full of gray molecules; the fore part truncated and hairy, and rather smaller than the other.

The vermicularis is found in river water; and is pel-D 2 lucid Micro- Incid in the fore part, with the hind part full of molescope- cules.

> The *melitæa* is found in salt water, but very rarely. It is oblong, ciliated, with a globular apex, a dilatable neck, and a kind of peristaltic motion perceivable within it.

The *perillum* is frequently found in marshes. It is cylindrical, pellucid, muscular, and capable of being folded up. It appears double; the interior part full of molecules, with an orbicular muscular appendage, which it can open and shut, and which forms the mouth. The external part is membranaceous, pellucid, dilated, and marked with transverse streaks; and it can protrude or draw in the orbicular membrane at pleasure. Some have four articulations in the tail, others five; and it has two pairs of bristles, one placed at the second joint, the other at the last.

The *delphis* is found in river water. It is smooth, pellucid, having the fore part dilated into a semicircle, gradually decreasing in breadth towards the tail. The front is hairy, the hairs standing as rays from the semicircular edge: one of the edges is sometimes contracted.

The *delphinus* is found in hay that has been infused for some months. It is pellucid, smooth, and egg-shaped; the hinder part terminating in a tail about half the length of the body, dilated at the upper end, truncated, and always bent upwards. It moves sometimes on its belly and sometimes on its side.

The rostrata is found in water where duckweed has been kept. It is depressed, capable of changing its shape, yellow, with long ciliated hairs; it has four feet tapering to a point, one of them longer than the rest. Both feet and hairs are within the margin. The shape of the body is generally triangular; the apex formed into an obtuse beak, which the creature sometimes draws in so that it appears quite round.

The *charon* was found in salt water. It is oval, and resembles a boat as well in its motion as shape; the upper part is hollowed, the under part furrowed and convex; the stern round, with several hairs proceeding from it.

XIV. Kerona.

An invisible worm with horns.

The *rastellum* is found in river water. It has three rows of horns on the back, which occupy almost the whole of it.

The *cypris* is found in water covered with lemna. It is somewhat of a pear shape, compressed, with a broad and blunt fore part; the front furnished with hairs, or little vibrating points inserted under the edge, shorter in the hind part, partly extended straight, and partly bent down, having a retrograde motion.

The calvitium is found in the infusion of vegetables. The body is broad and flat, both sides obtuse, filled with black molecules, and there is a black spot near the hinder part, where there are likewise a few short bristles.

The *pustulata* is found in salt water. It is oval, convex; one edge of the hinder part sinuated, both ends set with hairs, and some horns on the fore part.

M I C

XV. Himantopus.

A pellucid, invisible, and cirrated worm.

The acarus is lively, conical, ventricose, full of black molecules, with a bright and transparent fore part. The lower part of the apex has rows of long hairs on the under part set like rays. Four locks of long crooked hair or feet proceed from the belly, and it is continually moving these and other hairs in various directions.

The *ludio* is a lively diverting animalcule, smooth, pellucid, full of small points, the fore part clubbed and a little bent, the hinder part narrow; the base obliquely truncated, and terminating in a tail stretched out transversely. The top of the head and middle of the back are furnished with long and vibrating hairs; three moveable and flexible curls hang down from the side of the head at a distance from each other. When the creature is at rest, its tail is curled; but when in motion, it is drawn tight and extended upwards.

The sannio is found, though seldom, in water where the lemna grows. The cilia are longer than the hairs, and arc continually vibrating: it has two movcable curls hanging on the side of the head.

The *charon* is found in sea water, but rarely. It is oval, pellucid, and membranous, with longitudinal furrows and several bent diverging rows of hair below the middle, but none on the hinder part.

XVI. Vorticella.

A naked worm with rotatory cilia, capable of contracting and extending itself.

The *lunifera*, is found in salt water; has the fore part obtuse, the base broad, and hollowed away like a crescent, with a short protuberance in the middle of the concave part: the fore part is ciliated.

The *bursata* is found in salt water, and is ventricose, crammed with molecules; the fore part truncated, and both sides of it pellucid: there is a prominent papilla in the middle, which when the animalcule is at rest appears notched, the edge of the aperture being ciliated; the hairs are capable of moving in various directions.

The sputarium is found in October, with the lesser lemna, and is one of the most singular of the microscopic animalcules. When viewed sidewise, it is sometimes nearly cylindrical, only tapering a little towards the hinder part, and having a broad pellucid edge. Viewed from the top, it has sometimes a broad face or disk, furnished with radiating hairs, the under part contracted into a globular shape, of a dark green colour, and filled with small grains.

The *multiformis* is found in salt water, and very much resembles the former.

The nigra is found in August in meadows covered with water. It may be seen with the naked eye, appearing like a black point swimming on the surface. Through the microscope it appears as a small conical body, obtuse and ventricose at one end, and acute at the other. When the extremities are extended, two small white hooks become visible, by the assistance of which

Microscope.

The ocreata is met with in rivers, though very seldom, and in shape somewhat resembles the lower part of a boot. The apex of the upper part is truncated and ciliated, the heel pointed, and the foot round.

The valga is as broad as long, and the apex truneated and ciliated; both angles of the base projecting outwards, one somewhat like a wart, the other like a finger. It is found in marshy waters.

The papillaris is likewise found in marshes where the conserva nitida grows. It is ventricose ; the fore part truncated, with a papillary tail, and a beautiful papillary excrescence on the side.

The cratægaria is found in the month of April, both in the mud and on the tail of the monoculus quadricornis. They are generally heaped together in a spherical form, and united to one common stalk. They are likewise often to be found without a pedicle, the body rather contracted, the aperture circular, and surrounded with a marked margin. It has two small arms; and with a powerful magnifier a violent rotatory motion may be observed. Sometimes an individual will separate from the community, and move in a kind of spiral line for a little time, and then go back to the rest.

The rotatoria is the wheel animal described by Mr Baker; and of which an account is given under the article ANIMALCULE.

The furcata is commonly found in water, and has a cylindric body with a rotatory organ, consisting of a row of hairs at the apex : the tail is divided into two parts, turning a little inwards. When at rest it joins the segments, of the tail, but opens them when in motion.

The citrina is found in stagnant water; the head full of molecules, round, everywhere of an equal size, and very transparent. Both sides of the orifice are eiliated, and each has a rotatory motion, appearing sometimes without and sometimes within the edge of the mouth.

The convallaria is the same with the bell-animal mentioned by Mr Baker. Sce the article ANIMAL-CULE.

The acinosa inhabits that whitish substance which often entirely covers plants, wood, shells, &c. When this substance is examined by a microscope, it appears to be wholly composed of living animals of the polype kind. See POLYPE.

The pyraria.

The anastatica See the article POLYPE. The digitalis.

XVII. Brachionus.

A contractile worm, covered with a shell, and furnished with rotatory cilia.

The patella is found in marshy water in the wintertime. It is univalve, the shell oval, plain, crystalline, with the anterior part terminating in two acute points on both sides, though the intervening space is commonly filled up with the head of the animal. By these points it fastens itself, and whirls about the body erect. The rotatory cilia are perceived with great difficulty.

To what has been already said on this subject, under Microthe article ANIMALCULE, we shall here add the follow- scope. ing observations from Mr Adams .-... "How many kinds of these invisibles there may be (says he), is yet unknown; as they are discerned of all sizes, from those which are barely invisible to the naked eye, to such as resist the force of the microscope as the fixed stars do that of the telescope, and with the greatest powers hitherto invented appear only as so many moving points. The smallest living creatures our instruments can show, are those which inhabit the waters; for though animalcula equally minute may fly in the air, or creep upon the carth, it is searcely possible to get a view of them ; but as water is transparent, by confining the creatures within it we can easily observe them by applying a dropof it to the glasses.

" Animalcules in general are observed to move in all directions with equal ease and rapidity, sometimes obliquely, sometimes straight forward; sometimes moving in a circular direction, or rolling upon one another, running backwards and forwards through the whole extent of the drop, as if diverting themselves; at other times greedily attacking the little parcels of matter they meet with. Notwithstanding their extreme minuteness, they know how to avoid obstacles, or to prevent any interference with one another in their motions : sometimes they will suddenly change the direction in which they move, and take an opposite one; and, by inelining the glass on which the drop of water is, as it can be made to move in any direction, so the animalcules appear to move as easily against the stream as with it. When the water begins to evaporate, they flock towards the place where the fluid is, and show a great anxiety and uncommon agitation of the organs with which they draw in the water. These motions grow languid as the water fails, and at last cease altogether, without a possibility of renewal if they be left dry for a short time. They sustain a great degree of cold as well as insects, and will perish in much the same degree of heat that destroys insects. Some animalcules are produced in water at the freezing point, and some insects live in snow. -By mixing the least drop of urine with the water in which they swim, they instantly fall into convulsions and die.

" The same rule seems to hold good in those minute creatures, which is observable in the larger animals, viz. that the larger kinds are less numerous than such as are smaller, while the smallest of all are found in such multitudes, that there seem to be myriads for one of the others. They increase in size, like other animals, from their birth until they have attained their full growth; and when deprived of proper nourishment, they in like manner grow thin and perish."

The modes of propagation among these animalcules arc various, and the observation of them is extremely curious. Some multiply by a transverse division, as is observed under the article ANIMALCULE: and it is remarkable, that though in general they avoid one another, it is not uncommon, when one is nearly divided, to see another push itself upon the small neck which joins the two bodies in order to accelerate the separation .- Others, when about to multiply, fix themselves to the bottom of the water; then becoming first oblong, and afterwards round, turn rapidly as on a centre, but perpetually varying the direction of their rotatory motion.

Niero-

scope.

totion. In a little time, two lines forming a cross are perceived; after which the spherule divides into four, which grow, and are again divided as before. A third kind multiply by a longitudinal division, which in some begins in the fore part, in others in the hind part; and from others a small fragment detaches itself, which in a short time assumes the shape of the parent animalcule. Lastly, others propagate in the same manner as the more perfect animals.

In our observations under the article ANIMALCULE, we suggested some doubts whether all those minute bodies which go under the name of animalcules really do enjoy animal life; or whether they are not in many cases to be accounted only inanimate and exceedingly minute points of matter actuated by the internal motion of the fluid. This has also been the opinion of others : but to all hypotheses of this kind Mr Adams makes the following reply : " From what has been said, it clearly appears, that their motions are not purely mechanical, but are produced by an internal spontaneous principle; and that they must therefore be placed among the class of living animals, for they possess the strongest marks and the most decided characters of animation; and, consequently, that there is no foundation for the supposition of a chaotic and neutral kingdom, which can only have derived its origin from a very transient and superficial view of these animalcules .- It may also be further observed, that as we see that the motions of the limbs, &c. of the larger animals, are produced by the mechanical construction of the body, and the action of the soul thereon, and are forced by the ocular demonstration which arises from anatomical dissection to acknowledge this mechanism which is adapted to produce the various motions necessary to the animal; and as, when we have recourse to the microscope, we find those pieces which had appeared to the naked eye as the primary mechanical causes of particular motions, to consist themselves of lesser parts, which are the causes of motion, extension, &c. in the larger; when the structure therefore can be traced no farther by the eye, or by the glasses, we have no right to conclude that the parts which are invisible are not equally the subject of mechanism : for this would be only to assert in other words, that a thing may exist because we see and feel it, and have no existence when it is not the object of our senses .- The same train of reasoning may be applied to microscopic insects and animalcula : we see them move; but because the muscles and members which occasion these motions are invisible, shall we infer that they have not muscles, with organs appropriated to the motion of the whole and its parts? To say that they exist not because we cannot perceive them, would not be a rational conclusion. Our senses are indecd given us that we may comprehend some effects ; but then we have also a mind, with reason, bestowed upon us, that, from the things which we do perceive with our senses, we may deduce the nature of those causes and effects which are imperceptible to the corporeal eye."

Leaving these speculations, however, we shall now proceed to give a particular

Explanation of the figures of the various animals, with their parts, ova, &c. represented in the plates.

Plate With their parts, out, GC. represented in the plates. CCCXLII. Fig. 32. 33. represent the eggs of the phalæna åg. 32. 33. neustria, as they are taken from the tree to which

they adhere, and magnified by the microscope. The Micro-

strong ground-work visible in many places shows scope the gum by which they are fastered together; and this connexion is strengthened by a very tenacious substance interposed between the eggs, and filling up the vacant spaces. Fig. 34. shows a vertical Fig. 34. section of the eggs, exhibiting their oval shape.— Fig. 35. is an horizontal section through the middle Fig. 35. of the egg. These eggs make a beautiful appearance through the microscope. The small figures a, b, c, represent the objects in their natural state, without being magnified.

Fig. 36. shows the larva of the musca chameleon, an Fig 30. aquatic insect. When viewed by the naked eye, it appears (as here represented) to be composed of twelve annular divisions, separating it into an head, thorax, and abdomen; but it is not easy to distinguish the two last parts from each other, as the intestines lie equally both in the thorax and abdomen. The tail is furnished with a fine crown or circle of hair b, disposed in the form of a ring, and by this means it is supported on the surface of the water, the head and body hanging down dowards the bottom, in which posture it will sometimes remain for a considerable time without any motion .- When it has a mind to sink to the bottom, it closes the hairs of the ring, as in fig. 37. Thus an hol- Fig. 37. low space is formed, including a small bubble of air; by enlarging or diminishing which, it can rise or sink in the water at pleasure. When the bubble escapes, the insect can replace it from the pulmonary tubes, and sometimes considerable quantities of air may be seen to escape from the tail of the worm into the common atmosphere; which operation may easily be observed when the worm is placed in a glass of water, and affords an interesting spectacle. The snout of this inseet is divided into three parts, of which that in the middle is immoveable; the other two, which grow from the sides of the middle one, are moveable, and vibrate like the tongues of lizards or serpents. In these lateral parts lies most of the creature's strength; for it walks upon them when out of the water, appearing to walk on its mouth, and to use it as the parrot does its beak to assist it in climbing.

The larva is shown, fig. 38. as it appears through a Fig. 38. microscope. It grows narrower towards the head, is largest about that part which we may call the thorax, converges all along the abdomen, and terminates at length in a sharp tail surrounded with hairs, as has already been mentioned. The twelve annular divisions are now extremely visible, and are marked by numbers in the plate. The skin appears somewhat hard, and resembling shagreen, being thick set with grains pretty equally distributed. It has nine holes, or spiracula, probably for the purpose of breathing, on each side; but it has none of these on the tail division a, nor any easily visible on the third from the head. In the latter, indeed, it has some very small holes concealed under the skin, near the place where the embryo wings of the future fly are hid. " It is remarkable says Mr Adams) that caterpillars, in general, have two rings without these spiracula, perhaps because they change into flies with four wings, whereas this worm produces a fly with only two." The skin of the larva is adorned with oblong black furrows, spots of a light colour, and orbicular rings, from which there generally springs

a hair; but only those hairs which grow on the insect's Microsides are represented in the figure. There are also some scope. larger hairs here and there, as at c c. The difference of colour, however, in this worm arises only from the quantity of grains in the same space; for where they are in very great numbers, the furrows are darker, and paler where they are less plentiful.

The head d is divided into three parts, and covered with a skin which has hardly any discernible grains .--The eyes are rather protuberant, and lie near the snout; on which last are two small horns at i i. It is crooked, and ends in a sharp point as at f. The legs are placed near the snout between the sinuses in which the eyes are fixed. Each of these legs consists of three joints, the outermost of which is covered with stiff hairs like bristles g. From the next joint there springs a horny bonc h h, used by the insect as a kind of thumb; the joint is also composed of a black substance of an intermediate hardness between bone and horn; and the thirdjoint is of the same nature. In order to distinguish these parts, those that form the upper sides of the mouth and eyes must be separated by means of a small knife; after which, by the assistance of the microscope, we may perceive that the leg is articulated by some particular ligaments, with the portion of the insect's mouth which answers to the lower jaw in the human frame. We may then also discern the muscles which serve to move the legs, and draw them up into a cavity that lies between the snout and those parts of the mouthr which are near the horns i i. The insect walks upon these legs, not only in the water, but on the land also. It likewise makes use of them in swimming, kceping its tail on the surface contiguous to the air, and hanging downward with the rest of the body in the water. In this situation, the only perceptible motion it has is in its legs, which it moves in a most elegant manner, from whence it is reasonable to conclude, that the most of this creature's strength lies in its legs, as we have already observed.

The snout of this larva is black and hard : the back part quite solid, and somewhat of a globular form; the front f sharp and hollow. Three membranaceous divisions may be perceived on the back part; by means of which, and the muscles contained in the snout, the creature can contract or expand it at pleasure.

The extremity of the tail is surrounded with thirty hairs, and the sides adorned with others that are smaller; and here and there the large hairs branch out into smaller oncs, which may be reckoned single hairs. All these have their roots in the outer skin, which in this place is covered with rough grains, as may be observed by cutting it off and holding it against the light' upon a slip of glass. Thus also we find, that at the extremities of the hairs there are grains like those on the skin; and in the middle of the tail there is a small opening, within which are minute holes, by which the insect takes in and lets out the air it breathes. These hairs, however, are seldom disposed in such a regular order as is represented in fig. 38. unless when the insect floats with the body in the water, and the tail with its hairs a little lower than the surface, in which case they are disposed exactly in the order delineated in the plate. The least motion of the tail downwards produces a concavity in the water; and it then assumes the figure of a wine glass, wide at the top and narrow at the bottom. The

tail answers the double purpose of swimming and breathing, and through it the insect receives what is the principle of life and motion to all animals. By means of these hairs also it can stop its motion when swimming, and remain suspended quietly without motion for any length of time. Its motions in swimming are very beautiful, cspecially when it advances with its whole body floating on the surface of the water, after filling itself with air by the tail .- To set out, it first bends the body to the right or left, and then contracts it in the form of the letter S, and again stretches it out in a straight line : by thus contracting and then extending the body alternately, it moves on the surface of the water. It is very quiet, and is not disturbed by handling.

These creatures are commonly found in shallow standing waters in the beginning of June : but some years much more plentifully than others. They crawl on the grass and other plants which grow in such waters, and arc often met with in ditches, floating on the surface of the watcr by means of their tail, the head and thorax at the same time hanging down; and in this posture they turn over the clay and dirt with their snout and feet in search of food, which is commonly a viscous matter met with in small ponds and ditches. It is very harmless, though its appearance would scent to indicate the contrary. It is most easily killed for dissection by spirit of turpentine.

Fig. 39. shows in its natural size a beautiful insect, Fig. 39 described by Linnæus under the name of Leucopsis dorsigera, and which appears to be a kind of intermediatc genus between a sphex and a wasp. The antennæ are black and cylindrical, increasing in thickness towards the extremity; the joint nearest the head is yellow; the head and thorax are black, encompassed with a yellow line, and furnished with a cross line of the same colour near the head. The scutellum is yellow, the abdomen black, with two yellow bands, and a deep spot of the same colour on each side between the hands. A deep polished groove extends down the hack from the thorax to the anus, into which the sting turns and is deposited, leaving the anus very circular; a yellow line runs on each side of the sting .--The anus and whole body, when viewed with a small magnifier, appear punctuated; but when these points are seen through a large magnifier, they appear hexagonal. Fig. 40. shows the insect very much magni-Fig. 40, 4T fied. Fig. 41. gives a side view of it magnified in a smaller degrec.

Fig. 42. shows an insect discovered by Mr John Plate Adams of Edmonton, as he happened to be at an CCCXLIIL inn. It was first seen by some labouring pcople fig. 42. who were there at the time, by whom it was conjectured to be a louse with unusually long horns, a mite, &c. Mr Adams hearing the debate, procured the insect; and having viewed it through a microscope, it presented the appearance exhibited in fig. 42. The insect seems to be quite distinct from the phalangium capcroides of Linnæus. The latter has been described by several authors, but none of their descriptions agree with this. The abdomen of this insect is more extended, the claws larger, and much more obtuse; the body of the other being nearly orbicular, the claws slender, and almost terminating in a point, more transparent, and of a paler colour. Mr Marsham has one

Micro scope.

123.8

scope.

Microscope.

in his possession not to be distinguished from that represented in fig. 42. excepting only that it wants the break or dent in the claws, which is so conspicuous in this. He found that insect firmly fixed by its claws to the thigh of a large fly, which he caught on a flower in Essex in the first week of August, and from which he could not disengage it without great difficulty, and tearing off the leg of the fly. This was done upon a piece of writing paper; and he was surprised to see the little creature spring forward a quarter of an inch, and again seize the thigh with its claws, so that he had great difficulty in disengaging it. The natural size of this creature, which Mr Adams calls the lobster-insect, is exhibited at a.

Fig. 43.

Fig. 44.

Fig. 43. shows the insect named by M. de Geer Physapus, on account of the bladders at its feet, (Thrips physapus, Lin.). This insect is to be found in great plenty upon the flowers of dandelion, &c. in the spring and summer. It has four wings, two upper and two under ones (represented fig. 44.); but the two undermost are not to be perceived without great difficulty. They are very long; and fixed to the upper part of the breast, lying horizontally. Both of them are rather pointed towards the edges, and have a strong nerve running round them, which is set with a hair fringe tufted at the extremity. The colour of these wings is whitish : the body of the insect is black ; the head small, with two large reticular eyes. The antennæ are of an equal size throughout, and divided into six oval pieces, which are articulated together .--The extremities of the feet are furnished with a membranaceous and flexible bladder, which it can throw out or draw in at pleasure. It presses this bladder against the substances on which it walks, and thus seems to fix itself to them; the bladder sometimes appears concave towards the bottom, the concavity diminishing as it is less pressed. The insect is represented of its natural size at b.

Fig. 45. represents the cimex striatus of Linnæus, remarkable for very bright and elegantly disposed colours, though few in number. The head, proboscis, and thorax, are black : the thorax ornamented with yellow spots; the middle one large, and occupying almost one-third of the posterior part; the other two are on each side, and triangular. The scutellum has two yellow oblong spots, pointed at each end. The ground of the elytra is a bright yellow; spotted and striped with black. The nerves are yellow; and there is a brilliant triangular spot of orange, which unites the crustaceous and membranaceous parts; the latter are brown, and clouded. It is found in the elm tree in June. It is represented of its natural size at c.

Fig. 46. shows the chrysomela asparagi of Linnaus, so called from the larva of the insect feeding upon that plant. It is a common insect, and very beautiful. It is of 'an oblong figure, with black antennæ, composed of many joints, nearly oval. The head is a deep and bright blue; the thorax red and cylindrical : the elytra are blue, with a yellow margin, and having three spots of the same colour on each; one at the base, of an oblong form, and two united with the margin: the legs are black; but the under side of the belly is of the same blue colour with the elytra and head. This little animal, when viewed by the naked eye, scarcely

appears to deserve any notice; but when examined by Microthe microscope, is one of the most pleasing opaque objects we have. It is found in June on the asparagus after it has run to seed ; and it is shown of its natural size at d. De Geer says that it is very scarce in Sweden.

Fig. 47. shows an insect of a shape so remarkable, Fig. 47. that naturalists have been at a loss to determine the genus to which it belongs. In the Fauna Suecica, Linnæus makes it an attelabus : but in the last edition of the Systema Naturæ, it is ranged as a meloe, nnder the title of the Meloe monoceros ; though of this also there seems to be some doubt. The true figure of it can only be discovered by a very good microscope. The head is black, and appears to be hid or buried under the thorax, which projects forward like a horn : the antennæ are composed of many joints, and are of a dirty yellow colour, as well as the feet : the hinderpart of the thorax is reddish, the fore part black .---The elytra are yellow, with a black longitudinal line down the suture ; there is a band of the same colour near the apex, and also a black point near the base, the whole animal being curiously covered with hair. The natural size of it is shown at e. It was found in May. Geoffroy says that it lives upon umbelliferous plants.

Fig. 48 .- 54. exhibit the anatomy of the cossus ca- Plate terpillar, which lives on the willow. The egg from CCCXLIII. which it proceeds is attached to the trunk of the fig. 48-54. tree by a kind of viscous juice, which soon becomes so hard that the rain cannot dissolve it. The egg itself is very small and spheroidical, and, when examined by the microscope, appears to have broad waving furrows running through the whole length of it, which are again crossed by close streaks, giving it the appearance of a wicker basket. It is not exactly known what time they are hatched; but as the small caterpillars appear in September, it is probable that the eggs are hatched some time in August. When small, they are generally met with under the bark of the tree to which the eggs were affixed ; and an aqueous moisture, oozing from the hole through which they got under the bark, is frequently, though not always, a direction for find-ing them. These caterpillars change their colour but ing them. These caterpillars change their colour but very little, being nearly the same when young as when old. Like many others, they are capable of spinning as soon as they come from the egg. They also change their skin several times; but as it is almost impossible to rear them under a glass, so it is very difficult to know exactly how often this moulting takes place .--Mr Adams conjectures that it is more frequently than the generality of caterpillars do, some having been observed to change more than nine times.

The cossus generally fasts for some days previous to the moulting; during which time the fleshy and other interior parts of the head are detached from the old skull, and retire as it were within the neck. The new the old skin is to be opened, and all the members withdrawn from it; an operation naturally difficult, but which must be rendered more so from the soft and weak state of the creature at that time. It is always much larger after each change.

From Mr Lyonet's experiments, it appears, that the COSSUS

Fig. 46.

Fig. 45.

Micro-

scope.

Microscope.

cossus generally passes at least two winters, if not three, before it assumes the pupa state. At the approach of winter, it forms a little case, the inside of which is lined with silk, and the outside covered with wood ground like very fine saw-dust. During the whole season it neither moves nor eats.

This caterpillar, at its first appearance, is not above one-twelfth of an inch long; but at last attains the length of two, and sometimes of three inches. In the month of May it prepares for the pupa state; the first care being to find a hole in the tree sufficient to allow the moth to issue forth; and if this cannot be found, it makes one equal in size to the future pupa. It then begins to form of wood a case or cone; uniting the bits, which are very thin, together by silk, into the form of an ellipsoid, the outside being formed of small bits of wood joined together in all directions; taking care, however, that the pointed end of the case may always be opposite to the mouth of the hole : having finished the outside of the case, it lines the inside with a silken tapestry of a close texture in all its parts, cxcept the pointed end, where the texture is looser, in order to facilitate its escape at the proper time. The caterpillar then places itself in such a posture, that the head may always lie towards the opening of the hole in the tree or pointed end of its case. Thus it remains at rest for some time: the colour of the skin first becomes pale, and afterwards brown; the interior parts of the head are dctached from the skull; the legs withdraw themselves from the exterior case; the body shortens; the posterior part grows small, while the anterior part swells so much, that the skin at last bursts; and, by a variety of motions, is pushed down to the tail; and thus the pupa is exhibited, in which the parts of the future moth may be casily traced .--The covering of the pupa, though at first soft, humid, and white, soon dries and hardens, and becomes of a dark purple colour; the posterior part is moveable; but not the fore part, which contains the rudiments of the head, legs, and wings. The fore-part of the pupa is furnished with two horns, one above and the other under the eycs. It has also several rows of points on its back. It remains for some weeks in the case; after which the moth begins to agitate itself, and the points are then of essential service, by acting as a fulcrum, upon which it may rest in its endeavours to proceed forward, and not slip back by its efforts for that purpose.

The moth generally continues its endeavours to open the case for a quarter of an hour: after which, by redoubled efforts, it enlarges the hole, and presses forward until it arrives at the edge, where it makes a full stop, lest by advancing further it should fall to the ground. After having in this manner reposed itself for some time, it begins to disengage itself entirely; and having rested for some hours with its head upwards, it becomes fit for action. Mr Marsham says, that it generally pushes one-third of the case out of the hole before it halts.

The body of the caterpillar is divided into twelve rings, marked 1, 2, 3, &c. as represented in fig. 48, 49, 50, 51. each of which is distinguished from that which precedes, and that which follows, by a kind of neck or hollow; and, by forming boundaries to the rings, we make twelve other divisions, likewise expres-

VOL. XIV. Part I.

scd in the figures; but to the first of these the word ring is affixed, and to the second, division. To facilitate the description of this animal, M. Lyonet supposed a line to pass down through the middle of the back, which he called the superior line, because it marked the most elevated part of the back of the caterpillar; and another, passing from the head down the belly to the tail, he called the inferior line.

All caterpillars have a small organ, resembling an elliptic spot, on the right and left of each ring, excepting the second, third, and last; and by these we are furnished with a further subdivision of this caterpillar, viz. by lines passing through the spiracula, the one on the right side, the other on the left of the caterpil-These four lines, which divide the caterpillar lar. longitudinally into four equal parts, mark each the place under the skin which is occupied by a considerable viscus. Under the superior line lics the heart, or rather thread of hearts; over the inferior line, the spinal marrow; and the two tracheal arteries follow the course of the lateral lines. At equal distances from the superior and two lateral lines, we may suppose four intermediate lines. The two between the superior and lateral lines are called the intermediate superior; the two others opposite to them, and between the lateral and inferior lines, are called the intermediate inferior.

Fig. 48, 49. show the muscles of the caterpillar, ar-Fig. 48, ranged with the most wonderful symmetry and order, and 49. especially when taken off by equal strata on both sides, which exhibits an astonishing and exact form and correspondence in them. The figures show the muscles of two different caterpillars opened at the belly, and supposed to be joined together at the superior lines. The muscles of the back are marked by capitals; the gastric muscles by Roman letters; the lateral ones by Greek characters. Those marked θ are called, by M. Lyonet, dividing muscles, on account of their situation.

The caterpillar was prepared for dissection by being emptied, and the muscles, nerves, &c. freed from the fat in the manner formerly directed: after which the following observations were made.

The muscle A in the first ring is double; the anterior one being thick at top, and being apparently divided into different muscles on the upper side, but without any appearance of this kind on the under side. One insertion is at the skin of the neck towards the head; the other is a little above; and that of the sccond muscle A is a little below the first spiraculum, near which they are fixed to the skin.

The muscle marked α is long and slender, fixed by its anterior extremity under the gastric muscles a and b of the first ring, to the circumflex scale of the base of the lower lip. It communicates with the muscle c of the second ring, after having passed under some of the arteries, and introduced itself below the muscle θ .

The muscle β is so tender, that it is scarcely possible to open the belly of the caterpillar without breaking it. It is sometimes double, and sometimes triple.— Anteriorly it is fixed to the posterior edge of the side of the parietal scale, the lower fixture being at the middle of the ring near the inferior line.

There are three muscles marked ξ ; the first affixed E at Micro-

scope.

scope.

at one extremity near the lower edge of the upper part of the parietal scale; the other end divides itself into three or four tails, fixed to the skin of the caterpillar under the muscle d. The anterior part of the second is fixed near the first; the anterior part of the third a little under the first and second, at the skin of the neck under the muscle A. These two last passing over the cavity of the first pair of limbs, are fixed by several tails to the edge opposite to this cavity. In this subject there are two muscles marked ∂ , but sometimes there is only one anteriorly; they are fixed to the lower edge of the parietal scale, the other ends being inserted in the first fold of the skin of the neck on the belly-side. Fig. 50. best represents the muscles β and δ ; as in that figure they do not appear injured by any unnatural connection.

In the second and four following rings we discern two large dorsal muscles A and B. In the 7th, oth and 10th rings are three, A, B, and C; in the 11th are four, A, B, C, and D; and in the anterior part of the 12th ring are five, A, B, C, D, and E. All these ranges of muscles, however, as well as the gastric muscles a, b, c, d, appear at first sight only as a single muselc, running nearly the whole length of the caterpillar; but when this is detached from the animal, it is found to consist of so many distinct muscles, each consisting only of the length of one of the rings, their extremities being fixed to the division of each ring, excepting the middle muscle a, which, at the 6th, 7th, 8th, and 9th rings, has its insertions rather beyond the division. Each row of muscles appears as one, because they are closely connected at top by some of the fibres which pass from one ring to the other.

The muscles A, which are 12 in number, gradually diminish in breadth to the lower part of the last ring: at the 8th and three following divisions they communicate with the muscles B, and at the 11th with D. In the lower part of the last ring, Λ is much broader than it was in the preceding ring; one extremity of it is contracted, and communicates with B; the lower insertion being at the membrane I, which is the exterior skin of the fecal bag. The muscles A and B, on the lower part of the last ring, cannot be seen until a large muscle is removed, which on one side is fixed to the subdivision of the ring, and on the other to the fecal

bag. The right muscles B, which are also 12 in number, begin at the second ring, and grow larger from thence to the seventh. They are usually narrower from thence to the 12th ; the deficiency in width being supplied by the six muscles C, which accompany it from the 7th to the subdivision of the 12th ring. The muscles B and C communicate laterally with the 8th, 11th, and 12th divisions. C is wanting at the subdivision of the 12th; its place being here supplied by B, which becomes broader at this part.

The first of the three floating muscles V originates at the first ring, from whence it introduces itself under N, where it is fixed, and then subdivides, and hides itself under other parts. The second begins at the second division, being fixed to the anterior extremity B of the second ring; from thence directing itself towards the stomach; and, after communicating with the case of the corpus crassum, it divides, and spreads into eight

muscles which run along the belly. The third begins Microat the third division, originating partly at the skin, and partly at the junction of the muscles B of the second and third ring. It directs itself obliquely towards the belly, meeting it near the third spiraculum; and branching from thence, it forms the oblique muscles of some of the viscera.

The thin long muscle θ , which is at the subdivision of the last ring, and covers the anterior insertion of the muscle (a) where the ring terminates, is single. It begins at one extremity of the muscle (c); at the fore part of the ring runs along the subdivision round the belly of the caterpillar, and finishes, on the other side, at the extremity of a similar muscle C.

Fig. 49. shows the dorsal muscles of the cossus. To view which in an advantageous manner, we must use the following mode of preparation.

1. All the dorsal muscles, 35 in number, must be taken out, as well as the seven lateral ones already described.

2. All the straight muscles of the belly must be taken away, as well as the muscular roots (c), and the ends of the gastric muscles (c), which are at the third and fourth divisions.

3. At the second division the muscle θ must be removed ; only the extremitics being left to show where it was inserted.

The parts being thus prepared, we begin at the third ring; where there are found four dorsal muscles C, D, E, and F. The first one C, is inserted at the third division, under the muscles θ and α , where it communicates by means of some fibres with the muscle f of the second ring; proceeding from thence obliquely towards the intermediate superior line, and is fixed at the fourth division. As soon as C is retrenched, the muscle D is scen ; which grows wider from the anterior extremity : it lies in a contrary direction to the muscle C, and is inserted into the third and fourth divisions. The muscle E lies in the same direction as the middle C, but not so obliquely : the lower insertion is at the fourth division ; the other at the third, immediately under C. The muscle F is nearly parallel to D which joins it; the first insertion is visible, but the other is hid under the muscles E and G at the fourth division.

In the eight following rings, there are only two dorsal muscles; and of these D is the only one that is completely seen. It is very large, and diminishes gradually in breadth from one ring to the other, till it comes to the last, sending off branches in some places .--- E is one of the strait muscles of the back ; and is inserted under the dividing muscles θ , at the divisions of its own ring

On the anterior part of the 12th ring there are three dorsal muscles, D, E, and F. D is similar to that of the preceding ring, marked also D, only that it is no more than half the length; terminating at the subdivision of its own ring. E is of the same length, and differs from the muscle E of the preceding ring only in its direction. F is parallel to E, and shorter than it; its anterior end does not reach the twelfth division.

On the posterior part there is only one dorsal muscle, fastened by some short ones to the subdivision of the last ring, traversing the muscles a; and being fixed there as if designed to strengthen them, and

to

to vary their direction. - a Is a single muscle, of which the anterior insertion is visible, the other end being fixed to the bottom of the foot of the last leg; its use is to move the foot. The anterior part of the muscle & branches into three or four heads, which cross the superior line obliquely, and are fixed to the skin a little above it. The other end is fastened to the membrane T.

Micro-

scope

Fig. 50. 51. Fig. 50. and 51. show the muscles of the caterpillar when it is opened at the back. The preparation for this view is to disengage the fat and other extraneous matter, as before directed.

> The first ring has only two gastric muscles (c) and (d): the former is broad, and has three or four little tails : the first fixture is at the base of the lower lip, from whence it descends obliquely, and is fixed be-tween the inferior and lateral line. The small muscle (d) is fastened on one side to the first spiraculum; on the other, a little lower, to the intermediate inferior and lateral line; and seems to be an antagonist to the muscle P, which opens the spiracula. The posterior fixture of δ is under the muscle C, near the skin of the neck; β is fixed a little on the other side of C, at the middle of the ring.

> In the second ring there arc three gastric muscles, g, h, and i: g and h are fixed at the folds which terminate the ring; but only the anterior part of i is fixed there. The muscle h is triple, and in one of the divisions separated into two parts; that marked i comes nearer the inferior line, and is fixed a little beyond the middle of the ring, where the corresponding muscle of the opposite side is forked to receive it.

In the third ring, the muscle h, which was triple in the foregoing ring, is only double here, that part which is nearest the inferior line being broadest: it has three tails, of which only two are visible in the figure. It is exactly similar to that of the preceding ring; and is crossed in the same manner by the muscle from the opposite side of the ring.

Throughout the eight following rings, the muscle f which runs through them all is very broad and strong. The anterior part of it is fixed at the intermediate inferior line, on the fold of the first division of the ring : the other part is fixed beyond the lower division; with this difference, that at the 10th and 11th rings it is fixed at the last fold of its ring; whereas, in the others it passes over that ring, and is inserted into the skin of the following one. In all these, the first extremity of the muscle g is fastened to the fold which separates the ring from the preceding one, and is parallel to f, and placed at the side of it. The first six muscles marked g, are forked; that of the fourth ring being more so than the rest, nor does it unite till near its anterior insertion. The longest tail lays hold of the following, and is inserted near the inferior line; the other inserts itself near the same line, at about the middle of its own ring; the two last do not branch out; but terminate at the divisions, without reaching the following ring. The muscle h, placed at the side of f, has nearly the same direction, and finishes at the folds of the ring.

The anterior part of the 12th ring has only one gastric muscle, marked e: it is placed on the intermediate inferior line; and is inserted at the folds of the upper division, and at the subdivision of this ring. The lower part has a larger muscle marked c, with several divi- Microsions; one placed under b, with one extremity fixed near the lateral line, at the subdivision of its ring; the other to the feeal bag, a little lower than the muscle b.

In fig. 51. all the gastric muscles described in fig. 50. disappear, as well as those lateral and dorsal ones of which the letters are not to be found in this figure.

In the first ring are the gastric muscles, e, f, g, which are best seen here : the first is narrow and long, passing under and crossing f: one of its insertions is at the lower line, the other at the lateral, between the spiraculum and neck : f is short, broad, and nearly straight, placed along the intermediate line; but between it and the lateral it passes under e, and is fixed to the fold of the skin which goes from the one bag to the other; the lower insertion is near the second division. There are sometimes three muscles of those marked g, and sometimes four : the lower parts of them are fixed about the middle of the ring, and the anterior parts at the fold of the skin near the neck. The muscles i and h are fixed to the same fold; the other end of h being fixed under the muscle Π , near the spiraculum. Above the upper end of f, a muscular body, g, may be seen. It is formed by the separation of two floating muscles.

The second ring has six gastric muscles, k, l, m, n, o, p. The first is a large oblique muscle, with three or four divisions placed at the anterior part of the ring : the head is fixed between the inferior line and its intermediate one, at the fold of the second division; from whence it crosses the inferior line and its corresponding muscle, terminating to the right and left of the line. I is a narrow muscle, whose head is fixed to the fold of the second division; the tail of it lying under n, and fastened to the edge of the skin that forms the cavity for the leg. The two muscles marked *m* have the same obliquity, and arc placed the one on the other; the head is inserted in the skin under the muscle β , and communicates by a number of fibres with the tail of the muscle γ ; the other end is fixed to the intermediate inferior line at the fold of the third division. The large and broad muscle n, covers the lower edge of the cavity of the limb, and the extremity of the tail of l. It is fixed first at the skin, near the intermediate line, from whence it goes in a perpendicular direction towards m, and introduces itself under o and m, where it is fixed. The muscle o is narrow and bent, and covers the edge of the cavity of the leg for a little way; one end terminating there, and the other finishing at the third division near m. That marked p is also bent: it runs near the anterior edge of the cavity of the leg; one end meets the head of o, the other end terminates at a raised fold near the inferior line. There is a triangular muscle on the side of the lateral muscle o, similar to that marked g in the following ring; in this figure it is entirely concealed by the muscle m.

The third ring has no muscle similar to m; that marked k differs only from that of the second ring in being crossed by the opposite muscle. Those marked l, n, o, p, are similar to those of the preceding one. The muscle q is triangular; the base is fastened to the last fold of the ring; on the lower side it is fixed to the muscle o, the top to the skin at the edge of the cavity for the leg.

E 2

The

The eight following rings have the gastric muscles, i, k, l, and m. The muscle i is quite straight, and placed at some distance from the inferior line : it is broad at the fourth ring, but diminishes gradually in breadth to the 11th. In the fourth it is united; but divides into two heads, which divaricate in the following rings. In the six next rings these heads are fixed nearly at the same place with a and f; and in the other two it terminates at the fold of the ring. The anterior insertion of the first and last is at the fold where the ring begins; that of the six others is somewhat lower under the place where the muscle i terminates. The lower part of the oblique muscle k is inserted in the skin near i; the upper part at the intermediate inferior muscle upon the fold which separates the following ring, but is wanting in the 11th. The muscle l is large, and co-operates with M: in the opening and shutting the spiraculum, one of its fixtures is near the intermediate inferior line, at about the same height as i. The tail terminates a little below the spiracu-

lum. The twelfth ring has only the single gastric muscle d, which is a bundle of six, seven, or cight muscles : the first fixture of these is at the subdivision of the ring near the inferior line : one or two cross this, and at the same time the similar muscles of the opposite side. Their fixture is at the bottom of the foot; and their office is to assist the muscle a in bringing back the foot, and to loosen the claw from what it lays hold of. One of the insertions of this muscle a is observed in this figure near d, the other near the subdivision of the ring.

Fig. 52, 53-

Miero-

scope.

Fig. 52. and 53. show the organization of the head of the cossus, though in a very imperfect manner, as M. Lyonet found it necessary to employ twenty figures to explain it fully. The head is represented as it appears when separated from the fat, and disengaged from the neck. HH are the two palpi. The truncated muscles D belong to the lower lip, and assist moving it. K shows the two ganglions of the neck united. II are the two vessels which assist in spinning the silk. L, the œsophagus. M, the two dissolving vessels. The Hebrew characters racks show the continuation of the four cephalic arteries. In fig. 52. the ten abductor muscles of the jaw are represented by SS, TT, VV, and Z. Four occipital muscles are seen in fig. 53. under e e and ff. At a k is represented a nerve of the first pair belonging to the ganglion of the neck; b is a branch of this nerve.

Fig. 54.

Fig. 54. exhibits the nerves as seen from the under part ; but excepting in two or three nerves, which may he easily distinguished, only one of each pair is drawn, in order to avoid confusion. The nerves of the first ganglion of the neck are marked by capital letters, those of the ganglion (a) of the head by Roman letters; the nerves of the small ganglion by Greek characters. Those of the frontal gauglion, except one, by numbers.

The muscles of the cossus have neither the colour nor form of those of larger animals. In their natural state they are soft, and of the consistence of a jelly. Their colour is a gravish blue, which, with the silvercoloured appearance of the pulmonary vessels, form a glorious spectacle. After the caterpillar has been soaked for some time in spirit of wine, they lose their

elasticity and transparency, becoming firm, opaque, Microand white, and the air-vessels totally disappear. The number of muscles in a caterpillar is very great. The greatest part of the head is composed of them, and there is a vast number about the cesophagus, intestines, &c.; the skin is, as it were, lined by different beds of them, placed the one under the other, and ranged with great symmetry. M. Lyonet has been able to distinguish 228 in the head, 1647 in the body, and 2066 in the intestinal tube, making in all 3941.

At first sight the muscles might be taken for tendons, as being of the same colour, and having nearly the same lustre. They are generally flat, and of an equal size throughout; the middle seldom differing either in colour or size from either of the extremities. If they are separated, however, by means of very fine needles, in a drop of some fluid, we find them composed not only of fibres, membranes, and air-vessels, but likewise of nerves; and, from the drops of oil that may be seen floating on the fluid, they appear also to be furnished with many unctuous particles. Their ends are fixed to the skin, but the rest of the muscle is generally frec and floating. Several of them branch out considerably; and the branches sometimes extend so far, that it is not easy to discover whether they are distinct and separate muscles or parts of another. They are moderately strong; and those which have been soaked in spirit of wine, when examined by the microscope, are found to be covered with a membrane which may be separated from them; and they appear then to consist of several parallel bands lying longitudinally along the muscle, which, when divided by means of fine needles, appear to be composed of still smaller bundles of fibres lying in the same direction; which, when examined by a powerful magnifier, and in a favonrable light, appear twisted like a small cord. The muscular fibres of the spider, which are much larger than those of the caterpillar, consist of two different substances, one soft and the other hard; the latter being twisted round the former spirally, and thus giving it the twisted appearance just mentioned.

There is nothing in the caterpillar similar to the brain in man. We find indeed in the head of this insect a part from which all the nerves seem to proceed; but this part is entirely unprotected, and so small, that it does not occupy me-fifth part of the head; the surface is smooth, and has neither lobes nor any anfractuosity like the human brain. But if we call this a brain in the caterpillar, we must say that it has thirtcen: for there are twelve other such parts following each other in a straight line, all of them of the same substance with that in the head, and nearly of the same size; and from them, as well as from that in the head, the nerves are distributed through the body.

The spinal marrow in the cossus goes along the belly; is very small, forking out at intervals, nearly . of the same thickness throughout, except at the ganglions, and is not enclosed in any case. It is by no means so tender as in man; but has a great degree of tenacity, and dees not break without a considerable degree of tension. The substance of the ganglion differs from that of the spinal marrow, as no vessels can be discovered in the latter; but the former

scope.

韬

so"

scope.

scope.

Micro- mer are full of very delicate oncs. There are 94 principal nerves, which divide into inumerable ramifications.

> The cossus has two large tracheal arteries, creeping under the skin close to the spiracula: one at the right and the other at the left side of the insect, each of them communicating with the air by means of nine spiracula. They are nearly as long as the whole caterpillar; beginning at the first spiraculum, and extending somewhat farther than the last ; some branches also extending quite to the extremity of the body. Round each spiraculum the trachea pushes' forth a great number of branches, which are again divided into smaller ones, and these further subdivided and spread through the whole body of the caterpillar. The tracheal artery, with all its numerous ramifications, are open elastic vessels, which may be pressed close together, or drawn out considerably, but return immediately to their usual size when the tension ceases. They are naturally of a silver colour, and make a beautiful appearance. This vessel, with its principal hranches, is composed of three coats, which may be separated from one another. The outmost is a thick membrane furnished with a great variety of fibres, which describe a vast number of circles round it, communicating with each other by numerous shoots. The second is very thin and transparent, without any particular vessel being distinguishable in it. The third is composed of scaly threads, generally of a spiral form; and so near each other as scarcely to leave any interval. They are curiously united with the membrane which occupies the intervals; and form a tube which is always open, notwithstanding the flexure of the vessel. There are also many other peculiarities in its structure. The principal tracheal vessels divide into 1326 different branches.

> The heart of the cossus is very different from that of larger animals, being almost as long as the animal itself. It lies immediately under the skin at the top of the back, entering the head, and terminating near the mouth. Towards the last rings of the body it is large and capacious, diminishing very much as it approaches the head, from the fourth to the twelfth division. On both sides, at each division, it has an appendage, which partly covers the muscles of the back, but which, growing narrower as it approaches the lateral line, it forms a number of irregular lozengc-shaped bodies .---This tube, however, seems to perform none of the functions of the heart in larger animals, as we find no vessel opening into it which answers either to the aorta or vena cava. It is called the heart, because it is generally filled with a kind of lymph, which naturalists have supposed to be the blood of the caterpillar; and because in all caterpillars which have a transparent skin, we may perceive alternatc regular contractions and dilatations along the superior line, beginning at the eleventh ring, and proceeding from ring to ring, from the fourth; whence this vessel is thought to be a string or row of hearts. There are two white oblong bodies which join the heart near the eighth division ; and these have been called reniform bodies, from their having somewhat of the shape of a kidney.

> The most considerable part of the whole caterpillar with regard to bulk is the corpus crassum. It is the first and only substance that is seen on opening it. It

forms a kind of sheath which envelopes and covers all Microthe entrails, and, introducing itself into the head, enters all the muscles of the body, filling the greatest part of the empty spaces in the caterpillar. It very much resembles the configuration of the human brain, and is of a milk-white colour.

The œsophagus descends from the bottom of the mouth to about the fourth division. The fore part, which is in the head, is fleshy, narrow, and fixed by different muscles to the crustaceous parts of it; the lower part, which passes into the body, is wider, and forms a kind of membranaceous bag, covered with very small muscles; near the stomach it is narrower, and, as it were, confined by a strong nerve fixed to it at distant intervals. The ventricle begins a little above the fourth division, where the œsophagns ends, and finishes at the tenth. It is about seven times as long as broad ; and the auterior part, which is broadest, is generally folded. These folds diminish with the bulk as it approaches the intestines; the surface is covered with a great number of aerial vessels, and opens into a tube, which M. Lyonet calls the large intestine .- There are three of these large tubes, each of which differs so much from the rest, as to require a particular name to distinguish it from them.

The two vessels from which the cossus spins its silk are often above three inches long, and are distinguished into three parts ; the anterior, intermediate, and posterior. It has likewise two other vessels, which are supposed to prepare and contain the liquor for dissolving the wood on which it feeds.

Fig. 55. shows the wing of an earwig magnified; Plate a represents it of the natural size. The wings of this CCCXLIV. insect are so artificially folded up under short cases, fig. 55. that few people imagine they have any. Indeed, they very rarcly make use of their wings. The cases under which they are concealed are not more than a sixth part of the size of one wing, though a small part of the wing may be discovered, on a careful inspection, projecting from under them. The upper part of the wing is crustaceous and opaque, but the under part is beautifully transparent. In putting up their wings, they first fold back the parts AB, and then shut up the ribs like a fan; the strong muscles used for this purpose being seen at the upper part of the figure. Some of the ribs are extended from the centre to the outer edge; others only from the edge about half way: but they are all united by a kind of band, at a small but equal distance from the edge ; the whole evidently contrived to strengthen the wing, and facilitate its various motions. The insect itself differs very little in appearance in its three different states. De Geer asserts, that the female hatches eggs like a hen, and broods over her young ones as a ben docs.

Fig. 56. represents a wing of the hemerobius perla Fig. 56. magnified. It is an insect which seldom lives more than two or three days .- The wings are nearly of a length, and exactly similar to one another. They are composed of fine delicate nerves, regularly and elegantly disposed as in the figure, beautifully adorned with hairs, and lightly tinged with green. The body is of a fine green colour; and its eyes appear like two burnished beads of gold, whence it has obtained the name of golden eye. This insect lays its eggs on the leaves of the plum or the rose tree; the eggs are of a white colour,

Miera.

Microscope.

Fig. 58.

Fig. 59.

colour, and each of them fixed to a little pedicle or foot-stalk, by which means they stand off a little from the leaf, appearing like the fructification of some of the mosses. The larva proceeding from these eggs resembles that of the coccinella or lady-cow, but is much more handsome. Like that, it feeds upon aphides or pucerons, sucking their blood, and forming itself a ease with their dried bodics; in which it changes into the pupa state, from whence they afterwards emerge in the form of a fly.

Fig. E, F, I, represent the dust of a moth's wing magnified. This is of different figures in different moths. The natural size of these small plumes is represented at H.

Fig. 57. shows a part of the cornea of the libellula Tig. 57. magnified. In some positions of the light, the sides of the hexagons appear of a fine gold colour, and divided by three parallel lines. The natural size of the part magnified is shown at b.

Fig. 58. shows the part c of a lobster's cornea mag-

Fig. 59. shows one of the arms or horns of the lepas anatifera, or barnacle, magnified; its natural size being represented at d. Each horn consists of several joints, and each joint is furnished on the concave side of the arm with long hairs. When viewed in the microscope, the arms appear rather opaque; but they may be rendered transparent, and become a most beautiful object, by extracting out of the interior cavity a bundle of longitudinal fibres, which runs the whole length of the arm. Mr Necdham thinks that the motion and use of these arms may illustrate the nature of the rotatory motion in the wheel-animal. In the midst of the arms is an hollow trunk, consisting of a jointed hairy tube, which encloses a long round tongue that can be pushed occasionally out of the tube or sheath, and retracted occasionally. The mouth of the animal consists of six laminæ, which go off with a bend, indented like a saw on the convex edge, and by their circular disposition are so ranged, that the teeth, in the alternate elevation and depression of each plate, act against whatever comes between them. The plates are placed together in such a manner, that to the naked eye they form an aperture not much unlike the mouth of a contracted purse.

Plate fig. 60.

Fig. 60. shows the apparatus of the tabanus or gad-CCCXLV. fly, hy which it pierces the skin of horses and oxen, in order to suck the blood. The whole is contained in a fleshy case, not expressed in the figure. The feelers a a are of a spongy texture and gray coloured, covered with short hairs. They are united to the head by a small joint of the same substance. They defend the other parts of the apparatus, being laid upon it side by side whenever the animal stings, and thus preserve it from external injury. The wound is made by the two lancets b b and B, which are of a delicate structure, but very sharp, formed like the dissecting knife of an anatomist, growing gradually thicker to the back .-- The two instruments c c and C, appear as if intended to enlarge the wound, by irritating the parts round it; for which they are jagged or toothed. They may also serve, from their hard and horny texture, to defend the tube e E, which is of a softer nature, and tubular to admit the blood, and convey it to the stomach. This part is totally enclosed in a line d D, which entirely covers

it. These parts are drawn separately at B, C, D, E. De Geer observes, that only the females suck the blood of animals ; and Reaumur informs us, that having made . one, that had sucked its fill, disgorge itself, the blood it threw up appeared to him to be more than the whole body of the insect could have contained. The natural size of this apparatus is shown at f.

Fig. 61. shows a bit of the skin of a lump-fish (cy- Fig. 61. clopterus) magnified When a good specimen of this can be procured, it forms a most beautiful object. The tubercles exhibited in the figure probably secrete an unetuous juiee.

Fig. 62. shows the seale of a sea perch found on the Fig. 62. English coast; the natural size is exhibited at k.

Fig. 63. the scale of an haddock magnified ; its na-Fig. 63. tural size as within the circle.

Fig. 64. the seale of a parrot fish from the West In-Fig. 64. dies magnified ; l the natural size of it.

Fig. 65. the scale of a kind of perch in the West In-Fig. 65. dies magnified ; k the natural size of the scale.

Fig. 66. part of the skin of a sole fish, as viewed Fig. 66. through an opaque miscroscope ; the magnified part in its real size, shown at l.

The seales of fishes afford a great variety of beautiful objects for the microscope. Some are long ; others round, square, &c. varying considerably not only in different fishes, but even in different parts of the same fish. Leenwenhoeck supposed them to consist of an inlinite number of small scales or strata, of which those next to the body of the fish are the largest. When viewed by the microscope, we find some of them ornamented with a prodigious number of concentric flutings, too near each other, and too fine, to be easily enumerated. These flutings are frequently traversed by others diverging from the centre of the seale, and generally proceeding from thenee in a straight line to the cireumference.

For more full information concerning these and other microscopical objects, the reader may consult Mr Adams's Essays on the Microscope, who has made the most valuable collection that has yet appeared on the subject. See also the articles ANIMALCULE, CRY-STALLIZATION, POLYPE, PLANTS, and WOOD, in the present work.

MIDAS, in fabulous history, a famous king of Phrygia, who having received Bacchus with great magnificence, that god, out of gratitude, offered to grant him whatever he should ask. Midas desired that every thing he touched should be changed into gold. Baeehus consented ; and Midas, with extreme pleasure, everywhere found the effects of his touch. But he had soon reason to repent of his folly: for wanting to cat and drink, the aliments no sooner entered his month than they were changed into gold. This obliged him to have recourse to Bacchus again, to beseech him to restore him to his former state; on which the god ordered him to bathe in the river Pactolus, which from theneeforward had golden sands. Some time after, being chosen judge between Pan and Apollo, he gave another instance of his folly and bad taste, in preferring Pan's music to Apollo's; on which the latter being enraged, gave him a pair of asses ears. This Midas attempted to eoneeal from the knowledge of his subjccts: but one of his servants saw the length of his ears, and being unable to keep the secret, yet afraid to revcal

veal it from apprehension of the king's resentment, he opened a hole in the earth, and after he had whispered there that Midas had the ears of an ass, he covered the place as before, as if he had buried his words in the ground. On that place, as the poets mention, grew a number of reeds, which when agitated by the wind uttered the same sound that had been buried beneath, and published to the world that Midas had the ears of an ass. Some explain the fable of the ears of Midas, by the supposition that he kept a number of informers and spies, who were continually employed in gathering every seditious word that might drop from the mouths of his subjects. Midas, according to Strabo, died of drinking hull's hot blood. This he did, as Plutarch mentions, to frec himself from the numerous ill dreams which continually tormented him. Midas, according to some, was son of Cybele. He built a town which he called Ancyræ.

MIDAS, Ear-shell. See HALIOTIS, CONCHOLOGY Index.

MID-HEAVEN, the point of the ecliptic that culminates, or in which it cuts the meridian.

MIDDLEBURG, one of the Friendly islands in the South sea. The island was first discovered by Tasman, a Dutch navigator, in January 1642-3; and is called by the natives Ea-Oo-whe: it is about 16 miles from north to south, and in the widest part about 8 miles from east to west. The skirts are chiefly laid out in plantations, the south-west and north-west sides especially. The interior parts are but little cultivated, though very capable of it : but this neglect adds greatly to the beauty of the island; for here are agreeably dispersed groves of coeoa-nuts and other trees, lawns covered with thick grass, here and there plantations and paths leading to every part of the island, in such beautiful disorder, as greatly to enliven the prospeet. The hills are low; the air is delightful; but unfortunately water is denied to this charming spot. Yams, with other roots, bananas, and bread fruit, are the principal articles of food; but the latter appeared to be scarce. Here is the pepper-tree, or ava ava, with which they make an intoxicating liquor, in the same disgusting manuer as is practised in the Society islands. Here are several odoriferous trees and shrubs, particularly a species of the lemon trihe; and the botanical gentlemen met with various new species of plants. Here also are a few hogs and fowls.

There are no towns or villages ; most of the houses are built in plantations, which are laid out in different parts, with no other order than what convenience requires. They are neatly constructed, but are less roomy and convenient than those in the Society isles. The floors are a little raised, and covered with thick strong mats. The same sort of matting serves to enclose them on the windward side, the others being open. They have little areas before most of them, which are planted round with trees or ornamental shrubs, whose fragrance perfumes the air. Their household furniture consists of a few wooden platters, cocoa-nut shells, and pillows made of wood, and shaped like four-footed stools or forms : their common clothing, with the addition of a mat, serves them for bedding.

The natives are of a clear mahogany or chesnut brown, with black hair, in short frizzled curls, which seems to be burnt at the tips; their beards are cut or

shaven. The general stature of the men is equal to Middleour middle size, from five feet three to five feet ten inches; the proportions of the body are very fine, and the contours of the limbs extremely elegant, though something more muscular than at Otaheite, which may be owing to a greater and more constant exertion of strength in their agriculture and domestic economy. Their features are extremely mild and pleasing; and differ from the old Otaheitan faces in being more oblong than round, the nose sharper, and the lips rather thinner. The women are, in general, a few inches shorter than the men, but not so small as the lower elass of women at the Society islands. The practice of puneturing the skin, and blacking it, which is called tattowing, is in full force among the men here, for their belly and loins are very strongly marked in configurations more compounded than those at Otaheite. The tenderest parts of the body were not free from these punctures; the application of which, besides being very painful, must be extremely dangerous on glandulous extremities.

The men in general go almost naked, having only a-small piece of eloth round the loins, but some wrap it in great abundance round them from their waist : this cloth is manufactured much like that at Otaheite, but overspread with a strong glue, which makes it stiff, and fit to resist the wet. The women are likewise covered from the waist downwards : they often have loose necklaces, consisting of several strings of small shells, seeds, teeth of fishes; and in the middle of all, the round operculum, or cover of a shell as large as a crown-piece. The men frequently wear a string round their necks, from which a mother-of-pearl shell hangs down on the breast; both the ears of the women were perforated with two holes, and a cylinder cut out of tortoise-shell or bone was stuck through both the holes. The most remarkable circumstance observed of this people was, that most of them wanted the little finger on one, and sometimes on both hands : the difference of sex or age did not exempt them from this amputation; for even among the few children that were seen running about naked, the greater part had already suffered such loss. This circumstance was observed by Tasman. Another singularity which was observed to be very general among these people, was a round spot on each cheek-bone, which appeared to have been hurnt or hlistered. On some it seemed to have been recently made, on others it was covered with scurf, and many had only a slight mark of its former existence: how, or for what purpose it was made, could not be learnt. The women here, in general, were reserved; and turned, with disgust, from the immodest behaviour of ungovernable scamen : there were not, however, wanting some who appeared to be of easy virtue, and invited their lovers with lascivious gestures. The language spoken here is soft, and not unpleasing; and whatever they said was spoken in a kind of singing tone. Omai and Mahine, who were both passengers on board the ship, at first declared that the language was totally new and unintelligible to them; however the affinity of several words being pointed out, they soon canght the particular modification of this dialect, and conversed much better withthe natives than any on board the ships could have done, after a long intercourse. They have the neatesta

Middleburg, Middleham. est ornaments imaginable, consisting of a number of little flat sticks, about five inches long, of a yellow wood like box, firmly and elegantly connected together at the bottom by a tissue of the fibres of cocoanut, some of which were of their natural colour, and others dyed black ; the same fibres were likewisc used in the making of baskets, the taste of which was highly elegant, and varied into different forms and patterns. Their clubs are of a great variety of shapes, and many of them so ponderous as scarcely to be managed with one hand. The most common form was quadrangular, so as to make a rhomboid at the broad end, and gradually tapering into a round handle at the other. Far the greater part were carved all over in many chequered patterns, which seemed to have required a long space of time, and incredible patience, to work up; as a sharp stone, or a piece of coral, are the only tools made use of: the whole surface of the plain clubs was as highly polished as if an European workman had made them with the best instruments: Besides clubs, they have spears of the same wood, which were sometimes plain sharp-pointed sticks, and sometimes barbed with a sting-ray's tail. They have likewise bows and arrows of a peculiar construction; the bow, which is six feet long, is about the thickness of a little finger, and when slaek, forms a slight curve; its convex part is channelled with a single deep groove, in which the bow-string is lodged. The arrow is made of reed, near six feet long, and pointed with hard wood : when the bow is to be bent, instead of drawing it so as to increase the natural curvature, they draw it the contrary way, make it perfectly straight, and then form the curve on the other side. Most of their canoes have outriggers, made of poles; and their workmanship is very admirable : two of these canoes are joined together with a surprising exactness, and the whole surface receives a very curious polish. Their paddles have short broad blades, something like those at Otaheite, but more neatly wrought and of better wood.

They keep their dead above ground, after the manner of the Society islands; as a corpsc was seen deposited on a low hut.

Here were seen several men and women afflicted with leprous diseases, in some of whom the disorder had risen to a high degree of virulence: one man in particular had his back and shoulders covered with a large cancerous ulcer, which was perfectly livid within, and of a bright yellow all round the edges. A woman was likewise unfortunate enough to have her face destroyed by it in the most shocking manner; there was only a hole left in the place of her nose; her cheek was swelled up, and continually oozing out a purulent matter: and her eyes seemed ready to fall out of her head, being bloody and sore. Though these were some of the most miserable objects that could possibly be seen, yet they scencd to be quite unconcerned about their misfortunes, and traded as briskly as any of the rest.

MIDDLEHAM, a town in the north riding of Yorkshire, situated on the river Ure, 255 miles from London. It had once a castle, where was born Edward prince of Wales, only son of Richard III; and is noted for a woollen manufactory and frequent horseraces. Its market is on Monday; and fairs Nov. 6. and 7. The town stands on a rising ground; and the

castle was formerly moated round by the help of a Middlespring conveyed in pipes from the higher grounds. The ham population in 1811 was 714.

MIDDLESEX, a county of England, which de-Middlete rives its name from its situation amidst the three kingdoms of the East, West, and South Saxons. It is bounded on the north by Hertfordshire; on the south by the river Thames, which divides it from Surry; on the west by the river Colne, which separates it from Buckinghamshire; and on the east by the river Lea, which divides it from Essex. It extends about 23 miles in length, but hardly 14 in breadth, and is not more than 115 in circumference; but as it comprehends the two vast cities of London and Westminster, which are situated in the south-east part of the county, it is by far the wealthicst and most populous county in England. It is divided into 602 liberties, containing 200 parishes, besides a vast number of chapels of ease, and 5 market towns, exclusive of the citics of London and Westminister. The air is very pleasant and healthy. The soil, which is gravelly, produces plenty of eorn, and the county abounds with fertile meadows and gardeners grounds. In a word, the greater part of the county is so prodigiously assisted by the rich compost from London, that the whole of the cultivated part may be considered as a garden. The natural productions are cattle, corn, and fruit; but its manufactures are too many to be enumerated here, there being hardly a single manufacture practised in Great Britain but what is also established in this county .- Though London is the chief city, Brentford is the county town where the members of parliament are elected. In 1811 it contained 126,269 houses, and 904,358 inhabitants in towns, and 8670 houses, and 48,918 inhabitants in the country, making altogether 953,276 inhabitants. See MIDDLESEX, SUPPLEMENT.

MIDDLESEX is also the name of four different counties in the United States of America; one of them is in Massachussets, another in Connecticut, a third in New Jersey, and the fourth in Virginia.

MIDDLETON, DR CONYERS, a very celebrated English divine, the son of a clergyman in Yorkshire, was born at Richmond in 1683. He distinguished himself, while fellow of Trinity college, Cambridge, by his controversy with Dr Bentley his master, relating to some mercenary conduct of the latter in that station. He afterwards had a controversy with the whole body of physicians on the dignity of the medical profession ; concerning which he published De medicorum apud veteres Romanos degentium conditione dissertatio; qua, contra viros celeberrimos Jacobum Sponium et Richardum Meadium, servilem atque ignobilem cam fuisse ostenditur: and in the course of this dispute much resentment and many pamphlets appeared. Hitherto he had . stood well with his clerical brethren; but he drew the resentment of the church on him in 1729, by writing "A Letter from Rome, showing an exact conformity between Popery and Paganism," &c.; as this letter, though politely written, yet attacked Popishmiracles with a gaiety that appeared dangerous to the cause of miracles in general. Nor were his Objections to Dr Waterland's manner of vindicating Seripture against Tindal's " Christianity as old as the Creation," looked on in a more favourable point of view. In 1741, came out his great work, " The history of the life of M. Tullius Cicero,"

3

Midship-

frame.

Midshipman.

Middleton Cicero," 2 vols 4to : which is indeed a fine performance, and will probably be read as long as taste and polite literature subsist among us: the author has nevertheless fallen into the common error of biographers, who often give panegyrics instead of history. In 1748, he published, " A free inquiry into the miraculous powers which are supposed to have subsisted in the Christian church from the earliest ages, through several successive centuries." He was now attacked from all quarters; but before he took any notice of his antagonists, he supplied them with another subject, in " An examination of the Lord Bishop of London's discourses concerning the use and extent of prophecy," &c. Thus Dr Middleton continued to display talents and learning, which are highly esteemed by men of a free turn of mind, but by no means in a method calculated to invite promotion in the clerical line. He was in 1723 chosen principal librarian of the public library at Cambridge; and if he rose not to dignities in the church, he was in easy circumstances, which permitted him to assert a dignity of mind often forgotten in the career of preferment. He died in 1750, at Hildersham in Cambridgeshire, an estate of his own purchasing; and in 1752, all his works, except the life of Cicero, were collected in 4 vols 4to.

MIDDLEWICH, a town of Cheshire, 167 miles from London. It stands near the conflux of the Croke and Dan, where are two salt water springs, from which are made great quantities of salt, the brine being said to be so strong as to produce a full fourth part salt. It is an ancient borough, governed by burgesses; and its parish extends into many adjacent townships. It has a spacious church. By means of inland navigation, it has communication with the rivers Mersey, Dee, Ribble, Ouse, Trent, Darwent, Severn, Humber, Thames, Avon, &c.; which navigation, including its windings, extends above 500 miles, in the counties of Lincoln, Nottingham, York, Lancaster, Westmoreland, Stafford, Warwick, Leicester, Oxford, Worcester, &c. The river Wheelock, after a course of about 12 miles from Mowcop-hill, runs into the Dan a little above this town. Its population in 1811 was 1232.

MIDHURST, a town of Sussex, 52 miles from London, has been represented in parliament ever since the 4th of Edward II. It is a neat small town, on a hill surrounded with others, having the river Arun at the bottom; and is a borough by prescription, governed by a bailiff, chosen annually by a jury at a courtleet of the lord of the manor.

MIDIAN, or MADIAN, in Ancient Geography, a town on the south side of Arabia Petræa, so called from one of the sons of Abraham by Keturah .- Another Midian, near the Arnon and Æoplis, in ruins in Jerome's time. With the daughters of these Midianites the Israelites committed fornication, and were guilty of idolatry. A branch of the Midianites dwelt on the Arabian gulf, and were called Kenites : some of whom turned proselytes, and dwelt with the Israelites in the land of Canaan.

MID-LOTHIAN. See LOTHIAN and EDINBURGH-SHIRE.

MIDSHIP-FRAME, a name given to that timber, or combination of pieces formed into one timber, which determines the extreme breadth of the ship, VOL. XIV. Part I.

timbers. In the article SHIP-Building, the reader will find a full explanation of what is meant by a frame of timbers. He will also perceive the outlines of all the principal frames, with their gradual dimensions, from the midship-frame, delineated in the plane of projection annexed to that article.

MIDSHIPMAN, a sort of naval cadet, appointed by the captain of a ship of war, to second the orders of the superior officers, and assist in the necessary business of the vessel, either aboard or ashore.

The number of midshipmen, like that of several other officers, is always in proportion to the size of the ship to which they belong. Thus a first-rate man of war has 24, and the inferior rates a suitable number in proportion. No person can be appointed lieutenant without having previously served two years in the royal navy in this capacity, or in that of mate, besides having been at least four years in actual service at sea, cither in merchant ships or in the royal navy.

Midshipman is accordingly the station in which a young volunteer is trained in the several exercises necessary to attain a sufficient knowledge of the machinery, movements, and military operations of a ship, to qualify him for a sea officer.

On his first entrance in a ship of war, every midshipman has several disadvantageous circumstances to encounter. These are partly occasioned by the nature of the sea service; and partly by the mistaken prejudices of people in general respecting naval discipline, and the genius of sailors and their officers. No character, in their opinion, is more excellent than that of the common sailor, whom they generally suppose to be treated with great severity by his officers, drawing a comparison between them not very advantageous to the latter. The midshipman usually comes aboard tinctured with these prejudices, especially if his education has been amongst the higher rank of people; and if the officers happen to answer his opinion, he conceives an early disgust to the service, from a very partial and incompetent view of its operations. Blinded by these prepossessions, he is thrown off his guard, and very soon surprised to find, amongst those honest sailors, a crew of abandoned miscreants, ripe for any mischief or villany. Perhaps, after a little observation, many of them will appear to him equally destitute of gratitude, shame, or justice, and only deterred from the commission of any crimes by the terror of severe punishment. He will discover, that the pernicious example of a few of the vilest in a ship of war is too often apt to poison the principles of the greatest numbcr, especially if the reins of discipline are too much relaxed, so as to foster that idleness and dissipation, which engender sloth, diseases, and an utter profligacy of manners. If the midshipman on many occasions is obliged to mix with these, particularly in the exercises of extending or reducing the sails in the tops, he ought resolutely to guard against this contagion, with which the morals of his inferiors may be infected. He should, however, avail himself of their knowledge, and acquire their expertness in managing and fixing the sails and rigging, and never suffer himself to be excelled by an inferior. He will probably find a virtue in almost every

man.

2

Midship every private sailor, which is entirely unknown to many of his officers: that virtue is emulation, which is not indeed mentioned amongst their qualities by the gentlemen of terra firma, by whom their characters are often copiously described with very little judgment. There is hardly a common tar who is not envious of superior skill in his fellows, and jealous on all occasions to be outdone in what he considers as a branch of his duty: nor is he more afraid of the dreadful consequences of whistling in a storm, than of being stigmatized with the opprobrious epithet of lubber. Fortified against this scandal, by a thorough knowledge of his business, the sailor will sometimes sneer in private at the execution of orders which to him appear awkward, improper, or unlike a seaman. Nay, he will perhaps be malicious enough to suppress his own judgment, and, by a punctual obedience to command, execute whatever is to be performed in a manner which he knows to be improper, in order to expose the person commanding to disgrace and ridicule. Little skilled in the method of the schools, he considers the officer who cons his lesson by rote as very ill qualified for his station, because particular situations might render it necessary for the said officer to assist at putting his own orders in practice. An ignorance in this practical knowledge will therefore necessarily be thought an unpardonable deficiency by those who are to follow his directions. Hence the midshipman who associates with these sailors in the tops, till he has acquired a competent skill in the service of extending or reducing the sails, &c. will be often entertained with a number of scurrilous jests, at the expence of his superiors. Hence also he will learn, that a timely application to those exercises can only prevent him from appearing in the same despicable point of view, which must certainly be a cruel mortification to a man of the smallest sensibility.

If the midshipman is not employed in these services, which are undoubtedly necessary to give him a clearer idea of the different parts of his occupation, a variety of other objects present themselves to his attention. Without presuming to dictate the studies which are most essential to his improvement, we could wish to recommend such as are most suitable to the bent of his inclination. Astronomy, geometry, and mechanics, which are in the first rank of science, are the mate-

rials which form the skilful pilot and the superior ma- Midshipriner. The theory of navigation is entirely derived from the two former, and all the machinery and move- Midwife, ments of a ship are founded upon the latter. The action of the wind upon the sails, and the resistance of the water at the stem, naturally dictate an inquiry into the property of solids and fluids; and the state of the ship, floating on the water, seems to direct his application to the study of hydrostatics, and the effects of gravity. A proficiency in these branches of science will equally enlarge his views, with regard to the operations of naval war, as directed by the efforts of powder and the knowledge of projectiles. The most effectual method to excite his application to those studies, is, perhaps, by looking round the navy, to observe the characters of individuals. By this inquiry he will probably discover, that the officer who is eminently skilled in the sciences, will command universal respect and approbation ; and that whoever is satisfied with the despicable ambition of shining the hero of an assembly, will be the object of universal contempt. The attention of the former will be engaged in those studies which are highly useful to himself in particular, and to the service in general. The employment of the latter is to acquire those superficial accomplishments that unbend the mind from every useful science, emasculate the judgment, and render the hero infinitely more dexterous at falling into his station in the dance than in the line of battle.

Unless the midshipman has an unconquerable aversion to the acquisition of those qualifications which are so essential to his improvement, he will very rarely want opportunities of making a progress therein. Every step he advances in those meritorious employments will facilitate his accession to the next in order. If the dunces, who are his officers or messmates, arc rattling the dice, roaring bad verses, hissing on the flute, or scraping discord from the fiddle, his attention to more noble studies will sweeten the hours of relaxation. He should recollect, that no example from fools ought to influence his conduct, or seduce him from that laudable ambition which his honour and advantage are equally concerned to pursue.

MIDWIFE, one whose profession is to deliver women in labour. Sce MIDWIFERY.

MIDWIFERY,

Definition. THE art of assisting women in labour. In a more extended sense, it is understood to comprehend also the treatment of the diseases of women and children. In this work we shall consider it in the former limited sense, viz. as relating to the birth of the offspring of man.

> History of Midwifery .- It must be very obvious that this art must have been almost coeval with mankind: but in Europe it continued in a very rude state till the" 17th century; and even after physic and surgery had become distinct professions, it remained almost totally uncultivated.

It is a curious fact, that in the empire of China the very reverse of this has taken place. In that empirc, according to the latest accounts, both physic and surgery are still in a state of the utmost degradation, even more so than among the savages of America; but for some hundred years, the art of midwifery has been practised by a set of men destined to the purpose by order of government. These men, who hold in society the same rank which lithotomists did in this country about the beginning of last century, are called in whenever a woman has been above a certain number of hours in labour, and employ a mechanical contrivance for

3

X

History. for completing the delivery without injury to the infant. A certain number of such individuals is allotted to each district of a certain population.

It is said, that the Chinese government was led to make this provision for alleviating the sufferings of child-bearing women, in consequence of a representation, that annually many women died undelivered, and that in the majority of cases the cause of obstruction might have been removed by very simple mechanical expedients.

Both Sir George Staunton and Mr Barrow were ignorant of this fact; and the latter in particular expressly mentions, that there are no men-midwives in China. But the writer of this article had his information from a more authentic source than the works of gentlemen who were only a few months in that country, and were in a great measure treated as state prisoners. He has it, through the medium of a friend, from a gentleman who resided upwards of twenty years as surgeon to the British factory at Canton, and who had both the ability and the inclination to learn, during the course of so long a residence, all the customs and prejudices of the natives relating to the preservation of human health.

Towards the end of the 17th century, the same causes which had so long before led to the cultivation of midwifery in China produced the same effect in Europe. The dangers to which women are sometimes exposed during labour excited the compassion of the benevolent; so that a considerable part of the first hospital which was established for the reception of the indigent sick, the Hotel Dieu of Paris was appropriated to lying-in women.

The opportunities of practice which that hospital afforded, directed the attention of medical men to the numerous accidents which happen during labour, and to the various diseases which occur after delivery. Public teaching followed, and soon after the custom of employing men in the practice of midwifery began.

From this period the art became rapidly improved; and it is now in many parts of Europe, and particularly in Great Britain, in as great a state of perfection as physic or surgery.

In the year 1725, a professorship of midwifery was established in the university of Edinburgh; and the town-council at the same time ordained, that no woman should be allowed to practise midwifery within the liberties of the city, without having previously obtained a certificate from the professor of her being properly qualified. This salutary regulation has fallen into desuetude.

There can be no doubt that the improvement of the art of midwifery was chiefly in consequence of medical men directing their attention to the subject; but the propriety of men being employed in such a profession is much questioned by many individuals of considerable respectability.

Dr John Gregory, in his Comparative View, p. 22. says, " every other animal brings forth its young without any assistance, but we think a midwife understands it better." Had this eminent philosopher said, "other animals content themselves with the clothing which providence has bestowed, but we think it necessary to cover our bodies with the workmanship of weavers," very few in this northern climate would have attended

to the sneer. His son, the present professor, has im- or proved upon the idea. He seems to suppose that women Conception. without any instruction, and of course without any knowledge of the subject, are capable of assisting one another while in labour; and in the sportiveness of his lively imagination, he compares men-midwives to that species of frog, in which, according to the allegation of Reaumur, the male draws out the ova from the female, or, to use the naturalist's words, " accouche la femelle."

It appears to us that this question, on which much declamation has been employed by the parties who have agitated it, may be brought within a very narrow compass. It may be assumed as a fact established beyond the reach of controversy, that sometimes dangers and difficulties occur during labour (from causes to be explained in a subsequent part of this essay), which can be lessened or removed by those only who have an intimate knowledge of the structure of the human body and of the practice of physic. On such occasions, it must be admitted, medical men alone can be useful. But as such labours occur only in the proportion of two or three in the hundred, the general practice might be confided to midwives, if they could be taught to manage ordinary cases, and to foresee and distinguish difficulties or dangers, so as to procure in sufficient time additional assistance. It is on this point that the decision of the question must depend. It consists with the knowledge of the writer of this article, that women may be taught all this. But there are many who allege, that a little knowledge being a dangerous thing, midwives acquire a self-sufficiency which renders them averse from calling in superior assistance, and that, in consequence, they often occasion the most deplorable accidents both to mother and child. In England this is the popular opinion, so that there women are almost entircly excluded from the practice of midwifery. A similar prejudice against midwives has, it is believed, begun in some parts of Scotland; but it is presumed this will gradually cease, when it is considered that, in general, the Scotch midwives are regularly instructed, and are at the same time both virtuous and industrious. If they attend strictly to their duty, and invariably prefer their patients safety to their own feelings or supposed interest, they will deservedly retain the public confidence. But if in cases of difficulty or danger they trust to their own exertions, or from disinterested motives decline the assistance of able practitioners, and if they interfere in the treatment of the diseases of women and children, they will in a few years be excluded from practice.

Division of the subject. In order to exhibit an accurate view of what relates to the birth of man, we shall consider, in the first place, conception; secondly, the effects of impregnation ; thirdly, the act of childbearing; and lastly, the deviations from the ordinary course which sometimes happen. These topics will form the subjects of the following chapters.

CHAP. I. Of Conception.

THREE circumstances are required for conception in the human race, viz. puberty ; a healthy, vigorous, and natural state of the parts subservient to the operation in both sexes; and successful sexual intercourse.

8

1. The age of puberty in women differs considerably 111 Of Con- in different elimates. In Europe it takes place commonly between the fourteenth and sixteenth year. This ception.

important era is marked by certain changes both in the mind and body. The girl feels sensations to which she had been formerly unaccustomed. She loses a relish for her former amusements, and even for her youthful companions. She seeks solitude, indulges in the depressing passions, and these are excited by the most apparently triffing causes. She feels occasionally certain desires which modesty represses; and it is by degrees only that she regains her former tranquillity.

The changes in her body are even more strongly marked than those in her mind. Her breasts assume that form which adds to the beauty of her person, and renders them fit for nourishing her infant; and every part of the genital system is enlarged. A periodical discharge from the uterus renders the woman perfect.

In young men the same causes produce very different effects. The lad, about fifteen or sixteen, fcels a great increase of strength; his features expand, his voice becomes rough, his step firm, his body athletic; and he engages voluntarily in exercises which require an exertion of strength and activity. The changes in his mind are as strongly marked as those in his body. He loses that restless puerility which had distinguished his early years, and becomes capable of attending steadily to one object. His behaviour to the fair sex is suddenly altered. He no longer shows that contempt for women, which he had formerly betrayed. He is softened, approaches them with deference, and experiences a degree of pleasure in their company, for which he can scarcely account. In him too there is an important change in the condition of the genital organs.

2. Unless the parts which constitute peculiarity of sex be in a healthy, vigorous, and natural state, conception cannot take place.

In women, conception is prevented if the organs be too much relaxed; if there be obstruction between the external and internal parts; if any preternatural discharge take place from the internal parts; if the menstrual evacuation be not natural in every respect, and if the appendages of the uterus, called fallopian tubes, and ovaria, be not of the natural structure.

In men, the same circumstance happens if the organs be too much relaxed; if the orifice of the urethra be in an improper situation; if the urethra be diseased; if the testes he not in a natural healthy state; and if there be any defect in the erectores penis, which prevents the proper erection of that organ.

3. The sexual intercourse cannot be successful unless somewhat necessary for conception be furnished by both sexes. This consists in the male of a fluid secreted by the testes; and in the female, of a detachment of a substance, supposed to resemble a very minute vesicle situated in the ovarium, and called by physiologists ovum. Each ovarium contains a number of these vesicles. After every conception, certain marks of the detachment of the ovum remain in the respective ovarium.

When the circumstances required for conception concur, a being is produced which generally resembles both parents. This resemblance is most strikingly marked in the human subject, when one of the parents.

3

is an European, and the other an African. What is Of Conception. called a mulatto is produced.

The human race possesses the power of propagation in common with all the other species of the animal kingdom, and also, it has been said, with the vegetable kingdom.

As generation then, as it has been styled, is common to two of the kingdoms of nature, it has been imagined by ingenious men, that this wonderful operation is regulated in both by a certain general law. But they have differed much in their account of this law. The question at issue between the two parties is whether the embryos of animals be prepared by the sexual intercourse out of inorganic materials, or whether they pre-exist in the bodies of animals, and are only developed as it were by that intercourse. The former of these opinions is called the doctrine of epigencsis, the latter that of evolution.

Both doctrines have been maintained with much ingenuity by equally respectable authorities. Negative arguments have been adduced in favour of the one, positive in support of the other, and it must be confessed that the balance between them seems nearly equal. The prc-existence of ova in the oviparous animals appears a positive argument in favour of evolution; but the satirical remark of a late witty author, * that, were * Bhumenthis theory true, every individual of the human race bach. must have been lodged in the ovaria of our first parent, by affording a negative argument in favour of epigenesis, restorcs the balance.

The various arguments advanced on each side by the opposite parties in this dispute are so very numerous, that we cannot attempt to detail them in this work; and on a subject which has divided the opinions of so many able physiologists, it would be presumption to decide peremptorily.

If generation be regarded as an animal operation, one is led to inquire whether the product be the result of the combined influence of both sexes, or whether it be produced by either sex alone.

The first opinion was generally adopted by physiologists, till about the end of the 17th century, when an accidental discovery convinced many that the embryo was produced by the male parent alone; and another discovery some years afterwards again overturned that opinion, and rendered it believed by not a few that the embryo is furnished exclusively by the female parént.

Several circumstances concurred to render the first opinion probable; the structure of the organs which constitute peculiarity of sex in both parents, the circumstances necessary for successful impregnation, and the similitude of children to both parents, appear very strong arguments in its favour.

The second theory, although first brought into vogue about the end of the 17th century by the discoveries of Leeuwenhoeck, had been formerly proposed by the followers of Pythagoras. Their argument was analogy: the seed, said they, is sown in the earth, nourished and evolved there; so the male semen is sown in the uterus, and in the same manner nourished and evolved.

Leeuwenhoeck's discovery seemed a more conclusive argument in favour of the theory than vague analogy.

of Conception. He observed innumerable, animalcula in the seminal fluid of the males of many animals. These he imagined to be embryos.

> But as animalcula of apparently the same nature have been observed in many animal fluids besides the semen masculinum, the opinion of Leeuwenhoeck and the theory itself are overturned.

It was owing principally to the labours, industry, and ingennity of Baron Haller, that the third theory, that of the pre-existing germ, became fashionable.

His observations seem to contain a demonstration of the fact.

Those who have adopted this theory, imagine that the semen masculinum possesses the power of stimulating the various parts of the prc-existing embryo. And hence they attribute the similitude to both parents, and particularly the appearance of the hybrid productions, to that fluid nourishing certain parts, and new-arranging others. But if this worc true, then the somen masculinum of all animals should possess the power of stimulating the germs of all female animals; and besides, in each class of animals it should possess certain specific powers of giving a direction to the growth of parts. Experience, however, has not proved this to be the case, for the hybrid productions are very limited; and we may be permitted perhaps, without the imputation of arrogance in pretending to search into the intentions of the Author of nature, to observe, that had the somen masculinum been possessed of such powers, the whole species of animals would have been soon confounded, and the whole animal kingdom would soon have returned to that chaos from which it has been allegorically said it originated.

Yet we are reduced to the alternative of either rejecting the theory, or of believing that the semen does possess the powers alluded to. If we examine attentively the anatomical discovery on which this theory is built, we shall perhaps be inclined to believe that the foundation of the whole is very insufficient; and hence to conclude that the great superstructure is in a very tottering condition. If it be possible that the attachment of the chick to the yolk of the egg should be in consequence of inosculation, the theory must fall to the ground. Haller has endeavoured to obviate this objection, but not with his usual judgment.

Two circumstances, however, seem to show that the attachment is really by inosculation: 1. That vessels are seen in the membrane of the yolk evidently containing blood before the heart of the chick begins to beat; yet these vessels afterwards appear to depend on the vascular system of the chick. And, 2. That in many animals, as in the human subject, the umbilical cord seems to be attached to the abdomen by inosculation; for there is a circle round the root of the cord which resembles a cicatrix, and within a few days after birth, the cord uniformly drops off at that very circle, whatever portion may have been retained after delivery.

There is one objection equally applicable to all the three theories, viz. the difficulty of explaining the steps of the process. A variety of explanations have been offered by ingenious men. Spallanzani and Mr John Hunter lately, Haller and Bonnet formerly, have rendered themselves conspicuous on this subject. Spallanzani, in particular, appears to many to have produced, by his artificial impregnation, the most convincing Effects of proofs of the pre-existence of the germ. But to what Impregnado his celebrated experiments amount? They show, that in all animals it is necessary that the semen masculinum should be applied to the somewhat expelled by the female during the coitus, otherwise impregnation cannot take place. But was not this universally acknowledged before the abbé was born? In the unfortunate frogs who were the subjects of his experiments, the whole operation of generation was completed except the application of the male semen to the substances expelled by the female. Nature, by establishing that the business should be carried on in water, shows that the semen must be diluted, otherwise it cannot fecundate. The abbé only imitated nature. He left the question in the state in which he found it. His experiment on the bitch may appear more conclusive; hut alas! it has never succeeded with any person but himself.

On the whole, since the process of generation is so obscure that no rational explanation of it has yet been offered, are we not entitled to conclude that the general theory which accounts most satisfactorily for the various phenomena which impregnation exhibits is the best; and consequently, that the product of generation cannot pre-exist in the body of either parent exclusively?

CHAP. II. Effects of Impregnation.

In consequence of impregnation, certain important changes take place in the utcrine system of the human subject. We shall consider the natural changes only. On some occasions, there are morbid changes; but we shall not notice them, except in so far as some of them serve to illustrate the nature of the usual ones.

The first visible change is on the ovarium. One of those organs swells out at one point like a small papilla, then bursts, and somewhat is discharged.

A substance is found in the ovarium after this, which 19 is called corpus luteum. Recederer has described very accurately its appearance a few hours after delivery. He says " corpus luteum locatur in rotundo apice. Totam ovarii crassitiem occupat, immediate ponc ovarii membranam illa sede tenuiorem locatum; ab ovario cum quo cellulosæ ope cohæret separari sine læsione potest; nulli peculiari ovarii rimæ respondet: neque canalis in illo excavatus, sed totum solidum est. Luteus color est, substantia acinosa, acinis admodum compactis et ad sese pressis ambitus rotundus. Potest aliquo modo, velut in glandulis suprarenalihus, duplex substantia distingui, corticalis et medullaris; quarum illa inæqualis crassitiei 1-2 lin. lutea comprehendit hanc' medullarem albam, quæ tenuis et membrana quasi callosa, alium nucleum flavum includit cassioreni *." It is very * Roederer large soon after conception, and then gradually be- Icones, comes smaller; but never totally disappears. Rederer Uteri Hu-mani obobserves, " post pucrperium eo magis contrahi et indu-servat. ilrari illa corpora videntur, quo remotior fit partus ; lust. p. 42 qualia videlicet observantur in feminis quæ nuper partum non ediderunt.

"Lutea corpora quo serius à partu observantur cuncta glandulis suprarenalibus similia esse videntur, duplice nempe substantia, exteriore corticali, solida scu flava lutea et nucleo fusco: velut ctiam illæ glandulæ compressa sunt †." In cases where there is a plurality of [†] *Ibid.* children, 45

Effects of children, there is evidently a corpus luteum to each Impregua- child. In some quadrupeds, as in the bitch or eat, the tion. number of young in the nterus may be generally known

by the corresponding corpora lutea in the ovaria.

The next change in the human uterine system which deserves notice is that in the fallopian tubes. They swell out towards the fimbriated extremity, and form a cavity which has been called antrum. Reederer was the first who observed and accurately delineated this change.

He says, p. 14. loco citato, "In hoc ctiam ntero antrum tubæ dextræ apparet, c. f. tab. i. not. 5. ubi quidem in utraque tuba adest, in hujus iconis utero ad solam tubam dextram antrum pertinet. Ad uterum feminæ octiduum puerperæ non longe a fimbria in istiusmodi antrum tuba sinistra prominet : dextra quidem sine antro est, sed versus fimbriam ita flectitur ut ultima flexura dimidium pollicem ultra reliquam tubam efferatur. Tubæ feminæ quæ mox a maturo partu mortua est, et alterins tres dies puerperæ antris quidem carent, sed multum versus simbrias dilatantur. An est facta conceptione ista antra nascuntur?

"In uteri, tab. iv. ovario dextro lutcum corpus latet in uteri feminæ octiduum puerperæ ovario sinistro; in uteri, tab. i. ovario sinistro." He adds, "ulteriori indagine ista antra non indigna csse mihi videntur. Liccbit forsan conjectare aliquid liquoris ex vesicnla graafiana in tubam lapsum et ad introitum morans illam dilatam."

But the most astonishing changes are those produced in the uterus itself. Its parietes scparate, a cavity is formed which becomes filled with a fluid, and the os uteri is closed up. The matter contained within the cavity soon assumes an organized form. It is said that some time after conception, a small vesicle is observed attached at one point to the internal surface of the uterus; that the rest of the parietes is covered with a gelatinous fluid; and that the whole internal surface assumes a flocculent appearance. By degrees the vesicle, which is in fact the ovum containing the embryo, increases so much in size that it nearly fills the whole cavity in which it is contained, and then its structure becomes the object of our senses.

The increase of size in the uterus is very gradual. It is at first confined almost entirely to the fundus, and it proceeds so slowly that it does not leave the cavity of the pelvis till nearly the fourth month. The principal change in the cervix for the first five months is the complete closure of the orifice, which is effected by a gelatinous fluid : afterwards the cervix is gradually extended, and at last its form is obliterated, the whole uterus becoming like an oval pouch.

After the fifth month the increase of size in the uterus is very rapid. The fundus can be just felt above the pubes about the fifth month, but at the end of the ninth month it extends to the scrobiculus cordis.

Some authors have alleged that the changes in the cervix and in the situation of the fundus are so uniformly regular in every case, that by attending to them it is possible to ascertain the exact period of impregnation. But in this respect they are much mistaken; the changes being not only different in different women, but also in the same woman in different pregnancies.

The texture of the parietes of the uterns seems much

altered after impregnation. It becomes spongy and Effects of fibrous. The fibres run in very different directions, and Impregnafrom their power and appearance are certainly muscular. The blood-vessels become much enlarged, but are

lar. The blood-vessels become much emarged, but are still in a tortuous direction. They are particularly large at one part of the uterus.

The lymphatic vessels, which in the unimpregnated uterus cannot be demonstrated by anatomists, become, as well as the blood-vessels, remarkably large.

The ovum is not often expelled entire till after the eighth or twelfth week after conception. It is shaped somewhat like an egg, and is about the latter period about four inches in length. When cut into, it is found to consist of four layers or membranes, and to contain a fectus surrounded by a certain quantity of water, and connected to one part of the parietes (which is considerably thicker than the rest) by a vascular cord.

The external membrane covers the whole ovum. It is thick, spongy, and very vascular, the vessels evidently deriving their blood from the uterus; it has three perforations which correspond with the openings of the os tincæ and fallopian tubes. It has been called *decidua*, *tunica filamentosa*, & c. but its most ordinary appellation is spongy chorion.

The second membrane proceeds from the edges of that part into which the vascular rope which connects the fectus is attached. It was first pointed out to anatomists by Dr William Hunter, and called by him decidua reflexa. The name unfortunately records to posterity the absurd idea respecting its origin which was entertained by Dr Hunter. It is not so thick and spongy as the former membrane, nor so vascular. It lies loosely between the external membrane and that to be next described; but it appears only for a short time, as it soon becomes blended with the others.

The third membrane is thin and transparent, but strong. It is lined with the fourth membrane, and lies in the same situation with it. It contains no vessels at this period of impregnation conveying red blood in the human subject, but in the cow the vessels are very distinct at every period. This membrane however in the early period of impregnation is very vascular, and its versels are derived from the focus. The history of a case of morbid impregnation, where the foctus was ex-tra-uterine, detailed by Dr Clarke in the "Transactions of a Society for the Improvement of Medical and Chirurgical Knowledge," proves this circumstance very clearly. He says, p. 220. " a laceration was found to be in the fallopian tube about an inch and a half in length, each extremity of which was about an equal distance from the respective termination of the tube in the fimbriæ and in the uterus. The distension of the tube at this part was nearly of the size of a large walnut, forming a kind of pouch. More of the coagulated blood being removed from the lacerated part, the shaggy vessels of the chorion immediately appeared, interspersed with small coagula, and lying in contact with the internal surface of the pouch formed by the fallopian tube; these being separated, and the chorion divided, the amnios shewed itself, containing a foetus perfectly formed of above six or seven weeks growth," &c. This membrane is called the true chorion.

This membrane is cannot all chinner and more transparent

22

Chap. II.

28

Effects of parent than the former. It lines the whole internal mpregna- surface of the ovum, and together with the chorion is continued along the vascular cord which connects the ovum and fœtus. Between this membranc and the chorion, near the insertion of the vascular cord, a small white vesicle appears very distinct at this period; it was first described and delineated by Dr W. Hunter, and was called by him vesicula umbilicalis. At the full period of utero-gestation it is no longer visible, being then quite transparent.

> The foctus at this period is between two and three inches in length, and its external conformation is nearly complete.

> The fluid contained in the ovum is in such quantity as to prevent the fœtus from touching the parietes of the covering in which it is included. It is a clear watery fluid, of greater specific gravity than water, and of a saltish tastc. When examined chemically it is found not coagulable by heat or alcohol, and to contain a proportion of ammoniacal and sea salt. This fluid is called liquor amnii.

> The connection of the parts thus enumerated with the uterus cannot be explained, unless the appearance of the ovum at the full period of gestation be described.

> The ovum then consists of three membranes ; a spongy vascular substance called placenta, to which the fœtus is connected by a vascular rope, and the liquor amnii.

> The three membranes consist of the spongy chorion, the true chorion, and the amnios.

> The spongy chorion covers the whole. Its vessels are numerous, and they can be filled by throwing hot wax into the vessels of the uterus.

> The true chorion and amnios are in the same situation as in the early months, being continued along the navel-string. They are quite transparent, and contain no visible vessels of any description.

> The placenta is a large vascular spongy mass, of various forms in different cases, most generally approaching to a round one, placed on the outside of the true chorion, between it and the spongy chorion. Its external surface is lobulated; its internal or that towards the foctus is smooth, except from the rising of the blood-vessels.

> It is not attached to the uterus at any regular place, being sometimes at the cervix or side, but most generally about the fundus. On the one side it receives blood from the mother, and on the other from the child. Mr John Hunter was the first who clearly traced the insertion of the blood vessels in the uterus into the placenta. He describes it thus (D): "The late indefatigable Dr M'Kenzie, about the month of May 1754, when assistant to Dr Smellie, having procured the body of a pregnant woman who had died undelivercd at the full term, had injected both the veins and arteries with particular success; the veins being filled with yellow, the arteries with red.

> " Having opened the abdomen, and exposed the uterus, he made an incision into the forc part, quite through its substance, and came to somewhat having the appearance of an irregular mass of injected matter, which afterwards proved to be the placenta. This ap

pearance being new, he stopped, and greatly obliged Effects of me by desiring my attendance to examine the parts, in Impregnawhich there appeared something so uncommon.

"I first raised, with great care, part of the uterus from the irregular mass above mentioned; in doing which, I observed regular pieces of wax, passing obliquely between it and the uterus, which broke off, leaving part upon this mass ; and when they were attentively examined, towards the uterus, plainly appeared to be a continuation of the veins passing from it to this substance or placenta.

" I likewise perceived other vessels, about the size of a crow quill, passing in the same manner, although not so obliquely : these also broke upon separating the placenta and uterus, leaving a small portion on the surface of the placenta; and, on examination, they were discovered to be continuations of the arteries of the uterus. My next step was to trace these vessels into the substance of what appeared placenta, which I first attempted in a vcin; but that soon lost the regularity of a vessel, by terminating at once upon the surface of the placenta, in a very fine spongy substance, the interstices of which were filled with the yellow injected matter. This termination being new, I repeated the same kind of examination on other veins, which always led me to the same terminations, never entering the substance of the placenta in the form of a vessel. I next examined the arteries, and, tracing them in the same manner toward the placenta, found that they made a twist, or close spiral turn upon themselves, and then were lost on its surface. On a more attentive view, I perceived that they terminated in the same way as the veins; for opposite to the mouth of the artcry, the spongy substance of the placenta was readily observed, and was intermixed with the red injection.

"Upon cutting into the placenta, I discovered, in many places of its substance, yellow injection; in others red, and in many others these two colours mixed. This substance of the placenta, now filled with injection, had nothing of the vascular appearance, nor that of extravasation, but had a regularity in its form, which shewed it to be a natural cellular structure fitted for a reservoir for blood.

" In some of the vessels leading from the placenta to the uterus, I perceived that the red injection of the arterics (which had been first injected) had passed into them out of the substance of the placenta, mixing itself. with the yellow injection. I also observed, that the spongy chorion, called the decidua by Dr Hunter, was very vascular, its vessels coming from, and returning to, the uterus, being filled with the different coloured injections."

It appears then that the placenta has a cellular structure, which receives blood from the arteries of the mother, and that there are veins by which that blood is returned, so that not a drop passes into the foetus. Of this practitioners of midwifery have a very familiar proof. When the placenta is retained attached to the uterus, after the birth of the child, not a drop of blood passes from the umbilical cord, except what was contained in the ramifications of the fœtal vessels when the child

(D) Observations on certain parts of the Animal Oeconomy, by John Hunter, p. 127.

Effects of child was separated. Yet, if a small portion of the Impregna- edge of the placenta be detached, such a quantity of blood cscapes from the uterine vessels of the mother, as tion.

sometimes proves fatal to life: a circumstance which clearly shews that the blood is still conveyed into the cellular part of the placenta.

It has been said, that the placenta on ouc side receives blood from the foctus. In fact, the greatest part of the placenta seems to be made up of ramifications of the foetal vessels. The internal iliacs of the foetus are conveyed, through the vascular rope which connects the placenta and child, into the placenta : they then ramify into as many minute branches as the pulmonary arteries do in the lungs of the adult; they then terminate in various branches, which, uniting, form one large trunk that is conveyed along the vascular rope, and returns all the blood which had been distributed by the arteries.

As Mr Hunter remarks, " the arterics from the fœtus pass out to a considerable length, under the name of the umbilical cord ; and when they arrive at the placenta, ramify upon its surface, sending into its substance branches which pass through it, and divide into smaller and smaller, till at last they terminate in veins : these uniting, become larger and larger, and end in one which at last terminates in the proper circulation of the foctus. This course of vessels, and the blood's motion in them, is similar to the course of the vessels, and the motion of the blood, in other parts of the body*."

* J. Hunter, loc. cit. p. 135. 30

The foctus, at the full period, weighs from between 6 and 7, to between 10 and 11 pounds, and measures from 18 to 22 inches. It is placed within the ovum in such a manner as to occupy the least possible space. This position has been beautifully described by Harvey. " Infans in utero utplurimum reperitur, adductis ad abdomen genibus, flexis retrorsum cruribus, pedibus decussatis, manibusque ad caput sublatis, quarum alteram circa tempora vel auriculas, alteram ad genam detinet, ubi maculæ albæ, tanquam confricationis vestigia, in cute cernuntur : spina in orbem flectitur, caput ad genua incurvato collo propendet. Tali membrorum situ qualem in sommo per quietem quærimus t."

+ Harvey Exercit. de Partu. 31

The foctus is distinguished from the adult by a great many peculiarities in structure : these the limits of this work do not permit us to cnumerate. We shall therefore notice only one peculiarity, which distinguishes the foctus not only from the adult, but even from the natus, viz. the distribution of the blood through its body.

It is well known, that, in the adult and in the natus, all the blood of the body, brought by the two cavæ into the anterior auricle of the heart, and from that into the corresponding ventricle, is distributed by the pulmonary artery over the whole substance of the lungs, by means of the most minute ramifications ; from whence it is returned by the pulmonary veins into the posterior auricle, and being then sent into the posterior ventricle, is, by its action, transmitted to every part of the body, through the aorta and its ramifications.

But in the foctus the blood follows another course. All the blood of the foctus is returned from the placenta by the umbilical vein, which, penetrating the abdomen, passes between the lobes of the liver, and thence at right angles divides into two branches nearly, by one

of which, called ductus venosus, a considerable quantity Effects of of blood is carried into the vena cava; by the other the Impregna remainder of the blood is sent to the vena portarum; and, after having circulated through the liver, it too is brought by two short vencus trunks, the venæ cavæ hepaticæ, just above the diaphragm, into the vena cava. All the blood thus received into the vena cava, is carried to the anterior auricle ; but a part only is transmitted to the corresponding ventricle, for by a particular apparatus, a quantity is at once sent into the posterior or left auricle. Anatomists have differed in opinion concerning the apparatus by which this is accomplished. As there is a small oval hole of communication between the auricles of the fœtus, called foramen ovale, having a valve placed in such a manner as to prevent any fluid from passing from the left into the right, but to admit it from the right into the left, it has been generally imagined that the blood passed through that opening. But the simultaneous action of the auricles in the natus seemed to contradict this opinion. A discovery made by Dr Wolfe of Petersburgh appears to solve the riddle. He observed, that in the calf, before birth, the vena cava, at its entry into the heart, divides into two branches, by the one of which it sends blood to the right, and by the other to the left auricle. It is probable that a similar effect is produced in the human fœtus by a different structure.

Of the blood sent by the right ventricle into the pulmonary artery, a small quantity only is carried to the lungs; for near the point at which that artery is divided into the two branches that go into the lobes of the lungs, a large branch is sent off, which joining the aorta and pulmonary artery, carries a great proportion of the blood immediately into it. What is circulated through the lungs is conveyed by the pulmonary veins into the left auricle, &c.

All the blood thus received into the aorta is distributed through the several parts of the system, and a large part of it is sent out by the internal iliacs, which, passing out at the abdomen, constitute the umbilical arteries, and distribute the blood in the manner already mentioned over the placenta, from which it is returned by the veins .- The great difference then between the fectus and natus in the circulation of the blood, consists in the quantity distributed through the lungs.

To complete the description of the ovum at the full period of gestation, it only remains that we should say something on the vascular rope, which connects the placenta and fœtus, and on the liquor amnii.

This rope is called the funis umbilicalis. It terminates by one end at the placenta, and by the other at the centre of the abdomen of the foetus. Its length and thickness differ materially in different cases. It is longer in the human subject than in any other animal. It is found generally to be from eighteen to twenty-six inches in length, and in thickness about the size of the little finger. Externally it is formed of the chorion and amnios, together with cellular substance. Internally it is found to be composed of three blood-vessels, and a quantity of gelatinous matter. The vessels consist of two arteries and one vein: the vein being as large as both arteries united. These go in a spiral direction, and often form knots by their coils or twistings. A very small artery and vein are likewise perceived to go

18

Chap. II.

tion.

Effects of go along the cord between the two layers of chorion and Impregna- amnios, which cover it, into the vesicula umbilicalis. tion. These are called omphalo-mesenteric.

In quadrupeds, a canal, called urachus, is continued from the urinary bladder, along the umbilical cord, and communicates with a membrane, which, like this canal, does not exist in the human subject, called allantois. The urine of the young animal is collected in that membrane.

Some anatomists, as Albinus, have imagined, that the urachus and allantois do exist in the human subject. They were deceived by the appearance of the vesicula umbilicalis and omphalo-mensenteric vessels.

The liquor amnii is never in such proportion to the foctus in the latter, as in the early periods of pregnancy. It is less pure too at that period, being often polluted with the stools of the foctus. Except in this circumstance, its chemical qualitics are the same.

We shall now offer a few observations on the changes which have been described.

1. The cause of the increase of growth in the uterus is very obscure. The accession of fluids will account for the phenomenon; but a strong objection occurs against considering that as the cause, i. e. that the uterus increases to a certain degree in size, evcn although the direction of fluids be to another part, as where the foetus is extra-uterine. Bochmerus has marked this very accurately in a case of extra-uterine conception, which he has detailed (A). The development of its fibres seems to prove, that the increase of size depends on a certain energy of the utcrus itself; perhaps this may appear a very ambiguous mode of expression, yet we can offer no other explanation of this curious phenomenon.

2. The great bulk of the uterus during the latter months, sufficiently explains the cause of the various complaints which occur at that period. Van Doeveren has described this very accurately. He says, " uteri gravidi incrementum, adscensus è pelvis cavo, ct immanis expansio, innumcros excitat gravidarum morbos; primo quidem arctando abdomen, et mechanice comprimendo viscera quæ in co continentur, hepar, lienem, ventriculum, intestina, omentum, ncc minus partes iis vicinas, nempe, renes, urcteres, aortam, venam cavam, arterias et venas iliacas, nervosque è medulla spinali prodeuntes inferiores; accidit pectoris coarctatio, similesque effectus inde excitati in corde, pulmonibus vasisque majoribus; ex quibus multiplici modo circulatio, digestio, chylificatio et respiratio læduntur, inque tota corporis œconomia, ejusque functionibus ingentis, solent produci turbæ variaque vitia topica excitari, inter quæ, tensiones, spasmi, dolores, stupores, obturationes, obstructiones, inflammationes, congestiones, præ cæteris memorabiles sunt ; unde nascitur magna scries morborum abdominis, pectoris, ipsiusque capitis ; nec non artuum inferiorum VOL. XIV. Part I.

torpores, dolores, crampi, cedemata, erysipelata, varices, Effects of hæmorrhagiæ, ulcera, labiorum vulvæ inflationes, varia- Impregnaque vitia partium genitalium, et alia multa pro diversa partium compressarum aut distentarum actione, variis nominibus insignienda (B)."

3. The origin of the membrane, which appears about the third month, called by Dr Hunter membrana de. cidua reflexa, has afforded matter of dispute among physiologists. Dr Hunter imagined, that the decidua vera consisted of two layers, and that the ovum, envcloped in chorion and amnios, got somehow between these : but this is a very unsatisfactory opinion. The more probable opinion is, that the decidua vera and decidua reflexa are distinct membranes, although both formed in the same manner. If, as we have already stated, the uterus, soon after conception, be filled with a gelatinous fluid, and if the ovum bc in contact with that organ at one point only, then it is probable that the vessels of the internal surface of the uterus, by shooting into the fluid with which it is covered, will form one membrane, the decidua vera; while the vessels on the external surface of the chorion, will shoot into the fluid with which the ovum must have been covered in its descent, and form another membrane, the decidua reflexa.

In proof that both membranes are formed in this way, it may be observed, that where the foctus is extrautcrinc, the uterus is lined with the decidua vera, and there is no decidua reflexa.-Boehmer is the first who demonstrated this; and not Dr Hunter, as has been alleged. He says, " Quum vero uterus magnitudine gravido unius circiter mensis similis videretur, cundem posterius longitudinaliter, et superius transversaliter dissecuimus, inque ejus cavo, intuitu haud impregnati satis magno, nihil præter tenacem et flavescentem mucum, mollemque poroso-villosam et valvulosam quasi turgescentem membranam undique uteri parietes et tubas investentem, hinc inde inflammatam et crosam, structuram autem uteri satis compactam invenimus *."

* Boehmer 4. The formation of the placenta is a curious subject loc. cit. of inquiry. That it depends principally on the foetus, p. 27. 37 is proved by the appearances in extra-uterine conceptions. In the case of ventral conception, published by Mr Turnbull of London, this circumstance is very clearly pointed out (C).

38 5. The origin of the liquor amnii has been explained very differently by different physiologists. Some imagine that it is furnished by the mother; others by the child. Baron Haller adopts the former opinion. " Ergo (he says) ab utero est, et à matre, siquidem à fœtu esse non potest. Non ausim experimentum producere, in quo crocus, quam mater sumserat, liquorem amnii tinxit t." But if this were the case, How could + Halleri the liquor amnii exist when the foctus is extra uterine ? Physiolo-Yet it cannot be a secretion from the foctus itself, be-gie Elecause lib. xxix. G

Effects of cause it is in very large proportion when the foctus is Impregna- scarcely visible. From what source then does it pro-, cced ? Most probably from the coats of the amnios.

50

6. Since from the situation of the foetus it has no direct communication with the atmospheric air, two questions occur on the subject ; first, whether it be necessary that the foetus should receive the vivifying somewhat which the natus receives from the atmosphere. 2dly, If this be answered in the affirmative, by what means is this somewhat furnished ?

1. On looking into the works of Nature, we find that there is a class of animals placed in a similar situation with the foetus, viz. the locomotive fishes. These receive the vivifying somewhat furnished by the atmosphere through the medium of the fluid in which they arc immersed; for their blood is always distributed by the smallest ramifications over a substance in constant contact with the water, before it return into the artcrial system to serve for the purposes of nutrition.

From analogy therefore it must be allowed, that the foetus does receive, through some means or other, the vivifying principle of the atmosphere.

40

41

\$ 37.

2. By what means then is this furnished? Many circumstances concur to prove that it is by means of the placenta. For,

1st, The structure of the placenta resembles much that of the lungs. It is cellular, and has the whole blood of the foctus distributed in the smallest branches over its substance. See ANATOMY, ANIMAL, Chap. 4. SUPPLEMENT.

2dly, The blood returning from the placenta is sent by the nearest possible means to the left side of the heart. And, 3dly, Compression of the umbilical cord to such a degree as to interrupt the circulation through it, destroys the fectus as soon as compression of the trachea docs the natus.

It appears therefore that the placenta serves to the fætus the same purpose which lungs do to the natus.

The eelebrated Haller has objected to this probable use of the placenta in the following words. " Non pauci ctiam auctores secundis pulmonis officium tribuerunt, cum in vena umbilicali sanguis ruber sit et floridus, si cum sanguinis sodalis arteriæ comparetur. Idexperimentum mea non confirmant. In pullo arteria fere coccinea, vena violacea est. In fœtu humano nunquam floridum sanguinem vidi; neque intelligo ut placenta, in qua certissime nulla sint aereæ mutabiles vesiculæ possit pulmonis munere fungi *."

* Haller. But later observations have contradicted the assertions loc. cit. lib. xxix sect. 3. of Haller on this occasion. In particular, Dr Jeffray, professor of anatomy in the university of Glasgow, in 42 an inaugural dissertation published here in the year 1786, relates an experiment made by him which is completely opposite to the opinion of Haller. " Puero " he says" in obstetricatoris sinu jacenti, funiculus tribus vinculis circunijectis, et simul in arctum tractis colligatus est; quo dein juxta umbilicum inciso, in arteriis umbilicalibus et venis, inter duo vincula placentum proxime, sanguinis copia interceptum cst. Intercepti spatii vasa, gelatinosa funiculi parte cultro dempta, in conspectum vencrunt; et arteria, quæ sangui-

nem jam ante in parte circumlatum, ad placentum per- Natural ferebat, puncta est; quam prope arteriæ puncturam Parturition. vena quoque umbilicalis similiter puncta est. Quo facto ex vena sanguis effluens, cum eo qui ex arteria effluebat facile comparari poterat. Ille, venosi sanguinis instar, nigricabat; hic, sanguinis in adulta arteriis mox vivide florebat (D)."

7. The means by which the foctus is nourished have hitherto escaped the investigation of physiologists. That the stomach and intestines do not serve this purpose is obvious from many concurrent testimonies ; but particularly from these organs being on some oceasions entirely wanting, while other parts of the system of the foctus were complete. It is probable that the placenta supplies nourishment, as well as the vivifying principle. of the air to the feetus in utero.

CHAP. III. Natural Parturition.

HUMAN parturition, where every thing is natural, is perhaps one of the most beautiful and interesting operations in nature; for what can be more beautiful than a process accomplished by the combined action of a number of powers admirably well adapted to the intended. purpose ; and what can be more interesting than the continuation of our species which depends on the operation ?

In treating of this subject, we shall first consider the term of gestation; 2dly, the phenomena of natural parturition; and, 3dly, the causes of those phenomena.

SECT. I. Term of Gestation.

The ancients imagined that although nine kalendar months be the most usual period of human pregnancy, yet on some occasions that period may be, and actually is, protracted even beyond ten calendar months. Accordingly, it was laid down as a maxim in ancient jurisprudence, that children born within eleven months after the death of their supposed father should be declared legitimate.

In modern times the question has been often agitated, both among medical practitioners and among lawyers. Practitioners of midwifery however have had most frcquent occasion to investigate this subject, and they have differed materially in their conclusions.

Ræderer says, " Hunc terminum, finem nempc trigesimæ nonæ et nonnunquum quadragcsimæ hebdomadis partui maturo natura, uti accuratior observatio docet constituit, ultraque eum non facile differtur. Nihil hic valet energia scminis deficiens, morbosa vel debilis patris constitutio, matris dispositio phthisica, hectica, qua fœtus sufficienti alimento privatur; nihil, status matris cachecticus, fluxus menstruus tempore gestationis contingens, diarrhœa aliusve morbus; nihil nimia uteri amplitudo; nihil affectus matris vehementior, qualis tristitia; nihil diæta matris extraordinaria, vel inedia; nihil fœtus debilitas et dispositio morbosa; nihil plurcs fœtus in ntero detenti.

" Tantum enim abest ut hæ causæ fœtus moram in utero retardent, ut potius accelerent. Viduze quidem vanis hisce speciebus, illicitam venercm defendere atque hereditates aucupari, quin in eo medicos nimis credulos.

Natural dulos, vel lucri cupidos in suas partes trahere student, Parturition. sed mera hæc sunt ludibria, prætereaque nihil (E)."

But many eminent teachers of midwifery believe that in some cases human pregnancy is protracted for two or three weeks beyond the more common period.

Dr Hamilton especially says, " In the human species nine kalendar months seem necessary for the perfection of the foetus ; that is, nearly thirty-nine weeks, or two hundred and seventy-three days from conception. The term does not, however, appear to be so arbitrarily established, but that nature may transgress her usual laws; and as many circumstances frequently concur to anticipate delivery, it certainly may in some instances be protracted. Individuals in the same class of quadrupeds, it is well known, vary in their periods of pregnancy. May we not, therefore, from analogy reasonably infer, that women sometimes exceed the more ordinary period? In several tolerably well attested cases, the birth appears to have been protracted several weeks beyond the common term of delivery. If the character of the woman be unexceptionable, a favourable report may be given for the mother, though the child should not be produced till nearly ten kalendar months after the absence or sudden death of her husband *."

SECT. II. Phenomena of Natural Labour.

The sufferings of a woman during labour having been compared to the fatigues of a person on a journey, the phenomena of labour have been divided into three stages. The first stage consists of the opening of the mouth of the womb; the second, of the actual passage of the child; and the third, of the separation and expulsion of the secundines.

Phenomena of the First Stage .- In most instances the bulk of the belly subsides for a day or two before labour begins; but the first evidence of the actual commencement of that process is the occurrence of pains in the belly affecting the loins, and striking down the thighs, occasioning considerable irritation of the bladder and bowels. These pains, &c. however, often take place during some hours of the night, for days, or even weeks, before true labour begins, and are then styled spurious pains. It is not easy on many occasions to distinguish true labour throes from spurious pains, unless the state of the mouth of the womb be examined, so very nearly do they resemble each other. But in general spurious pains recur at irregular intervals, and do not increase in force according to their duration ; whereas true pains gradually recur at shorter intervals, and become more and more violent.

Spurions pains are sometimes attended with an occurrence which was first publicly noticed and described by the present professor of midwifery in the university of Edinburgh (F), viz. the protrusion of the urinary bladder. This resembles, to a superficial observer, the bag formed by the membranes which inclose the child, and in consequence has repeatedly been burst by the fingers of the operator. Incurable incontinence of urine, inflammation of the passages, &c. have followed this accident.

Protrusion of the urinary bladder may be readily Natural distinguished from that of the membranes which in-Parturition. clude the infant by two circumstances. First, the bag recedes completely during the interval of the pain; and secondly, when pushed down, the finger cannot be passed round it at the fore part of the pelvis; it seems as if fixed to the pubis. True labour-pains arise from the contractions of the womb by which that organ is shortened and thickened; and, at the same time, its contents are forced through its orifice. When they become regular and forcing, they have the effect of opening the mouth of the womb, so that a practitioner can readily ascertain the difference between them and spurious pains. The opening of the mouth of the womb, in most instances, is accompanied by the discharge of a slimy, bloody-like matter, termed shews; but in many women there is no such circumstance.

This process is generally gradual, the pains increasing in frequency and force; and eight, ten, or twelve hours, commonly elapse before they complete the opening of the womb. In some cases the dilatation takes place to a considerable extent before pains occur, so that a few pains accomplish this stage. But these exceptions are not so frequent as those of an opppsite description, where one or two complete days are required to open the womb, though the pains be unremitting.

In proportion as the first stage advances, the membranous bag containing the child is pushed through the mouth of the womb, and forced gradually into the vagina. During the pain it is tense, and during the interval it becomes relaxed. When this happens, the head of the infant can be distinctly felt behind it. At last, the passages being sufficiently opened, the pains having become stronger and more frequent, the membranes give way, and the water contained within them is discharged; which finishes the first stage. Shivering, vomiting, headach, thirst, and pain in the back, take place in many instances during this stage.

Phenomena of the Second Stage .-- Sometimes an interval of ease of some minutes duration succeeds the discharge of the waters. The pains then become much more violent and forcing, and the head, by the contractions of the uterus thus becoming more powerful, is pushed through the brim of the pelvis into the vagina. For this purpose the vertex is forced foremost, and the brow is turned to one sacro-iliac synchondrosis, so that the largest part of the head is applied to the widest part of the bason; for as the head is oval, and the opening through which it is to pass is of the same form, this is absolutely necessary.

After the head is in the vagina, the pains still continuing, the vertex is turned into the arch of the pubis, and the face into the hollow of the sacrum, by which the largest part of the head is brought into the direction of the widest part at the outlet. All the soft parts are now protruded in the form of a tumour, a portion of the vertex is pushed through the orifice of the vagina, and every pain advances the progress of the infant, till at last the head is expelled. An interval of a minute or two now ensues, after which another pain ta-G 2 king

(E) Rædereri Elementa Artis Obstetricæ. Goettingæ, 1766. page 98.

⁽F) Select Cases in Midwifery, by James Hamilton, M. D. 1795. page 16.

Parturition shoulders of the child being placed towards pubis and sacrum, the whole of the body is born. During this

process the patient generally adds voluntary efforts to the contractions of the uterus.

This stage is in many instances extremely tedious; but after the woman has had one child, it often is completed within the time of six or eight pains.

Phenomena of the Third Stage.-Whenever the in-fant is born, if there be no other in the womb, the parietes of the abdomen become relaxed, and the womb can be perceived through them, contracted almost into the size of a child's head. An interval of ease of some minutes duration now elapses, after which pains again recur, commonly attended with the discharge of some clots of blood; occasioning a kind of gurgling noise, and the placenta and membranes are thrown off, and the womb remains quite contracted or nearly so, with a cavity scarcely capable of containing a hen's egg. In some cases a single pain accomplishes this, and in others several pains are required ; but, generally speaking, this stage is completed within an hour after the birth of the child.

It sometimes, however, happens that the natural efforts are inadequate to the expulsion of the secundines. The causes are, want of sufficient contractile power in the uterus, irregular contraction of that organ, and indurated state of the placenta itself.

From the above description it is obvious that all the three stages of labour are completed by one simple power, viz. the contraction of the womb.

SECT. III. Causes of the Phenomena of Labour.

I. The first phenomenon which requires explanation is the action of the uterus. Why does that organ generally act at a certain period, after having remained in a quiescent state for so long a time?

This question has puzzled physiologists strangely. Some have attributed the circumstance to a stimulus communicated by the foctus: but their opinion is overturned by a well-known fact, that the same phenomena occur though the foetus be dead. Others have imagined that the uterus is excited to act in consequence of previous distension. But were this the case, women should never have the uterus of a larger bulk in one pregnancy than in another ; whereas, on the contrary, it is well known that women who have twins or triplets often have the womb distended to fully double the usual size.

Physiologists as well as physicians have fallen into very great errors from referring complex phenomena to a single cause. A variety of facts concur to prove, that in the present instance it is absurd to impute the action of the uterus to any single cause.

To what then should we attribute it ? To a variety of circumstances.

1st, To the structure of the uterus. From the appearance of that organ in its unimpregnated state, it would seem that nature had laid up in store a certain proportion of fibres to be developed during pregnancy.

When these fibres are evolved, if the uterus be distend- Natural ed farther, the edges of the os tincæ must be separated, Parturation. in consequence of which part of the uterine contents passing through it, the contraction of the uterus follows. A fact very familiar to practitioners of midwifery affords apparently a complete confirmation of this hypothesis, viz. that in some women labour occurs as regularly and naturally, in the seventh or eighth mouth of gestation, as in others it does at the end of the ninth,. the cervix uteri having become quite obliterated.

2d, It is probable, however, that in ordinary cases this store of muscular fibres is seldom entircly exhausted, from the circumstance of women having sometimes twins or triplets ; some other cause therefore must concur in exciting the action of the uterus. The contents of the uterus perhaps furnish this cause.

In the latter months of gestation, some parts of the feetus come in contact with the parietes of the uterus, in consequence of the decrease in proportion of the liquor amnii. This is principally the case with respect to the head, which presses on the cervix, and that part of the utcrus, it is probable, is more irritable than any other; for we find that the entrance or exit of all hollow muscular organs is more irritable than the other parts, as we see exemplified in the cardia of the stomach, and in the cervix of the urinary bladder.

3d, It is not improbable too, that the pressure of the neighbouring parts contributes somewhat to induce the action of the uterus; for it is remarked by practitioners of midwifery, that women seldom arrive at the full period of gestation in a first pregnancy, and the parietes of the abdomen yield with difficulty at first, as is observed in cases of dropsy. Besides all farmers know well; that in every succeeding pregnancy, cows exceed their former period of gestation.

II. The next phenomenon worthy of notice is the 53 manner in which the child's head enters the pelvis. Two circumstances contribute towards this, first the connection of the head of the child with the neck; and 2dly, The form of the brim of the pelvis.

The first of these circumstances has been accurately pointed out by Dr Osborn. He says, " after the os uteri has been first opened by the membranes and contained waters, forming a wedge-like bag, the next operation and effect of the labour-pains or contractions of the uterus (for they are convertible terms) must be on the body of the child, which being united to the basis of the cranium at the great foramen and nearer the occiput than forehead, the greater pressure will be applied to the occiput, which being likewise smaller, and making less resistance, will be the first part squeezed into the cavity of the pelvis (E)."

The latter circumstance has been clearly explained by Professor Saxtorph. He remarks, " causa hujus directionis capitis, concurrente toto mechanismo perfecti partus, potissimum hæret in pelvi. Nam agente utero in fœtum, in axi pelvis locatum, caput ejus hucusque liberum, in humore amnii fluctuans, propter molam suam majorem in introitum ipso pelvis magnam resistentiam patitur à prominentia? ossis sacri, quæ in posteriori parte segmenti inferioris uteri ita impressa est, ut promontorii

(E) Essays on the Practice of Midwifery, &c. by William Osborn, M. D.

54

Natural montorii instar fœtus frontem glabram, rotundam, unico Perturition puncto tantummodo illam tangentem et satis mobilem, blando motu ad latus dirigat, in spatium ei exacté respondens inter protuberantiam ipsam et marginem internum acutum ilii excavatum, quam ob rem, sincipitis prævii sutura sagittalis cadit neccssario in diametrum obliquum aperturæ superioris pelvis (F)."

It is remarkable, that neither of these celebrated authors discovered that a combination of both the circumstances just enumerated, is necessary to occasion the phenomenon.

Two advantages result from this position of the head of the child; for, 1st, The largest part of the head is applied to the widest part of the superior aperture; and, 2dly, The head, when the occiput is forced foremost, occupies the least possible space.

III. The phenomenon which next strikes us, is that change in the position of the head by which the face is turned into the hollow of the sacrum.

Although the advantage, and even necessity, of this change in the position of the head, has been long known to practitioners; yet Dr Osborn is, perhaps, the first author who has clearly explained the efficient cause of this. His remarks are these : " As it (viz. the head) descends obliquely through the pelvis, the pressure of the two converging ischia will not be exactly opposite to each other on the two parietal bones; but one ischium acting or pressing on the part of that bone contiguous to the occiput, and the other on the opposite side next to the face, the head being made up of different bones, united by membranes, and forming various sutures and fontanels, which permit the shape to be changed, and the volume to be lessened, it necessarily follows, that the head, thus compressed, will take a shape nearly resembling the cavity through which it passes; and, as from the convergency of the ischia, the cavity of the pelvis somewhat approaches the form of a cone, the child's head is moulded into that shape, the shape of all others best adapted to open the soft parts, and make its way through the os externum. This unequal pressure of the two ischia upon the head, will, in the first instance, direct the occiput, or apex of the cone, to turn under the arch of the pubis, where there is little or no resistance; while the pressure of the other ischium, in its further descent, will have the same effect on the other side, and direct or compel the face to turn into the hollow of the sacrum *."

* Dr Osborn, loc. cit. p. 30.

55

This change of position is productive of three advantages.

1st, The largest part of the head is again adapted to the widest part of the pelvis.

2dly, The smallest possible surface of the head is applied to the surface of the bones of the pubes. And,

3dly, As Dr Osborn, in the passage quoted, very justly observes, the head is moulded into that shape which is best calculated to pass without doing harm, through the soft parts.

IV. The phenomena which occur when the head passes through the external parts, are easily explained.

After the head has made that turn, by which the face is placed in the hollow of the sacrum, the coccyx

and perinceum resist its further descent in that direc- Natural tion, and by forcing the nape of the neck against the Parturition. inferior edge of the symphysis pubis, every successive pain contributes to make the occiput rise up towards the abdomen, by which the chin leaves the top of the thorax, on which it had rested during the preceding process of delivery.

By this simple mechanism, the soft parts are gradually prepared for the passage of the child, while, at the same time, the shoulders are brought into the most favourable position for passing through the pelvis.

V. The phenomena of the third stage of labour obviously originate from the contraction of the uterus, which both separates and expels the secundines. Some authors have imagined that nature has provided for this purpose a particular apparatus, placed at the fundus uteri; but as the placenta, when attached to the cervix uteri, is thrown off as readily as when it is attached to the fundus, it is very evident that these authors have been deceived by a seeming regularity of fibres, which is sometimes observed.

Lastly, The obstacles which nature has opposed to the passage of the child, occasion all the difficulties of human parturition. These obstacles are formed by the situation and shape of the pelvis, and the structure of the soft parts concerned in parturition.

The pelvis is situated in such a direction, that its axis forms an obtuse angle with that of the body ; consequently, it is not placed perpendicularly, but obliquely to the horizon; and hence nothing can pass through it by the force of gravity.

The shape of the pelvis, too, is such, that the head of the child cannot pass through the outlet in the same direction in which it entered the brim; and, from the structure of the soft parts concerned in parturition, they yield with considerable difficulty.

By these means, the Author of our existence has guarded against the effects of the erect posture of the body, and has prevented the premature expulsion of the child and the sudden laceration of the soft parts.

SECT. IV. Treatment of Natural Labour.

First stage .- When this stage proceeds naturally and regularly, there is very little else to be done, after having ascertained that labour has really begun, and that the child is in the ordinary position, than taking care that the bowels be open, and palliating any unpleasant symptoms, such as shivering or vomiting, &c. which may occur.

But if after the pains have become so regular as, by their continuance, to disturb the ordinary functions of life, that is, most commonly, after they have been quite regular for twelve or fifteen hours; if this stage be not completed; it is necessary to interfere, and to endeavour, by art, to effect the dilatation. The reason for this rule is abundantly evident. If this stage of suffering be longer protracted, the strength of the patient must be exhausted by the long-continued exertion, and, of course, the remaining process of labour cannot be completed. Hence the child may be lost, or alarming discharges

(F) Dissertatio inauguralis de Diverso Partu, &c. Auctore Matthia Saxtorph. Hafniæ, 1771. p. 19.

56

Natural discharges of blood may follow the birth of the in-Parturition fant.

This very obvious effect of the protraction, beyond certain limits, of the first stage of labour, was first publicly insisted on by the present professor of midwifery in the university of Edinburgh.

The means to be adopted for completing the dilatation, when that assistance becomes necessary, are venesection or opiates, or supporting the os uteri, according to circumstances.

When the resistance to the opening of the womb arises from the premature discharge of the water, or from natural rigidity of the womb, copious blood-letting affords the adequate remedy. But if the patient he already reduced by previous disease, so that she cannot safely he bled, an opiate, in the form of glyster, ought to be administered.

And when, on the recurrence of every pain, the mouth of the womb is forced down upon the external passages before the child, its edges ought to be supported, *in situ*, by the fingers cautiously applied to each side.

Second stage.—When it is found that the head has begun fairly to enter the pelvis in the natural direction, no assistance is necessary till the perineal tumour be formed; and then such support must be given to the protruded parts as shall both relieve the distressing feelings of the patient, and, at the same time, prevent any laceration from happening. Of course, the precise manner of supporting the perinœum must be varied according to the circumstances of the case. Inattention to this has very frequently occasioned the most deplorable accidents.

After the head is born, it must be ascertained whether there be any portion of the navel-string round the neek of the infant, and if there be, it must be slackened or drawn over the head, otherwise the infant will be

If possible, time should be allowed for the accommodation of the shoulders, and the expulsion of the body of the infant; and, at any rate, the utmost attention should be paid to supporting the perinœum during that part of the process.

Third stage.—When the child is born, and it is ascertained that there is no other infant remaining in the womb, the patient should be allowed to rest for a little, unless pains again come on, by which the secundines are separated. In that ease, the cord is to be firmly grasped, and pulled gently, till the placenta be brought down to the external parts, when it is to be drawn out carefully, in such a manner as to bring off at the same time the complete membranous bag.

Should pains not recur at the distance of an hour after the birth of the infant, it becomes necessary, for several reasons, to introduce the hand into the womb to separate and extract the secundines.

First, If the cord were pulled by before the womb had contracted, or the after-birth had become separated, the womb must inevitably be turned inside out; an accident that has occasionally happened.

Secondly, If a longer period than an hour were suffered to elapse, the passages would become so much contracted, that the force required again to dilate

them, would produce inflammation, with all its alarm-Natural ing consequences.

Thirdly, If the after-birth were allowed to remain ' longer than an hour, excessive flooding might take place, which would soon prove fatal.

Fourthly, Were the patient to escape the danger of flooding, she would incur that of putrefaction of the placenta, which is equally, though not so rapidly, productive of mortal event.

In thus introducing the hand to separate the placenta, the two great eautions to be attended to, are to apply the fingers to the substance of the placenta, not ta insinuate them between its surface and that of the uterus, and to bring off only that portion of the placenta which can be separated from the uterus without force.

When any alarming circumstance happens after the birth of the infant, requiring the extraction of the placenta, the practitioner is not to delay for an hour, indeed not for a minute, giving the requisite assistance.

CHAP. IV. Of the Deviations from Nature in Human Parturition.

FROM the view thus given of human parturition, under the most favourable circumstances, it must be obvious that many deviations from nature may occur.

These deviations may proceed; first, from the propelling powers concerned in parturition; secondly, from the state of the secundines; thirdly, from the state of the child itself; or, fourthly, from the state of the passages through which the child is forced. There may also be a combination of these causes. We shall consider each of these causes of deviation in the order just enumerated. But as a minute investigation of the subject would far exceed the necessary limits of this work, we shall treat each of these causes as shortly as possible, and notice only the most striking circumstances.

SECT. I. Of the Deviations from Natural Labour, which proceed from the Propelling Powers.

The propelling powers concerned in parturition consist of voluntary and involuntary muscular action. The diaphragm and abdominal muscles furnish the former, and the uterus the latter.

An excess or diminution of the action of those powers must interrupt the ordinary progress of labour.

a. The violent action of the diaphragm and abdominal muscles, if exerted at the beginning of labour, tends to exhaust the patient and to retard delivery, and if induced when the head is within the vagina, may, provided proper precautions be not taken, lacerate the perinæum, and render the future life of the patient miserable.

The action of these muscles being quite voluntary, may be readily prevented by the patient submitting to proper advice.

b. Impaired action of the diaphragm and abdominal muscles, generally originates from the improper exertion of those muscles at the beginning of labour, or from passions of the mind. It always retards delivery, and consequently protracts the sufferings of the patient. e. Violent

59

.60

63

64

62

Chap. IV.

Preterna-

65

c. Violent action of the uterus at the beginning of tural Par- labour, is frequently productive of much mischief. It turition. exhausts the patient, and renders the subsequent process of delivery exceedingly tedious and difficult. It also sometimes occasions an accident which generally proves almost immediately fatal, viz. rupture of the uterus.

This accident has been described by authors under the title of spontaneous rupture of the uterus. The laceration in the uterus in those cases is sometimes transverse and sometimes longitudinal. When the accident happens from this cause, the laceration is most frequently in the eervix. The aecident is preceded by excruciating pain, especially during the action of the uterus, at one part, as in the loins or towards the pubes; and it is annouseed by a most agonizing increase of the pain, succeeded by violent vomiting, the discharge of a little blood, a total eessation of the labour throes, very great irregularity and feebleness of the pulse, cold sweat, coldness of the extremities, difficulty of breathing, inability to lie in the horizontal posture, and sometimes delirium. Along with these symptoms, it often happpens that the presenting part of the child reecdes entirely, and the limbs of the infant may be readily distinguished through the parietes of the abdomen. But this eircumstance does not always take place, for sometimes the head of the child is so firmly wedged within the pelvis, that it does not recede although the other parts be in the cavity of the abdomen.

The rupture of the utcrus is generally fatal. A few cases, however, are on record, where, by prudent management, the patient, even under such dangerous circumstances has been saved. Such arc the eases recorded by Dr Hamilton (H), by Dr Douglas (1), and Dr Hamilton, junior (K). But the injuries which must ensue from loss of blood, acute pain, the presence of the child in the cavity of the abdomen, and the probable protrusion and strangulation of the intestines, are such, that it cannot be expected that many patients can survive the aceident.

The cause of violent action of the uterus at the beginning of labour, is obviously the premature discharge of the liquor amnii. By this circumstance, the body of the child comes in contact with the parietes of the uterus, by which the action of that organ is immediately and violently excited. How much mischief then may the rash interference of an ignorant operator produce ?

The cause of rupture of the uterus from its own violent action, is the resistance to the passage of the child, either from undilated os uteri, or from deformities of the pelvis, or from wrong position of the child. Whenever, therefore, the rupture is threatened, means must be instantly adopted to remove the resistance, or to suspend the action of the uterus. The former is in general the more easily accomplished.

When the uterus has actually burst, the only chance which can be afforded to the patient, is instant delivery ; per vias naturales, where that is practicable ; and where

there is extreme narrowness of the pelvis, by an incision Preternathrough the parietes of the abdomen. A case where tural Parthis latter practice was successfully had recourse to oc- turition. curred a few years ago in Lancashire.

Violent action of the uterus during the latter stage of labour, although not productive of the same dangers which ensue from it at the beginning, is by no means exempt from hazard; for if the soft parts be rigid or not sufficiently relaxed, the woman may be miserably torn.

The violent action of the uterus towards the termination of labour proceeds from some power of that organ itself, or from the stimulus communicated by the position of the child.

This circumstance, however, is sometimes beneficial; as, for instance, when the child is in an unfavourable position. Dr Denman was the first who discovered this effect of violent uterine action, and published it in the fifth volume of the London Medical Journal, page 64.

d. Impaired action of the uterus during the first stage of labour is in many instances productive of no other inconvenience than the protraction of labour; but if it exhausts the strength of the patient, it influences materially the subsequent process, as already stated. When it occurs during the second stage, it occasions the most dangerous symptoms. First, if the head of the child continue to press for a considerable time on the soft parts within the pelvis, these parts must necessarily from the impeded eirculation become swelled, and eonsequently the action of the uterus, though it should return, would then be totally insufficient for the expulsion of the child. This effect of the protraction of the second stage was first pointed out to the public in Dr Hamilton's letters to Dr Osborn. It merits most partieular attention; not only as it is one of the most frequent causes of the loss of the infant during labour, and of considerable danger to the parent, but also as it may be very readily prevented by an attentive practitioner. Previous to this swelling becoming so considerable as to impede the progress of the infant, there is a tenderness and heat, and dryness in the passage, which announces the actual commencement of the inflammation. Immediate delivery ought then to be had recourse to.

Many disagreeable symptoms also proceed from the same cause, such as suppression of urine, and violent eramos in the lower extremities.

When it is ascertained, that, in consequence of the deficiency of action of the uterns, the child is detained so long in the passage as to endanger the health or life of the mother, it becomes necessary to extract the infant, by mechanical mcans. Two contrivances have been thought of for this purpose, viz. the veetis or lever, and the forceps.

Roonhuysen, a Dutch practitioner, who flourished about the beginning of the 18th eentury, contrived the vectis, and from the great success which attended its use in his hands, an ediet was issued by the states-general, that no surgeon should practise midwifery without

⁽¹⁾ Observations on the rupture of the gravid uterus, &c. by A. Douglas, M. D. &c. 8vo. London 1780.

Preterna- out being possessed of the Roonhuysen secret, for the intural Par- strument was not publicly known. In the year 1756, turition. however, the secret having been purchased by two li-

beral-minded physicians, Vischer and Van de Poll, was published by them for the benefit of mankind. Since that time, the instrument has undergone a variety of alterations in its form; for a particular account of which, the reader is referred to Mulder's Historia Forcipis.

There can be no doubt that Roonhuysen and his successors employed the vectis as a lever of the first species, the head of the infant being the resistance, the parts of the woman the fulcrum, and the hand of the operator forming the moving power. The injuries arising from this practice have been well explained by Dr Osborn in his Essays on Laborious Labours. Although Dr Bland and Dr Denman still recommend the same practice, there can be no doubt that whenever the use of the vectis proves successful according to their directions, the fortunate termination is to be attributed to the action of the uterus being excited by the pressure of the instrument; or, in other words, the delivery might have been completed without any mechanical interference at all. On the other hand, whenever the action of the uterus is either quite suspended or much weakened, both mother and child suffer from the application of the vectis.

The late Dr Dease, in altering the shape of the veetis, wished to impress upon the profession the necessity for changing the mode of employing it; and accordingly he called his instrument an *extractor*. This power, however, seems to be possessed in a superior degree by Dr Lowder's instrument, of which a description is contained in the eighth volume, second decade, of Dr Duncan's Medical Commentaries, p. 400. As this instrument may be used with perfect safety, both to mother and child, and as in some cases it is superior to the forceps, we have represented its form in one of the plates, and now add the description and an account of the unanner of applying it from the work already referred to.

The instrument " consists of a blade and handle (between which there is a hinge, that renders it portable), measuring in length 111 inches. Its length, before it be enrved, is 12¹/₂ inches. The curve begins about half an inch from the hinge. It describes, reckoning an inch from its first curvature, as nearly as ean be estimated, an arc of 87 degrees of a circle, the radius of which is four inches. The breadth of the blade, at the beginning of the earve, is half an inch, and is gradually increased, till within three quarters of an inch of the extremity, where it measures an inch and three-fourths. Its extremity is semieircular. Within $2\frac{\tau}{2}$ inches of the extremity there is an oval opening, measuring $2\frac{1}{4}$ inches in length, and $1\frac{1}{4}$ at its greatest breadth. By this opening, the depth of the curve is considerably increased, without rendering the instrument inconvenient in its introduction."

"Let us suppose that it is found neccessary to use Lowder's lever, when the head of the child has just began to enter the eavity of the pelvis. The patient is to be placed in the ordinary position, on the left side, in bed. The occiput of the child is to be carefully distinguished, and the curve of the instrument is to be applied, with all the necessary precautions, over it. The extremity of the blade should be within a very little of the nape of the neck. To accomplish this part of the operation

I

with facility, it is necessary that the operator bc well Preternaacquainted with the shape of the pelvis, and that he tural Parhave accustomed himself to apply the instrument over a turition.

"When the instrument is applied in this manner, the operator will find, that ke can exert very considerable power in drawing down, without pressing on any other part than the occiput of the child. The mother cannot possibly feel the instrument; while, at the same time, the many points of the fœtal cranium, on which it rests, prevent any injury whatever to the infant.

"If there he any pains, however slight they may be, the operator should draw down only during the pain: in the intervals, a soft warm cloth should be wrapped round the handle. If there be no pains, he must draw down from time to time, imitating, as nearly as he can, the natural efforts. It is astonishing, of what use even the most trifling pains are, on such occasions. Without pains, a long time is required before the head be made to advance in a perceptible degree (though, after it has advanced a little, it soon yields entirely); while, with them, the progress is often rapid.

"The operator should continue to draw down in the same manner, till the head be completely in the cavity of the pelvis. Should any circumstance, as dangerous uterine hæmorrhagy, or convulsions, require that the delivery be expeditiously finished, after the head is brought into this position, the forceps must be applied; for it is in the power of the operator, by means of them, to accomplish the extraction of the head within a very short space of time, or at least, within a much shorter space than would be required, were the use of Lowder's lever continued.

"But if there be no dangerous symptom, the operation may be completed by the first instrument, without any assistance from the forceps.

" For this purpose, the operator should continue to draw down, by pressing on the occiput, as already directed, until the face shall have turned into the hollow of the sacrum. The direction of the instrument must then be changed. The reason of this is very obvious. After the face is in the hollow of the sacrum, the occiput becomes engaged in the arch of the pubis, and rises under it, while, at the same time, the chin leaves the top of the breast, on which it had rested during the preceding process of labour, and describes a course equal to a full quarter of a circle, which is the consequence of the occiput describing a similar eourse under the arch of the pubis. Were the practitioner then to continue to press in the same direction as he did while the head was passing through the brim, he would counteract this natural process, and hence would retard delivery, and injure the parts against which he would necessarily press the child.

"The instrument must, therefore, be withdrawn from the occiput, and applied with the proper precautions over the chin, when the operator is to imitate the process of nature, by disengaging the chin from the breast, and making the occiput rise under the arch of the pubis, while, with his left hand, he protects the pcrinæum from injury."

"From these observations it is obvious, that the instrument introduced into practice by Dr Lowder, affords exactly the assistance, in the first order of laborious labour, which is required; for it supplies the place of the propelling

Chap. IV.

56

69

08

Chap. IV.

71

Preterna- propelling powers, or increases their efficacy, by acting tural Par- on the body of the child, without injuring any part of tarition. the mother.

"This property renders it of great use in certain eases of deformed pelvis, viz. where the short diameter of the brim is about three inches. In such cases, the long continued strong action of the uterus, often eventually forces the head into the pelvis; but the strength of the patient is in consequence so much reduced, that after it has proceeded so far, the pains are entirely suspended, and the delivery must necessarily be finished by the use of mechanical expedients; but the child's life is commonly previously destroyed, by the compression of the brain.

" If, in such cases, it be possible to increase with safety the vis à tergo, the child would then be forced through the brim of the pelvis before the woman's strength were exhausted, and before its life were endangered; consequently, many children, commonly doomed to inevitable destruction, would be preserved.

" Lowder's lever, I apprehend, possesses this power. It may be ealculated, that, by its use, the efficacy of the labour throes is at least doubled. Hence the child, in eases of slight deformity of the pelvis, is forced through the opposing part within one half of the time which would be otherwise required; and this is accomplished without injury either to the mother or infant; for the instrument presses on no part of the former; and it rests on such parts of the latter, that no harm can possibly be done.

" In face-eases, too, where the interference of the practitioner is necessary (which, indeed, is a rare occurrence), this instrument may be employed with much advantage. The great aim should be, to draw down the occiput.

" As it appears, therefore, that Lowder's lever is applicable in many eases where the forceps are inadmissible, and that its use is not productive of so much hazard to the mother as that of the forceps, it might perhaps be inferred, that the latter instrument may be banished from practice, as unnecessary and dangerous. Accordingly, many practitioners of midwifery have adopted an opinion of this kind; and, indeed, there are very few who do not employ one or other of these instruments exclusively.

" But however desirable it may be to lessen the number of mechanical expedients, and to simplify practice, I apprehend, that many lives would be lost if we possessed or employed no such instrument as the forceps. As they have the property of a lever, delivery can in many cases be accomplished much more expeditiously by them than by Dr Lowder's instrument. This seems to be the sole advantage which they possess over it; and that is counterbalanced by several great disadvantages. Many authors, indeed, have alleged, that the forceps have exclusively the power of diminishing the size of the fœtal cranium, by the pressure of their bladcs, and hence have attributed a degree of pre-eminence to them, which in fact is not their due; for as the size of the child's head is, in natural cases, diminished as far as is necessary, by the contractions of the uterus forcing it forward through the bones of the pelvis, an increase of the vis à tergo will of course increase that diminution, if the shape of the passage require it. While Lowder's lever, therefore, possesses the power of compressing the

VOL. XIV. Part I.

cranium in common with the forceps, it has a decided Preternasuperiority over them in this, that it accomplishes that tural Parend by similar means with nature.

"The great disadvantages of the foreeps are, that they are inapplicable when the child's head is situated high in the pelvis; that their application is often difficult to the operator, and painful to the patient; and that, as their eentre of action is on the parts of the patient, they must injure her in proportion to the resistance opposed to the delivery.

" On the whole, then, in eases of the first order of laborious labours, both instruments must be occasionally had recourse to. When the head is not completely within the cavity of the pelvis, Lowder's lever must be employed; and even when it is in that position, the same means may be used, if there be pains. But, when the labour throes are entirely suspended, or when any circumstance renders it necessary to terminate the delivery with expedition, the forceps ought to be employed in preference to every other instrument, if the head of the child be within their reach."

The forceps are supposed to have been invented by Dr Hugh Chamberlain, who was physician to King Charles II.; but their form has been greatly altered since his time. The most approved form is that represented in the plate.

This instrument is only applicable in presentations of the head ; but it was formerly, by Dr Smellie and others, recommended in face cases.

In order that this instrument be applicable, it is necessary that the head be completely, or nearly so, in the eavity of the pelvis; but sometimes a lengthened pair is used for eases where the head is situated high. The employment of long foreeps, however, being extremely dangerous, is seldom justifiable; and therefore we shall limit our directions to the use of the common short forceps.

There are three principal eases in which that instrument may be had recourse to, viz. 1. where the face is in the hollow of the sacrum; 2. where the face is wedged under the pubis; and, 3. where it is on one side of the pelvis.

In whatever situation the head is, the instrument is to be applied over the ears, otherwise there could be no safe and secure hold. In the process of extracting the child with this instrument too, it is to be observed, that the convex edge of the blades is to be brought along the hollow of the sacrum.

The instrument being applied so eautiously over the ears of the infant that no part of the woman be injured by their introduction, the locking parts are to be brought together, and secured by a ligature; after which the operator, supporting carefully the perinæum with one hand, is to draw gently in a direction of from blade to blade during a pain, or now and then to imitate labour throes, while he at the same time favours the mechanism of labour by accommodating the child's head to the passage so as to make it take up the least possible room. If this be done with suitable eaution and gentleness, no part of the woman should be injured, and the parts of the infant on which the instrument had rested should not even be marked. But as there ean be no doubt, that in the process of using the forceps, the parts of the woman are pressed upon by the blades, if much force be exerted, or if due attention be not H

73

Preterna- not paid to the adaptation of the head of the infant to tural Partural Parturition, most dreadful effects result from the operation.

> SECT. II. Of the Deviations from Natural Labour, which proceed from the state of the Secundines.

> The membranes which envelope the fœtus are in some cases more tender, and in others more rigid, than in general they arc found; circumstances which have a considerable effect on the process of parturition. Besides this, the placenta is on some occasions attached to the cervix or os uteri, by which not only is the order of labour interrupted, the placenta being expelled before the child, but also is the patient's life exposed to much danger.

> a. Where the membranes are too tender, the liquor amnii is discharged at the beginning of labour before the os tincæ be dilated, and then all the bad consequences detailed under the article b, Sect. I. necessarily ensue.

b. Where the membranes are too rigid, the labour may be protracted to such a period as shall injure the mother most materially, and at last, as the whole ovum may be expelled entire, the life of the child may be endangered.

After the os uteri is completely dilated, if the child included in the membranes do not advance into the cavity of the pelvis, the membranes should be ruptured. But if it do, they ought not to be broken till they press on the external parts.

c. But the most alarming deviation from nature, which can proceed from the state of the secundines, is that which originates from the attachment of the placenta over the cervix or os uteri. As there can be no doubt that the uterine vessels dip into the substance of the placenta, and that they are lacerated when the placenta is separated from its attachment, it is obvious that in such a situation hæmorrhagy to a most dangerous extent must unavoidably ensue during the process of the labour.

Mr Rigby of Norwich was the first British practitioner who publicly explained this cause of hæmorrhagy. In the first edition of his work ; viz. that published in 1775, he expresses himself in the following words. " But from the uncertainty with which (as before observed) nature fixes the placenta to the nterus, it may happen to be so situated, that when the full term of pregnancy is arrived, and labour begins, a flooding necessarily accompanies it, and without the intervention of any of the above accidental circumstances; that is, when it is fixed to that part of the womb which always dilates as labour advances, namely, the collum and os uteri, in which case it is very certain that the placenta cannot, as before described, remain secure till the expulsion of the child, but must of necessity be separated from it, in proportion as the uterus opens, and by that means an hæmorrhage must unavoidably bc produced.

"That floodings, which arise from these two different

causes, which I will distinguish by the names of acci- Preternadental and unavoidable, though they may appear exact- tural Par. ly similar in their first symptoms, should terminate very turition. differently, if left to nature, assisted only by the palliative means before mentioned, cannot seem strange; nor can it be a doubt, that of these two kinds of floodings, only one of them, namely, that which is produced by an accidental separation of the placenta, can be relieved by the use of these palliatives; and that the other, in which the placenta is fixed to the os uteri, and the flooding is therefore unavoidable, cannot possibly be suppressed by any other method whatever than the timely removal of the contents of the womb; for supposing the discharge to be for a while restrained by bleeding, medicine, cool air, &c. it will inevitably return, when nature is so far recovered as again to bring on labour : in the first case, if the hæmorrhage have been checked by the use of the above means, it is not impossible but labour may come on, and the child be safely expelled by the natural pains before it returns; or if it should return, it may not increase in quantity; as in this case very probably the separated part of the placenta which occasions the discharge remains nearly the same; whereas in the other case, in which the dilatation of the os uteri produces the separation of the placenta, every return of pain must be a return of the bleeding, and it must become greater and greater as the uterus opens more and more, and the placenta is in proportion detached, till it increases to a degree that exhausts the patient, and she dics before nature has been able to expel the child. That such must inevitably be the progress and event of floodings arising from such a cause, if left

"That this attachment of the placenta to the os uteri is much oftener a cause of floodings than authors and practitioners are aware of, I am from experience fully satisfied, and so far am I convinced of its frequent occurrence, that I am ready to believe that most, if not all of those cases which require turning the child are produced by this unfortunate original situation of it (L)."

to nature, is too obvious further to be insisted on.

No case in practice requires more decision and more attention than this. It must be obvious that no internal remedy can be of any avail in flooding from such a cause, and that the life of the patient can be saved by immediate delivery alone, whenever considerable hæmorrhagy takes place. But it is to be recollected that the discharge in many instances threatens for days or even weeks before it becomes serious, and that for the sake of the child, the patient should be allowed to advance as near as her own safety will permit to the full period. These threatenings may often be removed by astringent injections, per vaginam, while at the same time every means of moderating the circulation of the blood should be suggested.

But whenever the discharge becomes profuse, delivery by art is to be had recourse to. The rule of Mr Rigby, and of some other eminent practitioners, "to watch from time to time the dilatability of the os uteri," and take advantage of that state, sounds well; but

(L) Essay on the Uterine Hæmorrhagy which precedes the delivery of the full-grown Fætus, illustrated by gases by Ed. Rigby, Lendon 1775, p. 14. Vide also 3d edition 1784, same page.

Preterna- but if followed in practice, must either give such a tural Par- shock to the woman's constitution, as shall end in turition., dropsy or marasmus, or must prove immediately fatal. In all those cases the os uteri may be forced, and although it be not more open than barely to admit the introduction of the finger, it may in a very few minutes, if the operator have steadiness and perseverance, be rendered capable of allowing the hand to pass.

> If possible, the hand should be carried forward at one side of the placenta, for if that part be torn (which it must be admitted is sometimes inevitable) the infant must be destroyed. After the feet are brought down, the child is to be extracted as expeditiously as regard to its safety will permit, and the hand is then to be again passed into the uterus for the purpose not merely of detaching completely the secundines, but chiefly of securing the contraction of that organ which is the great object of the delivery.

SECT. III. Of the Deviations from Natural Labour, 78 which proceed from the state of the Child.

The regular process of parturition may be interrupted, in consequence of the position and of the shape of the child.

I. Position of the child. The most natural position of the child, at the beginning of labour, is with the head placed at the brim of the pelvis, the face towards the sacro-iliac synchondrosis of one side, and the occiput towards the groin of the opposite side. But there are many deviations from this natural position.

a. Although the head be applied to the brim of the pelvis, it may be forced with the sinciput towards the promontory of the sacrum, and the occipit towards the symphysis pubis. In this situation the largest diameter of the head is opposed to the smallest of the pelvis, consequently the head remains firmly fixed in that position, for as the sinciput cannot advance a point beyond the promontory of the sacrum, the occiput is forced just so much below the brim at the pubis as to wedge the head firmly between the sacrum and pubis. By the long-continued pressure the soft parts become much swelled, and at last the head is found so immoveably fixed, that it can neither be made to recede, nor can it advance in the same direction. This constitutes what has been styled the caput incuneatum, or, as it is called by French practitioners, la tête enclavée. This case most commonly is the effect of mismanagement; for if a very little pressure be made on the head when it presents at the brim of the pelvis in this unfavourable position, the pairs will readily force it into the passage in the proper direction.

When the locked head has actually taken place, the practice must be varied according to the circumstances of the individual case; hence the long forceps, and sometimes even the crotchet, are required. Turning is quite inadmissible, and the three-bladed forceps so strenuously recommended by Dr Leake, in this case are totally inapplicable.

b. The long diameter of the head may also be applied to the short diameter at the brim, in a different manner, viz. with the face towards the pubis, and the occiput to the base of the sacrum. The obstacles to the progress of the head are not in this case so great as in the

former (a); for as the occiput is round, and its sur- Preternaface inconsiderable, while at the same time the promon- tural Partory of the sacrum is round, the labour throes, after, turition. some time, force the occiput either a little to one side, or at least past the promontory. The case, however, is tedious, painful, and even dangerous to the patient; for as the face presents a larger surface to the pubis than the occiput, it must require longer time to pass, and as there are many inequalities on the face, the patient must suffer much pain from their pressure, and from the same circumstance must incur the hazard of having the urinary bladder or the urethra irreparably injured.

In this case Professor Saxtorph remarks, " vel occiput primo descendit, quod cum accidit, frons ab ossibus pubis sustentata elevatur, mentumque pectori infantis imprimitur, urgentibus porro doloribus, versus anum et perinæum, adagitur acuminatum occiput, et nullo modo sub arcu ossium pubis extorqueri potest inflexile sinciput, hinc partus in exitu pelvisimpossibilis redditur."

That this is a mistake, the observation of other practitioners has sufficiently demonstrated; for it is well known that in such cases, after the perinæum has been much stretched the occiput is forced through the parts, and immediately slips back towards the anus, while the nape of the neck being applied to the anterior edge of the perinæum, moves on it as on an axis, so that the sinciput and face emerge from under the symphysis pubis, the chin leaving the top of the thorax in the same manner as if the face were situated naturally in the hollow of the sacrum.

Although in this case the natural efforts most ordinarily complete the process, yet in many instances the injury which threatens the urinary bladder renders the application of the forceps expedient.

c. Although the head may have entered the pelvis in the most natural position, yet it may not make those changes in situation which are required to accommodate it to the outlet; for the face may turn under the symphysis pubis instead of into the hollow of the sacrum. When this happens the phenomena already described (b)take place.

d. It sometimes happens, that instead of the smooth part of the cranium being forced first into the pelvis, the face presents. In this case it may be situated in three positions, viz. with the chin to the sacrum, or pubis, or side.

a a. The first case is esteemed the most dangerous both for the mother and child. For the mother, because the child in this position requires more room than the pelvis affords, consequently the soft parts in contact with the chin and smooth part of the cranium are much compressed, and hence if the delivery be not speedily accomplished, much injury to those parts will ensue. As the chin too must pass along a curved line formed by the sacrum and coccyx, the obstacles to delivery are very great; and even after the face has been forced so low as to press on the perinæum, that part is in much hazard of being torn by the violent distension which it undergoes. The delivery in such cases is very rarely accomplished naturally.

This species of labour is equally dangerous to the child as to the mother, not only on account of the longcontinued pressure on the brain, but also from the occiput being forced so strongly on the superior dorsal vertebra that the free return of the blood from the head is H 2 interrupted,

82

83

Preternatural Parturition. which is proved even by the appearance of children who in such cases are born alive, for the face of such children is perfectly livid. Jacobs has pointed out

these dangers pretty accurately. "Il est dangereux pour l'enfant, (he says), parce que la tête etant penchèe et portant sur son cou, elle comprime les vaisseaux sanguins au point que le sang ne pouvant plus circuler, il meure d'une apoplexie pour peu que l'on tarde á l'extraire." Ecole pratique des Accouchemens, par le Professeur J. B. Jacobs. A Paris, 1785. p. 366.

b b. The second case, viz. where the chin is placed towards the pubis and the sinciput to the sacrum, is neither so dangerous for the mother nor child. For if by the force of the pains the face be pushed so far forward that the chin becomes engaged within the arch of the pubis, then the inferior edge of the symphysis pubis forms a fulcrum on which the inferior jaw moves, by which the sinciput and occiput pass readily and easily along the hollow of the sacrum, their surface being well adapted to that of the sacrum, and the several parts of the face pass in succession through the vulva.

cc. The third case, viz. where the chin is to one side, is still more favourable than the second; for the face passes readily through the oblique diameter of the pelvis till stopt by the tuberosities of the ischia, when the chin turns into the arch of the pubis, and then the same phenomena which occur in the second case take place.

The cause most generally assigned for face-cases is the ill directed exertion of the propelling powers. May it not also depend in many cases on the original position of the focus?

When any extraordinary difficulty occurs in face-cases, Lowder's lever is the instrument to which recourse ought to be had. The forceps, as recommended by Smellie and others, being quite insufficient to afford a safe and secure hold of the infant.

e. On some rare occasions the side of the head presents, 50 that one car is in the centre of the pelvis. In such a case, the strongest contractions of the uterus cannot make the head enter the pelvis, and the woman would generally die undelivered were it not for the iuterference of art. Cases of this kind arc remarkably rare.

The hand of the operator must be carried up in such cases, and moderate pressure must be made in such a direction as shall allow the contractions of the uterus to push the smooth part of the cranium into the cavity of the pelvis.

f. The head of the child is not the part always applied to the pelvis; for sometimes the head passes last. Whenever any other part than the head presents, the labour is styled by authors *preternatural*.

All preternatural labours have been divided into two orders. A. Presentations of the inferior extremities; and B. Presentations of the superior extremities.

A. Presentations of the lower extremities comprehend cases where one or both feet, one or both knees, and the breech present.

g. Cases where both feet present are more frequent than those where one only presents. It has been cal-

culated that the feet present once in 105 cases of la-Preternahour.

Some authors have divided labours of this kind into a great variety of species. There is, however, no necessity for such divisions, and they tend to mislead and embarrass practitioners. All the varieties may be reduced under three heads; for the toes must be either towards the side of the pelvis, or towards the sacrum or puhes.

dd. Where the toes are towards the side of the pelvis, the child is generally placed in such a manner that the abdomen, breast, and face pass in succession along the sacro-iliac synchondrosis of that side. This is the most favourable situation in which the child under such circumstances can be placed; for the largest parts of its body pass through the largest aperture of the pelvis.

In this case, then, the action of the uterus forcing forward the child, the feet are by degrees excluded through the external parts, the toes being situated between the point of the coccyx and the tuberosity of the ischium; the thighs follow, then the abdomen and thorax; but the farther progress of the child is for some time interrupted by the arms passing up along each side of the head, which add considerably to its bulk; at last, however, the repeated contractions of the uterus force the face into the hollow of the sacrum, and then the nape of the neck turning on the inferior edge of the symphysis publs as on a pivot, the face is excluded, followed by the sinciput and occiput.

Where the efforts of nature in this process are solely trusted, the child, unless it be small and the pelvis be very capacious, while the soft parts are much relaxed, is generally still-born; for before the obstacles to the delivery of the head be overcome, the long-continued compression of the funis umbilicalis, by intercepting the course of the blood, proves fatal.

e c. Authors have generally considered that to be the most favourable position in which the feet can present, where the toes are towards the sacrum. Roedercr for example says, "pedum tune digiti si ossi sacro obvertantur, fœtus abdomini incumbens recte situs est (L.)" But two disadvantages attend this position : First, the largest part of the child's body is forced through the smallest part of the outlet of the pelvis; and 2dly, The longest diameter of the head is applied to the shortest diameter of the brim of the pelvis. In such cases, therefore, the patient commonly suffers much pain, and the child's life is destroyed.

ff. When the toes are turned to the pubes, it has been universally acknowledged, that the feet are in the worst possible position. Indeed not only do the disadvantages stated as resulting from the last position (*e e*) equally take place in this one, but another cause of difficulty and danger is added, viz. that the face being applied to the pubes, the progress of the child must be impeded in no inconsiderable degree. Hence in such a case the patient may be very much injured, and the child must be almost inevitably lost.

The management of footling cases was first explained, in as far as we know, in Dr Hamilton's Select Cases in Midwifery, p. 89.

"It

00

91

" It is a curious circumstance that the best mode of tural Par- delivery in footling cases has not yet been explicitly pointed ont by any author. This must appear surprising when it is considered that such presentations frequently occur; that the life of the child depends upon the practice adopted ; and that the management of every preternatural labour must be influenced by the rules applicable to footling cases.

"When the feet present, the infant's situation relatively to the mother must be with its belly placed towards her back, her belly, her side, or some intermediate point. The first of those positions has been generally considered as the most favourable, and the last as the reverse. But a little reflection must convince every practitioner that the infant occupies the least possible space, when its belly is towards the side of the mother, or, to speak more accurately, towards the sacro-iliac synchondrosis; for then the largest part of its body is within the largest diameter of the pelvis at the brim, while in its progress through the pelvis, the breech is not forced through the shortest diameter at the outlet, viz. that between the tuberosities of the ischia.

" In every case therefore where the feet are brought down, the toes should in the process of extraction be turned into such a position, that the belly, the breast, and the face, shall be made to pass in succession along the nearest sacro-iliac synchondrosis. After the arms are disengaged, the face can be readily turned into the hollow of the sacrum."

h. One foot may present in the same variety of directions as both feet. Where one foot presents naturally, if the pains be regular and strong, the case is attended with less pain to the mother and less danger to the child, than where under similar circumstances both fect present. It is less painful to the mother, because the child is formed into the shape of a cone, and the apex passes first through the pelvis, by which the parts are gradually prepared, and not suddenly forced open; and it is less dangerous for the child, because the one leg being folded along the belly and breast, the umbilical cord is protected from compression.

From these circumstances, a very crroneous inference has been deduced by some celebrated authors, viz. that in cases where it is necessary to perform the operation styled turning, the one foot should be brought down in preference to both. But as on such occasions the operator cannot be assisted by pains, it is obvious that he could not have a sufficient hold of the child by a single foot.

With the exceptions just stated, the phenomena where one foot presents are the same with those which occur in cases where both feet arc in the passage.

i. When the knees present, all the inconveniences of footling cases take place, with this additional danger to the child, that if the legs be crossed, one or both may be fractured before the knees be expelled.

The management of knee presentations must depend on the advance which these parts may have at the time assistance is procured. If they be still at the brim of the pelvis, the fect should be hooked down. But if they be fairly within the cavity of the pelvis, or in the vagina, they must be allowed to protrude without the parts until the feet be expelled.

k. Breech cases occur more frequently than footling

ones. It has been calculated that they happen once in Preternatural Par-52 cases of labour.

The breech may present in the same variety of po- turition. sitions as the feet, viz. with the belly of the child to the back, to the belly, or to the side of the mother. Certain advantages and disadvantages attend each of those positions.

When the belly is to the back of the mother, the thigh bones being straight, pass with difficulty along the curved line of the sacrum; after that obstacle is surmounted, the largest part of the child is applied to the smallest diameter at the brim of the pelvis; and after the body is delivered, the head is situated in such a direction that it cannot enter the brim; for the sinciput is opposite to the promontory of sacrum and the occiput to the symphysis pubis.

If the belly of the child be to the belly of the mother, then the thigh bones pass very readily along. the bones of the pubes, while the spine bending, accommodates itself admirably to the hollow of the sacrum, consequently at first the labour proceeds speedily and safely; but after the breech has passed through the cavity of the pelvis, it is applied with its largest diameter to the shortest diameter at the outlet, and after it has at last overcome the resistance occasioned by that circumstance, and the body is expelled, the face, being towards the symphysis pubis, subjects the patient to all the pain, and the child to all the dangers, already enumerated (ff).

When the belly of the child is placed towards the side of the mother in breech cases, then the same advantages attend the situation which have been enumerated under the first footling case (dd); for the largest part of the child is uniformly applied to the largest aperture of the pelvis. Besides this, the child incurs less hazard in this position than where the feet originally present; for the legs being folded on the belly protect the funis umbilicalis from compression.

Breech cases, where the pains are powerful, are to be left entirely to nature, taking care to support the perinæum, till the infant be expelled ; the navel-string is then to be taken off the stretch, and the child accommodated to the passage on the same principle as footling cases.

When the pains prove inadequate to the expulsion of the breech, various methods have been recommended, such as hooking the finger in the groin, first on the one side, and then on the other; employing a blunt hook for the same purpose ; fixing a garter or piece of tape over one or both thighs, and applying the forceps.

The first of these methods are useful where there are slight pains, and the infant is not large. The second and third methods are injurious both to the mother and child, for they add to the vis a tergo, without diminishing the resistance. But the fourth method, that is, applying the forceps, is invariably both safe and successful; because, while it enables the practitioner to draw forward the child without any uterine action, it at the same time puts it in his power to accommodate it to the passage by turning it round in the proper direction.

B. The second division of preternatural labours, includes all cases where any other part than the head or lower extremities presents; such as the neck, the arm or shoulder, the breast, the back, the belly, or the side.

92

It

It is obvious, that a full-grown child cannot possibly Preternatural Partu- be expelled through the natural passages in such posirition.

tions, and consequently, unless nature perform the operation first described by Dr Denman, both mother and child must be destroyed; for the unavailing contractions of the uterus will first operate in impeding the circulation of the child; and then by pushing forward its body with great force on the soft parts of the mother, will induce such a degree of pain and inflammation, that she must at last sink exhausted.

The practice of turning, as it is called, that is, of bringing down the feet in cases belonging to this division of preternatural labours, originally suggested by Pierre Franco, but first properly established by Ambrose Parrè, has been the means of saving many valuable lives. Indeed the superiority of this practice to that of making the present under such circumstances must be very obvious; for after the operator has got hold of the infant's feet, he can complete the delivery without requiring the assistance of pains.

The dangers to be dreaded in performing the operation of turning are rupture of the uterus, or subsequent inflammation of the passages, and loss of the child.

The first of these, is to be guarded against, by pursuing such means as shall suspend the labour-pains, and remove the uterine stricture, when the opportunity of turning before the discharge of the water which surrounds the infant has been lost. These are blood-letting and opiates in large doses, singly or combined, according to circumstances.

Great gentleness and caution, on the part of the operator, are indispensably requisite to prevent both rupture of the uterus and the subsequent inflammation of the passages. When it is added, that a perseverance for several hours is sometimes necessary for accomplishing this operation, it must be obvious, that it demands in many instances a greater degree of patience, as well as dexterity, on the part of the operator, than most cases of surgery.

The safety of the infant can only be secured, by attending very accurately to the rules for the management of footling cases.

Dr Denman, whose discovery of the spontaneous evolution has been already mentioned, at one time supposed that in the cases under consideration, the operation of turning might be dispensed with, and that the patient might be saved much hazard, and the practitioner great anxiety and trouble, by waiting for that change.

But although in the later editions of his valuable work (Introduction to Midwifery), he has relinquished this idea, his observations on the management of preternatural labour of the second order, are evidently influenced by his former opinion.

He says (vol. ii. p. 249.), "Yet the knowledge of this fact, however unquestionably proved, does not free us from the necessity and propriety of turning children presenting with the superior extremities, in every case in which that operation can be performed with safety to the mother, or give us a better chance of saving the child. Under such circumstances, the instructions given by former writers, and the observations we have before made, must still be considered as proper to guide our conduct. But when we are called to a patient with a preternatural labour, in which there is no room to hope for the preservation of the child, or in which we

3

are assured of its death, or when the operation of turn- Preterna. ing cannot be performed without violence and some tural Par. danger to the mother, then the knowledge of this pro- turition. bability of a spontaneous evolution, will set our minds at ease, and disengage us from the consideration of making any hasty attempts to perform a hazardous operation, from which no possible good can be derived, except that of extracting a dead child, and which at all

events might be effected by a method much more safe

to the mother. " The time required for the spontaneous evolution of the child, and the facility with which it may be made, will depend upon a variety of circumstances, but chiefly upon the size of the child, the aptitude of its position, the dimensions of the pelvis, and the power exerted by the uterus. If the child be very large or much below the common size, the slower I believe will be the evolution, nor can it be made at all without a strong action of the uterus. It is possible, therefore, when we have conducted ourselves on the ground of expectation that the evolution would be made, that the pains may fall off or be unequal to the effect, and we may be disappointed. It might then be apprehended, that the difficulty of extracting the child would be infinitely increased. But though the evolution was not perfected, I have not found this consequence; for the child, though not expelled, has been brought into such a state that I could afterwards pass my hand with ease, and bring down its feet, though in an attempt to do this at the beginning of the labour I had been foiled. In one case in which the evolution did not take place, I could not bring down the inferior extremities, but I had no difficulty in fixing an instrument upon the curved part of the body of the child, or in bringing it away with entire safety to the mother. It was before presumed that the child was dead, and the sole object was to free the mother from her danger; and with her safety no appearances of the child, however disagreeable, are to be put in competition. In cases of this kind another mode of practice has been recommended, that of separating the head from the body with a blunt hook or other convenient safe instrument; but as I have never practised the method, I give the description of it in a note."

There are two points in the above observations, in which it appears that Dr Denman has erred. In the first place, in sanctioning delay in having recourse to the operation of turning where the superior extremity presents. In many such cases, if the pains be not speedily suspended, or the position of the child altered, the uterus would burst; an accident which has repeatedly fallen under the observation of the writer of this article.

The second error is, the supposition that, after it has been found by experience in any given case, that the spontaneous evolution is not to happen, it is easy to extract the child either by the feet or by some instrument. But it will be found in the majority of such cases, that the infant is impacted into so close a body, while the parts are all in a state of swelling and inflammation, that immense difficulty and great danger attend the attempt.

The following observations on this subject cannot be too strongly impressed on the minds of, especially young, practitioners.

95

96

97

case, the position of the child is sometimes altered, and its expulsion accomplished, by the natural contractions of the uterus. Although the doctor, with his usual candour, has allowed, that this favourable event, under such alarming circumstances, is rather to be wished than expected; yet he has offered it as his opinion, that if all interference of art were avoided, "the woman would not, in this case, die undelivered."

"Several years ago it was discovered by Dr Den-

"The preceding history, however, affords a melancholy contradiction to this opinion. The midwife, who attended from the beginning, did nothing to interrupt the natural process, as far as could be learned. Her fatal error was having only looked on, and having neither given that assistance which was necessary, nor sent for others who could do so.

" The spontaneous evolution, as Dr Denman has called it, can only take place where the child lies in a particular situation, viz. where the action of the uterus cannot be exerted on the presenting part, or where that part is so shaped that it cannot be wedged within the pelvis. A practitioner may, therefore, by a careful examination, be able to decide whether the evolution will happen or not. This observation is by no means a matter of speculation, being, on the contrary, of much practical utility; for, if there be signs which indicate the event alluded to, it follows, as a consequence, not only that the natural process is not to be counteracted, but also, that it is to be assisted. Two cases occurred during one year, where the author of these remarks had an opportunity of prognosticating and assisting the evolution, in presence of two gentlemen then attending the professor of midwifery, as annual pupils.

" That the uterus should continue rigidly contracted on the body of the child, while the strength of the woman was so much exhausted that no pulse could be fclt, and that the appeared sinking very fast, is a singular and an instructive fact. It will, it is to be hoped, teach practitioners the fallacy of the assertion, that the longer the operation of turning is delayed, the more easily it will be accomplished.

" It may seem astonishing, that the body of the child could not be drawn down with the crotchet, since it was in a state of great putridity: But when it is considered, that the long-continued action of the uterus had wedged it very strongly within the pelvis, while, at the same time, the pressure on the soft parts lining that cavity had swelled them much, the circumstance will be readily understood (N)."

Authors have endeavoured to ascertain the causes of preternatural labours; but little sactisfaction has been derived from their researches. It is probable, that some cases depend on different causes from others. For example, in some women preternatural labour oocurs more than once. Such cases seem to depend on some peculiarity in the uterus or ovum. Again, it is well known to practitioners of midwifery, that, on some occasions, where the child had been found to present naturally at the commencement of labour, the position is

perceived to be preternatural after the first stage is com- Preternapleted (0). In these cases the change of position may tural Partuperhaps be justly attributed to irregularity of action of rition. the uterus. Besides, there can be little doubt that some cases of preternatural labours originate from the premature rupture of the membranes.

2. The bulk of the foetus also occasions considerable 98 deviations from nature in labour; for it may be either too small or too large.

l. The fœtus, at the full period of gestation, is never of so small size as to occasion any deviation from nature, unless it have been for some time dead. It is indeed, a very remarkable fact, that women often carry to the full time a foctus which had died about the fifth or sixth month.

In such cases, the child is sometimes expelled so rapidly, the passages opposing little or no resistance, that the uterus is suddenly emptied of its contents; and hence, from the irregularity of its contraction, the placenta is retained, or uterine hæmorrhagy takes place.

m. The patient, however, is exposed to more dangers from the increased than the diminished bulk of the foctus. The foctus may exceed the ordinary size, either from a natural increase of bulk, or from monstrosity, or from disease.

k k. It has been already stated that the foctus at the full term of gestation, generally weights from seven to ninc pounds; but on some rare occasions it is found to exceed ten or twelve pounds, or even thirteen. Although, however, the process of delivery is not so rapid where the child is so large, yet if no other circumstance occurs to impede labour, it will be eventually terminated with safety both to mother and child in most cases. Where indeed, under such circumstances, the patient has not formerly had a child, there is always reason to apprehend that the infant may be destroyed by apoplexy, or the mother may be very much bruised. In some cases of this kind, it becomes necessary to open the head of the infant.

11. When the child is monstrous, from the redundancy of some large parts, as from two heads or two bodies, it is sufficiently obvious that if the mother be at the full term of gestation, the obstacles to delivery will be insurmountable by the natural powers. Fortunately, however, in hy far the greatest number of cases of monsters of that kind, the action of the uterus is excited before the ordinary period.

mm. The most frequent disease of children, which proves an obstacle to labour, is the enlargement of the head from hydrocephalus. On some occasions the head is enlarged to an extraordinary size.

Sometimes too, the thorax or abdomen is distended too and enlarged by a watery fluid. Professor Saxtorph has recorded the following example of an obstacle to delivery from a very uncommon disease. " D. 18. Sept. 1775. in domo obstetricia regia, mox paritura admittebatur gravida. Instante partus principio dolores partus veri debito modo alternantes, sed solita proportione vehementia, duratione et celeriori recursu infligebant. Rite tendebatur

(N) Select Cases in Midwifery, p. 110. (0) Vide Denman's Introduction, vol. ii. p. 254.

Preterna- tendebatur orificium posteriora versus inclinans; justa tural Par- erant capitis situs, directio et aquarum formatio; pelvis turition. partesque molliores, viam partus constituentes, nullo la-

borabant vitio; quibus omnibus accessit adhuc sanus et robustus corporis feminei habitus, ct partus aliquoties autea perpessi felix eventus, quæ indubie ominabantur ineæptum hoece negotium partus felieiter quoque finicndum fore. In progressivo rite procedebat partus.

"In fine vero capite sponte nato, truncus solita facilitate sequi nolebat, quare obstetrix in arte adhuc novitia constitutam domus obstetricem expertem satis sociam sibi advocabat.

"Corpore fœtus ad latns revoluto, ut humeri in majore diametro aperturæ pelvis inferiori minorem facerent resistentiam, brachiisque eduetis, junctis viribus truncum ad axin pelvis extrahere moliebantur; attamen obstabat abdomen nulla illarum vi ulterius cedens.

"In auxilium tunc accedens, qui domum isto tempore artem addiscendi gratia habitabat studiosus, manum sub abdomine prudenter intulit, quod tensum atque complanatum sine omni obstaculo inveniebat; ulterius vero manum protrudens pedes tetigit, interque crura tumorem ingentem tensum fluidoque contento plenum reperiebat.

"Compressa hocce tumore, dum adstantes onmi vi truncum simul attrahebant, disrumpebatur subito, insignisque aquæ copia effluxit; superato sic obstaeulo, facillime extrahebatur fœtus, vitam per biduum trahens.

"Fœtus postea examinatus fæmellus erat, ingentem saccum inter femora gerens, qui ex elongatione integumentorum universalium corporis a tergo versus anteriora ita protraetorum, ut orificium ani ex facie anteriorie corporis prope vulvam conspiceretur, ortum habebat. In ipso sacco post effluxionem humoris, aquæ fere lib. iv. capiente, nihil præter hydatides parvas observatu dignum erat. Os sacro vero, ad angulum rectum versus posteriora curvatum caudæ instar prominebat (L)."

SECT. III. Of the Deviations from Natural Labour, which depend on the State of the Passages through which the Child is forced.

The deviations from natural labour occasioned by the state of the passages, originate either from the soft parts, or the bones.

The obstacles from the soft parts are tumours within the womb, thickening and induration of the neck and mouth of the womb, enlargement of the ovary, cicatrix in the vagina, collection of fæces within the rectum, swelling of the parts lining the pelvis, malformation and extreme rigidity of the external parts.

It is a curious fact, not only that conception sometimes takes place when there is a tumour within the womb, but also that pregnancy goes on to the full period. When this has happened, the tumour has been pushed down before the infant, and has filled up the passages.

If this obstacle be ascertained at an early period of the labour, which it must be if the practitioner be in

any ordinary degree skilful and attentive, the tumour Preternamay be pushed back, and the feet of the child may be tural Parbrought down. In a case of this kind, where the writurition. ter of this article was called in after the tumour had

become wedged within the pelvis, and the head had been opened, the delivery was accomplished with extreme difficulty, and the poor woman survived only a few hours.

The following singular case of an excrescence on the os uteri, is stated by Dr Denman, vol. ii. p. 65.

" In June 1770, I was desired to see a patient in the eighth month of her pregnancy, who in the preceding night had a profuse hemorrhage. Her countenance shewed the effects of the great loss of blood she had sustained; and from the representation of the case given me by the gentleman who was first called in, I concluded that the placenta was fixed over the os uteri. On examination I felt a very large fleshy tumour at the extremity of the vagina, representing and nearly equalling in size the placenta, which I judged it to be. Had this been the case, there could not be a doubt of the propriety and necessity of delivering the patient speedily; and with that intention I passed my finger round the tumour, to discover the state of the os uteri. But this I could not find, and on a more accurate examination, I was convinced that this tumour was an excrescence growing from the os uteri, with a very extended and broad basis. I then concluded that the patient was not with child, notwithstanding the distention of the abdomen, but that she laboured under some disease which resembled pregnancy, and that the hemorrhage was the consequence of the disease. A motion which was very evidently perceived when I applied my hand to the abdomen, did not prevail with me to alter this opinion.

"It was of all others a case in which a consultation was desirable, both to decide upon the disease, and the measures which it might be necessary to parsue; and several gentlemen of eminence were called in. That she was actually pregnant, was afterwards proved to the satisfaction of every one; and it was then concluded, that such means should be used as might prevent or lessen the hemorrhage, and that we should wait and see what efforts might be naturally made for accomplishing the delivery.

"No very urgent symptom occurred till the latter -end of July, when the hemorrhage returned in a very alarning way, and it was thought necessary that the patient should be delivered. There was not a possibility of extirpating the tumour, and yet it was of such a size, as to prevent the child from being born in any other way than by lessening the head. This was performed; but after many attempts to extract the child, the patient was so exhausted, that it became necessary to leave her to her repose, and very soon after our leaving her, she expired.

"We were permitted to examine the body. There was no appearance of disease in any of the abdominal viscera, or on the external surface of the uterus, which was of its regular form; and when a large oval piece was taken out of the anterior part, the child, which had

Chap. IV.

103

104

Preterna- had no marks of putrefaction, was found in a natural potural Par- sition. An incision was made on each side of the certurition., vix to the vagina, and then a large cauliflower excrescence was found growing to the whole anterior part of the os uteri. The placenta adhered with its whole surface; so that the blood which she had lost must have been wholly discharged from the tumour (M)."

> In two cases, where a great thickening and induration of the neck and mouth of the womb, approaching to the nature of schirrosity, had taken place previous to conception, the natural action of the uterus, though after a very considerable time indeed, assisted by copious blood-letting, eventually overcame the resistance. One of the patients died ten months after, with all the symptoms of real cancer uteri. The other was restored to perfect health after lying-in.

> Dr Denman has recorded (vol. ii. p. 73.) two cases, where the enlarged ovarium impeded the progress of the child. In the one case the head of the infant was opened, and the delivery completed by the crotchet; but the patient died at the distance of three weeks. In the other, a trocar was passed into the tumour, and a living child was born. The patient recovered from her lying-in; but died hectic at the end of six months. In such cases, the ovary may be pushed back, if the circumstance be discovered early enough.

Cicatrix of the vagina, in consequence of former injury, may appear at first to impede the progress of the infant; but it will always be found to yield to the pains, if the strength of the patient be supported, and proper means be adopted to counteract the effects of the long continued labour throes. A case occurred some time ago to Dr Hamilton, where a substance, of the hardness of gristle, as thick as an ordinary sized finger placed between the vagina and rectum, and apparently extending from the ramus of one ischium to that of the other, presented an unsurmountable obstacle to the passage of the child. He was called in after an unsuccessful attempt had been made to tear away the infant, and found the woman in a state of extreme danger. He was informed, that five years before that period, she had had a very severe tedious labour, followed by great inflammation and suppuration of the external parts. The indurated part was cut through without the patient making any complaint, and the child was very easily extracted; but she survived the delivery only two days. The relations would not permit the body to be opened.

A collection of fæces within the rectum has been known to occasion such resistance to the passage of the child, that the woman has died undelivered. In general, however, it is in the power of an active practitioner to empty the gut at the beginning of labour. But if, from neglect, the head of the child be jammed in the pelvis, and immoveably wedged in consequence of an accumulation of fæces, it then becomes necessary to open the head.

Perhaps the most frequent affection of the soft parts which impedes the process of the infant is, swelling of the parts lining the pelvis. This circumstance has been Vol. XIV. Part I. +

already hinted at. It can never happen where the prac- preternatitioner is ordinarily attentive; for the tenderness, heat, tural Parand dryness of the passages, which precede the actual turition. swelling, cannot be overlooked by one at all aware of the possibility of such an event. When it has actually happened, nothing can save the mother but opening the head of the infant. After this most unpleasant operation is completed, the extraction of the child is seldom a matter of much difficulty.

Malformation of the external parts in some cases does not prevent conception. Two cases have fallen within the knowledge of the writer of this article, where the woman had conceived though the orifice of the vagina had not been capable of permitting the introduction of even the little finger. And it consists with his knowledge, that about thirty years ago a woman under similar circumstances, was brought into the Royal Infirmary of this place, and was delivered by the Cæsarean operation. She died within two days.

It is sufficiently obvious that the safe practice under such circumstances is to enlarge the natural opening, by making an incision in the direction of the perinœum, taking care not to wound the sphincter ani.

Extreme rigidity of the external parts is one of the most frequent causes of deviation which depends on the state of the soft parts. It takes place, in a greater or less degree, in the greatest number of women who lie in for the first time ; and generally in all women who are considerably advanced in life before they have children.

It is seldom that the resistance opposed by the external parts is so very great as to prove an invincible obstacle to labour. But, on many occasions, the longcontinued pressure of the child on those parts produces the most disagreeable consequences, as inflammation of all these parts and of the bladder. Inflammation in those parts is always dangerous, for there seems to be a remarkable tendency to gangrene. Cases are on record where the whole parts have sloughed off, and where the rectum, vagina, and bladder, have formed one canal. Perhaps death is much preferable to life under such circumstances.

Copious blood-letting, and the liberal use of some unctuous application, with time and patience, in general overcome the rigidity of the external parts. Placing the patient over the steams of hot water was formerly recommended in such cases, but this practice is now exploded.

B. Many deviations from natural labour occur from the state of the bones of the pelvis, for they may be so much altered in shape as either to increase or diminish considerably the aperture of that part.

d. When the apertures of the pelvis are too large, the mother incurs much danger, and the child is not totally exempt from hazard.

aa. The danger incurred by the mother arises from there being no resistance to the passage of the child, so that when the action of the uterus begins, the child may be pushed by the force of the pains through the passage before the soft parts be dilated ; hence the uterus may be ruptured, or the soft parts lacerated. If, I on

65

108

IOg

IIO

(M) Were such a case again to occur, there could be doubt respecting the propriety of fixing a ligature round the neck of the tumour.

Preterna- on the other hand, the external parts be soft and tural Par- yielding, a considerable portion of the uterus may be turition, excluded without the parts. There is a very wonder-

ful history of a case of this kind alluded to by Saxtorph in the following words. "Memorabilius adhuc excanplum est illud à cel. Wolfg. Mullnero allatum, ubi totus uterus una cum foctu extra genitalia dilapsus, foctusque vivus extra pelvim versione extractus fuit, matre post reductionem uteri superstite. Vide ejus Bahrnehmung von einer samt dem Rinde ausgefallenen Debahrmutter, Nurnberg 1771 (L).

bb. The hazard which the child undergoes is that of being suddenly expelled, included within the entire ovum, so that it may be lost before proper assistance can be afforded. Another danger is, that the membranes having given way, it may be dashed with violence upon the floor on which the patient walks. Whenever from the great width of the hips, there is reason to suspect that the pelvis is too large, the practitioner should continue in constant attendance from the very commencement of labour, and should carefully adopt the appropriate and obvious means to prevent the hazards just enumerated.

e. But deficiency of space in the apertures of the pelvis occurs much more frequently than increase. The apertures of the pelvis may be diminished from natural small size or malformation of the bones, from exostosis, or from altered shape in consequence of mollities ossium.

Cases where the sacrum and ilia are of an uncommon small shape are not frequent. Narrowness of the base of the sacrum is sometimes met with; and in a few cases it has been found that the apex of the sacrum has approached too nearly to the anterior part of the pelvis, so as to diminish the apertures at the outlet

Exostoses seldom prove an obstacle to delivery; but one exception to this rule fell under the observation of the writer of this article several years ago. The exostosis extended along the whole extent of the symphysis public, and was fully as thick as an ordinary sized finger. The woman had been delivered previous to his being called in, but the exhaustion which followed, (for she had been allowed to continue five days and nights in constant hard labour) occasioned her sinking a very short time after delivery. In this instance both mother and child were lost from the self-sufficiency and ignorance of the midwife.

The deficiency may exist in the brim, the outlet, or the cavity singly or combined.

The brim is much more frequently affected by mollities ossium than the outlet; and, as was long ago remarked by Levret, it generally happens, that when the brim is narrowed from this cause, the outlet is widened.

The brim may be diminished in size by the projection of the promontory of the sacrum, or by the flattening of the pubes, or by the approximation of the bones where the pubes and ilia unite, or by a combination of some of these circumstances. The projection of the promontory of the sacrum, however, is by far the most

common. When this happens, the projection sometimes Preternarenders one side of the pelvis wider than the other, and tural Parthis constitutes what authors call the distorted pelvis.

The deficiency in the brim produced by these causes is very various; most frequently slight, but sometimes so great that there is not an inch between pubes and sacrum.

The outlet may be diminished by the approximation of the tuberosities and rami of the ischia, or by the apex of the sacrum and coccyx projecting more than usually forward, while they are at the same time hooked np.

When both the brim and outlet are diminished in aperture, the cavity of the pelvis is generally affected also; but when the deficiency of space is confined to either, the cavity is commonly more shallow than natural, by which both the resistance and the danger are considerably lessened. Melancholy are the cases where the cavity is rendered deeper than usual.

As the practice in cases of extreme deficiency in the apertures of the pelvis is to be regulated by the degree of narrowness, it is a matter of the first importance to be able to ascertain the dimensions in any given case with tolerable precision.

For this purpose, instruments called pelvimetres have been invented. M. Coutuoli has proposed one for internal use, and M. Baudelocque has recommended one for external application. But however plausible in theory the use of such contrivances may appear, it is now well known that no dependence can be placed upon them in actual practice, and therefore the hand of the operator must be had recourse to for determining both the shape and the extent of the apertures of the pelvis, wherever there is any narrowness. The following directions for this purpose given by Dr Wallace Johnson are extremely judicious.

" On passing the finger along the vagina, if the eoccyx, or any part of the sacrum, be felt unusually forwards or near at hand; or if the symphysis, or any other part of the pubes, is found projecting rather inwards than outwards, it is evident that the pelvis is distorted. In which case, as well as in those where it is not distorted, but only very small, the principal part of the child's head (allowing the presentation right) remains high, the vertex making only a little round tumor within the brim: so that when the os uteri is opened, and come a little forwards towards the pubes, the capacity of the pelvis may be found out by moving the end of the finger round that part of the head which has entered the upper strait. This method is used by several practitioners in London. However, should the finger not be long enough to effect it properly, as sometimes is the case, there is then another method, which, being more certain, may be used, provided it be done with tenderness and caution, and when the orifices are so well opened as to admit of it with safety. But previous to it, the operator must be well acquainted with the dimensions of his own hand, viz.

" First.

MIDWIFERY.

Chap. IV.

Preterna-

"First, The fingers of a middle-sized hand (as we tural Par- may suppose the operator's to be) being gathered togeturition ther equally into the palm, and the thumb extended and applied closely along the second or middle joint of the finger; the distance between the end of the thumb, and outer edge of the middle joint of the little finger, is usually four inches.

" Secondly, Whilst they are in the above position, the distance from the thumb, at the root of the nail, in a straight line to the outside of the middle joint of the little finger, is full three inches and a half.

" Thirdly, the fingers heing still in the same situation, and the thumb laid obliquely along the joints next the nails of the first two fingers, and bent down upon them; the distance between the outside of the middle joint of the fore finger, and the outside of that of the little finger is three inches and a quarter.

" Fourthly, The hand being opened, and the tops of the four fingers being a little bent, so as to come nearly in a straight line; their whole breadth, across the joint next the nails, is two inches and a half.

" Fifthly, when the first three fingers are thus bent, their breadth across the same joint is two inches.

"Sixthly, The breadth of the first two, across the nail of the first finger, is one inch and a quarter. "And, seventhly, The fingers being gathered into a

conical form, the thumb lying obliquely upon the palm of the hand, with its point upon the first joint of the ring finger, reckoning downwards, will measure in thickness, between its back and the fore part of the thumb, two inches and two-eighths.

" Now, as hands are extremely various, the operator ought always to know how much the size of his differeth from the above dimensions; and this being rightly understood, the application may be made as follows:

"The patient, being in the position as for natural delivery, and the operator's lcft hand being well anointed, and the fingers and thumb gathered into a cone, it must be gently passed into the vagina, and then through the os uteri, unless in this part there is still a rigidity to forbid it ; if so, the fingers only must be passed, their extremities formed into the fourth dimension, and then placed edgeways in the strait; which being dene, if the fore finger touch the angle of the sacrum, and the little one the symphysis of the pubes, the width is then manifestly no more than two inches and a half; a space through which a mature child can neither pass alive, nor be brought so by art, unless it happens to be preternaturally small indeed."

Three methods of practice have been adopted in cases of such narrowness of the pelvis as renders it impossible for the child to be protruded alive, viz. the operation of embryulcia or embryotomy, the Cæsarean section, and the division of the symphysis pubis.

I. Embryotomy. The cases requiring this most shocking operation are those where the infant cannot be extracted alive through the natural passages; while there is, nevertheless, such space that it may be torn

away piece-meal without injury to the mother. Of Preternacourse, in these cases the life of the woman can be saved tural Parturition. only at the expence of her infant.

But although authors and practitioners in modern times adopt in general this principle, they differ materially in their account of the precise cases requiring the operation.

Dr Osborn alleges, that, as the head of the infant at the full time of utero-gestation cannot be diminished to less than three inches between the parietal protuberances by the natural contractions of the uterus forcing it against the bones of the pelvis ; wherever the aperture at the brim or outlet falls under three inches, the operator ought to proceed as soon as possible to open the head of the infant.

But on so very scrious an operation as that by which one life is destroyed, it becomes a practitioner to adopt no rule which can be at all liable to error; and it is evident, that there are three very strong objections to this precept of Dr Osborn.

First, It is impossible in any case at the beginning of labour, to ascertain that the infant is at the full term of utero-gestation; but it is well known, that a child at the age of between seven and eight months, if born alive, may be reared to matnrity, and that such a child is capable of being expelled without injury, through an aperture incapable of permitting the passage of a full-grown foctus. Secondly, The heads of children, even at the full

time, are sometimes so small and so yielding as to admit readily of their short diameter being diminished below three inches.

Thirdly, every candid practitioner must allow, that it is quite impossible to ascertain with geometrical accuracy the precise tlimensions of the pelvis; and consequently what in any given ease may appear to the operator to be less than three inches, may in fact be above these dimensions.

For these reasons, wherever the narrowness is not obviously very considerable, the prudent rule is to ascertain the effect of the labour-throes, supporting the strength of the patient, and palliating distressing symptoms. By adopting this rule, the practitioner will not only have the consciousness of not having destroyed life unnecessarily, where he is eventually foreed to open the head, by the conviction that it is too large to pass unopened, but also the innate satisfaction of sometimes saving a life, which under less cautious management must have been sacrificed. Great care indeed is necessary in such cases not to be deceived in the estimate of the progress of the child, for the swelling of the scalp may mislead a young practitioner.

There has been a variety of opinion too, respecting the lowest dimensions of the pelvis which permit the operation of embryulcia with safety to the mother; and it is surely unnecessary to state, that unless there be a moral probability of saving the life of the mother by this operation, it ought never to be had recourse to.

Dr Kellie, of London (P), and Dr Osborn (Q), have recorded some cases where this operation was performed, I 2 although

68

Preterna. although the narrowness was very great; and the latter tural Par- gentleman, founding on a single case, assumes the printurition , ciple, that whenever there is a space equal to an inch and a half between pubes and sacrum, the operation of embryulcia is practicable. But a careful perusal of the case alluded to (A) must satisfy any unprejudiced person that there must have been some mistake, most probably, from the swelling of the soft parts lining the pelvis having added to the apparent narrowness, and having, after the head had been opened above 36 hours, subsided. And at any rate, since experience has now fully established the fact, that the danger resulting from this operation is always in proportion to the degree of resistance, it may be concluded that the operation of embryulcia cannot prove safe to the mother, unless, first, there be an aperture equal to about two inches by four; and, secondly, the narrowness be chiefly, if not altogether, confined either to the brim or the outlet. When both hrim and outlet arc deficient, and the cavity is deeper than usual, even although the several apertures be quite sufficient to allow the diminished head to be extracted, the injury that must accrue from the violent pressure on all the parts within the pelvis would deter any prudent practitioner from hazarding such an operation.

When it is determined to have recourse to the operation of embryotomy, the instruments required are the perforator, the crotchet, and the embryotomy forceps delineated in the plate.

The operation is to consist of two different processes; first, the diminution of the head; and, secondly, the extraction of the mangled child. In many cases the latter should be performed immediately after the former is accomplished; but whenever the resistance is very considerable, an interval should be interposed between the two. The advantages resulting from this practice were first publicly noticed by Dr Osborn, though there can be little doubt that the practice itself was the effect of necessity. By waiting after the head has been opened, the woman's strength will be restored, so that the assistance of the pains in the expulsion of the child may be obtained ; the swelling of the soft parts will subside, by which the resistance may be greatly lessened, as well as the danger of inflammation removed, and the child's body will become putrid, by which its extraction may be greatly facilitated.

In opening the head, which is to be done by mcans of the perforator, the two great points to he aimed at are to avoid injuring any part of the woman, and to make a sufficiently large opening of the head. On the complete accomplishment of the latter, the eventual success of the operation must depend in all cases of extreme deficiency of space.

Should it be found expedient to delay the extraction of the infant after the head has been opened and its contents evacuated, the teguments are to be carefully brought over the ragged edges of the bones, so that in the event of labour throes recurring, there shall be no risk of the parts within the pelvis being injured.

When it has been found proper to proceed to the ex- Preternatraction of the infant, the first thing to be attempted is tural Parto diminish the bulk of the cranium as much as possible. turition. This may be done by means of the embryulcia forceps, delineated in the plates, and contrived it is believed by Dr Lyon of Liverpool. It is an instrument far supcrior to the almisdach of the Arabians, in use even within these fifty years among the practitioners of this island (B).

After the head has been sufficiently reduced in bulk, the crotchet is to be fixed at first on the inside of the cranium; and while two fingers of the left hand are to be kept constantly so applied that if the instrument should slip in the process of extraction, it shall he received on the fingers, and cannot possibly touch any part of the mother, the operator is to draw down with a suitable exertion of force, in such a direction that the largest part of the head shall be brought through the widest part of the pelvis.

In some cases, much time and very violent exertions are required to accomplish the delivery; but, if the proper precautions to prevent any injury to the passages be adopted, and if at the same time the operator imitate nature by working only from time to time, and increase the force employed gradually as may be required, and persevere patiently, notwithstanding the resistance, taking care to support by nourishment and cordials the strength of the woman, the delivery at last will be completed.

The dangers to be dreaded from this most shocking operation, are injuries of the passages, from the instrument's slipping through the embarrassment of the practitioner; or violent inflammation of all the contents of the pelvis extending to the abdomen, in consequence of the parts through which the child must be so forcibly extracted being severely bruised. Accordingly, a greater number of women die from the effects of this operation than practitioners are willing to admit; and indeed, in every case of extreme deficiency of space, where embryotomy is performed, the recovery is to be regarded as doubtful.

This operation is sometimes had recourse to in cases where the forceps should have been used had the child been alive. But such cases are very rarc, because the evidence of the infant in utero being dead, is seldom so complete as to justify the practitioner proceeding on the principle that it is so.

II. By the Cæsarean section is meant the extraction of the infant through the parietes of the abdomen by an incision into the uterus.

This bold operation was perhaps never performed by the ancients on the living subject, and certainly was first recommended to practitioners by M. Rousset in his Traite nouvelle de l'Hysterotomie, &c. 1581. Since that time it has been often performed on the continent, and about twenty times in Great Britain. The success of this operation recorded in the early works has certainly been exaggerated; but it appears by an elaborate memoir by M. Baudelocque, translated into English

120

Preterna- by Dr Hull of Manchester, that during the 50 years tural Par- preceding 1802, the operation has been had recourse tarition. to on the continent 95 times, and that 37 of these cases

proved successful. In Great Britain, on the contrary, this operation has never yet succeeded, a circumstance to be attributed partly to the delay which has always taken place after the necessity for such an expedient had been dctermined, and hence the patient, at the time the operation was performed, must have been in a state of exhaustion; and partly, perhaps chiefly, to the previous very alarming state of health of the subjects of the operation in this island. It is at any rate certain that all over the continent practitioners have less horror at performing the Cæsarean section than British practitioners have commonly shewn; and it is decened necessary in cases where the operation of embryulcia is preferred in this country, and where of course the women are not in such a precarious state of health as those commonly are who have extreme narrowness of the pelvis.

In consequence of the fatality of the Cæsarean section in Great Britain, several eminent practitioners have regarded it as unjustifiable. Dr Osborn has rendered himself particularly conspicuous on this subject, and uses very strong language in reprobation of it. His arguments are, its acknowledged fatality ; the capability of completing the delivery by means of the crotchet, in cases of such deformity of the pelvis, that there is no more than one and a half inch between the pubis and sacrum, or to one side of the projecting sacrum ; and the impossibility of impregnation taking place in cases of greater deficiency of space. We shall notice these arguments in their turn.

1st, The acknowledged fatality of the operation .--This relates only to the result of the operation in Great Britain ; for, as already mentioned, a great proportion of the patients has been saved on the continent. But in insisting on this argument Dr Osborn has overlooked that the object of the operation is to save, if possible, two lives, and at any rate one. Now if it can be satisfactorily proved, that on some occasions the operation of embryotomy is absolutely impracticable, it becomes the duty of the practitioner to save one life at least; and it is well known that the Cæsarean operation is far less painful to the woman than that of embryotomy, even where that latter operation is eventually successful. In such cases of extreme deformity, either an attempt should be made to deliver the woman and save the child, or both must be allowed to perish; for the operation of embryotomy, if attempted, must be regarded as wilful murder.

2dly, The practicability of tearing away the child in pieces by means of the perforation and crotchet, in cases where there is no more than an inch and a half between the pubis and sacrum, or to one side of the projecting sacrum, is alleged by the doctor on the foundation of a single case, that of Elizabeth Sherwood already referred to. But any person who shall take the trouble to have the aperture of Sherwood's pelvis, as stated by Dr Osborn, cut out in wood, and to compare this with the basis of an infant's skull as much diminished as possible by the crotchet (which is done in the

course of his lectures by the professor of midwifery in Preternathis university), must be convinced, that there was tural Par some mistake in the supposed dimensions of that wo-man's pelvis. And it is quite obvious, that unless there be the space already stated, viz. three and a half or four inches by two, it is unsafe to extract the mangled child through the natural passages.

3dly, The allegation that where there is a greater degree of narrowness of the pelvis than that which was supposed to have happened in the case of Sherwood, impregnation cannot take place, is quite inconsistent with facts. One of the most remarkable cases of extreme deformity is that of Elizabeth Thompson, on whom the Cæsarean operation was performed at Manchester in 1802. The description as given by Dr Hull (G) is as follows: " The pelvis of this patient was not nearly so soft as has sometimes heen observed. It still had a considerable degree of hony firmness. The ossa innominata at their sacro-iliac synchondroses, and at the symphysis pubis, before the pelvis was dried, admitted of a slight degree of motion .- The distance from the crista of one os ilium to the other, at their most remote points, measures ten inches and a half.

" The alæ of both ossa ilia are very much bent; and on the left side the curvature is so great, that it measures only two inches from the anterior and inferior spinous process to the opposite posterior point. The lumbar vertebræ project forwards or inwards, and make a considerable curve to the left side of the pelvis. The distance from the lower part of the second lumhar vertebra to the anterior part of the spine of the os ilium, on the left side, is two inches. The distance from the lowest part of the second lumbar vertebra to the anterior part of the spine of the os ilium, on the right side, is five inches.

" Superior aperture. The conjugate or antero-posterior diameter, from the symphysis pubis to the upper edge of the last lumbar vertebra is one inch and a half. -This diameter is not taken from the os sacrum, or its junction with the last lumbar vertebra, because the point of their junction is so much sunk into the pelvis, that the place it should have occupied, is represented by the junction of the fourth and fifth lumbar vertebra. The tranverse diameter measures four inches and fiveeighths. It is taken from one sacro-iliac symphysis to the other. The distance of the point of this aperture, which is opposite to the anterior part of the right acetabulum, from the lumbar vertebra, is only half an inch. The distance from that part of this aperture, which corresponds with the posterior part of the right acetabulum, to the os sacrum, is three-fourths of an inch. The distance of the point, corresponding with the anterior part of the left acetabulum, from the lumbar vertebra, is five-eighths of an inch. The distance of the point of this aperture, opposite to the posterior part of the left acetabulum, from the os sa-crum, is three-fourths of an inch. The distance of one os pubis from the other, in the points marked in the plate, is seven-eighths of an inch. The distance from the right sacro-iliac symphysis to the symphysis pubis is three inches and three-fourths. The distance

60

130

131

(G) Observations on Mr Simmons's Detection, &c. p. 195.

Chap. IV. Chi

turition.

70

Preterna- stance from the right . aero-iliac symphysis to the left os tural Par- pubis is three inches and three-eighths. The distance from the left sacro-iliac symphysis to the symphysis pubis is three inches and five-eighths. The distance from the left saero-iliac symphysis to the right os pubis is three inches and one-fourth. The largest circle, that can be formed in any part of the superior aperture, does not exceed in diameter one inch.

132

" Inferior aperture. The distance from one ramus ossis ischii to the other, where they are united with the rami ossium pubis, measures only half an inch. The distance from the tuberosity of one os ischium to the other measures one inch and two-tenths. The conjugate or antero-posterior diameter, taken from the symphysis pubis to the point of the os coceygis is three inches.

" The angle, included by the rami of the ossa pubis, is very acute, viz. an angle of about 20 degrees. The perpendicular height from the tubera of the ossa ischia to the inferior margin of the symphysis pubis is two inches and a half. The perpendicular height of the symphysis pubis is one inch and a half. The tuberosity of the left os ischium advances forwards, beyond that of the right, about six-tenths of an inch, and the whole of the rami ossis pubis and ischii on the left side projects beyond those of the right. The perpendicular height of the os saerum and coccyx is two inches and one-fourth only, the os saerum being bent so as to form a very acute angle. The acetabula, at their nearest points, are only three inches distant. The symphysis pubis is much more prominent than natural. The upper margin of the symphysis pubis is situated as high as the bottom of the fourth lumbar vertebra."

It appears then that Dr Osborn's arguments are fallacious, and that cases occur where the operation of embryotomy is neither safe nor practicable. Under such circumstances, the Cæsarean section must be had recourse to; and it is therefore to be regarded as an operation of necessity, not one of choice. If this rule be adopted, the cases requiring so formidable an expedient will happily be very seldom met with.

Mr Simmons of Manchester, observing that Dr Osborn's third argument is untenable, has proposed in the following words, another substitute for the Cæsarcan operation.

"When a case shall arise in which the child eannot be delivered by the croehet, from the brim of the pelvis being no more than one inch in diameter I propose to combine the two operations, and to divide the symphysis pubis to make way for the crotchet. Dr Osborn has urged several objections against this proposal, although he admits that the operation at the symphysis is not so certainly fatal as the Cæsarean section. Weighty objections doubtless press against it; but while there are no other means for preserving life, bad as the chance is, it becomes a question whether it be worth risking; and, after maturely considering the case, should an attempt for saving the life of the mother be judged expedient, as the last resource it may be adopted.

" The space gained has been differently stated at from three to eight or nine lines in the diameter ;-- the medium distance would probably be sufficient to accomplish the delivery by the erotchet.

" The objections urged against this mode of delivery, when the head is of the full size, will not apply to its

4

reduced bulk ; and it should be remembered, that the Preterna. symphysis is formed of cartilage and ligament ; so that tural Parwhatever pressure shall be made against the divi- turition. ded edges, will not be made against the sharp angles of bone. That much injury may be done anteriorly will not be denied; but does the continued pressure of the child's head never produce misehief in other cases? By the introduction of a female sound for a guide, a cautious and steady operator will avoid wounding the urethra; and, as the base of the skull will probably be turned sideways, it will suffer less in extraction than in other cases of the crotchet; in which it must in general be injured from pressure against the pubis. If the separation, however, be carried beyond a certain length, laceration will probably ensue; and, should this accitent occur, I see no reason to apprehend more danger from it than follows the extraction of a large stone from the bladder through a small opening, which will induce a lacerated wound, but which we know will not uncommonly heal. The sacro-iliac ligaments would certainly not be injured by choice, but the consequences, I believe, are not generally fatal; and, should it be urged that great pain and lameness will afflict the patient for a long time after, a reply will readily occur, that life was at stake; and surely there are few who would not compound, for the prospect of temporary pain and inconvenience, to have it preserved to them.

" A spontaneous separation sometimes occurs, both there and at the pubis; and yet the patient has been again restored to health.

"I do not sec, in other respects, in what this compound operation differs from the most difficult crotchet case-the Cæsarean section is certainly fatal to the mother in this country-the life of the child, it is agreed, shall not be put in competition with the parent's lifethe section of the symphysis is neither so formidable nor so fatal as the Cæsarean section-and the crochet has been successfully applied in dimensions which will probably be thus acquired.

" Upon the whole, then, in that supposed ease of distortion (which I hope will never happen) in which the mother must be doomed to death, from the impossibility of delivering the child by the crotchet, the eompound operation I have recommended will furnish a resource, approved by reason and sanctioned by experience; inasmuch as the section of the symphysis pubis has been made, and the crotehet has been used, though separately, yet with safety. Such a case will be attended, unquestionably, with additional hazard; but it offers the only chance to the mother, to the preservation of whose life our chief care should be directed : and I hope that in future all trace of the Cæsarean operation will be banished from professional books; for it can never be justifiable during the parent's life, and stands recorded only to disgrace the art."

He himself has afforded the most satisfactory evidence of the absurdity of his own proposal; for he had not published it many months when the very case he had described as ideal actually occurred in his neighourhood, and he had the opportunity of making the experiment of his own plan. But he shrunk from it, and no wonder; for the woman was Elizabeth Thompson, whose pelvis has just been described. It is unfortunate that Mr Simmons has not had the candour to confess his error, and to retract his opinions, more especially since his reflections

reterna- flections against the Cæsarean operation, were couched and Par- in language poculiarly bitter and invective. witton With respect to the mode of performing the Cæsarean

With respect to the mode of performing the Cæsarean section, there has been considerable variety of opinion. On theoretical principles, the external ineision, viz. that through the parietes abdominis, ought to be in the direction of the linea alba, because there is less chance of any considerable retraction of muscular fibres, or of interfering with the intestines, than if it were made in any other direction. But the result of the practice seems at variance with the theory. According to the testimony of Baudelocque, of 35 operations, where the incision was made on the side of the abdomen, eighteen proved successful; of thirty in the direction of the linea alba, ten only succeeded ; and of eight in the manuer recommended by Lauverjat, that is, by a transverse incision between the recti muscles and spina dorsi, three succeeded. But it may be remarked, that the event, in many of those eases, may have been influenced by a variety of circumstances, totally independent of the line of direction of the external incision.

In whatever part of the abdomen the external ineision be made, it ought to be extended to six inches; and, previous to cutting into the uterus, any active arterial branch, which may have been divided, must be secured ; and the liquor aninii, if not already discharged, must be drawn off. The opening into the uterus need not be above five inches in length, and should be made as much towards the fundus as possible. Mcans are to be employed to prevent the protrusion of the intestines at the time the uterus is emptied. Both feetus and secundines are to be quickly extracted; after which, the hand is to be passed into the uterus, to clear out any coagula which may have formed within its cavity, to prevent the os tincæ being plugged up, and, at the same time, to promote the contraction of the uterus. The wound in the uterus is to be left to nature; but that of the parietes of the abdomen is to be carefully closed by means of the interrupted suture and adhesive straps; and the whole belly is to be properly supported. by a suitable bandage or waistcoat. In the after treatment of the patient, the great objects to be held in view, are to support the strength and moderate the degree of local inflammation.

III. Division of the symphysis publis.—This was originally proposed and performed by M. Sigault of Paris. His proposal was made in 1768; but he had no opportunity of making the actual experiment till September 1777.—The success of his first case was such, that a medal was struck to commemorate the event; and the operation was admired and recommended, with all the extravagance of French enthusiasm.

The operation consists of the division of the symphysis publis and separation of the innominata. For this purpose, a catheter is to be introduced into the urcthra, and, with a common scalpel, the articulation is to be cut through from the upper edge of the symphysis, to within a quarter of an inch of the inferior edge. By separating the thighs, the divided bones are forced asunder. After this, the operator is either to turn the

child, or to extract it by the forceps, according to the Preternacircumstances of the case.

This expedient was proposed as a substitute, both for the operation of embryulcia, and for the Cæsarean section, as it was alleged to be perfectly consistent with the safety both of mother and child.

It is quite unnecessary for us to offer any theoretical objections to this operation, because we can now reason on the event of thirty-six cases, which have been published.—But those who may wish to investigate this subject, may consult Baudelocque, par 1994. and 2091. inclusive; and Dr Osborn, p. 271. To that latter practitioner's professional zeal and ability is chiefly to be ascribed the total rejection of this operation in Great Britain.

Of the thirty-five subjects of the published cases (for in one woman it was performed twice), fourteen women and eighteen children died.—Of the twenty-one women who survived, nine had either had living children before the Siganltian operation, or had such at a subsequent period. Most of the remainder suffered much from the operation. Some had incurable incontinence of urine, others lameness, &c. But the most important fact is, that whenever the bones of the pelvis were separated from each other above an inch (and no space of any consequence could be added to the brim, unless they were so), the sacro-iliac synchondroses were torn, and no woman survived that accident.

These facts have at last convinced foreign practitioners of the futility of this expedient; and, accordingly, for above ten years, it has not been performed on the continent by any practitioners of respectability.

When a woman, with a narrow pelvis, who has had the good fortune to recover after the operation of embryotomy, again falls with child, she should not incur the hazard of a repetition of so horrible an operatiou; but ought to have premature labour induced between the seventh and the eighth month. Under the direction of an intelligent practitioner this operation is easily performed; and, while it affords the only chance of saving the infant, which it is the duty of the mother and of the practitioner to attempt, it at the same time, by lessening the resistance, diminishes both the suffering and the risk of the patient (N).

For a further account of the practice in cases of extreme deformity of the pelvis, the reader is referred to Osborn's Essays; Hamilton's Letters to Osborn; Simmons's Reflections, and Hull's Detection of Simmons.

SECT. IV. Of the Deviations from Natural Labour which happen from anomalous circumstances.

Certain circumstances besides those already enumerated occasion deviations in the process of labour. Some of these respect the child, and others the woman.

a. The child's life is endangered if the navel-string be so strongly convoluted round its neck, that after the head is born the remainder cannot be expelled without the cord being drawn so tight as to interrupt the circulation through it. Dr Denman, vol. ii. p. 16. has stated this as a cause of protracted labour, and has advised

(N) See a paper on this subject, in the 18th volume of the Medical Facts and Observations, by Mr Barlow.

137

IAG

Chap. IV.

Preterna- vised certain modes of practice in consequence. But tural Par- if there be pains, there cannot be any material protracturition. tion of the labour from this canse.

All risk of the infant may be prevented by slackening the cord, and waiting for the action of the uterus, if the operator find thut he cannot draw the loop of cord which surrounds the child's neck easily over its head. But this in most cases can be readily done.

b. The cord is sometimes pushed down before the presenting part of the child.

If this happen before the membranes are burst, the only certain method of saving the child is to perform the operation of turning as soon as the state of the passages will permit.

When the cord is pushed down along with some other part, as the head, after the waters are discharged, a variety of practice is required according to the circumstances of the particular case; hence merely keeping the cord for a little time beyond the presenting part by means of the fingers, or wrapping it up in a piece of soft rag, and pushing it above the presenting point, or the application of the forceps, are severally found useful in different cases.

c. Sometimes one or both arms of the child are forced down along with the head, where proper assistance is not had at the beginning of labour. If the pelvis he roomy, and the woman have formerly had children, the delivery may be at last completed by the natural powers, notwithstanding this increased degree of resistance. But in many cases of this kind an experienced practitioner is not called in till the strength of the woman be very much exhausted, and then it becomes necessary to use the forceps, or even on some occasions to have recourse to the operation of embryulcia.

d. It is well known, that sometimes there is more than one child in the womb. Instances where there are twins are not unfrequent; cases of triplets are alleged to happen once in between three or four thousand births; four at a birth have not occurred in this city for the last twenty-seven years; and there are only two, or at most three, well-authenticated cases of five at a birth having happened within a hundred years in this island.

All the signs by which the existence of more than one child in utero can be ascertained, previous to the actual commencement of labour, are fallacions; and in general it is not till after the birth of one child that it can be determined that, another remains in the womb; and, unless under very particular circnmstances, it is of no importance. The circumstances alluded to are where different parts of both children are forced into the passage at the same time. Of this a very remarkable case is recorded in the book of Genesis, verse 27, chan. xxxyiii.

27. chap. xxxviii. When the womb appears to remain bulky and hard after the hirth of one child, there is reason to suppose that it contains a second. But if there be any doubt on the subject, the practitioner has it in his power to ascertain the point by examination. When there is no second child in the uterus, the further the fingers are carried up within the passages, the more contracted do they feel; whereas, if there be a second child, the more open are they found.

When it is ascertained that another infant remains, the woman's belly should be immediately compressed by

I

means of a roller, in order to prevent faintishness from Preterna the sudden relaxation of the parietes abdominis, and tural Parthe portion of the navel-string remaining attached to the after-birth of the first born should be carefully secured, let the vessels of the placenta anastomose.

In regard to the subsequent treatment, there has been much variety of opinion among practitioners. Some have proposed waiting 'till the action of the nterus expel the second as it had done the first infant. Others urge strongly the necessity for immediate delivery.

Against the former of these practices it is to be objected; first, that in some cases, days or even weeks have been known to intervene between the birth of one child and the action of the uterns which expelled the second. Secondly, that if this happen, the passages must become contracted and their subsequent dilatation may be productive of inflammatory symptoms. Thirdly, that during the time the uterine action is suspended, internal hæmorrhagy may take place, and may destroy the patient. And, fourthly, the second child may be suddenly forced down in such a position, as may endanger its life, and at the same time occasion great pain to the mother.

For these reasons it is now an established rule among judicious practitioners, to examine the situation of the second infant, as soon as the patient shall have recoyered from the shock of the birth of the first child; and, if its position be natural and the patient have not been exhausted by the previous labour, and pains come on, to rupture the membranes, and allow the natural powers to complete the delivery. But if the infant present any other part than the head, or though the head do present, if the woman be exhausted, or if there be no appearance of the return of pains within an hour after the birth of the first, then the hand is to be passed up to bring down the feet of the second child, and the delivery is to be expedited. The extraction of the placentæ is to be conducted with great care, and every possible precaution is to be adopted against the occurrence of flooding, which is always to be dreaded as the consequence of plurality of children.

The same principles apply to the management of triplets, &c.

d. Umbilical hernia, to which women are perhaps more subject than to any other species of rupture, may influence the labour materially.

If it be reducible, it disappears after the fifth month of pregnancy; but immediately after the expulsion of the child it returns, and occasions frightful faintings and floodings. This may be prevented by the simple expedient of having the belly compressed by a roller in such a manner, that in proportion as the infant advances, the compression may be increased.

Should it be irreducible, if the hernia be affected by the continuance of labour, as may be known by the colour, &c. the operation of turning must be had recourse to.

e. Convulsions sometimes happen during labour, and occasion great danger both to the mother and the child. The woman is quite insensible during the fit, which consists of violent convulsions of the muscles which move the body, and of those of the eyes, the face, and the lower jaw; it lasts in some cases only a few seconds, and

149

reterna- and in others for several minutes. After the fit has anal Par- ceased, it sometimes happens that the patient remains in turition a comatose state ; in other cases the sensibility returns.

The circumstances which distinguish this disease from epilepsy were first stated explicitly by Dr Hamilton in the following words : " The old distinction between eclampals, vol. v. sia and epilepsia has been rejected by Dr Cullen, without sufficient reason. The convulsions that occur during pregnancy and labour, should be distinguished by the former name, for the disease is always an acute one, and it never, as far as my experience goes, lays the foundation for habitual epilepsy. To an inattentive practitioner, indeed, the phenomena appear similar to those of epilepsy; but, independent of its violence and fatality, there are many circumstances peculiar to it. This has been remarked by several authors, particularly Dr Denman ; but those circumstances have never been accurately pointed out in any publication which has fallen into my hands.

" The celampsia, peculiar to pregnancy and labour, differs from epilepsy in the following respects.

" I. The symptoms which precede the attack are well marked, announcing to an experienced practitioner the approach of the disease.

" 2. If the first fit do not prove fatal, and if no means of cure be attempted, it is within a few hours followed by other paroxyms, provided delivery do not take place.

"3. After the paroxysms, even where they have been very severe, the patient in many cases continues quite sensible during the intervals, and the sensibility returns the moment the fit is off.

"4. What may appear still more extraordinary is, that in some cases there is a remarkably increased susceptibility of impression of the external senses ; and this supersensation is not confined to patients in whom the convulsions are slight.

"The aura epileptica never occurs in the cases alluded to.

" 6. The pulse is, in every case, affected in some degree during the remissions of the fits. It is slow, or oppressed, or intermitting, or frequent and rapid. But it is most commonly slow and oppressed, becoming fuller and more frequent after blood-letting.

The symptoms above hinted at as preceding the fits arc, violent hcadach, or sudden delirium, or violent tremors during the second stage of labour. Impaired or depraved vision commonly prove the immediate harbingers of the fit. The event of this occurrence is always precarious, for a single fit may destroy the patient. Death happens in such cases in two ways, viz. either by rupture of some of the vessels within the head, or by the rupture of the womb itself.

The cause of the disease is evidently an overload in the vessels within the cranium, and this may be occasioned from a variety of causes, as violent labour throes, passions of the mind, irritations in the primæ viæ, &c.

In cases of so very alarming a nature, it is not wonderful that practitioners have differed much respecting the practice to be adopted. The following is what has been recommended by Dr Hamilton in the volume of Dr Duncan's annals already referred to.

"When fits have actually occurred during the latter months of pregnancy, the first remedy to be employed, after having adopted the suitable means for protecting the tongue, is blood-letting, both general and topical.

Vol. XIV. Part I.

Opening the external jugular might answer both pur- Preternaposes, but the restlessness of the patient in many cases tural Parmakes the surgeon or attendants dread this operation. turition. A quantity of blood, therefore, adapted to the exigency of the case, is to be drawn from the arm, and either a branch of the temporal artery is to be divided, or several leeches are to be applied to the temples. After the bleeding, a powerful laxative glyster ought to be exhibited. And if there be any evidence of disordered primæ viæ, an emetic must, if possible, be given. The state of the os uteri is then to be ascertained; and if labour have not commenced, no attempts whatever are to be made to promote that process. In some rare cases however, where the bulk of the gravid uterus is enormous, it may be necessary to remove a part of its contents; but such cases cannot happen once in a thousand instances of the disease.

"Should the fits still continue, the head must be shaved, and covered with a large blister ; and if the oppression or fulness, or hardness of the pulse, be not removed, the blood-letting is to be repeated.

" As soon as the patient becomes capable of swallowing, the camphor, in doses of ten grains, ought to be given every three or four hours. The most efficacious and palatable form in which this medicine can be prescribed, is by suspending it in boiling water, through the medium of alcohol, sugar and magnesia. Its use must be persevered in for several days, gradually lessening the number of doses.

"Where the eclampsia has been preceded by cedema, the digitalis may be employed with much success.

" Convulsions during labour are to be treated upon the same principles, with these additional precautions, that delivery is to be accomplished by the most expeditious possible means, and that if the delivery be followed by uterine hæmorrhagy, the discharge is for some time to be rather encouraged than checked. I knew two instances of the fits, which had been suspended for some hours, recurring, in consequence of the flooding being stopped, and in both cases the convulsions were removed, by allowing the discharge to return.

"When the symptoms that precede eclampsia, take place in the latter months of pregnancy, the most certain method of guarding against the threatening accident is, having recourse to immediate blood-letting, and afterwards prescribing camphor, attention to the state of the bowels, and a spare diet.

"When the same symptoms occur during labour, a copious bleeding should be instantly ordered, and the appropriate means of terminating the delivery should be adopted with as much expedition as may be consistent with the safety both of mother and child.

" In these concise practical suggestions, practitioners will observe circumstances omitted, which have been recommended by gentlemen of deserved professional eminence, and novelties of practice proposed, which I believe have not hitherto been explicitly advised. Some explanation, therefore, of the plan above recommended may perhaps be expected. "The most obvious remedy apparently omitted is

opium. This powerful medicine was not prescribed, as far as we have reason to know, by the practitioners who lived at the end of the 17th and beginning of the 18th centuries. The first author who, in strong terms, asserts the efficacy of opium in such cases, appears to be the K translator

Preterna- translator of Astruc's Midwifery (A); and his opinion tural Par- has been adopted by Dr Denman (B), and by Dr Bland (c). But in every case of true eclampsia, during pregnancy or labonr, opiates do irreparable mischief, where a copious bleeding has not been premised; and even where that precaution has been attended to, they have been found useless, if not hurtful. Melancholy experience has completely established in my mind this practical precept; and I consider it to be a matter of very great moment, that it should be universally known; for general practitioners, who are often first called to those cases where the fits happen during pregnancy, are extremely apt to prescribe opium: I can solemnly declare, that no patient to whose assistance I have been called, who had taken a dose of opium previous to my arrival, has recovered, and I have known that medicine given in almost every variety of dose. My father, Dr A. Hamilton, of whose judgment and practical knowledge it does not become me to speak in the terms they so justly merit, prevented my ever employing

opium under such circumstances. "A second remedy extolled by Dr Denman, and now, after a fair trial, rejected in my practice, is vomiting. This seems to have been a very common prescription in the time of Mauriceau, as he takes great pains to point out its hurtfulness in several parts of his works (D). Where there are unequivocal marks of disordered stomach, an emetic may be prescribed with advantage after blood-letting, but it should be avoided under all other circumstances.

"With regard to the warm-bath, which is a favourite remedy among foreign practitioners, and has been advised by several British authors, I have never had an opportunity of trying its effects. Upon theoretical principles I should reject it; but my chief reason for never having directed its use, has been the impossibility, in ordinary cases of practice, of commanding a warm bath into which a woman in such a situation could be put.

" Dashing cold water by surprise upon the face is a practice suggested by Dr Denman, and on which he had much dependence at one period. Experience lessened his hopes, and, many years ago, prevented my ever indulging any. I gave it several fair trials, (once or twice in public in the lying-in-ward of the Royal Infirmary), and had even reason to be convinced, that it rather aggravated than diminished the violence of the paroxysms."

In addition to these observations it may be proper to remark, that a much larger quantity of blood should be drawn in those cases than has commonly been done. Dr H. advises forty ounces to be taken at this first bleeding, and the same quantity to be again drawn within an hour, if the symptoms be not mitigated; and he talks with the utmost confidence of the utility of this practice.

152

f. Although the woman be delivered safely both of

the child and afterbirth, she may sink very soon af- Preternater in consequence of internal flooding. This is to tural Parbe suspected if the patient suddenly complain of giddi- turition. ness or sickness, or singing in the ears, or impaired vision ; or if she become delirious, with a pallid face and cold limbs. The state of the pulse at the wrist too should lead a judicious practitioner to suspect the existence of internal flooding. Positive certainty of this accident may be obtained by feeling through the belly the condition of the uterus; or, more certainly still, by feeling the state of the vagina, for if its parietes approach, there is not much probability of there being any considerable internal hæmorrhagy; whereas, if it be found filled with coagulated blood, there is a certainty, that the womb too is distended from the same cause. This accident is entirely owing to the womb not

having contracted with sufficient energy. It very often proves the cause of sudden and unexpected death.

The boldest and apparently most violent measures are required to save the patient in many of those cases. The womb and vagina must be immediately emptied, and such pressure must be made on the inside of the uterus with the hand, as shall force it into contraction. In some cases cold water in great quantity must be dashed from a height on the naked belly at the same time; and in the mean while the strength of the patient must be supported with large doses of opium. If there be vomiting, which is a frequent symptom in such cases, five grains of solid opium should be given at first, and afterwards three grains every three or four hours, till the pulse becomes steady and the strength recruited, when the opiates are to be withdrawn and lessened by degrees. The writer of this article cannot avoid this opportunity of paying a just tribute of respect to the practical discernment of the able editor of the New London Medical Dictionary, who seems the first author who has mentioned this practice of giving large doscs of opium; a practice by which many valuable lives have been saved.

Conclusion .- In the preceding account of the deviations, which sometimes happen in the process of human parturition, although we have endeavoured to give a full view of the subject, we have not pursued the beaten tract. But as this article may rather be consulted by many as a dictionary, than pursued regularly as a treatise, we shall add the ordinary arrangement of labours, with the reference to the numerical articles, under which the several varieties may be found.

Labours are divided into four classes; viz. natural, laborious, preternatural, and complex.

Natural labour comprehends all cases where the head of the infant is forced foremost; and the whole process is completed with safety, both to mother and child, within twenty four hours from the commencement. It is described under articles 48. to 60.

Laborious

(A) The Art of Midwifery, &c. 8vo. London, printed for J. Nourse 1767. Appendix, p. 295. (c) Loco citato, page 136. (B) Vol. ii. p. 418.

(D) Particularly in Aphorism 232. " L'émétique est pernicieux aux femmes grosses, on nouvellement accouchées, qui sont surprises des convulsions." And Levret, page 451. of his L'Art des Accouchemens, says, in reference to that aphorism, " Cette sentence est des mieux fondées, et elle doit être rigoureusement observée dans tous ses points.'

turition.

Laborious labour is that where, although the head onclusion. of the infant be forced foremost, the process is protracted beyond twenty-four hours from the commencement. It is divided into three orders : First, where the natural powers at last, after much suffering on the part of the mother, complete the delivery. See article 64.

hap. IV.

Secondly, Where, although the action of the uterus be inadequate to the expulsion of the infant, it is practicable to extract the child through the natural passages, without injury either to it or to the mother. See articles 66. to 74-82. and 84. Thirdly, Where it is impossible to extract the child

alive through the natural passages. See articles 80. and 99. to 133.

Preternatural labours comprehend all cases where any other part of the child than the head is forced foremost; and consist of two orders:

First, Presentations of the lower extremities, viz. footling cases, article 87. Breech cases, article 91. Cases where one foot presents, article 89. and kneecases, article 90.

Secondly, Presentations of the superior extremities Explanaor other parts than the head or lower extremities, ar- tion of the ticles 192. to 196.

Complex labours include all cases where any other circumstances than those enumerated under the former three classes take place, viz.

Cases where the pelvis is too large, articles 110. and

Cases where hæmorrhagy occurs at the beginning of labour, article 76. or at the conclusion of that process, articles 152. and 153.

Cases where there is more than one child, articles 143, 144, 145.

Cases where the patient had previously been affected with umbilical herniæ, article 146.

Cases where convulsions happen, articles 147, 148.

Cases where the navel-string is twisted round the neck of the infant, article 140. or where it is forced down along with some part of the child, article 141.

And cases of rupture of the uterus, article 65.

EXPLANATION OF THE PLATES.

Plate CCCXLVI.

Fig. 1. A front view of the uterus in the unimpregnated state, in situ, suspended in the vagina; the anterior parts of the ossa ischia, with the ossa pubis, pudenda, perineum, and anus being removed, in order to show the internal parts.

A, The last lumbar vertebra.

B, B, The ossa ilia. C, C, The acetabula.

D, D. The inferior and posterior parts of the ossa ischia.

E, The part covering the extremity of the coccyx. F. The inferior part of the rectum.

G, G, The vagina cut open longitudinally, and stretched on cach side of the cervex uteri, in order to show the manner in which the uterus is suspended in it.

H, H, Part of the urinary bladder stretched on each side of the vagina and inferior part of the fundus uteri.

I, The cervix uteri. K, The fundus uteri.

L, L, The fallopian tubes. M, M, The ovaria. N, N, The broad ligaments. O, O, The superior part of the rectum.

Fig. 2. A view of the internal parts as seen from the right groin, the pelvis having been divided vertically. A, The lowest vertebra of the loins.

B, C, The os sacrum and coccyx with the integuments.

D, The left os ilium. E, The inferior part of the os ischium, E, The inferior part of the same side. F, The os pubis of the same side.

G, The foramen magnum. H, The acetabulum.

I, The inferior part of the rectum.

K, The os externum and vagina, the os uteri lying loosely in the latter.

L, The vesica urinaria.

M, N, The cervix and fundus uteri, with a view of the cavity of the uterus. The attachment of the vagina to the uterus, and the situation of the uterus when pressed down by the intestines and bladder into the concave part of the os sacrum, are likewise shown.

O, The broad ligament of the left side.

P, P, The left fallopian tube.

Q, The left ovarium.

R, R, The superior part of the rectum and inferior part of the colon.

Fig. 3. Is a sketch taken from Dr Hunter's magnificent plate, Nº 6. of the gravid uterus. All the fore part of the uterus and secundines (which included the placenta) is removed. The navel-string is cut, tied, and turned to the left side over the edge of the womb. At the fundus the investing membranes are likewise turned over the edge of the womb, that they might be more apparent. The head of the child is lodged in the lower part of the womb, or in the cavity of the pelvis, and its body lies principally in the right side. Its position is diagonal or oblique, so that its posterior parts are turned forwards, and to the right side of the mother, and its fore parts are directed backwards, and to the left side. Its right foot appears between its left thigh and leg. Every part is stated by Dr Hunter to have been represented just as it was found.

Fig. 4. A front view of the gravid uterus in the first stage of labour; the anterior parts are removed, but the membranes not being ruptured, form a large bag containing the foctus and the liquor amnii.

A, A, The substance of the uterus.

MIE

MIEDNIKI, or MEDNIKI, or Warmic, a town of Samogitia, and the residence of the bishop. It is 28 miles N. E. from Konigsberg, and 60 miles S.S.W. from Mittau.

MIEKOW, a towa of Austrian Poland, in the palatinate of Cracow. The founder of this town is said to have been Gripsius Jana, who built it after the model of Jerusalem, when he returned from a pilgrimage to that city. It is 12 miles north from Cracow.

MIEL, JAN, ealled Giovanni della Vite, a most eminent painter, was born in Flanders in 1590. He was at first a disciple of Gerard Seghers, in whose school he made a distinguished figure; but he quitted that artist, and went to Italy, to improve himself in design, and to obtain a more extensive knowledge of the several branches of his art. At Rome he particularly studied and copied the works of the Caraeci and Corregio; and was admitted into the academy of Andrea Saeehi, where he gave such evident proofs of extraordinary merit and genius, that he was invited by Andrea to assist him in a grand design which he had already begun. But Miel, through some disgust, rejeeted those elevated subjects which at first had engaged his attention, refused the friendly proposal of Saeehi, and chose to imitate the style of Bamboccio, as having more of that nature which pleased his own imagination. His general subjects were huntings, earnivals, gypsies, beggars, pastoral seenes, and conversations; of those he composed his easel pictures, which are the finest of his performances. But he also painted history in a large size in fresco, and in oil; which, though they seem to want elevation of design, and a greater degree of grace in the heads, yet appear superior to what might be expected from a painter of such low subjects as he generally was fond of representing. His pictures of huntings are particularly admired : the figures and animals of every species being designed with uncommon spirit, nature, and truth. The transparence of his colouring, and the clear tints of his skies, enliven his compositions; nor are his paintings in any degree inferior to those of Bamboccio either in their force or lustre. His large works are not so much to be commended for the goodness of the design as for the expression and colouring; but it is in his small pieces that the pencil of Miel appears in its greatest delicacy and beauty. The singular merit of this master recommended him to the favour of Charles Emanuel duke of Savoy, who invited him to his court, where he appointed Miel his principal painter, and afterwards honoured him with the order of St Mauritius, and made him a present of a cross set with diamonds of great value, as a particular mark of his esteem. He died in 1664.

MIERIS, FRANCIS, the Old, a justly eclebrated painter, was born at Leyden in 1635; and was at first placed under the direction of Abraham of the uterus eannot force it through the pelvis in this direction.

Fig. 4. Represents an arm presentation, and communicates an idea of the difficulty of bringing down the feet, and turning the infant in that position.

MIE

Toorne Vliet, one of the best designers of the Low Countries, and afterwards entered himself as a disciple u with Gerard Douw. In a short time he far surpassed all his companions, and was by his master called the prince of his disciples. His manner of painting silks, velvets, stuffs, or carpets, was so singular, that the different kinds and fabric of any of them might easily be distinguished. His pictures are rarely to be seen, and as rarely to be sold; and when they are, the purchase is extremely high, their intrinsic value being so incontestably great. Besides portraits, his general subjects were conversations, persons performing on musical instruments, patients attended by the apothecary or doetor, ehemists at work, mercers shops, and such like ; and the usual valuation he set on his pictures was estimated at the rate of a dueat an hour. The finest portrait of this master's hand is that which he painted for the wife of Cornelius Plaats, which is said to be still preserved in the family, although very great sums have been offered for it. In the possession of the same gentleman was another picture of Mieris, representing a lady fainting, and a physician applying the remedies to relieve For that performance he was paid (at his usual her. rate of a dueat an hour) so much money as amounted to fifteen hundred florins when the picture was finished. The grand duke of Tuscany wished to purchase it, and offered three thousand florins for it; but the offer was not accepted. However, that prince procured several of his pictures, and they are at this day an ornament to the Florentine collection. One of the most eurious of them is a girl holding a eandle in her hand, and it is accounted inestimable. This painter died in 1681.

MIERIS, William, called the Young Mieris, was son of the former, and born at Leyden in 1662. During the life of his father, he made a remarkable progress: but, by being deprived of his director when he was only arrived at the age of nineteen, he had recourse to nature, as the most instructive guide ; and by studying with diligence and judgment to imitate her, he approached near to the merit of his father. At first he took his subjects from private life, in the manner of Francis; such as tradesmen in their shops, or a peasant selling vegetables and fruit, and sometimes a woman looking out at a window; all which he copied minutely after nature, nor did he paint a single object without his model. As Mieris had observed the composition of Gerard Lairesse, and other great historical painters, with singular delight, he attempted to design subjects in that style; and began with the story of Ri-naldo sleeping on the lap of Armida, surrounded with the Loves and Graces, the fore ground being enriched with plants and flowers; a work which added greatly to his fame, and was sold for a very high price. This master also painted landseapes and animals with equal truth and neatness; and modelled in elay and wax, in so sharp and accurate a manner, that he might justly he

Mieris.

78

Mieris

be ranked among the most eminent sculptors. In the delicate finishing of his works, he imitated his father ; Mignon. as he likewise did in the lustre, harmony, and truth, of his paintings, which makes them to be almost as highly prized ; but they are not equal in respect of design, or of the striking effect, nor is his touch so very exquisite as that of the father. The works of the old Mieris are better composed, the figures are better grouped, and they have less confusion; yet the younger Mieris is acknowledged to be an artist of extraordinary merit, although inferior to him, who had scarcely his equal. He died in 1747.

MIERIS, Francis, called the Young Francis, was the son of William, and the grandson of the celebrated Francis Mieris; and was born at Leyden in 1689. He learned the art of painting from his father, whose manner and style he always imitated; he chose the same subjects, and endeavoured to resemble him in his colouring and pencil. But with all his industry he proved far inferior to him : and most of those pictures which at the public sales are said to be of the young Mieris, and many also in private collections ascribed to the elder Francis, or William, are perhaps originally painted by this master, who was far inferior to both; or are only his copies after the works of those excellent painters, as he spent abundance of his time in copying their performances.

MIEZA, in Ancient Geography, a town of Macedonia, which was anciently called Strymonium, situated near Stagira. Here, Plutarch informs us, the stone seats and shady walks of Aristotle were shown. Of this place was Peucestas, one of Alexander's generals, and therefore surnamed Miezæus, (Arrian).

MIGDOL, or MAGDOL, in Ancient Geography, a place in the Lower Egypt, on this side Pihabiroth, or between it and the Red sea, towards its extremity. The term denotes a tower or fortress. It is probably the Magdolum of Herodotus, seeing the Septuagint render it by the same name.

MIGNARD, NICHOLAS, an ingenious French painter born at Troyes in 1628; but, settling at Avignon, is generally distinguished from his brother Peter by the appellation of Mignard of Avignon. He was afterwards employed at court and at Paris, where he became rector of the royal academy of painting.

There is a great number of his historical pieces and portraits in the palace of the Thuilleries. He died in 1690.

MIGNARD, Peter, the brother of Nicholas, was born at Troyes in 1610; and acquired so much of the taste of the Italian school, as to be known by the name of the Roman. He was generally allowed to have a superior genius to his brother Nicholas; and had the honour of painting the popes Alexander VII. and Urban VIII. besides many of the nobility at Rome, and several of the Italian princes : his patron, Louis, sat ten times to him for his portrait, and respected his talents so much as to ennoble him, make him his principal painter after the death of Le Brun, and appointed him director of the manufactories. He died in 1695, and many of his pieces are to be seen at St Cloud.

MIGNON, or MINJON, Abraham, a celebrated painter of flowers and still life, was born at Francfort in 1639; and his father having been deprived of the greatest part of his substance by a series of losses in trade, left him in very necessitous circumstances when

he was only seven years of age. From that melan- Mignon. choly situation he was rescued by the friendship of Migration James Murel, a flower painter in that city; who took Mignon into his own house, and instructed him in the art, till he was 17 years old. Murel had often observed an uncommon genius in Mignon : he therefore took him along with him to Holland, where he placed him as a disciple with David de Heem; and while he was under the direction of that master he laboured with incessant application to imitate the manner of De Heem, and ever afterwards adhered to it; only adding daily to his improvement, by studying nature with a most exact and curious observation .-"When we consider the paintings of Mignon, one is at a loss (Mr Pilkington observes) whether more to admire the freshness and beauty of his colouring, the truth in every part, the bloom on his objects, or the perfect resemblance of nature visible in all his performances. He always shows a beautiful choice in those flowers and fruits from which his subjects are composed : and he groups them with uncommon elegance. His touch is exquisitely neat, though apparently easy and unlaboured; and he was fond of introducing insects among the fruits and flowers, wonderfully finished, so that even the drops of dew appear as round and as translucent as nature itself." He had the good fortune to be highly paid for his works in his lifetime; and he certainly would have been accounted the best in his profession even to this day, if John Van Huysum had not appeared. Weyerman, who had ssen many admired pictures of Mignon, mentions one of a most capital kind. The subject of it is a cat, which had thrown down a pot of flowers, and they lie scattered on a marble table. That picture is in every respect so wonderfully natural, that the spectator can scarce persuade himself that the water which is spilled from the vessel is not really running down from the marble. This picture is distinguished by the title of Mignon's Cat. This painter died in 1679, aged only 40.

MIGRATION, the passage or a removal of a thing out of one place into another.

MIGRATION of Birds .- It has been generally be-Migration lieved, that many different kinds of birds annually pass generally from one country to another, and spend the summer or the winter where it is most agreeable to them; and that even the birds of our own island will seek the most distant southern regions of Africa, when directed by a peculiar instinct to leave their own country. It has long been an opinion pretty generally received, that swallows reside during the winter season in the warm southern regions; and Mr Adanson particularly relates his having seen them at Senegal when they were obliged to leave this country. But besides the swallow, Mr Pennant enumerates many other birds which migrate from Britain at different times of the year, and are then to be found in other countries; after which they again leave these countries, and return to Britain. The reason of these migrations he supposes to be a defect of food at certain seasons of the year, or the want of a secure asylum from the persecution of man during the time of courtship, incubation, and nutrition. The following is his list of the migrating species.

1. Crows. Of this genus, the hooded crow migrates Birds th regularly with the woodcock. It inhabits North Bri-migrate. tain the whole year : a few are said annually to breed on

igration. on Dartmoor, in Devonshire. It breeds also in Sweden and Austria: in some of the Swedish provinces it only shifts its quarters, in others it resides throughout the year. Our author is at a loss for the summer retreat of those which visit us in such numbers in winter, and quit our country in the spring; and for the reason why a bird, whose food is such that it may be found at all scasons in this country, should leave us.

2. Cuckoo. Disappears early in autumn; the retreat of this and the following hird is quite unknown to us.

3. Wryneck. Is a bird that leaves us in the winter. If its diet be ants alone, as several assert, the cause of its migration is very evident. This bird disappears before winter, and revisits us in the spring a little earlier than the euckoo.

4. Hoopoc. Comes to England but by aceident; Mr Pennant once indeed heard of a pair that attempted to make their nest in a meadow at Selborne, Hampshire, butwere frightened away by the curiosity of people. It breeds in Germany.

5. Grous. The whole tribe, except the quail, lives here all the year round : that bird either leaves us, or else retires towards the sea coasts.

6. Pigeons. Some few of the ring doves breed here; but the multitude that appears in the winter is so disproportioned to what continue here the whole year, as to make it certain that the greatest part quit the country in the spring. It is most probable they go to Sweden to breed, and return from thence in autumn; as Mr Ekmark informs us they entirely quit that country before winter. Multitudes of the common wild pigeons also make the northern retreat, and visit us in winter; not but numbers breed in the high cliffs in all parts of this island. The turtle also probably leaves us in the winter, at least changes its place, removing to the southern countries.

7. Scare. Breeds here. Possibly several remove to other countries for that purpose, since the produce of those that continue here seems unequal to the clouds of them that appear in winter. It is not unlikely that many migrate into Sweden, where Mr Berger observes they return in spring.

8. *Thrushes.* The fieldfare and the redwing breed and pass their summers in Norway and other cold countries; their food is berries, which abounding in our kingdoms, tempts them here in the winter. These two and the Royston erow are the only land birds that regularly and constantly migrate into England, and do not breed here. The hawfinch and erossbill come here at such uncertain times as not to describe the name of birds of passage.

birds of passage. 9. Chatterer. The chatterer appears annually about Edinburgh in flocks during winter; and feeds on the berries of the mountain ash. In South Britain it is an accidental visitant.

10. Grosbeaks. The grosbeak and crossbill come here but seldom; they breed in Austria. The pine grosbeak probably breeds in the forests of the Highlands of Scotland.

11. Buntings. All the genus inhabits England throughout the year; except the greater brambling, which is forced here from the north in very severe seasons.

12. Finches. All continue in some parts of these kingdoms, except the fiskin, which is an irregular visitant, said to come from Russia. The linnets shift

their quarters, breeding in one part of this island, and Migration. remove with their young to others. All finches feed of plants.

13. Larks, fly-catchers, wag-tails, and warblers. All of these feed on insects and worms; yet only part of them quit these kingdoms; though the reason of migration is the same to all. The nightingale, blackcap, fly-catcher, willow-wren, wheat-car, and whitethroat, leave us before winter, while the same and delicate golden-crested wren braves our severest frosts. The migrants of this genus continue longest in Great Britain in the southern counties, the winter in those parts being later than in those of the north; Mr Stillingfleet having observed several wheat-cars in the isle of Purbeck on the 18th of November. As these birds are incapable of very distant flights, Spain, or the south of France, is probably their winter asylum.

14. Swallows and goatsucker. Every species disappears at the approach of winter.

WATER-FOWL.

On the vast variety of water fowl that frequent Water-Great Britain, it is amazing to reflect how few are fowl. known to breed here: the cause that principally urges them to leave this country, seems to be not merely the want of food, but the desire of a secure retreat. Our country is too populous for birds so shy and timid as the bulk of these are : when great part of our island was a mere waste, a tract of woods and fen, doubtless many species of birds (which at this time migrate) remained in sceurity throughout the year .---Egrets, a species of heron now scarcely known in this island, were in former times in prodigious plenty; and the crane, that has totally forsaken this country, bred familiarly in our marshes : their place of incubation, as well as of all other cloven footed water-fowl (the heron excepted), being on the ground, and exposed to every one. As rural economy increased in this country, these animals were more and more disturbed ; at length, by a series of alarms, they were necessitated to seek, during the summer, some lonely safe habitation.

On the contrary, those that build or lay in the almost inaccessible rocks that impend over the Britisl; seas, breed there still in vast numbers, having little to fear from the approach of mankind : the only disturbance they meet with in general heing from the desperate attempts of some few to get their eggs.

CLOVEN-FOOTED WATER-FOWL.

15. Herons. The white heron is an uncommon bird, and visits us at uncertain seasons; the common kind and the bittern never leave us.

16. Curlews. The curlew breeds sometimes on our mountains: but, considering the vast flights that appear in winter, it is probable that the greater part retire to other countries: the whimbrel breeds on the Grampian hills, in the neighbourhood of Invercauld,

Grampian hills, in the neighbourhood of Invereauld. 17. Snipes. The woodcock breeds in the moist woods of Sweden, and other cold countries. Some snipes breed here, but the greatest part retire elsewhere: as do every other species of this genus. 18 Sandpipers. The lapwing continues here the

18 Sandpipers. The lapwing continues here the whole year: the ruff breeds here, but retires in winter; the Migration. the redshank and sandpiper breed in this country, and reside here. All the others absent themselves during summer.

19. Plovers and oyster-catcher. The long-legged plover and sanderling visit us only in winter; the dottrel appears in spring and in autumn; yet, what is very singular, we do not find it breeds in South Britain. The oyster-catcher lives with us the whole year. The Norfolk plover and sea-lark breed in England. The green plover breeds on the mountains of the north of England, and on the Grampian kills.

We must here remark, that every species of the genera of curlews, woodcocks, sandpipers, and plovers, that forsakes us in the spring, retires to Sweden, Poland, Prussia, Norway, and Lapland, to breed : as soon as the young can fly, they return to us again, because the frosts which set in early in those countries totally deprive them of the means of subsisting ; as the dryness and hardness of the ground, in general, during our summer, prevent them from penetrating the earth with their bills, in search of worms, which are the natural food of these birds. Mr Ekmark speaks thus of the retreat of the whole tribe of cloven-footed water-fowl out of his country (Sweden) at the approach of winter ; and Mr Klein gives much the same account of those of Poland and Prussia.

20. Rails and gallinules. Every species of these two genera continues with us the whole year; the land-rail excepted, which is not seen here in winter. It likewise continues in Ireland only during the summer months, when they are very numerous, as Mr Smith tells us in the History of Waterford, p. 336. Great numbers appear in Anglesea the latter end of May; it is supposed that they pass over from Ireland, the passage between the two islands being but small. As we have instances of these birds lighting on ships in the Channel and the bay of Biscay, we may conjecture their winter quarters to be in Spain.

FINNED-FOOTED WATER BIRDS.

21. Phalaropes. Visit ns but seldom ; their breeding place is Lapland, and other arctic regions.

22. Grebes. The great crested grebe, the black and white grebe, and little grebe, breed with us, and never migrate; the others visit us accidentally, and breed in Lapland.

WEB-FOOTED BIRDS.

23. Avoset. Breed near Fossdike in Lincolnshire, but quit their quarters in winter. They are then shot in different parts of the kingdom, which they visit, not regularly, but accidentally.

24. Auks and guillemots. The great auk or pinguin sometimes breeds in St Kilda. The auk, the guillemot, and puffin, inhabit most of the maritime cliffs of Great Britain, in amazing numbers, during summer. The black guillemot breeds in the Bass isle, and in St Kilda, and sometimes in Llandidno rocks. We are at a loss for the breeding place of the other species; neither can we be very certain of the winter residence of any of them, excepting of the lesser guillemot and black-billed auk, which, during winter, visit in vast flocks the frith of Forth.

25. Divers. These chiefly breed in the lakes of Sweden and Lapland, and in some countries near the

pole; but some of the red-throated divers, the northern Migration and the imber, may breed in the north of Scotland and <u>we</u> its isles.

26. Terms. Every species breeds here; but leaves us in the winter.

27. Petrels. The fulmar breeds in the isle of St Kilda, and continues there the whole year except September and part of October : the shearwater visits the isle of Man in April; breeds there; and, leaving it in August or the beginning of September, disperses over all parts of the Atlantic occan. The stormfinch is seen at all distances from land on the same vast watery tract; nor is ever found near the shore except by some very rare accident unless in the breeding season. Mr Pennant found it on some little rocky isles off the north of Skye. It also breeds in St Kilda. He also suspects that it nestles on the Blasquet isles off Kerry, and that it is the gourder of Mr Smith.

28. Mergansers. This whole genus is mentioned among the birds that fill the Lapland lakes during summer. Mr Pennant has seen the young of the red-breasted in the north of Scotland : a few of these, and perhaps of the goosanders, may breed there.

29. Ducks. Of the numerous species that form this genus, we know of few that breed here: The swan and goose, the shield duck, the eider duck, a few shovelers, garganics, and teals, and a very small portion of the wild ducks.

The rest contribute to form that amazing multitude of water-fowl that annually repair from most parts of Europe to the woods and lakes of Lapland and other arctic regions, there to perform the functions of incubation and nutrition in full security. They and their young quit their retreat in September, and disperse themselves over Europe. With us they make their appearance the beginning of October ; circulate first round our shores ; and, when compelled by severe frost, betake themselves to our lakes and rivers. Of the web-footed fowl there are some of hardier constitutions than others : these endure the ordinary winters of the more northern countries; but when the cold reigns there with more than common rigour, they repair for shelter to these kingdoms : this regulates the appearance of some of the diver kind, as also of the wild swans, the swallow-tailed shield duck, and the different sorts of goosanders which then visit our coasts. Barenta found the barnacles with their nests in great numbers in Nova Zembla. (Collect. Voy. Dutch East-India Company, 8vo, 1703, p. 19.). Clusius, in his Exot. 368. also observes, that the Dutch discovered them on the rocks of that country and in Waygate straits. They, as well as the other species of wild geese, go very far north to breed, as appears from the histories of Greenland and Spitzbergen, by Egede and Crantz. These birds seem to make Iceland a resting place, as Horrebow observes : few continue there to breed, but only visit that island in the spring, and after a short stay retire still further north.

30. Corvorants. The corvorant and shag breed on most of our high rocks: the gannet in some of the Scotch isles and on the coast of Kerry: the two first continue on our shores the whole year. The gannet disperses itself all round the seas of Great Britain, in pursuit of the herring and pilchard, and even as far as the Tagus to prey on the sardina.

But

But of the numerous species of fowl here enumeratgration ed, it may be observed how very few intrust themselves to us in the breeding season, and what a distant w breed flight they make to perform the first great dictate of nature.

this

untry.

uments

tion.

There seems to be scarcely any but what we have traced to Lapland, a country of lakes, rivers, swamps, and alps, covered with thick and gloomy forests, that afford shelter during summer to these fowls, which in winter disperse over the greatest part of Europe. In those arctic regions, by reason of the thickness of the woods, the ground remains moist and penetrable to the woodcocks, and other slender-billed fowl : and for the web-footed birds, the waters afford larvæ innumerable of the tormenting gnat. The days there are long; and the beautiful meteorous nights indulge them with every opportunity of collecting so minute a food : whilst mankind is very sparingly scattered over that vast northern waste.

Why then should Linnæus, the great explorer of these rude deserts, be amazed at the myriads of waterfowl that migrated with him out of Lapland? which exceeded in multitude the army of Xerxes; covering, for eight whole days and nights, the surface of the river Calix ! His partial observation as a botanist, would confine their food to the vegetable kingdom, almost denied to the Lapland waters; inattentive to a more plenteous table of insect food, which the all-bountiful Creator had spread for them in the wilderness. It may be remarked, that the lakes of mountainous rocky countrics in general are destitute of plants : few or none are seen on those of Switzerland; and Linnæus makes the same observation in respect to those of Lapland; having, during his whole tour, discovered only a single specimen of a lemma trisculca, or "ivy-leaved duck's meat," Flora Lap. Nº 470.; a few of the scir-pus lacustris, or "bulrush," Nº 18.; the alopecurus geniculatus, or "flote foxtail-grass," Nº 38.; and the ranunculus aquatilis, Nº 234.; which are all he enumerates in his Prolegomena to that excellent performance.

We shall afterwards state the principal arguments for inst mi-and against the migration of swallows ; but here we shall give a short abstract of the arguments used by the Hon. Daines Barrington against the migration of birds in general, from a paper published by him in the 62d volume of the Philosophical Transactions. This gentleman denies that any well-attested instances can be produced of this supposed migration ; which, he thinks, if there were any such periodical flight, could not possibly have escaped the frequent observation of scamen. It has indeed been asserted that birds of passage become invisible in their flight, because they rise too high in the air to he perceived, and because they choose the night for their passage. The author, however, expresses his doubts "whether any bird was over seen to rise to a greater height than perhaps twice that of St Paul's cross;" and he further endeavours to show, that the extent of some of these supposed migrations (from the northern parts of Europe, for instance, to the line) is too great to be accounted for, by having recourse to the argument founded on a nocturnal passage.

The author next recites, in a chronological order, all the instances that he has been able to collect, of birds having been actually seen by mariners when they VOL. XIV. Part I.

were crossing a large extent of sea ; and he endeavours Migration. to show that no stress can be laid on the few casual' observations of this kind that have been produced in support of the doctrine of a regular and periodical migration.

Mr Barrington afterwards proceeds to invalidate M. Adanson's celebrated observation with respect to the migration of the swallow in particular, and which has been considered by many as perfectly decisive of the present question. He endeavours to show that the four swallows which that naturalist caught, on their settling upon his ship, on the 6th of October, at about the distance of 50 leagues from the coast of Senegal, and which he supposes to have been then proceeding from Europe to pass the winter in Africa, could not be true Europeau swallows; or, if they were, could not have been on their return from Europe to Africa. His objections are founded principally on some proofs which he produces of M. Adanson's want of accuracy on this subject, which has led him, in the present instance, to mistake two African species of the swallow tribe, described and engraved by Brisson, for European swallows, to which they bear a general resemblance; or granting even that they were European swallows, he contends that they were flitting from the Cape de Verd islands to the coast of Africa; " to which short flight, however, they were unequal, and accordingly fell into * Natural the sailors hands."-We shall here only add, in oppo-History of sition to the remarks of Mr Barrington, the following Selborne, observations of the Rev. Mr White* in a letter to Mr p. 139. Pennant on this subject.

"We must not (says he) deny migration in general ; Arguments because migration certainly does subsist in some places, in support as my brother in Andalusia has fully informed mc. Of of itthe motions of these birds he has ocular demonstration, for many weeks together, both spring and fall: during which periods myriads of the swallow kind traverse the Straits from north to south, and from south to north, according to the season. And these vast migrations consist not only of hirundines, but of bee-birds, hoopoes, oro pendolos or golden thrushes, &c. &c. and also of many of our soft-billed summer birds of passage; and moreover of birds which never leave us, such as all the various sorts of hawks and kites. Old Belon, 200 years ago, gives a curious account of the incredible armies of hawks and kites which he saw in the spring time traversing the Thracian Bosphorus from Asia to Europe. Besides the above mentioned, he remarks that the procession is swelled by whole troops of eagles and vultures.

" Now it is no wonder that birds residing in Africa should retreat before the sun as it advances, and retire to milder regions, and especially birds of prey, whose blood being heated with hot animal food, are more impatient of a sultry climate : but then I cannot help wondering why kites and hawks, and such hardy birds as arc known to defy all the severity of England, and even of Sweden and all northern Europe, should want to migrate from the south of Europe, and be dissatisfied with the winters of Andalusia.

" It does not appear to me that much stress may be laid on the difficulty and hazard that birds must run in their migrations, by reason of vast oceans, cross winds, &c.; because, if we reflect, a bird may travel from England to the equator without launching out and exposing

M IG

Migration. posing itself to boundless seas ; and that by crossing the water at Dover and again at Gibraltar. And I with the more confidence advance this obvious remark, because my brother has always found that some of his birds, and particularly the swallow kind, are very sparing of their pains in crossing the Mediterranean : for when arrived at Gibraltar, they do not,

> "" rang'd in figure, wedge their way, -" and set forth

" Their airy caravan high over seas

" Flying, and over lands with mutual wing

MILTON. " Easing their flight"-

but scout and hurry along in little detached parties of six or seven in a company; and sweeping low, just over the surface of the land and water, direct their course to the opposite continent at the narrowest passage they can find. They usually slope across the bay to the southwest, and so pass over opposite to Tangier, which it seems is the narrowest space.

" In former letters we have considered whether it was probable that woodcocks in moon-shiny nights cross the German ocean from Scandinavia. As a proof that birds of less speed may pass that sea, considerable as it is. I shall relate the following incident, which, though mentioned to have happened so many years ago, was strictly matter of fact :- As some people were shooting in the parish of Trotton, in the county of Sussex, they killed a duck in that dreadful winter 1708-9, with a silver collar about its neck (I have read a like anecdote of a swan), on which were engraven the arms of the king of Denmark. This anecdote the rector of Trotton at that time has often told to a near relation of mine; and, to the best of my remembrance, the collar was in the possession of the rector.

"At present I do not know any body near the sea side that will take the trouble to remark at what time of the moon woodcocks first come. One thing I used to observe when I was a sportsman, that there were times in which woodcocks were so sluggish and sleepy that they would drop again when flushed just before the spaniels, nay, just at the muzzle of a gun that had been fired at them : whether this strange laziness was the effect of a recent fatiguing journey, I shall not presume to say.

" Nightingales not only never reach Northumherland and Scotland, but also, as I have been always told, Devonshire and Cornwall. In those two last counties we cannot attribute the failure of them to the want of warmth: the defect in the west is rather a presumptive argument that these birds come over to us from the continent at the narrowest passage, and do not stroll so far westward."

Upon the subject of the migration of the swallow there are three opinions. Some say that it migrates to swallows in a warmer climate; some, that it retires to hollow trees and caverns, where it lies in a torpid state; and others have affirmed, that it lies in the same state in the bottom of lakes and under the ice. The first opinion is supported by Marsigli, Ray, Willoughby, Catesby, Reaumur, Adanson, Buffon, &c. The first and second opinion are both adopted by Pennant and White. The third is sanctioned by Schæffer, Hevelius, Derham, Klein, Ellis, Linnæns, Kalm : and the second and

third have been strongly defended by the honourable Migration Daines Barrington.

Though we cannot help giving a preference to that opinion which appears the most probable, yet we do not think that any one of them is established upon such evidence as so curious a subject requires, and as the advanced state of natural history would lead us to expect. We shall therefore state the arguments upon which each opinion is founded as fairly and distinctly as we can, and as often as possible in the very words of their respective advocates. By doing so, we shall place the whole subject before the eyes of our readers, who will thus have an opportunity of examining it attentively, and of making such observations and experiments as may lead to the truth.

Those who assert that the swallow migrates to a war- First op mer country in winter, argue in this manner : That nion many birds migrate, is a fact fully proved by the obser-that the vations of natural historians. Is it not more probable, warm c therefore, that swallows, which disappear regularly mates. every season, retive to some other country, than that they lie in a state of torpor in caverns or lakes? But this opinion does not rest on probability, it is founded on facts.

We often see them collected in great flocks on churches, roeks, and trees, about the time when they annually disappear. The direction of their flight has been observed to be southward. Mr White, the ingenious Natural historian of Selborne, travelling near the coast of the History British Channel one morning early, saw a flock of p. 64. swallows take their departure. At the beginning of his journey he was environed with a thick fog; but on a large wild heath the mist began to break, and discovered to him numberless swallows, clustered on the standing bushes, as if they had roosted there : as soon as the sun burst out, they were instantly on wing, and with an easy and placid flight proceeded towards the sea. After this he saw no more flocks, only now and then a straggler.

Mr Laskey of Exeter observed attentively the direction which a flock of swallows took in the autumn of 1703. On the 22d of Sept. about seven o'clock in the morning, the wind being easterly, accompanied with a cold drizzling rain, Mr Laskey's house was entirely covered with house-swallows. At intervals large flocks arrived and joined the main body, and at their arrival an unusual chirping commenced. The appearance of the whole company was so lethargic, that he found it an easy matter to catch a considerable number Gent. M of them, which he kept in a room all that day. By for 1790 heating the room they all revived : he opened four of them, and found their stomachs quite full. The main body occupied the house top all day, except for two hours. About half an hour after nine in the morning of the 23d, there was a great commotion, with very loud chirping, and within a few minutes after, the whole multitude took their flight, in a direct south-east direction, having ascended to a great height in the atmosphere. He let go the birds which he had caught, at certain intervals till four o'clock, and they all flew toward the same quarter.

Not only has the direction of their flight been observed, but they have also been found on their passage at a great distance from land. Mr Adanson informs us, that about 50 leagues from the coast of Senegal four swallows settled upon the ship on the 6th of October; that

Question, What bewinter?

MIG

Rigration that these birds were taken ; and that he knew them to be European swallows, which, he conjectures, were returning to the coast of Africa. Sir Charles Wager's hilosophi authority may also be appealed to : " Returning home (says he) in the spring of the year, as I came into soundings in our channel, a great flock of swallows came and settled on all my rigging ; every rope was covered, they hung on one another like a swarm of bees; the decks and carving were filled with them. They seemed almost famished and spent, and were only feathers and bones ; but, being recruited with a night's rest, took their flight in the morning." This vast fatigue proves that their journey must have been very great, considering the amazing swiftness of these birds : in all probability they had crossed the Atlantic ocean, and were returning from the shores of Senegal, or other parts of Africa ; so that this account from that most able and honest scaman, confirms the later information of Mr Adanson.

Mr Kalm, who is an advocate for the opinion that swallows lie immersed in lakes during winter, acknowledges that in crossing the Atlantic from Europe a swallow lighted on the ship on the 2d September, when it had passed only two-thirds of the ocean. Since, therefore, swallows have been seen assembled in great L i. p. 24. flocks in antumn flying off in company towards southern climes, since they have been found both in their passage from Europe and returning again, can there be any doubt of their annual migration ?- Mr Barrington's objections to this opinion have been noticed above in Nº s.

The second notion (says Mr Pennant) has great antiquity on its side. Aristotle and Pliny give it as their belief, that swallows do not remove very far from their summer habitation, but winter in the hollows of rocks, and during that time lose their feathers. The former part of their opinion has been adopted by several ingenious men ; and of late several proofs have been brought of some species, at least, having been discovered in a torpid state. Mr Collinson favoured us with the evidence of three gentlemen, eyc-witnesses to numbers of sand martins being drawn out of a eliff on the Rhine, in the month of March 1762. And the honourable Daines Barrington communicated to us the following fact, on the authority of Lord Belhaven, That numbers of swallows have been found in old dry walls and in sand-hills near his Lordship's seat in East Lothian; not once only, but from year to year; and that when they were exposed to the warmth of a fire, they revived. We have also heard of the same annual discoveries near Mörpeth in Northumberland, but cannot speak of them with the same assurance as the two former : neither in the two last instances are we certain of the particular species.

" Other witnesses crowd on us to prove the residence of those birds in a torpid state during the severe season. First, in the chalky cliffs of Sussex ; as was seen on the fall of a great fragment some years ago. Secondly, In a decayed hollow tree that was cut down, near Dolgelli, in Merionethshire. Thirdly, In a cliff near Whitby, Yorkshire; where, on digging out a fox, whole bushels of swallows were found in a torpid condition. And, lastly, The reverend Mr Conway of Sychton, Flintshire, was so obliging as to communicate the following fact: A few years ago, on looking down an old leadmine in that county, he observed numbers of swallows Migration. clinging to the timbers of the shaft, seemingly asleep; and on flinging some gravel on them, they just moved, but never attempted to fly or change their place : this was between All Saints and Christmas.

" These are doubtless the lurking places of the later hatches, or of those young birds which are incapable of distant migrations. There they continue insensible and rigid; but like flies may sometimes be reanimated by an unseasonable hot day in the midst of winter : for very near Christmas a few appeared on the moulding of a window of Merton college, Oxford, in a remarkably warm nook, which prematurely set their blood in motion, having the same effect as laying them before a fire at the same time of year. Others have been known to make this premature appearance ; but as soon as the cold natural to the season returns, they withdraw again to their former retreats.

" The above are circumstances we cannot but assent to, though seemingly contradictory to the common course of nature in regard to other birds. We must, therefore, divide our belief relating to these two so different opinions; and conclude, that one part of the swallow tribe migrate, and that others have their winter quarters near home. If it should be demanded, why swallows alone are found in a torpid state, and not the other many species of soft-billed birds, which likewise disappear about the same time? reasons might be assigned."

The third opinion we shall state and support in the Third opiwords of Mr Kalm. " Natural history (says he), as nion, that all other histories, depends not always upon the intrin-some lie immersed sic degree of probability, but upon facts founded on the in water. testimony of people of noted .veracity .- Swallows are seldom seen sinking down into water; swallows have not such organs as frogs or lizards, which are torpid during winter; ergo, swallows live not, and cannot live, under water.-This way of arguing, I believe, would carry us, in a great many cases, too far: for though it is not clear to every one, it may however be true ; and lizards and frogs are animals of a class widely different from that of birds, and must therefore of course have a different structure; hence it is they are classed separately. The bear and marmot are in winter in a torpid state, and have, however, not such organs as lizards and frogs; and nobody doubts of their being, during some time, in the most rigid climates, in a torpid state : for the Alpine nations hunt the marmots frequently by digging their holes up; and find them so torpid, that they cut their throats, without their reviving or giving the least sign of life during the operation; but when the torpid marmot is brought into a warm room, and placed before the fire, it revives from its lethargy. The question must therefore be decided by facts, nor are these wanting here. Dr Wallerius, the celebrated Swedish chemist, informs us, That he has seen, more than once, swallows assembling on a reed. till they were all immersed and went to the bottom; this being preceded by a dirge of a quarter of an hour's length. He attests likewise, that he had seen a swallow caught during winter out of a lake with a net, drawn, as is common in northern countries, under the ice; this bird was brought into a warm room, revived, fluttered about, and soon after died.

" Mr Klein applied to many farmers-general of the L 2 king

miles from thence, and it revived, but died about an Migration

Migration. king of Prussia's domains, who had great lakes in their districts, the fishery in them being a part of the revenue. In winter the fishery thereon is the most considerable under the ice, with nets spreading more than 200 or 300 fathoms, and they are often wound by screws and engines on account of their weight. All the pcople that were questioned made affidavits upon oath before the magistrates. First, The mother of the countess Lehndorf said, that she had seen a bundle of swallows brought from the Frishe-Haff (a lake communicating with the Baltic at Pillaw), which, when brought into a moderately warm room, revived and fluttered about. Secondly, Count Schileben gave an instrument on stamped paper, importing, that by fishing on the lake belonging to his estate of Gerdauen in winter, he saw several swallows caught in the net, one of which he took up in his hand, brought it into a warm room, where it lay about an hour, when it began to stir, and half an hour after, it flew about in the room. Thirdly, Farmer-general (Amtman) Witkouski made affidavit, that, in the year 1740, three swallows were brought up with the net in the great pond at Didlacken; in the year 1741, he got two swallows from another part of the pond, and took them home (they being all caught in his presence); after an hour's space they revived all in a warm room, fluttered about, and died in three hours after. Fourthly, Amtman Bonke says, that having had the estate of Kleskow in farm, he had seen nine swallows brought up in the net from under the ice, all which he took into a warm room, where he distinctly observed how they gradually revived; but a few hours after they all died. Another time his people got likewise some swallows in a net, but he ordered them to be again thrown into the water. Fifthly, Andrew Rutta, a master fisherman at Oletsko, made affidavit, in 1747, that 22 years ago, two swallows were taken up by him in a net, under the ice, and, being brought into a warm room, they flew about. Sixthly, Jacob Kosiulo, a master fisherman at Stradauen made affidavit, that, in 1736, he brought up in winter, in a net, from under the ice of the lake at Raski, a seemingly dead swallow, which revived in half an hour's time in a warm room; and he saw, in a quarter of an hour after, the bird grow weaker, and soon after dying. Seventhly, I can reckon myself (says our author) among the eye-witnesses of this paradox of natural history. In the year 1735, being a little boy, I saw several swallows brought in winter by the fishermen from the river Vistula to my father's house; where two of them were brought into a warm room, revived, and flew about. I saw them several times settling on the warm stove (which the northern nations have in their rooms); and I recollect well, that the same forenoon they died, and I had them, when dead, in my hand. In the year 1754, after the death of my uncle Godcfroy Wolf, captain in the Polish regiment of foot guards, being myself one of his heirs, I administered for my co-heirs several estates called the Starosty of Dischau, in Polish Prussia, which my late uncle farmed under the king. In January, the lake of Lybshaw, belonging to these estates, being covered with ice, I ordered the fishermen to fish therein, and in my presence several swallows were taken, which the fishermen threw in again; but one I took up myself, brought it home, which was five X

" These are facts attested by people of the highest quality, by some in public offices, and by others who, though of a low rank, however, made these affidavits upon oath. It is impossible to suppose indiscriminately that they were prompted, by views of interest, to assert as a fact a thing which had no truth in it. It is therefore highly probable, or rather incontestably true, that swallows retire in the northern countries, during winter, into the water, and stay there in a torpid state till the return of warmth revives them again in spring. The question therefore, I believe, ought for the future to be thus stated : The swallows in Spain, Italy, France, and perhaps some from England, remove to warmer climates; some English ones, and some in Germany and other mild countries, retire into clefts and holes in rocks, and remain there in a torpid state. In the colder northern countries the swallows immerse in the sea, in lakes, and rivers; and remain in a torpid state, under ice, during winter. There are still some objections to this latter assertion, which we must remove. It is said, Why do not rapacious fish, and aquatic quadrupeds and birds, devour these swallows? The answer is obvious, swallows choose only such places in the water for their winter retreat as are near reeds and rushes; so that sinking down there between them and their roots, they are by them secured against the rapaciousness of their enemies. But others object, Why are not these birds caught in such fresh waters as are continually harassed by nets? I believe the same answer which has been made to the first objection will serve for this likewise. Fishermen take care to keep off with their nets from places filled with reeds and rushes, for fear of entangling and tearing their net; and thus the situation of swallows under water, is the reason that they are seldom disturbed in their silent winter retreats. What confirms this opinion still more is, that swallows were never caught in Prussia according to the abovementioned affidavits, but with those parts of the net which passed near to the reeds and rushes; and sometimes the swallows were yet fastened with their feet to a reed, when they were drawn up by the net. As to the argument taken from their being so long under water without corruption, I believe there is a real difference between animals suffocated in water and animals being torpid therein. We have examples of things being a long time under water; to which we may add the intense cold of these northern regions, which preserves them. Who would have thought that snails and polypes might be dissected, and could reproduce the parts severed from their bodies, if it was not a fact ? Natural history ought to be studied as a collection of facts, not as the history of our guesses or opinions. Nature varies in an infinite manner; and Providence has diversified the instinct of animals and their economy, and adapted it to the various seasons and climates."

With Mr Kalm's concluding observations we hearti- This que ly concur. Natural history ought to be studied as a tion ough collection of facts; and it was from this very notion to be dethat we have stated the above-mentioned opinions so not by re fully, and brought together the facts which the best soning, b advocates for each opinion have judged most proper for by experisupporting ment, figration. supporting them. We are sensible of the great improbahility of the third opinion, and know that many arguments have been used to prove its absurdity : such as these, The swallow is lighter than water, and therefore cannot sink; if it moults at all, it must moult under water during its torpid state, which is very improbable; there is no instance of land animals living so long under water without respiration. Many other arguments of the same sort have been advanced, and certainly afford a short way of deciding the question; but unless they were sufficient to prove the immersion of swallows a physical impossibility, they are of no force when opposed to the evidence of testimony, if there be no cause to suspect the witnesses of inaccuracy or design. The true way to refute such an opinion is by accurate observation and experiment. We have not heard of any accurate inquirics being made by philosophers in those northern countries where swallows are said to pass the winter under water. The count de Buffon, indeed, shut up some swallows in an ice-house by way of experiment, which died in a few days; but as he does not tell us what precautions he took to make the experiment succeed, it is not entitled to any attention.

Mr John Hunter made a very judicious experiment on the banks of the Thames, which is describan's Ma- ed by a correspondent in the Gentleman's Magazine, who asserts that he had it from Mr Hunter himlay 1796. self.

mates.

One year in the month of September, he prepared a room, with every accommodation and convenience which he could contrive, to serve as a dormitory for swallows, if they were disposed to sleep in winter. He placed in the centre a large tub of water with twigs and reeds, &c. which reached to the bottom. In the corners of the room he contrived artificial caverns and holes, into which they might retire; and he laid on the floor, or suspended in the air, different lengths of old wooden pipes, which had formerly been employed in conveying water through the streets, &c.

When the receptacle was rendered as complete as possible, he then engaged some watermen to take by night a large quantity of the swallows that hang upon the reeds in the Thames about the time of their departure. They brought him, in a hamper, a considerable number; and had so nicely hit the time of their capture, that on the very day following there were none to be seen.

He put the swallows into the room so prepared, where they continued to fly about, and occasionally perch on the twigs, &c. But not one ever retired into the water, the caverns, holes, or wooden pipes, or shewed the least disposition to grow torpid, &c. In this situation he let them remain till they all died but one. This appearing to retain some vigour, was set at liberty; when it mounted out of sight, and flew away. All the birds lay dead scattered about the room; but not one was found asleep or torpid, or had, if the correspondent remembers, so much as crept into any of the receptacles he had so provided.

This experiment was ingenious, and certainly docs render the doctrine of immersion much more improbablc; but it is not decisive; for it may still be urged by the advocates for that doctrine, as Mr Kalm has done, that it may only be in the colder countries where swallows retire into the water. We formerly said that

none of the three opinions is supported by such evi- Migration. dence as to satisfy the mind completely. Opinions respecting events which happen every year ought to be confirmed by a great number of observations, and not by a few instances divested of almost all their concomitant circumstances. Can no better proofs be brought to prove the migration of swallows than those of Adanson and Sir Charler Wager, or the circumstances mentioned by Mr White and Mr Laskey respecting their disappearing? We ought not merely to know that some swallows have taken a southerly flight in autumn, that some have been found at a great distance from land in the spring, or in harvest; but we ought to know to what countries they actually retire. Before we can rest satisfied, too, that it is a general fact that swallows remain in a torpid state during winter, either in caverns or in the bottom of lakes, &c. we must have more proofs; we must know what species of swallows they are said to be, in what countries this event takes place, and several other circumstances of the same kind.

We cannot help being of opinion that much remains Many to be done in order properly to ascertain what becomes things yet of the swallows in Europe during winter. It would be remain to be done in nccessary, in the first place, to know accurately what order to are the countries in which swallows are found. 2. Do determine they remain visible the whole year? or, if they disap-this point. pear, at what season does this happen, and when do they appear again ? 3. Do they ever appear while a strong north wind blows, or do they only come in great numbers with a south wind ? We will endcavour to answer some of these questions in part; hut must regret, that all the information on this subject which we have been able to cull from the best writers in natural history is very scanty; and we mercly give it by way of specimen, hoping that future observations will render it more complete.

There are five species which visit Britain during the A few imsummer months; the common or chimney swallow, the portant martin, sand martin, swift, and goat-sucker. I. The factsstated. chimney swallow frequents almost every part of the old continent; being known (says Dr Latham) from Norway to the Cape of Good Hope on the one side, and from Kamtschatka to India and Japan on the other. It is also found in all parts of North America, and in several of the West Indian islands. In Europe it disappears during the winter months. It appears generally a little after the vernal equinox ; but rather earlier in the southern, and later in the northern latitudes. It adheres to the usual seasons with much regularity; for though the months of February and March should be uncommonly mild, and April and May remarkably cold, it never deviates from its ordinary time. In the cold spring of 1740 some appeared in France before the insects on which they feed had become numerous enough to support them, and great numbers died +. + Buffon's In the mild and even warm spring of 1774 they ap-*Natural* peared no earlier than usual. They remain in some Birds, warm countries the whole year. Kolben assures us vol. vi. that this is the case at the Cape of Good Hope; but p. 527. (he says) they are more numerous in winter. Some birds of this species live, during winter, even in Europe; for example on the coast of Genoa, where they spend the night in the open country on the orange shrubs.

2. The

14

Migration. 2. The martins are also widely diffused through the - old continent; but the countries where they reside or visit have not been marked by naturalists with much attention. 3. The sand martins are found in every part

‡ Ibid. 527. of Europe, and frequently spend the winter in Malta ‡. Two birds of this species were seen in Perigord in France, on the 27th December 1775, when there was

Ibid. 484. a southerly wind, attended with a little rain ||. 4. The swift visits the whole continent of Europe; has also been observed at the Cape of Good Hope, and in Carolina in North America. . The goat suckers are not very common birds, yet are widely scattered. They are found in every country between Sweden and Africa: they arc found also in India. In April the southwest wind brings them to Malta, and in autumn they repass in great numbers.

Transac-Linnæan Society, vol. i.

Mr Markwick of Catsfield, near Battle in Sussex, tions of the has drawn up an accurate table, expressing the day of the month on which the birds, commonly called migratory, appeared in spring, and disappeared in autumn, for 16 years, from 1768 to 1783 inclusive. The observations were made at Catsfield. From this table we shall extract the dates for five years, and add the very few observations which we have been able to collect respecting the time when the swallow appears and disappears in other countries.

Were tables of the same kind made in every different country, particularly within the torrid zone, it would be easy to determine the question which we have been considering. To many, perhaps, it may not appear a matter of such importance as to be worth the labour.

IG M

We acknowledge it to be rather a curious than an im- Migration portant inquiry; yet it is one which must be highly Miguel. gratifying to every mind that can admire the wisdom of the Great Architect of nature. The instinct of the swallow is indeed wonderful : it appears among us just at the time when insects become numerous; and it continues with us during the hot weather, in order to prevent them from multiplying too much. It disappears when these insects are no longer troublesome. It is never found in solitude; it is the friend of man, and always takes up its residence with us, that it may protect our houses and our streets from being annoyed with swarms of flies.

MIGRATION of Fishes. See CLUPEA.

ST MIGUEL, or St MICHAEL, one of the Azore islands, situated in W. Long. 25. 45. N. Lat. 38. 10. This island appears to be entirely volcanic. The best account we have of it hath been published in the 68th volume of the Philosophical Transactions by Mr Francis Masson. According to him, the productions differ greatly from those of Madeira, insomuch that none of the trees of the latter are found here, except the faya : it has a nearer affinity to Europe than Africa The mountains are covered with the erica vulgaris, and an elegant evergreen shrub very like a phillyrea, which gives them a most beautiful appearance.

It is one of the principal and most fertile of the Azorian islands, lying nearly east and west. Its length is about 18 or 20 leagues; its breadth unequal, not exceeding five leagues, and in some places not more than two. It contains about 80,200 inhabitants.

Its capital, the city of Ponta del Guda, which contains about 12,000 inhabitants, is situated on the south side of the island, on a fine fertile plain country, pretty regularly built; the streets straight, and of a good breadth. It is supplied with good water, which is brought about the distance of three leagues from the neighbouring mountains. The churches and other religious edifices are elegant and well built for such an island. There is a large convent of Franciscan friars and one of the order of St Augustinc, four convents for professed nuns, and three Ricollimentos for young women and widows who are not professed. The vessels anchor in an open road; but it is not dangerous, as no wind can prevent their going to sea in case of stormy weather.

The country round the city is plain for several miles, well cultivated, and laid out with good taste into spacious fields, which arc sown with wheat, barley, Indian corn, pulse, &c. and commonly produce annually two crops; for as soon as one is taken off, another is immediately sown in its place. The soil is remarkably gentle and easy to work, being for the most part composed of pulverized pumice stone. There arc in the plains a number of pleasant country seats, with orchards of orange trees, which are esteemed the best in Europe.

The second town is Ribeira Grandc, situated on the north side of the island, containing about as many inhabitants as the city; a large convent of Franciscan friars, and one of nuns. It gives title to a count, called the Conde Ribeira Grande, who first instituted linen and woollen manufactories in the island.

The third town is Villa Franca, on the south side of the island, about six leagues east of Ponta del Guda.

It

Miguel. It has a convent of Franciscan friars and one of nuns. which contains about 300. Here, about half a mile from the shore, lies a small island (Illiao), which is hollow in the middle, and contains a fine bason with only one entrance into it, fit to hold 50 sail of vessels secure from all weather; at present it wants cleaning out, as the winter rain washes down great quantities of earth into it, which has greatly diminished its depth. But vessels frequently anchor between this island and the main.

> Besides these towns are several smaller, viz. Alagao, Agoa de Pao, Brelanha, Fanaes de Ajuda, and a number of hamlets, called lugars or places.

> About four leagues north-east from Villa Franca, lies a place called the Furnas, being a round deep valley in the middle of the east part of the island, surrounded with high mountains, which, though steep, may be easily ascended on horseback by two roads. The valley is about five or six leagues in circuit. The face of the mountains, which are very steep, is entirely covered with beautiful evergreens, viz. myrtles, laurels, a large species of bilberry called uva de serra, &c. and numberless rivulets of the purest water run down their sides. The valley below is well cultivated, producing wheat, Indian corn, flax, &c. The fields are planted round with a beautiful sort of poplars, which grow into pyramidal forms, and by their careless irregular disposition, together with multitude of rivulets, which run in all directions through the valley, a number of boiling fountains throwing up clouds of steam, a fine lake in the south-west part about two leagues round, compose a prospect the finest that can be imagined. In the bottom of the valley the roads are smooth and easy, there being no rocks, but a fine pulverized pumice stone that the earth is composed of.

> There are numerous hot fountains in different parts of the valley, and also on the sides of the mountains : but the most remarkable is that called the chaldeira, situated in the eastern part of the valley, on a small eminence by the side of a river, on which is a bason about 30 feet diameter, where the water continually boils with prodigious fury. A few yards distant from it is a cavern in the side of the bank, in which the water boils in a dreadful manner, throwing out a thick, muddy, unctuous water, several yards from its mouth with a hideous noise. In the middle of the river are several places where the water boils up so hot, that a person cannot dip his finger into it without being scalded; also along its banks are several apertures, out of which the steam rises to a considerable height, so hot that there is no approaching it with one's hand : in other places, a person would think that 100 smiths bellows were blowing altogether, and sulphureous steams issuing out in thousands of places; so that native sulphur is found in every chink, and the ground covered with it like hoar frost; even the bushes that happen to lie near these places are covered with pure brimstone, condensing from the steam that issues out of the ground, which in many places is covered over with a substance like burnt alum. In these small caverns from which the stcam issues, the people often boil their yams.

Near these boiling fountains are several mineral springs; two in particular, whose waters have a very

strong quality, of an acid taste, and bitter to the Miguel. tongue.

About half a mile to the westward, and close by the river side, are several hot springs, which are used by sick people with great success. Also, on the side of a hill west of St Anne's church, are many others, with three bathing houses, which are most commonly used. These waters are very warm, although not boiling hot; but at the same place issue several streams of cold mineral water, by which they are tempered, according to every one's liking.

About a mile south of this place, and over a low ridge of hills lics a fine lake about two leagues in circumference, and very deep, the water thick, and of a greenish colour. At the north end is a plain piece of ground, where the sulphureous steams issue out in many places, attended with a surprising blowing noise. Our author could observe strong springs in the lake, but could not determine whether they were hot or cold : this lake seems to have no visible evacuation The other springs immediately form a considerable river, called Ribeira Quente, which runs a course about two or three leagues, through a deep rent in the mountains, on each side of which are several places where the smoke issues out. It discharges itself into the sea on the south side, near which are some places where the water boils up at some distance in the sea.

This wonderful place had been taken little notice of until very lately : so little curiosity had the gentlemen of the island, that scarcely any of them had seen it, until of late some persons, afflicted with very virulent disorders, were persuaded to try its waters, and. found immediate relief from them. Since that time it has become more and more frequented; several nersons who had lost the use of their limbs by the dead palsy have been cured; and also others who were troubled with eruptions on their bodies.

A clergyman, who was greatly afflicted with the gout, tried the said waters, and was in a short time perfectly cured, and has had no return of it since. When Mr Masson was there, several old gentlemen, who were quite worn out with the said disorder, were using the waters, and had reeived incredible benefit from them ; in particular, an old gentleman about 60 years of age, who had been tormented with that disorder more than 20 years, and often confined to his bed for six months together: he had used these waters for about three weeks, had quite recovered the use of his limbs, and walked about in the greatest spirits imaginable. A friar also who had been troubled with the said disorder about 12 years and reduced to a cripple, by using them a short time was quite well, and went a-hunting every day.

There are several other hot springs in the island, particularly at Ribeira Grand; but they do not possess the same virtues, at least not in so great a degree.

The east and west part of the island rises into high mountains; but the middle is low, interspersed with round conic hills, all of which have very recent marks of fire; all the parts below the surface consisting of melted lava lying very hollow.

Most of the mountains to the westward have their tops hollowed out like a punch bowl, and contain water.

1

Miguel, ter. Near the west end is an immense decp valley Milan. like the Furnas, called the Sete Cidades. This valley is surrounded with very abrupt mountains, about seven or eight leagues round; in the bottom is a deep lake of water about three leagues in circuit, furnished with great numbers of water fowls. This water has no mineral quality; neither are there any hot springs in the valley. All these mountains are composed of a white crumbly pumice stone, which is so loose, that if a person thrust a stick into the banks, whole waggon loads of it will tumble down. The inhabitants of the island relate a story, that he who first discovered it observed an extraordinary high peak near the west end; but the second time he visited it, no such peak was to be seen, which he supposed must have certainly sunk; but, however improbable this story may be, at some period or other it must have certainly been the case. See AZORES, SUPPLEMENT.

MILAN, or the ducky of the Milanese, a country of Italy, bounded on the west by Savoy, Piedmont, and Montferrat; by Switzerland on the north; by the territories of Venice, the duchies of Mantua, Parma, and Placentia on the east; and by the territories of Genoa on the south. It is 150 miles long, and 78 broad.

Anciently this duchy, containing the north part of the old Liguria, was called Insubria, from its inhabitants the Insubres; who were conquered by the Romans, as these were by the Goths; who in their turn were subdued by the Lombards. Didier, the last king of the Lombards, was taken prisoner by Charlemagne, who put an end to the Longobardic empire, and appointed governors of Milan. These governors being at a distance from their masters, soon began to assume an independency, which brought a dreadful calamity on the country; for, in 1152, the capital itself was levelled with the ground by the emperor Frederic Barbarossa, who committed great devastations otherwise throughout the duchy. Under this emperor lived one Galvian, a nobleman who was descended from Otho a Milanese. Galvian, along with William prince of Montferrat, served in the crusade, when Godfrey of Boulogne took Jerusalem : he killed in single combat the Saracen general, whom he stripped of his helmet, which was adorned with the image of a scrpent swallowing a youth; and this ever afterwards was the badge of that family. His grandson Galvian, having opposed the emperor, was taken prisoner, and carried in irons into Germany, from whence he made his escape, and returning to Milan, died in the service of his country. From him descended another Otho, at the time that Otho IV. was emperor of Germany, and who soon distinguished himself by the accomplishments both of his mind and body. When he grew up, he was received into the family of Cardinal Octavian Ubaldini at Rome. This prelate, who was himself aspiring at the popedom, was in a short time greatly taken with the address and accomplishments of young Otho, and predicted his future greatness. In the mean time, one Torres, or Torriano, a Milanese nobleman of unbounded ambition, was attempting to make himself master of Mi-lan. The popular faction had some time before been caballing against the nobility; and at last, Torriano putting himself at their head, expelled the bishop, and

put to death or banished all the nobility; by which Milar. means the popular government was fully established; and Torriano, under this pretence, ruled every thing as he pleased. He was, however, soon opposed by one Francisco Sepri, who formed a great party, pretending to deliver the city from Torriano's haughtiness and cruelty. But while the two parties were collecting their forces against each other, Cardinal Ubaldini was projecting the destruction of both, by means of his favonrite Otho. This prelate had for some time borne an implacable hatred to Torriano, because he had been by him prevented from carrying out of the treasury of St Ambrose's church at Milan, a carbuncle or jewel of great value, which he pretended to reserve for adorning the papal tiara; for which reason he now determined to oppose his ambition.

Ubaldini began with naming Otho archbishop of Milan ; which, as the pope's legate, he had a right to do. This nomination was confirmed by Pope Urban IV.; and the party of the nobility having now got a head from the pope himself, began to gather strength. Otho in the mean time employed himself in collecting troops; and had no sooner procured a show of an army than he advanced towards Lago Maggiore, and took possession of Arona, a strong post near that lake : but Torriano, marching immediately against him with all his troops, obliged him to abandon the place, and leave his party to make the best terms they could with the conqueror. This was followed by the destruction of the castles of Arona, Anghiari, and Brebia: soon after which Torriano died, and was succeeded by his brother Philip, who had sufficient interest to get himself elected podesta, or prætor of Milan, for ten years. During his lifetime, however, the party of the nobility increased considerably under Otho, notwithstanding the check they had received. Philip died in 1265, having lost ground considerably in the affections of the people, though he obtained a great reputation for his courage and conduct. His successor Napi rendered himself terrible to the nobility, whom he proscribed, and put to death as often as he could get them into his power. He proceeded such lengths, and acted with such fury against that unfortunate party, that Pope Clement IV. who had succeeded Urban, at last interdicted Milan, and excommunicated Napi and all his party. By this Napi began to lose his popularity, and the public disaffection towards him was much heightened by the natural cruelty of his temper. But in the mean time, the party of the nobility was in the utmost distress. Otho himself and his friends, having spent all their substance, wandered abont from place to place; the pope not being in a capacity of giving them any assistance. Otho, however, was not discouraged by his bad success, but found means still to keep up the spirits of his party, who now chose for their general Squarcini Burii, a man of great eminence and courage, whose daughter was married to Matthew Visconti, afterwards called Matthew the Great. At the same time they renewed their confederacy with the marquis of Montferrat, who was son-in-law to the king of Spain. The marquis agreed to this confederacy chiefly with a view to become master of the Milanese.

The nobility now again began to make head; and baving collected an army, which was joined by 600 Spanish

Milan.

Spanish cavalry and a body of foot, gained some advantages. But in the mean time Napi, having gathered together a superior army, suddenly attacked Otho and Burri, and defeated them. After this disaster Otho applied to the pope; from whom, however, he did not obtain the assistance he desired; and in the mean time Napi invited the emperor Rodolph into Italy, with the promise of being crowned at Milan. This invitation was accepted of with great readiness by Rodolph; who constituted Napi his governor and vicar-general in Lombardy, sending to him at the same time a fine body of German horse, the command of which was given to Cassoni, Napi's nephew. On this Otho again applied to the pope (Gregory X.); but he was so far from granting him any assistance, that he is said to have entered into a scheme of assassinating him privately; but Otho escaped the danger, and in 1276 began to recover his affairs. The reason of Pope Gregory's cumity to him was, that he and his party were thought to be Gibelines, and were opposed by great numbers of the nobility themselves; but after that pope's death, the Milanese exiles being united under one head, soon became formidable. They now chose for their general Godfrey count of Langusio, a noble Pavian, and an inveterate enemy of the Torriano family. This nobleman being rich and powerful, enlisted many German and other mercenarics, at whose head he marched towards the Lago Maggiore. All the towns in that country opened their gates to him, through the interest of the Visconti family, who resided in these parts. But this success soon met with a severe check in an unfortunate engagement, where Godfrey was defeated and taken prisoner; after which he and 34 nobles had their heads struck off, and sent from the field of battle piled up in a common waggon.

This defeat greatly affected Otho; but having in a short time recovered himself, he again attacked his enemies, and defeated them ; but, suffering his troops to grow remiss after their victory, the fugitives rallied, and entirely defeated him. The next year, however, Otho had better success, and totally defeated and took prisoner Napi himself. After this victory Cassoni was obliged to abandon Milan to his competitor, who kept possession of it till his death, which happened in 1295, in the 87th year of his age.

Otho was succeeded by Matthew Visconti above mentioned; and Milan continued in subjection to that family without any very memorable occurrence till the year 1378, when, by the death of Galeazzo II. his brother Barnabo became sovereign of Milan. He was of a brave and active disposition; but excessively profuse in his expenses, as his brother Galeazzo had also been; and to procure money to supply his extravagancies, was obliged to oppress his subjects. Galeazzo had engaged in an enterprize against Bologna, and the siege of it was continued by Barnabo. It lasted for nine years; and during this time is said to have cost 300 millions of gold, a prodigious sum in those days, near 40 millions sterling, the lowest gold coin being in value somewhat more than half a crown English. Both the brothers were excessively fond of building. Barnabo erected a bridge over the Adda, consisting of three stories; the lowest for chariots and heavy carriages, the middle for horses, and the uppermost for foot passengers. He built also another

VOL. XIV. Part I.

bridge which was carried over houses without touching Milan. them. To accomplish these, and many other expensive schemes, he became one of the greatest tyrants imaginable, and every day produced fresh instances of his rapacity and cruelty. He instituted a chamber of inquiry, for punishing all those who had for five years before been guilty of killing boars, or even of eating them at the table of another. They who could not redeem themselves by money were hanged, and above 100 wretches perished in that manner. Those who had any thing to lose were stripped of all their substance, and obliged to labour at the fortifications and other public works. He obliged his subjects to maintain a great many hunting dogs, and each district was taxed a certain number. The overseers of his dogs were at the same time the instruments of his rapacity. When the dogs were poor and slender, the owners were always fined; but when the dogs were fat, the owners were also fined for suffering them to live without exercise.

The extravagant behaviour of Barnabo soon rendered public affairs ready for a revolution, which was at last accomplished by his nephew John Galeazzo. He affeeted a solitary life, void of ambition, and even inclining to devotion ; but at the same time took eare to have his uncle's court filled with spies, who gave him information of all that passed. He reduced his table and manner of living, pretending that he took these steps as preparatives to a retirement from the world, which was soon to take place after he had paid a religious vow. In short, he acted his part so well, that even Barnabo, though abundantly cautious, had no suspicion of his having any designs against him; and so entirely did he conceal his ambition, that he several times made application to his uncle for his interest to procure him a quiet retreat as soon as his religious vows were performed. One of these was to pay a visit to the church of the blessed Virgin upon Mount Varezzio. This was to be done with so much secrecy that all kinds of eye witnesses were to be excluded; and it was with difficulty that Barnaho himself and two of his sons were allowed to accompany our devotee. But, in the mean time, the hypocritical Galeazzo had soldiers advancing from all quarters; so that Barnabo and his sons were immediately seized, and the houses of those who had sided with them given up to be plundered. The booty in plate, money, and all kinds of rich furniture, was immense. The ministers of the late government were dragged from their hiding places, and put to death; and at last the citadel itself fell into the hands of Galeazzo, who found in it an immense sum of money. Barnabo was carried prisoner to Tritici, a castle of his own building, where he had the happiness to find one person still faithful to him. This was his mistress, named Doninia Porra; who, when he was abandoned by all the world, shut herself up a voluntary prisoner in his chamber, and remained with him as long as he lived, which was only seven months after his degradadation.

John Galeazzo was the first who took upon him the title of the Duke of Milan, and was a prince of great policy and no less ambition. He made war with the Florentines, became master of Pisa and Bologna, and entirely defeated the emperor in 1401, so that he entertained hopes of becoming master of all Lombardy, and cutting off all possibility of invading it either from M France

Milan. France or Germany; but his designs were frustrated - by death, which happened in 1402, in the 55th year of his age. After his decease the Milanese government fell into the most violent distractions, so that it could not be supported, even in time of peace, without an army of 20,000 foot and as many horse. In the year 1421, however, Philip duke of Milan became master of Genoa; but though he gained great advantages in all parts of Italy, the different states still found means to counterbalance his successes, and prevent him from enslaving them : so that Milan never became the capital of any extensive empire; and in 1437 Genoa rcvolted, and was never afterwards reduced.

Philip died in 1448, and by his death the male line of the Visconti family was at an end. The next lawful heir was Valentina his sister, who had married the duke of Orleans, son to Charles V. of France. By the contract of that marriage, the lawful progeny of it was to succeed to the duchy of Milan in failure of the heirs male of the Visconti family; but this succession was disputed by Sforza, who had married Philip's natural daughter. It is certain, however, that the rightful succession was vested in the house of Orleans and the kings of France; and therefore though the Sforza family got possession of the duchy for the present, Louis XII. afterwards put in his claim, being a grandson to John Galeazzo. For some time he was successful; but the French behaved in such an insolent manner, that they were driven out of the Milanese by the Swiss and Maximilian Sforza. The Swiss and Milanese were in their turn expelled by Francis I. who obliged the Sforza family to relinquish the government for a pension of 30,000 ducats a-year. Francis Sforza, the son of Maximilian, however, being assisted by the emperor and the pope, regained the possession of the Milancse about the year 1521; and, eight years after, the French king, by the treaty of Cambray, gave up his claim on the duchy.

But, in fact, the emperors of Germany seem to have had the fairest title to the Milanese in right of their being for a long time sovereigns of Italy. On the death of Francis Sforza, therefore, in the year 1536, the emperor Charles V. declared the Milanese to be an imperial fief, and granted the investiture of it to his son Philip II. king of Spain. In his family it continued till the year 1706, when the French and Spaniards were driven out by the Imperialists, and the emperor again took possession of it as a fief. It was confirmed to his house by the treaty of Baden in 1714, by the quadruple alliance in 1718, and by the treaty of Aix-la-Chapelle in 1748.

The duchy of Milan is one of the finest provinces in Italy. It is bounded on the south by the Apennine mountains, and the territory of Genoa; on the north by Switzerland; on the east by the Venetian territories, and the duchies of Mantua, Parma, and Placentia; and on the west by Savoy, Piedmont, and Montferrat; extending from north to south about 100 miles, and from east to west about 108. It is well watered by the Tessino, the Sesia, the Adda, the Po, the Oglio, the Lombro, Serio, &c. and also by scveral canals and lakes. Of the latter, the Lago Maggiore is between 30 and 40 miles in length, and in some places six or seven miles broad. In it lie the Boromcan islands, as they are called, viz. Isola Bella

and Isola Madre, the beauty of which almost exceeds Milan. imagination : art and nature seem to have vied with one another in embellishing them. In each of them is a palace with delicious gardens, belonging to the Boromean family. 'The water of the lake is clear and of a greenish colour, and abounds with fish. The hills with which it is surrounded present a most charming landscape, being planted with vines and chesnut trees, interspersed with summer houses. There is a canal running from it towards Switzerland, with which the city of Milan has a communication. It was anciently called Lacus Verbanus. The Lago de Como, which was called by the Latin poets Lacus Larius, but had its modern name from the city near which it lies, extends itself about 30 miles northward from Como, but its greatest breadth is not above five miles. From the Lago Maggiore issues the Tessino ; and from that of Como the Adda. Of the other lakes, that of Lugano and Guarda are the chief: that of Guarda was anciently called Benacus.

The trade and manufactures of this duchy consist principally in silk stuffs, stockings, gloves, and handkerchiefs, linen and woollen cloth, hardware, curious works of crystal, agate, hyacinths, and other gems; but their exports are usually far short of their imports. It produces also abundance of rice, corn, fruit, wine, and hemp. Great quantities of cheese are also made here.

In the year 1767, the Austrian government of Milan published a law, by which all the rights which the popeor the bishops had till then exercised over ecclesiastics, either with regard to their effects or persons, was transferred to a council established for that purpose at Milan. By the same edict, all ecclesiastics were obliged to sell the estates which they had become possessed of. since the year 1722; and no subject, whether ecclesiastic or secular, was to go to Rome to solicit any favour, except letters of indulgence, without the consent. of the said council.

This duchy was subdued by the French in the year. 1796, when it formed a part of the Cisalpine republic. When hostilities recommenced in 1799, it was again taken by the allies, but afterwards reconquered by. Bonaparte in 1800. From this period it formed a part of the kingdom of Italy, till the overthrow of Bonaparte's government in 1814, when it was restored to Austria with the rest of Lombardy.

MILAN, the capital of the duchy of that name, in Latin Mediolanum, is a large city, and has a wall and rampart round it, with a citadel; yet is thought to be incapable of making any great resistance. The gardens within the city take up a great deal of ground. In the citadel is a foundery for cannon, and an arsenal furnished with arms for 12,000 men. Milan hath experienced a great variety of fortune, having been subject sometimes to the French, sometimes to the Spaniards, and sometimes to the Germans. A great number of persons of rank and fortune live in it, especially during the winter. The ladies in France are not allowed more liberty than those of this eity : even the austerities of the monastic life are so far mitigated here, that gentlemen have not only the liberty of talking with the nuns, and of rallying and laughing at the grate, but also of joining with them in concerts of music, and of spending whole afternoons m

Milan.

in their company. The place where the beau monde take the air, either in their coaches or on foot, is the rampart betwixt the Porta Orientale and the Porta Tosa, where it is straight and broad, and extremely pleasant, being planted with white mulberry trees, and commanding a prospect on one side of the open country, and on the other of the gardens and vineyards between the ramparts and the city. Milan, which is said to have been built by the Gauls about 200 years after the foundation of Rome, contains a great number of stately edifices, as churches, convents, palaces, and hospitals. The cathedral is a vast pile, all of marble; and is the largest in Italy, except that of St Peters at Rome. It is 449 feet in length, 275 in breadth, and 238 in height, under the cupola. Though founded in 1386, the façade was only completed a few years ago by order of Bonaparte. Of the great number of statues about it, that of St Bartholomew, just flead alive, with his skin hanging over his shoulders; and of Adam and Eve, over the main portal, are the finest. The pillars supporting the roof of the church are all of marble, and the windows finely painted. This church contains a treasure of great value, particularly a shrine of rock crystal, in which the body of St Charles Boromæo is deposited. The other churches most worthy a stranger's notice arc those of St Alexander, St Jerome, St Giovanni di Casarotti della Passione, that of the Jesuits, and of St Ambrose, in which lie the bodies of the saint and of the kings Pepin and Bernard. In the Ambrosian college, founded by Frederic Boromæo, 16 professors teach gratis. In the same college is also an academy of painting, with a museum, and a library containing about 45,000 printed books and manuscripts; among the last of which is a translation of Josephus's History of the Jews, done by Rufinus about 1 200 years ago, and written on the bark of a tree; St Ambrosc's works on vellum, finely illuminated; the orations of Gregory Nazianzen, and the works of Virgil, in folio, with Petrarch's notes. In the museum are Leonardi da Vinci's mathematical and mechanical drawings, in 12 large volumes. The seminary for sciences, the college of the nobles, the Helvetian college, and the mathematical academy, are noble foundations, and stately buildings. Of the hospitals, the most remarkable are the Lazaretto, and that called the great hospital; the latter of which receives sick persons, foundlings, and lunatics, and has six smaller hospitals depending on it, with a revenue of 100,000 rix dollars.

The number of the inhabitants of this city is said to be about 130,000. It has been 40 times besieged, taken 20 times, and four times almost entirely demolished; yet it hath always recovered itself. It is said that gunpowder is sold here only by one person, and in one place. The houses of cntertainment, and the ordinaries here, are represented as very indifferent.-Mr Keysler says, it is not unusual for young travellers, when they go to any of the taverns in Milan, to be asked, " whether they choose a letto fornito, or fcmale bedfellow," who continues masked till she enters the bedchamber. Milan is described as inferior to Turin both in beauty and conveniency, many of the streets being crooked and narrow, and paper windows much more frequent than in that city; even in grand pafaces, the windows are often composed promiscuously

of glass and paper. There are four theatres in the Milan. city : the great theatre Della Scala, built in 1778; that of the Canobiana, the theatre Re; and the Careano. On the right of the Place d'Armes is a magnificent amphitheatre, appropriated to horsemanship and games, erected during the French rule. Two large canals extend from hence, the one to the Tessino, and the other to the Adda; the Tessino having a communication with the Lago Maggiore, and, by a canal, with the Sesia; and the Adda issuing from the Lago di Como, and having a communication by canals with the Lombro and Scrio. In a void space in one of the streets of Milan, where stood the house of a barber who had conspired with the commissary of health to poison his fellow citizens, is erected a pillar called Colonna Infame, with an inscription to perpetuate the memory of the execrable design. The environs of this city arc very pleasant, being adorned with beautiful seats, gardens, orchards, &c. About two Italian miles from it, at the seat of the Simonetti family, is a build . ing, that would have been a masterpiece of its kind had the architect designed it for an artificial echo. It will return or repeat the report of a pistol above 60 times; and any single musical instrument well touched will have the same effect as a great number of instruments, and produce a most surprising and delightful concert.

Bonaparte was crowned king of Italy in this city in May 1805, and it was visited by the emperor of Austria in 1816. It is now the capital of the kingdom of Venetian Lombardy.

According to Dr Moore, "there is no place in Italy. perhaps in Europe, where strangers are received in such an easy hospitable manner as at Milan. Formerly the Milanese nobility displayed a degree of splendour and magnificence, not only in their entertainments, but in their usual style of living, unknown in any other country of Europe. They are under a necessity at present of living at less expence, but they still show the same obliging and hospitable disposition. This country having, not very long since, been posscssed by the French, from whom it devolved to the Spaniards, and from them to the Germans, the troops of those nations have, at different periods, had their residence herc, and in the course of these vicissitudes, produced a style of manners, and stamped a character on the inhabitants of this duchy, different from what prevails in any other part of Italy; and nice observers imagine they perceive in Milanese manners, the politeness, formality, and honesty imputed to those three nations, blended with the ingenuity natural to Italians. In Italy, the ladies have no notion of quitting their carriages at the public walks, and using their own legs as in England and France. On seeing the number of servants, and the splendour of the equipages which appear every evening at the Corso on the ramparts, one would not suspect that degree of depopulation, and diminution of wealth, which we are assured has taken place within these few years all over the Milanese; and which proceeds from the burdensome nature of some late taxes, and the insolent and oppressive manner in which they are gathered."-Milan is situated 29 leagues N. E. of Turin, 110 N. W. of Rome, and 143 S. E. of Paris.-E. Long. 9. 11. N. Lat. 45. 28.

M 2

MILBORN-PORT.

MILBORN-PORT, a town of Somersetshire in Eugland, seated on a branch of the river Parret, 115 miles from London. Though represented in parliament, it is no market town nor corporation; but it appears in Domesday-hook to have had a market once, and 56 burgesses. It is in a manner surrounded hy Dorsetshire. Here are nine capital burgesses, who yearly choose two bailiffs, that have the government of the borough under them, and jointly return the members to parliament with the two stewards, who are chosen yearly out of nine commonalty stewards, and have the custody of the corporation-scal. These two stewards also distribute the profits of the lands given to the poor here, of which the said commonalty stewards are trustees. The number of inhabitants in 1811 was 1000, of houses 230. W. Long. 2. 37. N. Lat. 50. 50.

MILBROOK, a town of Cornwall, on the west side of Plymouth haven. It has a good fishing trade, and has forn.erly furnished our fleet with many able hands.

MILDENHALL, a town of Suffolk, seven miles from Newmarket, 12 from Bury, and 70 from London. It is situated on the river Lark, a branch of the Ouse, with a harbour for boats, and contained in 1811, 2493 inhabitants. It has a well frequented market on Fridays. Its church has a tower or steeple 120 feet high. E. Long. 0. 33. N. Lat. 52. 24.

MILDEW, is said to be a kind of thick, clammy' sweet juice, exhaled from, or falling down upon, the leaves and blossoms of plants. By its thickness and clamminess it prevents perspiration, and hinders the growth of the plant. It sometimes rests on the leaves of trees in form of a fatty juice, and sometimes on the ears of corn. It is naturally very tough and viscous, and becomes still more so by the sun's heat exhaling its more fluid parts; by which means the young ears of corn are so daubed over, that they can never arrive at their full growth. Bearded wheat is less subject to the mildew than the common sort; and it is observed that newly dunged lands are more liable to mildew than others. The best remedy is a smart shower of rain, and immediately afterwards a brisk wind. If the mildew is seen before the sun has much power, it has been recommended to send two men into the field with a long cord, each holding one end; and drawing this along the field through the ears, the dew will be dislodged from them, before the heat of the sun is able to dry it to that viscous state in which it does the mischief. Some also say, that lands which have for many years been subject to mildews, have heen cured of it by sowing soot along with the corn, or immediately after it.

Mr J. S. Segar, the author of a treatise upon this subject, observes, that the mildew is of such a sharp corrosive nature, that it raises blisters on the feet of the shepherds who go barefoot, and even consumes the hoofs of the cattle. He suspects that it possesses some arsenical qualities, though he does not pretend to affirm this positively. Its pernicious influence, according to him, is rendered still more powerful by a variety of circumstances; such as sending the cattle into the fields too early in the spring; their drinking water mixed with ice, or but lately thawed; their being

kept in stables that arc too close and filthy, and which Mildew are not sufficiently aired. The same author considers the mildew as a principal cause of epidemical distem- Milete pers among the cattle. The mildew producing these diseases, he says, is that which dries and burns the grass and leaves. It falls usually in the morning, particularly after a thunder storm. Its poisonous quality (which does not continue above 24 hours) never operates but when it has been swallowed immediately after its falling. The disorder attacks the stomach, is accompanied with pimples on the tongue, loss of appetite, a desiccation of the aliments in the stomach, a cough, and difficulty of respiration. As a preservative, the author prescribes purging in spring and in winter. The medicine he advises is composed of 30 grains of sulphur of antimony, and 60 grains of resin of jalap. He is against vomiting, and every thing that is of a heating nature.

MILE, a measure of length or distance, containing eight furlongs. The English statute mile is 80 chains, or 1760 yards; that is, 5280 feet.

We shall here give a table of the miles in use among the principal nations of Europe, in geometrical paces, 60,000 of which make a degree of the equator.

	Geometrical paces.

MILETUS, in Ancient Geography, a town of Crete mentioned by Homer; but where situated does not appear. It is said to he the mother town of Miletus in Caria, whither a colony was led by Sarpedon, Minos's brother, (Ephorus, quoted by Strabo). Milesii, the people, (Ovid).

MILETUS, in Ancient Geography, a celebrated town of Asia Minor, on the confines of Ionia and Caria. It was the capital city of all Ionia, and famous both for the arts of war and peace. It was situated about 10 stadia south of the month of the river Mæander, near the sea coast. It was founded by a Cretan colony under Miletus, the companion of Baechus; or (according to others) by Neleus the son of Codrus; or by Sarpedona son of Jupiter. It has successively been called Lelegeis, Pithyusa, and Anactoria. The inhabitants, called Milesii, were very powerful, and long maintained an obstinate war against the kings of Lydia. They early applied themselves to navigation; and planted no less than 80 colonies, or (according to Sencea) 380, in different parts of the world. It was the only town that made head against Alexander, and was with much difficulty taken. It gave birth to Thales,

Milan |) Mildew. filetus

Ailford.

Thales, one of the seven wise men, and the first who applied himself to the study of nature. It was also the country of Anaximander, the scholar and successor of Thales, the inventor of sun dials and the gnomon, and the first that published a geographical map; of Anaximenes, scholar and successor to the foregoing; and of other great men. It was noted for its excellent wool, according to Virgil; and was also celebrated for a temple and oracle of Apollo Didymæus. This famous people, from being powerful, becoming afterwards opulent and abandoned to pleasures, lost both their riches and their power .- At present it is called by the Turks Melas, and not far distant from it runs the river Mæander. St Paul going from Corinth to Jerusalem passed by Miletus, and as he went by sea, and could not take Ephesus in his way, he caused the bishops and priests of the church of Ephesus to come to Miletus (Acts xx. 15. &c.), which was about 12 leagues from them.

MILFOIL, or YARROW. See ACHILLEA, BOTANY Index.

MILFORD, a town of North America, in Sussex county, in the Delaware state, is situated at the source of a small river, 15 miles from Delaware bay, and 150 southward of Philadelphia. This town, which contains about 80 houses, has been built, except one house, since the revolution. It is laid out with much taste, and is by no means disagreeable. The inhabitants are Episcopalians, Quakers, and Methodists.

MILFORD Haven, one of the finest harbours in Europe, and indisputably the best in Britain, is situated in Pembrokeshire in South Wales, and lies on the north side of the Bristol channel. It is very large, safe, and deep; there is no danger of going in or out with the tide, or almost with any wind. If a ship comes in without a cable or anchor, she may run ashore on the ooze, and there lie safe till she is refitted; and in an hour's time she may get out of the harbour into the open sea. It lies extremely convenient for ships bound from the English or Bristol channels to Ireland, or farther west, and from thenee to the channels. It is said, that 1000 sail of any size may ride secure in this haven. It has 16 deep and safe creeks, five bays, and 13 roads, all distinguished by their several names. The spring tide rises 36 feet, so that ships may at any time be laid ashore. Dale harbour is a ready outlet for small vessels, where they may ride in two or three fathoms at low water .- In the reign of Queen Elizabeth, before the Spanish invasion, two forts were begun at the entrance of Milford Haven, one on each side, called Nangle and Dale blockhouses ; but they were not then finished .--The Stack rock rises here above water, lying near the middle of the entrance between Nangle and Dale. Penermouth is the opening of that branch of the haven on which the town of Pembroke is seated, and where the customhouse of Milford is kept. The breadth of the entrance between rock and rock is but 200 yards at high water, and 112 at low water. There is a ridge of rocky ground that has the name of Carrs, which runs almost across Milford Haven, from Peter church towards Llandstadwell, where it renders the landing place difficult to strangers, from its not appearing at low water. The great convenience of this harbour is, that in an hour's time a ship

MIL

may be in or out of it, and in the way between the Milford Land's End and Ireland. As it lies near the mouth of the Severn, a ship in eight or ten hours may be Military. over on the coast of Ireland, or off the Land's End in the English channel; and a vessel may get out hence to the west much sooner than from either Plymouth or Falmouth. This harbour has been greatly improved by new works, at the expence of the go-vernment. The parliament on April 14. 1759 granted 10,000l. for fortifying the harbour of Milford, all of which was expended on the fort at Neyland, which, however, still remains unfinished.

MILIARY, in general, something resembling millet seed.

MILIARY Fever. See MEDICINE Index.

MILITANT, or CHURCH-MILITANT, denotes the body of Christians while here on earth.

MILITARY, something belonging to the soldiery or militia.

MILITARY Discipline, the training of soldiers, and the due enforcement of the laws and regulations instituted by authority for their conduct.

Next to the forming of troops, military discipline is the first object that presents itself to our notice; it is the soul of all armies; and unless it be established amongst them with great prudence, and supported with unshaken resolution, they are no better than so many contemptible heaps of rabble, which are more dangerous to the very state that maintains them than even its declared enemies.

MILITARY Execution, the ravaging or destroying of a country, or town, that refuses to pay the contribution inflicted upon them.

MILITARY Exercise. See EXERCISE and WORDS of Command.

MILITARY State, in British polity, one of the three divisions of the laity. See LAITY.

This state includes the whole of the soldiery, or such persons as are peculiarly appointed among the rest of the people for the safeguard and defence of the realm.

In a land of liberty, it is extremely dangerous to make a distinct order of the profession of arms. In absolute monarchies, this is necessary for the safety of the prince; and arises from the main principle of their constitution, which is that of governing by fear; but, in free states, the profession of a soldier, taken singly and merely as a profession, is justly an object of jealousy. In these no man should take up arms but with a view to defend his country and its laws : he puts not off the citizen when he enters the camp; but it is because he is a citizen, and would wish to continue so, that he makes himself for a while a soldier. The laws therefore, and constitution of these kingdoms, know no such state as that of a perpetual standing soldier, bred up to no other profession than that of war; and it was not till the reign of Henry VII. that the kings of England had so much as a guard about their persons.

In the time of the Anglo-Saxons, as appears from Edward the Confessor's laws, the military force of England was in the hands of the dukes or heretochs, who were constituted through every province and county in the kingdom; being taken out of the principal nobility, and such as were most remarkable for be-

ing

Military ing sapientes, fideles. et animosi. Their duty was to lead and regulate the English armies with a very unlimited power; prout eis visum fuerit, ad honorem coronæ et utilitatem regni. And because of this great power they were elected by the people in their full assembly, or folkmote, in the same manner as sheriffs were clected: following still that old fundamental maxim of the Saxon constitution, that where any officer was entrusted with such power, as, if abused, might tend to the oppression of the people, that power was delegated to him by the vote of the people themselves. So too, among the ancient Germans, the ancestors of our Saxon forefathers, they had their dukes, as well as kings, with an independent power over the military, as the kings had over the civil state. The dukes were elective, the kings hereditary: for so only can be consistently understood that passage of Tacitus, Reges ex nobilitate, duces ex virtute summent. In constituting their kings, the family or blood royal was regarded; in choosing their dukes or leaders, warlike merit : just as Cæsar relates of their ancestors in his time, that whenever they went to war, by way either of attack or defence, they electcd leaders to command them. This large share of power, thus conferred by the people, though intended to preserve the liberty of the subject, was perhaps unreasonably detrimental to the prerogative of the crown: and accordingly we find a very ill use made of it by Edric duke of Mercia, in the reign of King Edmund Ironside; who, by his office of duke or heretoch, was cntitled to a large command in the king's army, and by his repeated treacheries at last transferred the crown to Canute the Dane.

> It seems universally agreed by all historians, that King Alfred first settled a national militia in this kingdom, and by his prudent discipline made all the subjects of his dominions soldiers: but we are unfortunately left in the dark as to the particulars of this his so celebrated regulation; though, from what was last observed, the dukes seem to have been left in possession of too large and independent a power: which enabled Duke Harold, on the death of Edward the Confessor, though a stranger to the royal blood, to mount for a short space the throne of this kingdom, in prejudice of Edgar Etheling the rightful heir.

> Upon the Norman conquest, the feodal law was introduced here in all its rigour, the whole of which is built on a military plan. In consequence thereof, all the lands in the kingdom were divided into what were called knight's fees, in number above 60,000; and for every knight's fee, a knight or soldier, miles, was bound to attend the king in his wars, for 40 days in a year; in which space of time, before war was reduced to a science, the campaign was generally finished, and a kingdom either conquered or victorious. By this mcans the king had, without any expence, an army of 60,000 men always ready at his command. And accordingly we find one, among the laws of William the Conqueror, which in the king's name commands and firmly enjoins the personal attendance of all knights and others; quod habeant et teneant se semper in armis et equis, ut decet et oportet : et quod semper sint prompti et parati ad servitium suum integrum nobis explendum et peragendum, cum opus adfuerit, secundum quod debent de feodis et tenementis suis de jure nobis facere. This personal service in process of time degenerated into

pecuniary commutations or aids; and at last the military part of the feodal system was abolished at the Restoration, by stat. 12 Car. II. c. 24. See FEODAL System.

In the mean time, we are not to imagine that the kingdom was left wholly without defence in case of domestic insurrections, or the prospect of foreign invasions. Besides those who by their military tenures were bound to perform 40 days service in the field, first the assize of arms, cnacted 27 Hen. II. and afterwards the statute of Winchester, under Edward I. obliged every man, according to his estate and degree, to provide a determinate quantity of such arms as were then in use, in order to keep the peace; and constables were appointed in all hundreds by the latter statute, to see that such arms were provided. These weapons were changed, by the statute 4 and 5 Ph. and M. c. 2. into others of more modern scrvice; but both this and the former provisions were repealed in the reign of James I. While these continued in force, it was usual from time to time for our princes to issue commissions of array, and send into every county officers in whom they could confide, to muster and array (or set in military order) the inhabitants of every district; and the form of the commission of array was settled in parliament in the 5 Hen. IV. But at the same time it was provided, that no man should be compelled to go out of the kingdom at any rate, nor out of his shire, but in cases of urgent necessity; nor should provide soldiers unless by consent of parliament. About the reign of King Henry VIII. and his children, lord-lieutenants began to be introduced, as standing representatives of the crown, to keep the counties in military order; for we find them mentioned as known officers in the statute 4 and 5 Ph. and M. c. 3. though they had not been then long in use; for Camden speaks of them in the time of Queen Elizabeth as extraordinary magistrates, constituted only in times of difficulty and danger.

In this state things continued till the repeal of the statutes of armour in the reign of King James I.; after which, when King Charles I. had, during his northern expeditions, issued commissions of lieutenancy, and exerted some military powers which, having been long exercised, were thought to belong to the crown, it became a question in the long parliament, how far the power of the militia did inherently reside in the king; being now unsupported by any statute, and founded only upon immemorial usage. This question, long agitated with great heat and resentment on both sides, became at length the immediate cause of the fatal rupture between the king and his parliament: the two houses not only denying this prerogative of the crown, the legality of which claim perhaps might be somewhat doubtful; but also seizing into their hands the entire power of the militia, the illegality of which step could never be any doubt at all.

Soon after the restoration of King Charles II. when the military tenures were abolished, it was thought proper to ascertain the power of the militia, to recognize the sole right of the crown to govern and command them, and to put the whole into a more regular method of military subordination : and the order in which the militia now stands by law, is principally built upon the statutes which were then enacted. It is true, the two last of them are apparently repealed ; but many of their provisions

3

1 litary, provisions are re-enacted, with the addition of some new regulations, by the present militia laws; the general scheme of which is to discipline a certain number of the inhabitants of every county, chosen by lot for three years, and officered by the lord-lieutenant, the deputy lieutenants, and other principal landholders, under a commission from the crown. They are not compellable to march out of their counties, unless in case of invasion or actual rebellion, nor in any case compellable to march out of the kingdom. They are to be exercised at stated times : and their discipline in general is liheral and easy; but, when drawn out into actual service, they are subject to the rigours of martial law, as necessary to keep them in order. This is the constitutional security which our laws have provided for the public peace, and for protecting the realm against foreign or domestic violence; and which the statutcs declare as essentially necessary to the safety and prosperity of the

kingdom. When the nation was engaged in war, more veteran troops and more regular discipline were estecmed to he necessary, than could be expected from a mere militia; and therefore at such times more rigorous methods were put in use for the raising of armies and the due regulation and discipline of the soldiery, which are to be looked upon only as temporary excresscences bred out of the distemper of the state, and not as any part of the permanent and perpetual laws of the kingdom. For martial law, which is built upon no settled principles, but is entirely arbitrary in its decisions, is, as Sir Matthew Hale observes, in truth and reality no law, but. something indulged rather than allowed as a law. The necessity of order and discipline in an army is the only thing which can give it countenance; and therefore it ought not to be permitted in time of peace, when the king's courts are open for all persons to receive justice according to the laws of the land. Wherefore, Thomas earl of Lancaster being convicted at Pontefraet, 15 Edward II. by martial law, his attainder was reversed I Edward III. because it was done in time of peace. And it is laid down, that if a lieutenant, or other, that hath commission of martial authority, doth in time of peace hang or otherwise exceute any man by colour of martial law, this is murder; for it is against magna charta. And the petition of right enacts, that no soldier shall be quartered on the subject without his own consent; and that no commission shall issue to proceed within this land according to martial law. And whereas, after the Restoration, King Charles II. kept up about 5000 regular troops, by his own authority, for guards and garrisons, which King James II. by degrees increased to no less than 30,000, all paid from his own civil list; it was made one of the articles of the bill of rights, that the raising or keeping a standing army within the kingdom in time of peace, unless it be with consent of parliament, is against law.

But as the fashion of keeping standing armies (which was first introduced by Charles VII. in France 1445) has of late years universally prevailed over Europe (though some of its potentates, being unable themselves to maintain them, are obliged to have recourse to richer powers, and receive subsidiary pensions for that purpose), it has also for many years past been annually judged necessary by our legislature for the safety of the kingdom, the defence of the possessions of the crown of

Great Britain, and the prescrvation of the balance of Military. power in Europe, to maintain even in time of peace a standing body of troops, under the command of the crown; who are however ipso facto disbanded at the expiration of every year, unless continued by parliament. And it was enacted by statute 10 William III. c. 1. that not more than 12,000 regular forces should be kept on foot in Ireland, though paid at the charge of that kingdom: which permission is extended by statute 8 Geo. III. c. 13. to 16,235 mcn in time of peace.

To prevent the executive power from being able to oppress, says Baron Montesquieu, it is requisite that the armies with which it is intrusted should consist of the people, and have the same spirit with the people : as was the case at Rome, till Marius new-modelled the legions by culisting the rabble of Italy, and laid the foundation of all the military tyranny that ensued. Nothing then, according to these principles, ought to be more guarded against in a free state, than making the military power, when such a one is necessary to be kept on foot, a body too distinct from the people. Like ours, therefore, it should wholly be composed of natural subjects; it ought only to be enlisted for a short and limited time; the soldiers also should live intermixed with the people ; no separate camp, no barracks, no inland fortresses should be allowed. And perhaps it might be still better, if, by dismissing a stated number, and enlisting others at every renewal of their term, a circulation could be kept up between the army and the people, and the citizen and the soldier be more intimatcly connected together.

To keep this body of troops in order, an annual act of parliament likewise passes, " to punish mutiny and desertion, and for the better payment of the army and , their quarters." This regulates the manner in which they are to be dispersed among the several inn-keepers and victuallers throughout the kingdom; and establishes a law martial for their government. By this, among other things, it is enacted, that if any officer or soldier shall excite, or join any mutiny, or, knowing of it, shall not give notice to the commanding officer, or shall . desert, or list in any other regiment, or sleep upon his post, or leave it before he is relieved, or hold correspondence with a rebel or cuemy, or strike or use violence to his superior officer, or shall disobey his lawful commands; such offender shall suffer such punishment as a court martial shall inflict, though it extend to death . itself.

However expedient the most strict regulations may be in time of actual war, yet in times of profound peace, a little relaxation of military rigour would not, one should hope, he productive of much inconvenience. And, upon this principle, though by our standing laws (still remaining in force, though not attended to) descrtion in time of war is made felony without benefit of clergy, and the offence is triable by a jury, and before the judges of the common law; yet, by our militia laws before mentioned, a much lighter punishment is inflicted for desertion in time of peace. So, by the Roman law also, desertion in time of war was punished with death, but more mildly in time of tranquillity. But our mutiny act makes no such distinction : for any of the faults above mentioned, are equally at all times, punishable with death itself, if a court martial shall think proper. This discretionary power of the

MIL

96

Military. the court martial is indeed to be guided by the direc-- tions of the crown : which, with regard to military offences, has almost an absolute legislative power. " His Majesty (says the act) may form articles of war, and constitute courts martial, with power to try any crime by such articles, and inflict such penalties as the articles direct." A vast and most important trust ! an unlimited power to create crimes, and annex to them any punishments not extending to life or limb! These are indeed forbidden to be inflicted, except for crimes declared to be so punishable by this act; which crimes we have just enumerated, and among which, we may observe, that any disobedience to lawful commands is onc. Perhaps in some future revision of this act, which is in many repects hastily penned, it may be thought worthy the wisdom of parliament to ascertain the limits of military subjection, and to enact express articles of war for the government of the army, as is done for the government of the navy; especially as, by our present constitution, the nobility and gentry of the kingdom, who serve their country as militia officers, are annually subjected to the same arbitrary rule during their

time of exercise. One of the greatest advantages of our law is, that not only the crimes themselves which it punishes, but also the penalties which it inflicts, are ascertained and notorious: nothing is left to arbitrary discretion: the king by his judges dispenses what the law has previously ordained, but is not himself the legislator. How much, therefore, is it to be regretted, that a set of men, whose bravery has so often preserved the liberties of their country, should be reduced to a state of servitude in the midst of a nation of freemen; for Sir Edward Coke will inform us, that it is one of the genuine marks of servitude, to have the law, which is our rule of action, either concealed or precarious; Misera est servitus, ubi jus est vagum aut incognitum. Nor is this state of servitude quite consistent with the maxims of sound policy observed by other free nations. For the greater the general liberty is which any state enjoys, the more cautious has it usually been in introducing slavery in any particular order or profession. These men, as Baron Montesquieu observes, seeing the liberty which others possess, and which they themselves are excluded from, are apt (like eunuchs in the eastern scraglios) to live in a state of perpetual envy and hatred towards the rest of the community, and indulge a maliguant pleasure in contributing to destroy those privileges to which they can never be admitted. Hence have many free states, by departing from this rule, been endangered by the revolt of their slaves; while, in absolute and despotic governments, where no real liberty exists, and consequently no invidious comparisons can be formed, such incidents are extremely rare. Two precautions are therefore advised to he observed in all prudent and free governments: I. To prevent the introduction of slavery at all : or, 2. If it be already introduced, not to intrust those slaves with arms who will then find themselves an overmatch for the freemen. Much less ought the soldiery to be an exception to the people in general, and the only state of servitude in the nation.

But as soldiers, by this annual act, are thus put in a worse condition than any other subjects; so, by the humanity of our standing laws, they are in some cases M Ι L

put in a much better. By statute 43 Fliz. c. 3. a Militar weekly allowance is to be raised in every county for the relief of soldiers that are sick, hurt, and maimed : not forgetting the royal hospital at Chelsea for such as are worn out in their duty. Officers and soldiers, that have been in the king's service, are by several statutes, enacted at the close of several wars, at liberty to use any trade or occupation they are fit for, in any town in the kingdom (except the two universities), notwithstanding any statute, custom, or charter to the contrary. And soldiers in actual military service may make nuncupative wills, and dispose of their goods, wages, and other personal chattels, without these forms, solemnities, and expences, which the law requires in other cases. Our law does not indeed extend this privilege so far as the civil law, which carried it to an extreme that borders upon the ridiculous : for if a soldier, in the article of death, wrote any thing in bloody letters on his shield, or in the dust of the field with his sword, it was a very good military testament.

MILITARY Court. See CHIVALRY, Court of.

MILITARY Tenures. See TENURE, FEODAL System, and KNIGHT.

MILITARY Ways (viæ militares), are the large Roman roads which Agrippa procured to be made through the empire in the time of Augustus, for the more convenient marching of troops and conveyance of carriages. N. Bergier bas written the history of the origin, progress, and amozing extent, of these military roads, which were paved from the gates of Rome to the extreme parts of the empire. See WAY.

MIL!'IIA, in general, denotes the body of soldiers, or these who make profession of arms.

In a more restrained sense, militia denotes the trained bands of a tewn or country, who arm themselves, upon a short warning, for their own defence. So that, in this sense, militia is opposed to regular or stated troops. See MILITARY State, and FEODAL System.

MILIUM, MILLET, a genus of plants, belonging to the triandria class; and in the natural method ranking under the 4th order, Gramina. See BOTANY Index.

MILK, a well known fluid, prepared by nature in the breasts of women, and the udders of other animals, for the nourishment of their young .- According to Dr Cullen*, milk is a connecting and intermediate * Lect. substance between animals and vegetables. It seems Mat. M. immediately to be secreted from the chyle, both being a white liquor of the same consistence: it is most copiously secreted after meals, and of an acescent nature. In most animals who live on vegetables, the milk is acescent; and it is uncertain, though at the same time no observation proves the contrary, whether it is not so likewise in carnivorous animals. But, whatever be in this, it is certain, that the milk of all animals who live on vegetables is acescent. Milk being derived from the chyle, we thence conclude its vegetable nature; for in those who live on both promiscuously, more milk is got, and more quickly, from the vegetable than the animal food. Milk, however, is not purely vegetable; though we have a vegetable liquor that resembles its tastc, consistence, colour, acescency, and the separability of the oily part, viz. an emulsion of the nuces oleosæ and farinaceous substances. But these want the coagulable part of milk, which seems

Blackst. Comment.

Milk.

to be of animal nature, approaching to that of the coagulable lymph of the blood. Milk, then, seems to be of an intermediate nature, between chyle taken up from the intestines and the fully elaborated animal fluid.

Its contents are of three kinds: 1st, An oily part, which, whatever may be said concerning the origin of other oils in the body, is certainly immediately derived from the oil of the vegetables taken in; as with these it agrees very exactly in its nature, and would entirely, if we could separate it fully from the coagulable part. Another mark of their agreement is the separability, which proves that the mixture has been lately attempted, but not fully performed. 2dly, Besides this oily, there is a proper coagulable part : And, 3dly, Much water accompanies both, in which there is dissolved a saline saccharine substance. These three can be got separate in cheese, butter, and whey; but never perfectly so, a part of each being always blended with every other part.

Nothing is more common, from what has been said of its immediate nature, than to suppose that it requires no assimilation; and hence has been deduced the reason of its exhibition in the most weakly state of the human body. But wherever we can examine milk, we always find that it coagulates, suffers a decomposition, and becomes acescent. Again, Infants, who feed entirely on milk, are always troubled with eructations, which every body observes are not of the same quality with the food taken; and therefore it appears, that, like all other food, milk turns naturally accscent in the stomach, and only enters the chyle and blood in consequence of a new recomposition. It approaches then to the nature of vegetable aliment, but is not capable of its noxious vinous fermentation, and therefore has an advantage over it; neither from this quality, like animal food, is it heating in the stomach, and productive of fever; though at the same time, from its quantity of coagulable matter, it is more nourishing than vegetables.

Milk is the food most universally suited to all ages and states of the body; but it seems chiefly designed by nature as the food of infants. When animals are in the foetus state, their solids are a perfect jelly, incapable of an assimilatory power. In such state nature has perfectly assimilated food, as the albumen ovi in the oviparous, and in the viviparous animals certainly somewhat of the same kind, as it was necessary the vessels should be filled with such a fluid as would make way for an after assimilation. When the infant has attained a considerable degree of firmness, as when it is separated from the mother, yet such a degree of weakness still remains as makes somewhat of the same indication necessary; it behoves the infant to have an alkalescent food ready prepared, and at the same time its noxious tendency to be avoided. Milk then is given, which is alkalescent, and, at the same time, has a sufficient quantity of acidity to correct that alkalescency. As the body advances in growth, and the alkalescent tendency is greater, the animal, to obviate that tendency, is led to take vegetable food, as more suited to its strength of assimilation.

Dr Cullen observes, that milk is suited to almost all temperaments; and it is even so to stomache disposed Vol. XIV. Part I.

to acescency, more than those substances which have undergone the vinous fermentation ; nay, it even cures the heartburn, checks vinous fermentation; and precipitates the lees, when, by renewal of fermentation, the winc happens to be fouled. It therefore very properly accompanies a great deal of vegetable aliment : although sometimes its acescency is troublesome, either from a large propertion taken in, or from the dcgree of it; for, according to certain unaccountable circumstances, different acids are formed in the stomach in different states of the body; in a healthy body e.g. a mild one; in the hypochondriac disease sometimes, one of a very acrid quality. When the acidity of milk is carried to a great degree, it may prove remarkably refrigerant, and occasion cold crudities, and the recurrence of intermittent fevers. To take the common notion of its passing unchanged into the

blood, it can suffer no solution. But if we admit its coagulum in the stomach, then it may be reckoned among soluble or insoluble foods, according as that coagulum is more or less tenacious. Formerly rennet, which is employed to coagulate nilk, was thought an acid; but, from late observations, it appears, that, if it be an acid, it is very different from other acids, and that its coagulum is stronger than that produced by acids. It has been imagined, that a rennet is to be found in the stomachs of all animals, which causes coagulation of milk; but according to Dr Cullen the coagulation of milk seems to be owing to a weak acid in the stomach, the relics of our vegetable food, inducing, in healthy persons, a weak and soluble coagulum : but in different stomachs this may he very different, in these becoming heavy and less soluble food, and sometimes even evacuated in a coagulated undissolved state both by stomach and stool.

As milk is ascescent, it may be rendered sometimes purgative by mixing with the bile; and some examples of this have been remarked. More commonly, however, it is reckoned among those foods which occasion costiveness.

Hoffman, in his experiments on milk, found that all kinds of it contained much water; and when this was dissipated, found the residuums very different in their solubility. But we must not thence conclude, that the same insolubility takes place in the stomach; for extracts made from vegetables with water are often very insoluble substances, and hardly diffusible through water itself: therefore, in Hoffman's extracts, if we may so call them, of milk, somewhat of the same kind might have appeared; and these substances, which in their natural state were not so, might appear very insoluble. However, we may allow that milk is always somehow insoluble in the intestines, as it is of a drying nature, and as cheese, &c. is very costive. And this effect shows that milk is always coagulated in the stomach; for if it remained fluid, no fæces would be produced, whereas sometimes very hard ones are observed. In the blood vessels, from its animal nature, it may be considered as nutritious; but when we consider its vegetable contents, and accscency in the primæ viæ, we find that, like animal food, it does not excite that degree of fever in the time of digestion, and that from its accscency it will resist putrefaction. Hence its use in hectic fevers, which, whatever be their cause, N appear

Milk.

MIL

appear only to be exaccibations of natural feverish paroxysms, which occur twice every day, commonly after meals, and at night. To obviate these, therefore, we give such an aliment as produces the least exacerbation of these fevers : and of this nature is milk, on account of its acescent vegetable nature.

There appears also somewhat peculiar to milk, which requires only a small exertion of the animal powers in order to its assimilation; and besides, in hectic complaints there is wanted an oily, bland food, approaching to the animal nature; so that on all these accounts milk is a diet peculiarly adapted to them, and, in general, to most convalescents, and to those of inflammatory temperaments. So far of milk in general. We shall now speak of the particular kinds which are in common use.

The milks of women, mares, and asses, agree very much in their qualities, being very dilute, having little solid contents, and, when evaporated to dryness, having these very soluble, containing much saccharine matter, of a very ready acescency, and, when coagulated, their coagulum being tender and easily broke down. From this view they have less oil, and seem to have less coagulable matter than the rest.

The milks of cows, sheep, and goats, agree in opposite qualities to the three just mentioned; but here there is somewhat more of gradation. Cows milk comes nearest to the former milk : goats milk is less fluid, less sweet, less flatulent, has the largest proportion of insoluble part after coagulation, and indeed the largest proportion of coagulable part; its oily and coagulable parts are not spontaneously separable, never throwing out a cream, or allowing butter to be readily extracted from it. Hence the virtues of these milks are obvious, being more nourishing, though at the same time less easily soluble in weak stomachs, than the three first, less acescent than these, and so more rarely laxative, and peculiarly fitted for the diet of convalescents without fever. The three first again are less nourishing, more soluble, more laxative, as more accscent, and adapted to the convalescents with fever.

These qualities, in particular milks, are considerably diversified by different circumstances. First, Different animals, living on the same diet, give a considerably different milk ; for there seems to be something in the constitution, abstracting from the aliment, which constitutes a considerable diversity of milk, not only in the same species of animals, but also in the some animal, at different ages, and at different distances after delivery : this applies to the choice of nurses. Secondly, Milk follows the nature of the aliment more than any other juice in the human body, being more or less fluid and dilute, more or less solid and nourishing, in proportion as these qualities are more or less in the aliment. The nature of the aliment differs according to its time of growth, e.g. old grass being always found more nourishing than young. Aliment, too, is always varied according to the season, as that is warm or dry, moist or cloudy.

The milk of cach particular kind of animal is fitter for particular purposes, when fed on proper food.— Thus the cow delights in the succulent herbage of the vale : if the sheep be fed there he certainly rots, but on the higher and more dry side of the mountain he

feeds pleasantly and healthy; while the goat never Milik. stops near the bottom, but ascends to the craggy summit : and certainly the milks of these animals are always best on their proper soil, and that of goats is best on a mountainous country. From a dissertation of Linnæus, we have many observations concerning the diversity of plants on which each animal chooses to feed. All the Swedish plants which could be collected together, were presented alternately to domestic animals, and then it appeared that the goat lived on the greatest variety, and even on many which were poisonous to the rest; that the cow chose the first succulent shoots of the plant, and neglected the fructification; which last was preferred by the goat. Hence may be deduced rules concerning the pasturage of different animals; e.g. Farmers find, that, in a pasture which was only fit to feed a certain number of sheep, an equal number of goats may be introduced; while the sheep are no less nourished than before.

It is not easy to assign the difference between milk fresh drawn and that detained in the open air for some time: but certainly there is some material one, otherwise nature universally would not have directed infants to sucking; and indeed it seems better than the other, fitted for digestion and nourishment. Physicians have supposed that this depended on the evaporation of some spt. rector : but our author cannot conceive any such, except common water here; and besides, these volatile parts can hardly be nutritious. A more plausible account scems deducible from mixture : milk new drawn has been but lately mixed, and is exposed to spontaneous separation, a circumstance hurtful to digestion; none of the parts being, by themselves, so easily assimilated as when they are all taken together. Hence, then, milk new drawn is more intimately blended, and therefore then is most proper to the weakly and infants.

Another difference in the use of milk exposed for some time to the air, is taking it boiled or unboiled. Physicians have generally recommended the former; but the reason is not easily assigned. Perhaps it is this : Milk kept for some time exposed to the air has gone so far to a spontancous separation; whereas the heat thoroughly blends the whole, and hence its resolution is not so easy in the stomach; and thus boiled milk is more costive than raw, and gives more fæces. Again, When milk is boiled, a considerable quantity of air is detached, as appears from the froth on the surface; and air is the chief instrument of fermentation in bodies; so that after this process it is not liable to accesency : for these reasons it is proper for the robust and vigorous.

Another difference of milk is, according as it is fluid or coagulated. The coagulated is of two kinds, as induced by rennet, or the natural accscency of the milk. The former preparation makes the firmer and less easily soluble coagulum; though, when taken with the whey unseparated, it is less difficult of solution, though more so than any other coagulum in the same case. Many nations use the latter form, which is easier soluble, but very much acescent, and therefore, in point of solution, should, be confined to the vigorous, in point of acescency, to those who live on alkalescent food; and in the last case, the Laplanders use it as their chief acescent

Milk.

Milk.

acescent condiment. From the same considerations it is more cooling, and in its other effects like all other acescent vegetables.

Milk by evaporation yields a sweet salinc matter, of which Dr Lewis gives the following proportion :

Twelve ounces of	Left of dry matter	From which water extract- ed a sweetsaline substance amounting to
Cows milk Goats milk Human milk Asses milk	13 drachms. 12 1 8 8	$ \begin{array}{c} \mathbf{I} \frac{\mathbf{I}}{2} \\ \mathbf{I} \frac{\mathbf{I}}{2} \\ 0 \\ 6 \\ 6 \end{array} $

The saline substance extracted from asses milk was white, and sweet as sugar; those of the others brown or yellow, and considerably less sweet ; that from cows milk had the least sweetness of any.

On distilling 12 quarts of milk in balneo mariæ, at least nine quarts of pure phlegm were obtained; the liquor which afterwards arose was acidulous, and by degrees grew sensibly more and more acid as the distillation was continued. After this came over a little spirit, and at last, the empyreumatic oil. The remaining solid matter adhered to the bottom of the retort, in the form of elegant shining black flowers, which being calcined and elixated yielded a portion of fixed alkaline salt.

Milk set in a warm place, throws up to the surface an unctuous cream, from which, by agitation, the butter is easily separated. The addition of alkaline salts prevents this separation, not (as some have supposed) by absorbing an acid from the milk, but by virtue of their property of intimately uniting oily bodies with watery liquors. Sugar, another grand intermedium betwixt oils and water, has this effect in a greater degree, though that concrete is by no means alkaline, or an absorbent of acids.

The sweet saccharine part of the milk remains dissolved in the whey after the separation of the curd or cheesy matter, and may be collected from it in a white crystalline form, by boiling the whey till all remains of the curdled substance have fallen to the bottom; then filtering, evaporating it to a due consistence, setting it to shoot, and purifying the crystals by solution in water and a second crystallization. Much has been said of the medicinal virtues of this sugar of milk, but it does not seem to have any considerable ones : It is from cows milk that it has been generally prepared ; and the crystals obtained from this kind of milk have but little sweetness.

When milk is suffered to coagulate spontaneously, the whey proves acid, and on standing grows more and more so till the putrefactive state commences. Sour whey is used as an acid, preferable to the directly vegetable or the mineral acids, in some of the chemical arts; as for dissolving iron in order to the staining of linen and leather. This acid was commonly made use of in the bleaching of lincn, for dissolving and extracting the earthy particles left in the cloth by the alkaline salts and lime employed for cleansing and whitening it. Butter milk is preferred to plain sour milk or sour whey: This last is supposed to give the cloth a yellow colour. Dr Home, in his ingenious treatise on this subject, recommends water acidulated with sulphuric acid (in the proportion of about half an ounce, or at most three quarters of an ounce, to a gallon), as preferable in many respects to the acid of milk, or of the more directly vegetable substances.

He observes, that the latter are often difficultly procurable, abound with oleaginous particles, and hasten to corruption; whilst the vitriolic acid is cheap, and pure, and indisposed to putrefy: That milk takes five days to perform its office, whilst the vitriolic acid docs it in as many hours, perhaps in as many minutes : That this acid contributes also to whiten the cloth, and docs not make it weaker though the cloth be kept in it for months. He finds, that acid, as well as alkalies, extract an oily matter from the cloth, and lose their acidity and alkalicity. Since this treatise appeared, the use of sour milk is very generally superseded by oil of vitriol.

It is observable, that asses milk is greatly disposed, on standing for a little time, to become thick and ropy. In the Breslaw collection for the year 1720, there is a remarkable account of milk (which probably was that of the ass) grown so thick and tenacious as to be drawn out into long strings, which, when dried, were quite brittle.

New cows milk, suffered to stand for some days on the leaves of butterwort or sun-dew, becomes uniformly thick, slippery, and coherent, and of an agreeable sweet taste, without any separation of its parts. Fresh milk, added to this, is thickened in the same manner, and this successively. In some parts of Sweden, as we are informed in the Swedish Memoirs, milk is thus prepared for food.

New milk has a degree of glutinous quality, so as to be used for joining broken stone ware. There is a far greater tenacity in cheese properly prepared.

Milk, when examined by a microscope, appcars composed of numerous globules swimming in a transparent fluid. It boils in nearly the same degree of heat with common water; some sorts rather sooner, and some a little later : after boiling, it is less disposed to grow sour than in its natural state. It is coagulated by acids both mineral and vegetable, and by alkalies both fixed and volatile. The coagulum made by acids falls to the bottom of the serum; that made by alkalies swims on the surface, commonly forming (especially with volatile alkalies) a thick coriaceous skin. The scrum, with alkalies, proves green or sanious; with acids, it differs little in appearance from the whey that separates spontaneously. The coagulum formed by acids is dissolved by alkalies, and that formed by alkalies is redissolved by acids; but the milk does not in either case resume its original properties. It is coagulated by most of the middle salts, whose basis is an earth or a metallic body; as solution of alum, fixed sal ammoniac, sugar of lead, green and blue vitriol; but not by the chalybeate or purging mineral waters, nor by the bitter salt extracted from the purging waters. Among the neutral salts that have been tried, there is not one that produces any coagulation. They all dilute the milk, and make it less disposed to coagulate with acids or alkalies : Nitre seems to have this effect in a greater degree than the other neutral salts. It is instantly coagulated by highly rectified

N2

It has generally been supposed by medical authors, that the milk of animals is of the same nature with chyle, and that the human milk always coagulates in the stomach of infants; but in a late dissertation upon the subject by Mr Clarke, member of the Royal Irish Academy, we find both these positions controverted. According to him, women's milk, in a healthy state, contains no coagulable, mucilaginous, or cheesy principle, in its composition; or it contains so little, that it cannot admit of any sensible proof. Dr Rutty states, that it does not afford even a sixth part of the curd which is yielded by cows milk ; and Dr Young denies that it is at all coagulable either by rennets or acids. This is confirmed by Dr Ferris, who in 1782 gained the Harveian prize medal at Edinhurgh by a dissertation upon milk. Mr Clarke informs us, that he has made a vast number of experiments upon women's milk with a view to determine this point. He made use of ardent spirits, all the different acids, infusions of infants stomachs, and procured the milk of a great many different women; but in no instance, excepting one or two, did he perceive any thing like curd. This took place in consequence of a spontaneous acescency; and only a small quantity of soft flaky matter was formed, which floated in the serum. This he looked upon to be a morbid appearance.

The general opinion that women's milk is coagulable has arisen from a single circumstance, viz. that infants frequently vomit the milk they suck in a state of apparent coagulation. This greatly perplexed Dr Young ; who, after having tried in vain to coagulate human milk artificially, concluded, that the process took place spontancously in the stomach; and that it would always do so if the milk were allowed to rcmain in a degree of heat equal to about 96 degrees of Fahrenheit. Mr Clarke took equal quantities of three different kinds of milk, and put them into bottles slightly corked, and these bottles into water, the temperature of which was kept up by a spirit of wine lamp as near as possible to 96° of Fahrenheit : but after frequently examining each bottle during the course of the experiment, at the expiration of several hours there was not the smallest tendency towards coagnlation to be perceived in any of them; the cream was only thrown to the surface in a thick and adhesive form, and entirely separated from the fluid below, which had something of a gray and wheyish appearance. As the matter vomited by infants is sometimes more adhesive than we can suppose cream to be, Mr Clarke supposed that the curd might be so entangled with the cream, as to be with difficulty separated from it; but having collected a quantity of rich cream from the milk of different women, he repeated the experiment with precisely the same event, not being able in any one instance to produce the smallest quantity of card. To determine, however, what effects might be produced upon milk by the stomach of an infant, Mr Clarkc made the following experiment : Having taken out the stomach of a foetus which had been deprived of life by the use of instruments, he infused it in a small quantity of hot water, so as to make a strong infusion. He added a tea-spoonful of this infusion to

equal quantities of cows and human milk ; the conse-Milk. quence of which was, that the cow's milk was firmly coagulated in a short time, but the human milk was not altered in the least; neither was the least coagulation produced by adding a second and third spoonful to the human milk. "Upon the whole, then, (says Mr Clarke), I am persuaded it will be found, that buman milk, in an healthy state, contains little or no curd, and that the general opinion of its nature and properties is founded upon fallacious analogy and superficial observations made on the matter vomited by infants. We may presume, that the cream of women's milk, by its inferior specific gravity, will swim on the surface of the contents of the stomach; and being of an oily nature, that it will be of more difficult digestion than any other constituent part of milk. When an infant then sucks very plentifully, so as to over-distend the stomach, or labours under any weakness in the powers of digestion, it cannot appear unreasonable to suppose, that the cream shall be first rejected by vomiting. Analogous to this, we know that adults affected with dyspepsia often bring up greasy fluids from the stomach by eructation, and this especially after eating fat meat. We have, in some instances, known this to blaze when thrown into the fire like spirit of wine or oil." Our author derives a confirmation of his opinion from the following observation, viz. that curds vomited by infants of a few days old are yellow, while they become white in a fortnight or three weeks. This he accounts for from the yellow colour of the cream thrown up by the milk of women during the first four or five days after delivery.

Mr Clarke likewise controverts that common opinion of the human milk being so prone to acidity, that a great number of the diseases of children are to be accounted for from that principle. "Whoever (says he) takes the trouble of attentively comparing human milk with that of ruminant animals, will soon find it to be much less prone to run into the acescent or acid process. I have very often exposed equal quantities of human and cows milk in degrees of temperature, varying from the common summer heat, or 65°, to 100°; and I have constantly found that cows milk acquires a greater degree of acidity in 36 hours than the human did in many days: cows milk becomes offensively putrid in four or five days; a change which healthy human milk, exposed in the same manner, will not undergo in many weeks, nay, sometimes in many months. I once kcpt a few ounces of a nurse's milk, delivered about six or seven days, for more than two years in a bottle moderately corked. It stood on the chimneypiece, and was frequently opened to be examined. At the end of this period it showed evident marks of moderate acidity, whether examined by the taste, smell, or paper stained with vegetable blues or purples; the latter it changed to a florid rcd colour, whereas cows milk kept a few days changed the colour of the same paper to a green, thereby clearly showing its putrescent tendency."

Our author next goes on to consider of the probability there is of milk becoming so frequently and strongly acid as to occasion most of the diseases of infants. He begins with an attempt to show that the plienomena commonly looked upon to be indications of acrimony are by no means certain. Curdled milk has

Irish Trans. for 1788.

Milk.

has already been shown to be no sign of acidity; and the other appearance, which has commonly been thought to be so certain, viz. green fæces, is, in the opinion of Mr Clarke, equally fallacious. In support of this he quotes a letter from Dr Sydenham to Dr Cole; in which he says, that the green matter vomited by hysterical women is not any proof of acrid humours being the cause of that disease, for sea-sick people do the same. The opinion of green fæces being an effect of acidity, proceeds upon the supposition that a mixture of bile with an acid produces a green colour: but it is found, that the vegetable acid, which only can exist in the human body, is unable to produce this change of colour, though it can be effected by the strong mineral acids. As nothing equivalent to any of these acids can be supposed to exist in the bowels of infants, we must therefore take some other method of accounting for the green fæces frequently evacuated by them. "Why should sour milk, granting its existence, give rise to them in infants and not in adults? Have butter milk, summer fruits of the most acescent kind, lemon or orange juice, always this effect in adults by their admixture with bile? This is a question which, I believe, cannot be answered in the affirmative."

On the whole, Dr Clarke considers the disease of acidity in the bowels, though so frequently mentioned, to be by no means common. He owns indeed, that it may sometimes occur in infancy as well as in adults, from weakness of the stomach, costiveness, or improper food; and an indubitable evidence is afforded by fæces which stain the blue or purple colour of vegetables to a red, though nothing can be inferred with certainty from the colour or smell.

The doctor next proceeds to state several reasons for his opinion, that the greater number of infantile diseases are not owing to acidity: 1. Women's milk in a healthy state contains little or no coagulable matter or curd. 2. It shows less tendency out of the body to become acescent than many other kinds of milk. 3. The appearances which have been generally supposed to characterize its acidity do not afford satisfactory evidence of such a morbid cause. 4. Granting this to be the case, we have plenty of mild absorbents, capable of destroying all the acid which can be supposed to be generated in the bowels of an infant; yet many children are observed to die in consequence of these diseases supposed to arise from acidity. 5. Though the milk of all ruminant animals is of a much more acescent nature than that of the human species, yet the young of these animals never suffer any thing like the diseases attributed to acidity in infants. 6. History informs us that whole nations use sour curdled milk as a considerable part of their food, without feeling any inconvenience; which, however, must have been the case, if aeidity in the stomach were productive of such deleterious effect as has been supposed.

The reasoning of Dr Clarke seems here to be very plausible, and nothing has as yet been offered to contradict it. The reviewers in taking notice of the treatise only observe, that the doctor's positions arc supported by great probability; yet "they have seen them, or think they have seen them, contradicted by the appearance of diseases and the effects of medicines ;" so that they must leave the subject to farther Milk. examination.

In a memoir by Messrs Parmentier and Deyeux, members of the royal college of pharmacy, &c. in Paris, we have a great number of experiments on the milk of asses, cows, goats, sheep, and mares, as well as women. The experiments on cows milk, were made with a view to determine whether any change was made in the milk by the different kinds of food eaten by the animal. For this purpose some were fed with the leaves of maize or Turkey wheat; some with cabbage; others with small potatoes; and others with common grass. The milk of those fed with the maize or Turkey wheat was extremely sweet; that from the potatocs and common grass much more serous and insipid; and that from the cabbages the most disagrecable of all. By distillation only eight ounces of a colourless fluid were obtained from as many pounds of cach of these milks; which from those who fed upon grass had an aromatic flavour; a disagreeable one from cabhage; and none at all from the potatoes and Turkey wheat. This liquid became fetid in the snace of a month, whatever substance the animal had been fed with, acquiring at the same time a viscidity and becoming turbid; that from cabbage generally, but not always, becoming first putrid. All of them separated a filamentous matter, and became clear on being exposed to the heat of 25° of Reaumur's thermometer. In the residuums of the distillation no difference whatever could be perceived. As the only difference therefore existing in cows milk lies in the volatile part, our anthors conclude, that it is improper to boil milk either for common or medicinal purposes. They observed also that any sudden change of food, even from a worse to a better kind was attended by a very remarkable diminution in the quantity of milk. All the residuums of the distillations yielded, in a strong fire, a yellow oil and acid, a thick and black empyreumatic oil, a volatile alkali, and towards the end a quantity of inflammable air, and at last a coal remained containing some fixed alkali with muriatic acid.

On agitating in long bottles the creams from the milk of cows fed with different substances, all of them were formed into a kind of half-made butter; of which that formed from the milk from maize was white, firm, and insipid; that from potatoes was softer and more pinguedinous; but that from common grass was the best of all. Cabbage, as in other cases, gave a strong taste.

In the course of their experiments, it was endeavoured to determine whether butter is actually contained in the cream, or whether it be a chemical production of the operation of churning. They could not find any reason absolutely satisfactory on either side, but incline to the latter opinion; because when cream is allowed to remain among the milk, and the whole curdled promiscuously, only fat cheese, without any butter, is produced. The oily parts cannot be separated into butter either by acids or any other means than churning: even the artificial mixture of oil with the cream is insufficient for the purpose.

The serum of milk was reduced by filtration to a clear and pellucid liquor; and, by mixture with fixed alkali, deposited a portion of cheesy matter which had been

been dissolved in the whey. The sngar of milk was also found in this liquor.

MIL

102

In their experiments upon the milk of various animals, it was found that the milk of asses yielded by distillation an insipid liquor, and deposited a liquor similar to the lymph of cows milk. It is coagulated by all the acids, but not into an uniform mass; exhibiting only the appearance of distinct flocculi. It affords but little cream, which is converted with difficulty into a soft butter that soon becomes rancid. It has but a small quantity of saccharine particles, and these arc often mixed with muriatic sclenite and common salt. Goats milk has a thick cream, and agreeable to the taste; and the milk itself may be preserved longer in a sound state than any other species, the scum on its surface being naturally convertible into palatable cheese. It is easily made into firm butter, which does not soon become rancid, and has a good flavour. The butter milk contains a large quantity of cheesy matter, which readily coagulates; but has still less saccharine matter than that of asses. Sheeps milk ean scarce be distinguished from that of a cow, and easily parts with its cream by standing. It is of a yellow colour, an agreeable flavour, and yields a great proportion of butter; but this is not solid, and soon becomes rancid. Marcs milk is the most insipid and least nutritious of any; notwithstanding which it has been much recommended for weak and consumptive patients : in which cases it is probable that it proves efficacious by being more consonant than any other to the debilitated powers of digestion. It boils with a smaller fire than any other kind of milk, is casily coagulated, and the distilled water does not soon change its nature. It has but a small quantity of cheesy matter, and very few oily particles: the cream cannot be made into butter; and the whey contains about as much sugar as cows or goats milk.

In this memoir our authors remark, that in order to augment the quantity, as well as to improve the quality, of the milk of animals, they should be well fed, their stalls kept clean, and their litter frequently renewed: they should be milked at stated hours, but not drained: great attention should also be paid to the breed; because inferior eattle are maintained at as great expence as the most valuable kinds. No change ought to be made in the food; though if the milk be employed for medicinal purposes, it may be improved by a proper mixture of herbs, &c.

In their experiments on women's milk, Messrs Parmentier and Deycux differ somewhat from Dr Clarkc. They first tried the milk of a woman who had been delivered four months: and observed, that after the cream had been separated the other part appeared of a more perfect white, and that it could not be coagulated either by vinegar or mineral acids; which they attributed to a superabundance of scrum. But they found that in proportion to the age of the milk it was found to be more easily coagulable; and this was confirmed by experiments made upon the milk of 20 nurses. Its eoagulability was not increased by heat. The cream, by agitation, formed a viscid unctuous matter, but could not be changed into perfect butter; but they found that it was extremely difficult to determine the proportions of the various component parts in human milk, as it differs remarkably,

not only in different subjects, but in the same subject at different times. In a nurse aged about 32 years, who was extremely subject to nervous affections, the milk was one day found almost quite colourless and transparent. In two hours after, a second quantity drawn from the breast was viscid like the white of an egg. It became whiter in a short time, but did not recover its natural colour before the evening. It was afterwards found that these changes were occasioned by her having some violent hysteric fits in the mean time.

Sugar of MILK. Different methods have been proposed for obtaining the sugar of milk. The following is an account of a method used by some of the Tartar nations of preserving their milk by means of frost: in which operation great quantities of the sugar of milk are accidentally formed. The account was given by Mr Fahrig of Petersburgh, who undertook a journey, by order of the academy of Petersburgh, among the Mogul tribes who inhabit the country beyond the lake Baikal, on the banks of the river Salenga. These people allow their milk to freeze in large quantity in iron kettles; and, when it is perfectly congealed, they place them over a gentle fire to soften the edges of the cake, after which it may be taken out with a wooden spatula. They commence these operations at the beginning of the cold, when they have milk in the greatest abundance ; after which it may be prcserved with great ease throughout the whole winter. Mr Fabrig having frequent opportunities of seeing these cakes, soon observed, that the surface of them was covered to a considerable depth with a farinaceous powder; and having established a dairy upon the same plan with those of the Moguls, he found the same thing take place with himself. This powder was extremely sweet, and he received platefuls of it from the natives, who used it in their food, and sweetened their other victuals with it. Having caused a number of cakes of frozen milk to be conveyed to the top of his house, where they were directly exposed to the violent cold, he found that the separation of the saccharine powder was greatly promoted by this means. He scraped the cakes every week to the depth of two inches, and afterwards spread out the powder upon an earthen plate in order to destroy the remains of moisture which might have prevented it from keeping for any length of time. When exposed in this manner it had a very agreeable and strong saccharine taste; dissolved in warm water; and when strongly stirred by means of a chocolate stick, would at all times produce an excellent and well tasted milk. Raw milk affords a much larger quantity of this saccharine matter than such as has been boiled, or which has had the cream taken off Neither must the milk be suddenly exposed to the it. cold before it has lost its natural heat; for the sudden contact of the cold drives all the cheesy and fat part towards the middle, while the external parts consist of little else than water. In order to allow the parts of the milk to be all properly mixed together, Mr Fahrig allowed the milk when newly taken from the cows to cool, and then poured it out into shallow kettles.

Our author is of opinion that this method of making milk would be of great service to navigators to supply themselves with milk during long sea voyages: and he

4

Hilk.

he assures us, from his own experience, that it will always succeed, if proper attention be paid to it. He is of opinion, however, that all countries are not equally proper for the preparation of this saccharine matter: and indeed this seems very evidently to be the case, as the process appears to be a crystallization of the saccharine parts of the milk, and a separation of them from the aqueous ones by means of extreme cold. The country in which he made the experiments is one of the most elevated in all Asia; and so cold, that, though it lies only in the 50th degree of north latitude, its rivers are frozen up for six months of the year. A very dry cold wind also prevails throughout almost the whole year; and the dry winds generally come from the north, being almost always preceded by a warm wind from the south, which blows for some time. The dry rarefied air increases the evaporation from the ice cakes, and leaves nothing but the saccharine or purc constituent parts of the milk, which with the addition of water can always recompose the fluid.

MILK, in the wine trade. The coopers know very well the use of skimmed milk, which makes an innocent and efficacious forcing for the fining down of all white wines, arracks, and small spirits; but it is by no means to be used for red wines, because it discharges their colour. Thus, if a few quarts of well skimmed milk be put into a hogshead of rcd wine, it will soon precipitate the greater part of the colour, and leave the whole nearly white: and this is of known use in the turning of rcd wines, when pricked, into white; in which a small degree of acidity is not so much perceived.

Milk is, from this quality of discharging colour from wines, of use also to the wine coopers, for the whitening of wines that have acquired a brown colour from the cask, or from having been hastily boiled before fermenting; for the addition of a little skimmed milk, in these cases, precipitates the brown colour, and leaves the wines almost limpid, or of what they call a *water whiteness*, which is much coveted abroad in wines as well as in brandics.

MILK of Lime; Milk of Sulphur. The name of milk is given to substances very different from milk properly so called, and which resemble milk only in colour. Such is water in which quicklime has been slaked, which acquires a whiteness from the small particles of the lime being suspended in it, and has hence been called the milk of *lime*. Such also is the solution of liver of sulphur, when an acid is mixed with it, by which white particles of sulphur are made to float in the liquor.

 M_{ILK} of Vegetables. For the same reason that milk of animals may be considered as a true animal emulsion, the emulsive liquors of vegetables may be called vegetable milks. Accordingly emulsions made with almonds are commonly called milk of almonds. But besides this vegetable milk, which is in some measure artificial, many plants and trees contain naturally a large quantity of emulsive or milky juices. Such are lettuce, spurge, fig tree, and the tree which furnishes the elastic American resin. The milky juices obtained from all these vegetables derive their whiteness from an oily matter, mixed and undissolved in a watery or mucilaginous liquor. Most resinous gums were originally such milky juices, which afterwards become solid by the evaporation of their more fluid and volatile parts.

MILK-Fever. See MEDICINE Index.

MILKY-Hedge, the English name of a shrub growing on the coast of Coromandel, where it is used for hcdging. The whole shrub grows very bushy, with numerous erect branches, which arc composed of cylindrical joints as thick as a tobacco pipe, of a green colour, and from three to six inches long : the joints are thicker than the other parts, but always give way first on any accidental violence offered to the plant. When broken it yields a milk of an excessively caustic quality, which blisters any part of the skin it touches. When the joints are broken off at each end, the tube then contains but very little milk. In this state Mr Ives ventured to touch it with his tongue, and found it a little swect. In the hedges it is seldom very woody; but when it is, the wood is very solid, and the hark gray and cracked. This plant, he informs us, has acquired great reputation in curing the venereal disease, on the following account: A poor Portuguese woman, the eldest female of her family, had wrought surprising cures in the most inveterate venereal disorders, even such as the European physicians had pronounced incurable. These facts bccame so notorious, that the servants of the Company, and especially their surgeons, were induced to offer her a very considerable premium for a discovery of the medicine; but she always refused to comply, giving for a reason, that while it remained a scoret, it was a certain provision for the maintenance of the family in the present as well as in future generations. On account of this denial the English surgeons were sometimes at the pains to have her motions without doors carefully watched; and as they were not able to discover that she ever gathered of any other plant or tree but this, they conjectured that the milk of this tree was the specific employed. Mr Ives inquired at the black doctors concerning the virtues of this plant; who all agreed, that it will cure the lues venerca, but differed as to the manner of administering it; some saying that a joint of it should be eaten every morning; others that the milk only should be dropped upon sugar; and then pnt into milk, oil, &c. and given daily to the patient.

MILKY-Way. See ASTRONOMY Index.

MILL, a machine for grinding corn, &c. of which there are various kinds, according to the different mcthods of applying the moving power; as water-mills, wind-mills, mills worked by horses, &c. Sce MECHA-NICS Inder.

The first obvious method of reducing corn into flour for bread would be by the simple expedient of pounding. And that was for ages the only one which was practised by the various descendants of Adam, and actually continued in use among the Romans below the reign of Vespasian. But the process was very early improved by the application of a grinding power, and the introduction of millstones. This, like most of the common refinements in domestic life, was probably the invention of the antediluvian world, and certainly practised in some of the earliest ages after it; and, like most of them, it was equally known in the east and west. Hence the Gauls and Britons appear familiarly acquainted with the use of hand-mills before the time of their submission to the Romans; the Britons particularly

MI L

larly distingnishing them, as the Highlanders and we

distinguish them at present, by the simple appellations of

querns, carnes, or stones. And to these the Romans added the very useful invention of water mills. For

this discovery the world is pretty certainly indebted to

the genius of Italy; and the machine was not uncom-

mon in the country at the conquest of Lancashire.

This, therefore, the Romans would necessarily intro-

duce with their many other refinements among us.

And that they actually did, the British appellation of a

water-mill fully suggests of itself; the melin of the

Welsh and Cornish, the mull, meill, and melin of the

Armoricans, and the Irish muilcan and muilind, being

all evidently derived from the Roman mola and molen-

dinum. The subject Britons universally adopted the

Roman name, but applied it, as we their successors do,

only to the Roman mill ; and one of these was proba-

bly erected at every stationary city in the kingdom.

purposes of the town and the accommodation of the

garrison .- And one alone would be sufficient, as the

use of handmills remained very common in both, many

having been found about the site of the station particu-

larly; and the general practice having descended a-

mong us nearly to the present period. Such it would

be peculiarly necessary to have in the camp, that the

garrison might be provided against a siege. And the

water-mill at Manchester was fixed immediately below

the Castlefield and the town, and on the channel of the

Medlock. There, a little above the ancient ford, the

eluice of it was accidentally discovered about 30 years

ago. On the margin of Dyer's croft, and opposite to

some new constructions, the current of the river, acci-

dentally swelled with the rains, and obstructed by a

dam, broke down the northern bank, swept away a

large oak upon the edge of it, and disclosed a long tun-

nel in the rock below. This has been since laid open

in part with a spade. It appeared entirely uncovered

at the top, was about a yard in width, and another in

depth, but gradually narrowed to the bottom. The

sides showed everywhere the marks of the tool on the

rock, and the course of it was parallel with the channel.

It was bared by the flood about 25 yards only in length,

but was evidently continued for several further; hav-

ing originally begun, as the nature of the ground evin-

ces, just above the large curve in the channel of the

there were no public bread bakers in the city of Rome.

They were first introduced into it from the east, at the

conclusion of the war with Perseus, and about the year 167 before Christ. And, towards the close of the

first century, the Roman families were supplied by

them every morning with fresh loaves for breakfast .---

But the same custom, which prevailed originally among

the Romans and many other nations, has continued nearly to the present time among the Mancunians. The

providing of bread for every family was left entirely

to the attention of the women in it; and it was

baked upon stones, which the Welsh denominate grei-

diols and we gredles. It appears, however, from the

kiln-burnt pottery which has been discovered in the British sepulchres, and from the British appellation of

an odyn or oven remaining among us at present, that

furnaces for baking were generally known among the

For the first five or six centuries of the Roman state,

Medlock.

M I L

original Britons. An odyn would, therefore, be erect-Mill. ed at the mansion of each British baron, for the use Millston of himself and his rctainers. And, when he and they removed into the vicinity of a Roman station, the oven would be rebuilt with the mansion, and the public bakehouses of our towns commence at the first foundation of them. One bakehouse would be constructed, as we have previously shown one mill to have been set up, for the public service of all the Mancunian families. One oven and one mill appear to have been equally established in the town. And the inhabitants of it appear immemorially accustomed to bake at the one and grind at the other. Both, therefore, were in all probability constructed at the first introduction of watermills and ovens into the country. The great similarity of the appointments refers the consideration directly to one and the same origin for them. And the general nature of all such institutions points immediately to the first and actual introduction of both. And, as the same establishments prevailed equally in other parts of the north, and pretty certainly obtained over all the extent of Roman Britain, the same erections were as certainly made at every stationary town in the kingdom.

MILL, John, a very learned divine, was born at Shap in Westmoreland, about the year 1645; and became a servitor of Queen's college, Oxford. On his entering into orders he became an eminent preacher, and was made prebendary of Exetcr. In 1681, he was created doctor of divinity; about the same time he was made chaplain in ordinary to King Charles II. and in 1685 he was elected principal of St Edmund's hall in Oxford. His edition of the Greek Testament, which will ever render his name memorable, was published about a fortnight before his death, which happened in June 1707. Dr Mills was employed 30 years in preparing this edition.

MILLSTONE, the stone by which corn is ground. -The millstones which we find preserved from ancient times are all small, and very different from those in use at present. Thoreshy mentions two or three such found in England, among other Roman antiquities, which were but 20 inches broad; and there is great reason to believe that the Romans, as well as the Egyptians of old, and the ancient Jews, did not employ horses, or wind, or water, as we do, to turn their mills, but made their slaves and captives of war do this laborious work : they were in this service placed behind these millstones, and pushed them on with all their force. Sampson, when a prisoner to the Philistines, was treated no better, but was con-demned to the millstone in his prison. The runner or loose millstone, in this sort of grinding, was usually very heavy for its size, being as thick as broad. This is the millstone which is expressly prohibited in Scripture to take in plcdge, as lying loose it was more easily removed. The Talmudists have a story, that the Chaldeans made the young men of the captivity carry millstones with them to Babylon, where there seems to have been a scarcity at that time; and hence, probably, their paraphrase renders the text " have borne the mills or millstones;" which might thus be true in a literal sense. They have also a proverbial expression of a man with a millstone about his neck; which they use to express a man under the severest weight

Whitaker's One plainly was at Manchester, serving equally the Hist of Manchester.

Will.

Millennium.

fillstone weight of affliction. This also plainly refers to this small sort of stones.

Rhenish MILLSTONE, a stone which has been classed among volcanic products, on account of its appearance, which is a blackish gray, porous, and very much resembling a lava of Mount Vesuvius.

MILLEDGEVILLE, a town in the state of Georgia in North America, situated on the river Occonee, about 150 miles from the sea. Its population in 1810 was 1257. W. Long. 83. 10. N. Lat. 32. 40.

MILLENARIANS, or CHILIASTS, a name given to those in the primitive ages, who believed that the saints will reign on earth with Christ 1000 years. See MILLENIUM.

MILLENER, or MILLINER, one who sells ribbands and dresses, particularly head dresses for women; and who makes up those dresses. Of this word different etymologies have been given. It is not derived from the French. The French cannot express the notion of milliner, otherwise than by the circumlocution marchand or marchande des modes. Neither is it derived from the Low Dutch language, the great, but neglected, magazine, of the Auglo-Saxon. For Sewel, in his Dictionary English and Dutch, 1708, describes millener to be "a pedlar who sells ribbands and other trimmings or ornaments; a French pedlar."

Littleton, in his English and Latin Dictionary, published 1677, defines millener, " a jack of all trades ;" q. d. millenarius, or mille mercium venditor; that is, " one who sells a thousand different sorts of things." From this ctymology, which seems fanciful, we must hold, that it then implied what is now termed " a haberdasher of small wares."

Before Littleton's time, however, a somewhat nicer characteristic than seems compatible with his notion, appears to have belonged to them; for Shakespearc, in his Henry IV. makes Hotspur, when complaining of the daintiness of a courtier, say,

"He was perfumed like a milliner.

The fact seems to be, that there were milleners of several kinds : as, horse milleners, (for so those persons were called who make ornaments of coloured worsted for horses); haberdashers of small wares, the milleners of Littleton; and milleners such as those now peculiarly known by that name, whether male or female, and to whom Shakespeare's allusion seems most appropriate.

Lastly, Dr Johnson, in his dictionary, derives the word from milaner, an inhabitant of Milan, from whence people of this profession first came, as a Lombard is a banker.

MILLE PASSUS, or Millia Passuum; a very common expression among the ancient Romans for a measure of distance, commonly called a mile. Milliarium, rarely used. Which Hesychius made to consist of seven stadia; Plutarch, little short of eight; but many others, as Strabo and Polybius, make it just eight stadia. The reason of this difference seems to be, that the former had a regard to the Grecian foot, which is greater than the Roman or Italic. This distance is oftentimes called lapis, which see. Each passus consisted of five feet (Columella).

MILLENNIUM, " a thousand years ;" generally VOL. XIV. Part I.

employed to denote the thousand years, during which, Millen. according to an ancient tradition in the church, grounded on some doubtful texts in the Apocalypse and other Scriptures, our blessed Saviour shall reign with the faithful upon earth after the first resurrection, before the final completion of beatitude.

Though there has been no age of the church in which the millennium was not admitted by individual divines of the first eminence, it is yet evident from the writings of Eusebius, Irenæus, Origen, and others among the ancients, as well as from the histories of Dupin, Mosheim, and all the moderns, that it was never adopted by the whole church, or made an article of the established creed in any nation.

About the middle of the fourth century the Millennians held the following tenets :

1st, That the city of Jerusalem should be rebuilt, and that the land of Judea should be the habitation of those who were to reign on earth 1000 years.

2dly, That the first resurrection was not to be confined to the martyrs; but that after the fall of Antichrist all the just were to rise, and all that were on the earth were to continue for that space of time.

3dly, That Christ shall then come down from heaven, and be seen on earth, and reign there with his servants.

4thly, That the saints during this period shall enjoy all the delights of a terrestrial paradise.

These opinions were founded upon several passages of Scripture, which the Millenarians among the fathers understood in no other than a literal sense, but which the moderns, who hold that opinion, consider as partly literal and partly metaphorical. Of these passages, that upon which the greatest stress has been laid, we believe to be the following :-- " And I saw an angel come down from heaven, having the key of the bottomless pit, and a great chain in his hand. And he laid hold on the dragon, that old serpent, which is the devil and Satan, and bound him a thousand years, and cast him into the bottomless pit, and shut him up, and set a seal upon him, that he should deceive the nations no more till the thousand years should be fulfilled; and after that he must be loosed a little season. And I saw thrones, and they sat upon them, and judgment was given unto them: and I saw the souls of them that were beheaded for the witness of Jesus, and for the word of God, and which had not worshipped the beast, neither his image, neither had received his mark upon their foreheads, or in their hands; and they lived and reigned with Christ a thousand years. But the rest of the dead lived not again till the thousand years were finished. This is the first resurrection *." This passage all the ancient * Rom. xx. Millenarians took in a sense grossly literal; and taught, 1-5. that during the millennium the saints on earth were to cnjoy every bodily delight. The moderns, on the other hand, consider the power and pleasure of this kingdom as wholly spiritual; and they represent them as not to commence till after the conflagration of the present earth. But that this last supposition is a mistake, the very next verse except one assures us : for we are there told, that " when the thousand years are expired, Satan shall be loosed out of his prison, and shall go out to deceive the nations which are in the four quarters of the earth;" and we have no reason to 0 believe

nium.

nium

nium.

Milles. believe that he will have such power or such liberty in " the new heavens and the new earth wherein dwelleth rightcousness."

For this and other reasons, which onr limits will not permit us to enumerate, the most judicious critics contend, that the proplicsics of the millennium point, not to a resurrection of martyrs and other just men to reign with Christ a thonsand years in a visible kingdom upon earth, but to that state of the Christian church, which, for a thousand years before the general judgment, will be so pure and so widely extended, that, when compared with the state of the world in the ages preceding, it may, in the language of Scripture, be called a resurrection from the dead. In support of this interpretation they quote two passages from St Paul, in which a conversion from Paganism to Christianity, and a reformation of life, is called a resurrection from the dead :---" Neither yield ye your members as instruments of unrighteousness into sin; but yield yourselves unto God *Rom. vi. as those that are alive from the dead *:" And again, 13. "Wherefore he saith, Awake thou that sleepest, and Eph. v. arise from the dead, and Christ shall give thee light +." It is likewise to be observed, that in all the descriptions of the resurrection and future judgment which are given us at such length in the gospels and epistles, there is no mention made of a first and second resurrection at the distance of a thousand years from cach other. There is indeed an order in the resurrection: for we are told ‡, that " every man shall rise in his own order ; Christ the first fruits, afterwards they that are Christ's at his coming," &c. But were the millennarian hypothesis well founded, the words should rather have run thus : " Christ the first fruits, then the martyrs at his coming, and a thousand years afterwards the residue of mankind. Then cometh the end," &c.

These arguments strongly incline us to believe, that by the reign of Christ and the saints for a thousand years upon earth, nothing more is meant, than that before the general judgment the Jews should be converted, genuine Christianity be diffused through all nations, and mankind enjoy that peace and happiness which the faith and precepts of the gospel are calculated to confer on all by whom they are sincerely embraced.

Our Saviour's own account of his religion is, that from a small beginning it will increase to the full harvest. The millennium therefore is to be considered as the full effect of the Christian principles in the hearts of men, and over the whole world; and the divines who have treated of this subject endeavour to prove, that this is to be expected from the facts which have already existed, and from the importance of the Christian doctrine.

1. The gradual progress of Christianity is no objection to this fact. This is similar to the progress and advancement from less to greater perfection in every thing which possesses vegetable or animal life. The same thing is observed in the arts, in civilization, in societies, and in individuals-and why should it not be admitted to have place in religion? There is, indeed, a general principle on which a gradual progression, both in the natural and moral world, is founded. The Almighty never employs supernatural means where the thing can be accomplished by those which are natural. This idea is of the most general extent through the

whole of the present system of nature. The possibility Miller of another plan could casily be admitted ; but in this case there would be a total alteration of every part of the works of God or of man that we are acquainted with. In the same manner, if the religion of Christ had been irresistible, it would have totally altered its natural consequences. It was necessary, therefore, from the present condition of man, as an active, intelligent, and accountable being, that means should be employed; and wherever means are employed, the effects produced must be gradual, and not instantaneous.

2. Though the progress of a divine revelation be gradual, yet it is to be expected, from the wisdom and compassion of God, that it will still be advancing in the hearts of men, and over the world. In the first stage of the church, the word of God, supported by miracles, and by the animated zeal of men who spake what they saw and heard, grew and prevailed. In this case supernatural means were necessary, because the prejudices of the world could not be subdued without them. It was the first watering of a plant which you afterwards leave to the dew of heaven. Miracles at the same time were employed only as the means of conviction; and they were not continued, because in this case they would have become a constant and irresistible principle, incompatible with the condition of man as a reasonable agent. After this power was withdrawn, there were many ages of ignorance and superstition in the Christian church. But what is necessary to be established on this subject is, not that the progress of Christianity has never been interrupted, but that on the whole it has been advancing. The effects of this religion on mankind, in proportion as it was received, were immediate and visible: It destroyed the gross superstition of idol worship; it abolished the practice, which was general in the heathen world, of reducing to the lowest state of servitude the greatest part of our brethren; it softened the horrors of war, even when the vices of mankind made defence necessary; it entered into social and private life, and taught men benevolence, humanity, and mercy. It is in these blessed effects that we can observe the progress of Christianity even to this day. Superstition and idolatry were soon engrafted on the stem which our Saviour planted in the world; but the simplicity of the gospel has been gradually undermining the fabric of superstition ; and the men who are most nearly interested in the deceit are now almost ashamed to show their faces in the cause. The practice of slavery has, generally speaking, been extinguished in the Christian world ; yet the remains of it have been a disgrace to the Christian name, and the professors of that religion have now begun to see the inconsistency. War is not only carried on with less animosity, and less havock of the human species; but men begin to cultivate more generally, and to delight in, the arts of peace. The increasing spirit of charity and benevolence, of which it were easy to give unexampled instances in the present age, is a decided proof of the incrcasing influence of Christianity. At the same time, if, instead of these general principles, we were to descend to private examples of infidelity or of wickedness, it would be easy to bring proofs in support of an opposite opinion: but the reasoning would by no means be equally conclusive; for if the general principles by which society is regulated be more liberal and merciful,

14.

MI L

nor destruction within thy border ; hut thou shalt call Millenthy walls salvation, and thy gates praise." (Is. 1x. 18.).

Without entering more minutely on the prophecy Millepora. already quoted from chap. xx. of the book of the Revelation, it is sufficient to observe, that Dr Whitby, in his treatise on the millennium at the end of his commentary, proves, in the clearest manner, from the spirit of the passage and the similarity of the expressions with those of other prophets, that it refers to a state of the church for a thousand years, which shall he like life from the dead. The commencement of this period is connected with two events : the fall of antichrist, and the conversion of the Jews. The latter of these events must be considered as a key to all the prophecies concerning the millennium. As the Jews were the ancient people of God, and as their conversion is to be the previous step to the general knowledge of Christianity, the prophecies of the millennium have a chief relation to this important event. We have already observed, that God never interposes with miraculous power to produce what ean be effected by natural means; and from what we know of human nature, we cannot but perceive that the conversion of the Jews will powerfully operate to the general conversion of mankind. Freed from those prejudices which now make them the objects of hatred in all nations, and fired with that zeal by which new converts are always actuated, they will preach the gospel with a fervour of which we, who have long been blessed with its rays, can hardly form a conception; and, by their present dispersion over the whole earth, they will be enabled to adapt their instructions to every individual of the human race in the language of his fathers. Indeed, if they are not at some future period to be employed by Providence for this purpose, it is difficult, if not impossible, to give any reason for their dispersed state and political existence. Just now it must be confessed that they are the most implacable enemies of the Christian name; but their conversion is not on that account more unlikely or improhable than were events which have taken place of nearly equal importance a very few years ago. On the whole, the perfection of Christianity is a doctrine of reasonable expectation to the ehurch; and it is impossible for the advocates for natural religion to deny, that unlimited obedience to its precepts is consistent with the purest state of liberty and of happiness. This is the only millennium which the prophets and apostles, as we understand them, promise to the saints; but as men figuring in the very first ranks of learning have thought otherwise, we would not be too confident that our interpretation is just .- Such of our readers as wish for further information, will find it in the works of Mr Mede, Bishop Newton, Dr Whitby and Dr Gill; and to those masterly writers we refer them for that satisfaction which in such an article as this cannot be given.

MILLEPES, or WOOD-LOUSE ; a species of ONIS-CUS. See ENTOMOLOGY Index.

MILLEPORA, in Natural History, a name by which Linnæus distinguishes that genus of lithophytes, of a hard structure and full of holes, which are not stellated or radiated, and whose animal is the hydra, in which it differs from the madrepora, and comprehending 14 different species.

In the millepora, the animal which forms and inhabits it occupies the substance; and it is observed that nium

it is evident that there is more goodness in a greater number of the human race. Society is nothing more than a collection of individuals; and the general tone, especially when it is on the side of virtue, which almost in every instance opposes the designs of leading and interested men, is a certain evidence of the private spirit. To show that this reformation is connected with Christianity, it is unnecessary to state any eomparison between the influence of heathen, and the influence of Christian principles : between civilization as depending on the powers of the human understanding, and on the efficacy of the word of God. The whole of this controversy may be appealed to an obvious faet, viz. that as any nation has come nearer to the simplicity of the gospel in the standard of its worship, it has been more possessed of those national virtues which we have ascribed to the influence of Christianity. This fact is worth a thousand volumes of speculation on this subject. 3. A revelation sanctioned by God, for a benevolent

purpose, will be expected to produce effects corresponding to the wisdom which gave it, and to the purpose for which it is employed. It may be gradual; but it will be increasing, and it must increase, to the full harvest. He that has begun the good work will also finish it. It is reasonable to expect this illustrious success of the gospel, both from the nature of the thing, and from the prophecies contained in the sacred seriptures. The precepts of the gospel, in their genuine sense, are admirably calculated for the peace and welfare both of individuals and society. The greatest liberality of mind, the greatest generosity of temper, the most unbounded love, and the greatest indifference to the accumulation of this world's property, if they glowed from breast to breast, and operated with equal force on all men, would be productive of equal good and happiness to all. We are searcely able to perceive the force of this at first view, because the deceit and imposition which yet exist in the world, prevent the operation of the best principles even in the best hearts. But in proportion to the improvement of mankind, what is their real interest, and what are the real objects of happiness, will gradually unfold. The contempt of viee will be greater in proportion to the scarcity of it : for one villain gives countenance and support to another, just as iron sharpeneth iron. This opens to our view another fact connected with the practice of Christianity, namely, that the nearer it arrives to its perfect state, it will be the more rapid in its progress. The beauty of holiness will he more visible; and, in the strong language of the prophet, " the earth shall bring forth in one day, "Ixvi. 8. and a nation shall be born at once "." This future perfection of the gospel is consistent with its nature and importance .- We can searcely believe that means so admirably adapted to the reformation of mankind should be without their effect; and if the most difficult part be already accomplished, we have no reason to apprehend that the scheme will not be completed. This fact is also clearly the subject of ancient prophecy. For t er. 12. "thus saith the Lord +, I will extend peace to her like a river, and the glory of the Gentiles like a flowing stream. And it shall come to pass, from one sabbath to another, and from one new moon to another, shall all flesh come to worship before me, saith the Lord."-" Violence shall be no more heard in thy land, wasting

02

the

Millot.

Millepora the milleporæ grow upon one another; their little animals produce their spawn; which attaching itself either to the extremity of the body already formed, or underneath it, gives a different form to this production. Hence the various shapes of the millepora, which is composed of an infinite number of the cells of those little insects, which all together exhibit different figures, though every particular cellula has its essential form, and the same dimensions, according to its own species.

MILLET. See MILIUM, BOTANY Index.

MILLIARE, or MILLIARIUM, a Roman mile, which consisted of 1000 paces, mille passus, whence the name.

MILLIARIUM AUREUM, was a gilded pillar in the forum of Rome, at which all the highways of Italy met, as one common centre. From this pillar the miles were counted, and at the end of every mile a stone was put down. The milliary column was erected by Augustus Cæsar, and, as we are informed by travellers, is still to be seen.

MILLING of CLOTH. See FULLING.

MILLION, in Arithmetie, the sum of ten hundred thousand, or a thousand times a thousand. See ARITH-METIC.

MILLO, a part of Mount Zion at its extremity ; and therefore called Millo of the city of David (2 Chron. xxxii.), taken in with the wall that encompassed Mount Zion. Uncertain whether Beth Millo, (Judges ix. 20.) denotes a place; if it did, it lay near Sechem.

MILLOT, CLAUDE FRANCIS XAVIER, of the French academy, was born at Besançon, March 1726, and was for some time a Jesuit. He was consecrated for the pulpit, and continued to preach after he left the society : But the weakness of his voice, his timidity, and the awkwardness of his manner, not permitting him to continue in this profession, he relinquished it, although he had preached Advent sermons at Versailles, and Lent sermons at Luneville. The marquis de Felino, minister of Parma, instituted an historical class for the benefit of the young nobility; and, at the desire of M. le Duc de Nivernois, he gave the charge of it to the abbé Millot. The minister having occasioned a kind of rebellion among the people by some innovations which he had made in the state, the abbé continued attached to the interests of his patron, and would not desert him till the storm was blown over. When he was told that he would lose his place by this conduct, he replied, " My place is with a virtuous persecuted man who has been my benefactor; and that I shall never lose." At length, having filled the historical chair with great approbation, he returned to France, and was appointed preceptor to M. le Duc d'Enghien. In this situation he died, A. D. 1785, aged 59. The abbé Millot did not shine in company; he was cold and reserved in his manner; but every thing he said was judicious, and exactly in point .- D'Alembert said, that of all his acquaintance the abbé Millot had the fewest prejudices and the least pretension. He composed several works, which are digested with great care, and written in a pure, simple, and natural style. The principal are, 1. Elemens de l'Histoire de France, depuis Clovis jusqu' à Louis XIV. 3 vols. in 12mo. The author, selecting the most curious and important facts, has

suppressed every thing foreign to the subject; and has Millot, not only arranged the materials in their proper order, but chosen them with the greatest judgment. Querlon thought this the best abridgement which we have of the history of France, and preferred it to that of the president Henault. 2. Elemens de l'Histoire d'Angleterre depuis son origine sous les Romains, jusqu' à George II. 3 vols. 12mo. In this valuable abridgement, the author satisfies, without tiring, his readers. It is all that is necessary for those who wish to gain a general knowledge of the English history, without entering minutely into its particular parts .-- 3. Elemens de l'Histoire Universelle, 9 vols. 12mo. A certain critic maintains, that this work is merely a counterfeit of Voltaire's general history. But this consure is altogether unjust. The ancient history in this work is wholly composed by the abbé Millot; and, no less than the modern part, discovers his abilities in the choice of facts, in divesting them of useless circumstances, in relating them without prejudice, and in adorning them with judicious reflections. 4. L'Histoire des Troubadours, 3 vols. 1 2mo, compiled from the manuscripts of M. de Saint Palaie. This work appears rather tedious, because it treats of men almost unknown, and most of them deserving to be so. What is there quoted from the Provençal poets is not at all interesting; and, according to the observation of a man of wit, "it serves no purpose to search curiously into a heap of old ruins while we have modern palaces to engage our attention." 5. Memoires Politiques et Militaires pour servir à l'Histoire de Louis XIV. et de Louis XV. composed from original papers collected by Adrian Maurice duc de Noailles, marshal of France, in 6 vols. 12mo. 6. The abbé Millot published also several Discourses, in which he discusses a variety of philosophical questions, with more ingenuity of argument than fire of expression; and a translation of the most select harangues in the Latin historians; of which it has been remarked, as well as of the orations of the abbé d'Olivet, that they are coldly correct, and elegantly insipid. The character of the author, more prudent and circumspect than lively and animated, seldom elevated his imagination above a noble simplicity without warmth, and a pure style without ostentation. Some of the critics, however, have accused him of declamation in some parts of his histories, particularly in those parts which concern the clergy. But, in our opinion, the word declamation is totally inapplicable to the writings of the abbé Millot. He flatters, it is true, neither priests nor statesmen; and he relates more instances of vicious than virtuous actions, because the one are infinitely more common than the other: But he relates them coldly; and he appears to be guided more by sincerity and a love of truth, than by that partial philosophy which blames the Christian religion for those evils which it condemns.

MILO, a celebrated athlete of Crotona in Italy. His father's name was Diotimus. He early accustomed himself to carry the greatest burdens, and by degrees became a prodigy of strength. It is said that hc carried on his shoulders a young bullock, four years old, for above forty yards; and afterwards killed it with one blow of his fist, and eat it up in one day. He was seven times crowned at the Pythian games, and six at the Olympian. He presented himself a seventh time; but no one had the courage or boldness to enter the lists against against him. He was one of the disciples of Pythagoras; and to his uncommon strength, it is said, the learned preceptor and his pupils owed their life: The pillar which supported the roof of the school suddenly gave way; but Milo supported the whole weight of the building, and gave the philosopher and his auditors time to escape. In his old age, Milo attempted to pull up a tree by the roots, and break it. He partly effected it; but his strength being gradually exhausted, the tree when half cleft re-united, and his hands remained pinched in the body of the tree. He was then alone; and, being unable to discntangle himself, he was devoured by the wild beasts of the place, about 500 years before the Christian era.

MILO, T. Annius, a native of Lanuvium, who attempted to obtain the consulship at Rome by intrigue and seditious tumults. Clodius the tribune opposed his views; yet Milo would have succeeded but for the following event: As he was going into the country, attended by his wife and a numerous retinue of gladiators and servants, he met on the Appian road his enemy Clodius, who was returning to Rome with three of his friends and some domestics completely armed .- A quarrel arose between the servants. Milo supported his attendants, and the dispute became general .- Clodius received many severe wounds, and was obliged to retire to a neighbouring cottage. Milo pursued his enemy in his retreat, and ordered his servants to despatch him. The body of the murdered tribune was carried to Rome, and exposed to public view. The enemies of Milo inveighed bitterly against the violence and barbarity with which the sacred person of a tribune had been treated. Cicero undertook the defence of Milo; but the continual clamours of the friends of Clodius, and the sight of an armed soldiery, which surrounded the seat of judgment, so terrified the orator, that he forgot the greatest part of his arguments, and the dcfence he made was weak and injudicious .- Milo was condemned, and banished to Massilia. Cicero soon after sent his exiled friend a copy of the oration which he had prepared for his defence, in the form in which we have it now; and Milo, after he had read it, cxclaimed, O Cicero, hadst thou spoken before my accusers in these terms, Milo would not be now eating figs at Marseilles. The friendship and cordiality of Cicero and Milo were the fruits of long intimacy and familiar intercourse. It was to the successful labours of Milo that the orator was recalled from banishment, and restored to his friends.

MILO, (anciently *Melos*), an island in the Archipelago, about 50 miles in circumference, with a harbour, which is one of the largest in the Mediterranean. The principal town is of the same name as the island, and was prettily built, but abominably nasty: the houses are two stories high, with flat roofs; and are built with a sort of pumice stone, which is hard, blackish, and yet very light.

This island was formerly rich and populous. From the earliest times of antiquity it enjoyed pure liberty. The Athenians, not being able to persuade the Melians to declare in their favour in the Peloponnesian war, made a descent upon the island, and attacked them vigorously. In two different expeditions they failed of their purpose : but returning with more numerous forces, they laid siege to Melos; and obliging the besieged to surrender at discretion, put to the sword all the men who were able to bear arms. They spared only the women and children, and these they carried into captivity. This act of cruelty puts humanity to the blush, and disgraces the Athenian name. But war was then carried on with a degree of wild rage, unexampled in the present times. Republics know not how to pardon, and always carry their vengeance to an extravagant height. When Lysander, the Lacedæmonian general, came to give law to the Athenians, he expelled the colony which they had sent to Melos, and re-established the unfortunate remains of its original inhabitants.

This island lost its liberty when Rome, aspiring to the empire of the world, conquered all the isles of the Archipelago. In the partition of the empire, it fell to the share of the eastern emperors, was governed by particular dukes, and was at last conquered by Soliman II. Since that period, it has groaned under the yoke of Turkish despotism, and has lost its opulence and splendour. At the commencement of the present century, it boasted of 17 churches and 11 chapels, and contained more than 20,000 inhabitants. It was very fertile in corn, wine, and fruits; and the whole space from the town to the harbour, which is nearly two miles, was laid out in beautiful gardens. M. Tournefort, who visited it in the year 1700, gives a fine description of it. " The earth, being constantly warmed by subterraneous fires, produced almost without interruption plenteous crops of corn, barley, cotton, exquisite wines, and delicious melons. St Elias, the finest monastery in the island, and situated on the most elevated spot, is encircled with orange, citron, cedar, and fig trees. Its gardens are watered by a copious spring. Olive trees, of which there are but few in the other parts of the island, grow in great numbers around this monastery. The adjacent vineyards afford excellent wine. In a word, all the productions of the island are the very best of their kinds; its partridges, quails, kids, and lambs, are highly valued, and yet may be bought at a very cheap price."

Were M. Tournefort to return to Milo, M. Savary **Letters assures us, he would no longer see the fine island which he has described. "He might still see alum, in the form of feathers, and fringed with silver thread, hanging from the arches of the caverns; pieces of pure sulphur filling the cliffs of the rocks; a variety of mineral springs; hot baths (though these are now only a set of small dirty caves); the same subterraneous fires which in his days warmed the bosom of the earth, and were the cause of its extraordinary fertility: but instead of 5000 Greeks, all paying the capitation tax (A), he would now find no more than about 700 inhabitants

⁽A) Grown up men are the only persons who pay the capitation tax. Therefore, by adding to the number of 5000 who paid the tax, the women, boys, and girls, we find that Melos, in the days of Tournefort, contained at least 20,000 souls.

Milo.

MI L IIO 1

inhabitants on an island 18 leagues in circumference. - He would sigh to behold the finest lands lying uncultivated, and the most fertile valleys converted into morasses; of the gardens scareely a vestige is left; threefourths of the town in ruins, and the inhabitants daily decreasing. In short, during the last 50 years, Melos has assumed a quite different appearance. The plague, which the Turks propagate everywhere, has eut off one part of its inhabitants; the injudicious administration of the Porte, and the oppressive extortions of the captain pacha, have destroyed the rest. At present, for want of hands, they cannot cut out a free channel for their waters, which stagnate in the valleys, corrupt, and infect the air with their putrid exhalations. The salt marshes, of which there are numbers in the island, being equally neglected, produce the same effects. Add to these inconveniences, those sulphurcous exhalations which arise all over the island, and by which the inhabitants of Melos are afflicted with dangerous fevers during three-fourths of the year. Perhaps they may be obliged to forsake their country. Every countenance is yellow, pale, and livid; and none bcars any marks of good health. The prudent traveller will be earcful to spend but a very short time in this unwholesome country, unless he chooses to expose himself to the danger of catching a fever. To sleep over night, or to spend but one day in the island, is often enough to occasion his being attacked with that distemper.

" Yet (continues our author) a judicious and enlightened government might expel those evils which ravage Melos. Its first care would be to cstablish a lazaret, and to prohibit vessels whose crews or cargoes are infected with the plague from landing. Canals might next be cut, to drain the marshes whose exhalations are so pernicious. The island would then be repeopled. The sulphureous vapours are not the most noxious. These prevailed equally in ancient times, yet the island was then very populous. M. Tournefort, who travelled through it at a time less distant from the period when it was conquered by the Turks, and when they had not yet had time to lay it waste, reckons the number of its inhabitants (as we have said) at about 20,000. The depopulation of Melos is therefore to be ascribed to the despotism of the Porte, and its detestable police."

up the Straits, p. 146.

The women of Milo, once so celebrated for their land's Tour beauty, are now sallow, unhealthy, and disgustingly ugly; and render themselves still more hideous by their dress, which is a kind of loose jacket, with a white coat and netticoat, that scarcely eovers two-thirds of their thighs, barcly meeting the stocking above the knce. Their hind hair hangs down the back in a number of plaits; that on the fore part of the head is combed down each side of the face, and terminated by a small stiff curl, which is even with the lower part of the cheek. All the inhabitants are Greeks, for the Turks are not fond of trusting themselves in the small islands; but every summer the captain bashaw goes round with a squadron to keep them in subjection, and to collect the revenue. When the Russians made themselves masters of the Archipelago, many of the islands dcclared in their favour; but being abandoned by the peace, they were so severely muleted by the grand signior, that they have professed a determination to remain perfectly Mile

quiet in future. As the Turks, however, do not think them worth a garrison, and will not trust them with arms and ammunition, all those which the Russians may Miltiade choose to invade will be obliged to submit. The two points which form the entrance of the harbour, erossing each other, render it imperceptible until you are close to it. Thus, while you are perfectly secure within it, you find great difficulty in getting out, particularly in a northerly wind; and as no trade is carried on except a little in eorn and salt, Milo would scarcely ever be visited, were it not that, being the first island which one makes in the Archipelago, the pilots have chosen it for their residence. They live in a little town on the top of a high rock, which, from its situation and appearance, is called the Castle .- Partridges still abound in this island; and are so cheap, that you may buy one for a charge of powder only. The peasants get them hy standing behind a portable screen, with a small aperturc in the centre, in which they place the muzzle of their piece, and then draw the partridges by a call. When a sufficient number are collected, they fire among them, and generally kill from four to seven at a shot; but even this method of getting them is so expensive, from the scareity of ammunition, that the people can never afford to shoot them, except when there are gentlemen in the island, from whom they can beg a little powder and shot.

Milo is 60 miles north of Candia; and the town is situated in E. Long. 25. 15. N. Lat. 36. 27.

MILSTONE. See MILLSTONE.

- MILT, in Anatomy, a popular name for the SPLEEN.

MILT, or Melt, in Natural History, the soft roe in fishes; thus called from its yielding, by expression, a whitish juice resembling milk. Sec RoE.

The milt is properly the seed or spermatic part of the male fish. The milt of a earp is reckoned a choice bit. It consists of two long whitish irregular bodies, each included in a very thin fine membrane. M. Pctit considers them as the testieles of the fish wherein the seed is preserved; the lower part next the anus, he supposes to be the vesiculæ seminales.

MILTHORP, a port town of Westmoreland, at the mouth of the Can, eight miles south from Kendal. It is the only sea port in the county; and goods are brought hither in small vessels from Grange in Laneashire. Here are two paper mills. It has a market on Friday, and a fair on Old May day; and there is a good stone bridge over the river Betha, which runs through the town. Population 1016 in 1811.

MILTIADES, an Athenian captain, son of Cypselus. He obtained a victory in a chariot race at the Olympic games. He led a colony of Athenians to the Chersonesus. The causes of this appointment are striking and singular. The Thracian Dolonci, harassed by a long war with the Absynthians, were directed by the oracle of Delphi to take for their king the first man they met in their return home, who invited them to come under his roof and partake his entertainments. This was Miltiades, whom the appearanee of the Dolonci, with their strange arms and garments, had struck. He invited them to his house, and was made acquainted with the commands of the oracle. He obeyed; and when the oracle of Delphi had approved a second time the choice of the Dolonci,

iades. lonci, he departed for the Chersonesus, and was invested by the inhabitants with sovereign power. The first measures he took were to stop the further incursions of the Absynthians, by building a strong wall across the isthmus. When he had established himself at home, and fortified his dominions against foreign invasion, he turned his arms against Lampsacus. His expedition was unsuccessful; he was taken in an anibuscade, and made prisoner. His friend Crossus king of Lydia was informed of his captivity, and procured his release. He lived a few years after he had recovered his liberty. As he had no issue, he left his kingdom and possessions to Stefagoras the son of Cimon, who was his brother by the same mother. The memory of Miltiades was greatly honoured by the Dolonci, and they regularly celebrated festivals and exhibited shows in commemoration of a man to whom they owed their greatness and preservation.

MILTIADES, the son of Cimon, and brother of Stcfagoras mentioned in the preceding article, was some time after the death of the latter, who died without issue, sent by the Athenians with one ship to take possession of the Chersonesus. At his arrival Miltiades appeared mournful, as if lamenting the recent death of his brother. The principal inhahitants of the country visited the new governor to condole with him; but their confidence in his sincerity proved fatal to them. Miltiades seized their persons, and made himself absolute in Chersonesus. To strengthen him-self, he married Hegesipyla, the daughter of Olorus the king of the Thracians. His triumph was short. In the third year of his government, his dominions were threatened by an invasion of the Scythian Nomades, whom Darius had some time before irritated by entering their country. He fled before them; but as their hostilities were of short duration, he was soon restored to his kingdom. Three years after, he left Chersonesus; and set sail for Athens, where he was received with great applause. He was present at the celebrated battle of MARATHON; in which all the chief officers ceded their power to him, and left the event of the battle to depend upon his superior abilities. He obtained an important victory over the more numerous forces of his adversaries. Some time after, Miltiades was intrusted with a fleet of 70 ships, and ordered to punish those islands which had revolted to the Persians. He was successful at first, hut a sudden report that the Persian fleet was coming to attack him, changed his operations as he was besieging Paros. He raised the siege, and returned to Athens. He was accused of treason, and particularly of holding correspondence with the enemy. The falsity of these accusations might have appeared, if Miltiades had been able to come into the assembly. But a wound which he had received before Paros detained him at home; and his enemies, taking advantage of his absence, became more eager in their accusations, and louder in their clamours. He was condemned to death; but the rigour of his sentence was retracted on the recollection of his great services to the Athenians, and he was put into prison till he had paid a fine of 50 talents to the state. IIis inability to discharge so great a sum detained him in confinement; and his wounds becoming incurable, he died a prisoner about 489 years before the Christian era. His

body was ransomed by his son Cimon ; who was obli- Miltiades, ged to borrow and pay the 50 talents, to give his father Milton. a decent burial .- The accusations against Miltiades were probably the more readily believed by his countrymen, when they remembered how he made himself absolute in Chersonesus; and in condemning the barbarity of the Athenians towards a general, who was the source of their military prosperity, we must remember the jealousy which ever reigns among a free and independent people, and how watchful they are in defence of the natural rights which they see wrested from others by violence. Cornelius Nepos has written the life of Miltiades the son of Cimon; but his history is incongruous and unintelligible, from his confounding the actions of the son of Cimon with these of the son of Cypselus. Greater reliance is to be placed on the narration of Herodotus, whose veracity is confirmed, and who was indisputably better informed and more capable of giving an account of the life and exploits of men who flourished in his age, and of which he could see the living monuments. Herodotus was born about six years after the famous battle of Marathon : and C. Nepos, as a writer of the Augustan age, flourished about 450 years after the age of the father of history.

MILTON, JOHN, the most illustrious of the English poets, was descended of a genteel family, seated at a place of their own name, viz. Milton, in Oxfordshire. He was horn December 9. 1608, and received his first rudiments of cducation under the carc of his parents, assisted by a private tutor. He afterwards passed some time at St Paul's school, London ; in which city his father had settled, being engaged in the business of a scrivener. At the age of 17, he was sent to Christ's college, Cambridge; where he made great progress in all parts of academical learning; but his chief delight was in poetry. In 1628, he proceeded bachelor of arts, having performed his excreise for it with great applause. His father designed him for the church; but the young gentleman's attachment to the Muses was so strong, that it became impossible to engage him in any other pursuits. In 1632, he took the degree of master of arts; and having now spent as much time in the university as became a person who dctcrmined not to engage in any of the three professions, he left the college, greatly regretted by his acquaintance, but highly displeased with the usual method of training up youth there for the study of divinity; and being much out of humour with the public administration of ecclesiastical affairs, he grew dissatisfied with the established form of church government, and disliked the whole plan of education practised in the university. His parents, who now dwelt at Horton, near Colnhrook, in Buckinghamshire, received him with unabated affection, notwithstanding he had thwarted their views of providing for him in the church, and they amply indulged him in his love of retirement; wherein he enriched his mind with the choicest stores of Grecian and Roman literature; and his poems of Comus, l'Allegro, Il Penseroso, and Lycidus, all wrote at this time, would have been sufficient, had he never produced any thing more considerable, to have transmitted his fame to the latest posterity. However, he was not so absorbed in his studies as not to make frequent excursions to London; neither did so much excellence pass

pass unnoticed among his neighbours in the country, with the most distinguished of whom he sometimes chose to relax his mind, and improve his acquaintance with the world as well as with books .- After five years spent in this manner, he obtained his father's permission to travel for farther improvement. At Paris he became acquainted with the celebrated Hugo Grotius; and from thence travelling into Italy, he was everywhere caressed by persons of the most eminent quality and learning.

Upon his return home, he set up a genteel academy in Aldersgate street .- In 1641, he began to draw his pen in defence of the Presbyterian party; and the next vear he married the daughter of Richard Powell, Esq. of Forest Hill in Oxfordshire. This lady, however, whether from a difference on account of party, her father being a zealous royalist, or some other cause, soon thought proper to return to her relations; which so incensed her husband, that he resolved never to take her again, and wrote and published several tracts in defence of the doctrine and discipline of divorce. He even made his addresses to another lady; but this incident proved the means of a reconciliation with Mrs Milton.

In 1644, he wrote his Tract upon Education; and the restraint on the liberty of the press being continued by act of parliament, he wrote boldly and nobly against that restraint. In 1645, he published his juvenile poems; and about two years after, on the death of his father, he took a smaller house in High Holborn, the back of which opened into Lincoln's-Inn Fields .- Here he quietly prosecuted his studies, till the fatal catastrophe and death of Charles I.; on which occasion he published his Tenure of Kings and Magistrates, in justification of the fact. He was now taken into the service of the commonwealth, and made Latin secretary to the council of state, who resolved neither to write to others abroad, nor to receive any answers, except in the Latin tongue, which was common to them all. The famous Einer Barihing coming out about the same time, our author, by command, wrote and published his Iconoclastes the same year. It was also by order of his masters, backed by the reward of 1000l. that in 1651 he published his celebrated piece, entitled Pro Popula Anglicano Defensio; "A Defence of the people of England," in answer to Salmasius's Defence of the King; which performance spread his fame over all Europe. He now dwelt in a pleasant house with a garden in Petty France, Westminster, opening into St James's Park. In 1652 he buried his wife, who died not long after the delivery of her fourth child; and about the same time he also lost his eye-sight, by a gutta serena, which had been growing upon him many years.

Cromwell took the reins of government into his own hand in the year 1653; but Milton still held his office. His leisure hours he employed in prosecuting his studies; wherein he was so far from being discouraged by the loss of his sight, that he even conceived hopes, monuments. Here is an almshouse for six people, who this misfortune would add new vigour to his genius ; have 12s. a-week, and three yards of cloth for a gown, which in fact seems to have been the case .- Thus , one pair of shoes and stockings, and 10s. each on St animated, he again ventured upon matrimony : his second lady was the daughter of Captain Woodstock of Hackney: she died in childbed about a year after. On the deposition of the protector, Richard Crom-

2

well, and on the return of the long parliament, Milton Miltor being still continued secretary, he appeared again in print; pleading for a farther reformation of the laws relating to religion; and, during the anarchy that ensued, he drew up several schemes for rc-cstablishing the commonwealth, exerting all his faculties to prevent the return of Charles II. England's destiny, however, and Charles's good fortune prevailing, our author chose to consult his safety, and retired to a friend's house in Bartholomew Close. A particular prosecution was intended against him; but the just esteem to which his admirable genius and extraordinary accomplishments entitled him, bad raised him so many friends, even among those of the opposite party, that he was included in the general amnesty.

This storm being over, he married a third wife, Elizabeth, daughter of Mr Minshall a Cheshire gentleman; and not long after he took a house in the Artillery Walk, leading to Bunhill Fields. This was his last stage : here he sat down for a longer continuance than he had been able to do anywhere; and though he had lost his fortune (for every thing belonging to him went to wreck at the Restoration), he did not lose his taste for literature, but continued his studies with almost as much ardour as ever ; and applied himself particularly to the finishing his grand work, the Paradise Lost ; one of the noblest poems that ever was produced by human genius. -It was published in 1667, and his Paradise Regained came out in 1670 .- This latter work fell short of the excellence of the former production; although, were it not for the transcendent merit of Paradise Lost, the second composition would doubtless have stood forcmost in the rank of English epic poems. After this he published many pieces in prose; for which we refer our readers to the edition of his Historical, Poetical, and Miscellaneous Works, printed by Millar, in 2 vols. 4to, in 1753.

In 1674, this great man paid the last debt to nature at his house in Bunhill Fields, in the 66th year of his age; and was interred on the 12th of November, in the chancel of St Giles's, Cripplegate .- A decent monument was erected to his memory, in 1737, in Westminster Abbey, by Mr Benson, one of the auditors of the imprest .- Milton was remarkably handsome in his person; but his constitution was tender, and by no means equal to his incessant application to his studies. -Though greatly reduced in his circumstances, yet he died worth 1500l. in money, besides his household . goods .- He had no son : but left behind him three daughters, whom he had by his first wife.

MILTON, the name of several places in England; particularly,

MILTON, or Middleton, in Dorsetshire, south-west of Blandford, near the road to Dorchester, 114 miles from London. It is chiefly noted for its abbey, built by King Athelstan. The church stands near the south side of the abbey. It is a large and magnificent pile of Gothic architecture, and contains several ancient Thomas's day yearly. Here is a free school, and a market on Tuesdays.

MILTON, in Kent, near Sittingbourn and the isle of Sheppey, 6 miles north-west of Feversham, and 40 from

Milton.

Milton

Himner-

mus.

from London. It is also called Middleton from its situation near the middle of the county, i. e. from Deptford to the Downs. The kings of Kent had a palace here, which was castellated, and stood below the church ; but was burnt down in Edward the Confessor's time by Earl Goodwin, &c. Its church stands near a mile off. On approaching the town up the Thames, by the East Swale, it scems hid among the creeks : yet it is a large town; and has a considerable market on Saturdays, and a fair on July 24. The oysters taken here are the most famous of any in Kent. This town is governed by a portreeve, chosen yearly on St James's day, who supervises the weights and measures all over the hundred. Population 2470 in 1811.

MILTON, in Kent, a mile on the east side of Gravesend, was incorporated with it in the reign of Queen Elizabeth, by the name of the portreeve, jurats, and inhabitants of the towns of Graveseud and Milton. King Henry VIII. raised a platform or blockhouse here, for the defence both of this town and Gravesend, and the command of the river. It has a fair, January 25.

MILVIUS, MOLVIUS, or MULVIUS, Pons; a bridge on the Tiber, built by Æmilius Scaurus the censor, in the time of Sylla, at two miles distance from the city, on the Via Flaminia, and repaired by Augustus. From this bridge the ambassadors of the Allobroges were brought back to Rome, by Cicero's management, and made a discovery of Catiline's conspiracy (Sallust). Near it Maxentius was defeated by Constantine (Eutropius). Now called Ponte Molle.

MILVIUS, a species of FALCO. See FALCO, OR-NITHOLOGY Index.

MIMI, MIMES, in the ancient comedy, were buffoons or mimics, who entertained the people by taking off certain characters, using such gestures as suited the persons or subjects they represented. There were on the Roman stage female performers of this kind, ealled mina. The word is derived from puperous, I imitate. Some of the *mimi* acted their parts to the sound of the tibia; these they called mimauli.

MIMI were also a kind of farces or ludierous comedics, generally performed by one person. They had no acts, nor any *exordium*.—The *mimi* were introduced upon the Roman stage long after comedy and tragedy had arrived at their full perfection. The actor wore no mask, but smeared his face with soot, was dressed in lambskin, wore garlands of ivy, and carried a basket of flowers and herbs, in honour of Baeehus, and diverted the audience with apish tricks and ridiculous dances. This was the state of the mimi soon after their first introduction; but they underwent many alterations, which it would take up too much room to relate, and which are not of sufficient importance to justify a dctailed account. See PANTOMIMES.

MIMESIS, in Rhetoric, the imitating the voice and gestures of another person.

MIMNERMUS, an ancient poet and musician, flourished about the beginning of the sixth century B. C. He was of Smyrna, and cotemporary with Solon. Athenæus gives him the invention of pentameter verse. His elegies, of which only a few fragments are preserved, were so much admired in antiquity, that Horace preferred them to those of Callimachus. He composed a poem of this kind, as we learn from Pausanias, VOL. XIV. Part I.

upon the battle fought between the people of Smyrna, Mimner and the Lydians under Gyges. He likewise was author of a poem in elegiac verse, quoted by Strabo, Minagugha which he entitled Nanno, and in which we may suppose he chiefly celebrated a young and beautiful girl of that name, who, according to Athenaus, was a player on the flutc, with whom he was enamoured in his old age. With respect to love matters, according to Propertius, his verses were more valuable than all the writings of Homer.

Plus in amore valet Mimnermi versus Homero. Lib. I. Eleg. ix. v. 11:

And Horace bears testimony to his abilities in describing that seducing passion :

> Si Mimnermus uti censet, sinc amore jocisque Nil est jucundum, vivas in amore jocisque. Lib. I. Epist. vi. v. 65.

If, as wise Minnermus said, Life unblest with love and joy Ranks us with the senseless dead, Let these gifts each hour employ.

Alluding to some much admired lines of the Greek poet, which have been preserved by Stobæus.

Tis de Bios, Ti de TECTION aTHE REUTHS 'AQEODITAS, &cc.

What is life and all its pride, If love and pleasure be denied ? Snatch, snatch me hence, ye Fates, whene'er The am'rous bliss I cease to share. Oh let us crop each fragrant flow'r While youth and vigour give us pow'r : For frozen age will soon destroy The force to give or take a joy; And then, a prey to pain and care, Detested by the young and fair, The sun's best beams will hateful grow, And only shine on seenes of wo.

MIMOSA, the SENSITIVE PLANT; a genus of plants belonging to the monœcia class; and in the natural method ranking under the 33d order, Lomentacca. See BOTANY and MATERIA MEDICA Index.

The name mimosa, signifying "minnie," is given to this genus on account of the sensibility of the leaves, which, by their motion, mimic or imitate, as it were, the motion of animals.

MINA, or MANEH, a species of money which properly significs one part or ounce. It is observed that this word occurs only in the books of Kings, Chronieles, Ezra, and Ezekiel. This prophet (xlv. 12.) tells us, that the mina or manch was valued at 60 shekels, which in gold make of our English money about $54\frac{3}{4}$ pounds, and in silver almost seven pounds. Thus for the Hebrew manch. But the Greek or Attie mina, which is probably that mentioned in the books of the Maceabees and in the New Testament, is valued at 100 drachmæ, or about 2l. 17s. sterling. There was also a lesser mina, which was valued at 75 drachmæ.

MINAGNGHINIM, a pulsative instrument of music, among the Hebrews, which was a square table of wood, fitted with a handle; over this table was P stretched

Minagn- stretched an iron chain, or hempen cord, passing through ghinim balls of wood or brass, which struck against the table, when the instrument was shaken, and occasioned a clear Mindanao sound, which might be heard at a great distance.

MINCHA, in the Jewish customs, offerings of meal, cakes, or biscuits, made in the temple of the The Seventy have sometimes preserved this Lord. word in their translation; but instead of mincha they read manaa, which doubtless was the received pronunciation in their time. We find manaa in the same sense, in Baruch i. 10. Levit. ii. 3. &c. See the Greek of Jerem. xvii. 26. Dan. ii. 46. 2 Kings viii. 5. 9. xvii. 7. xx. 12. 2 Chron. vii. 7. Nehem. xiii. 5. 9. &c.

MINCHING-HAMPTON, a town of Gloucestershire, 20 miles from Bath and Bristol, and near 90 from London, with a market on Tuesdays, and two fairs. The parish is pretty large, being bounded on the north by the Stroud, and on the south by the brook Avening; and has 12 handets belonging to it, with a common called Amberley. Here is a good large rectory church, built in form of a cross. In 1811 the inhabitants amounted to 3246, many of whom are employed in the woollen manufacture. W. Long. 2. 14. N. Lat. 51. 38.

MINCIUS, a river of the Transpadana in Italy; running from, or rather transmitted through, the Lacus Benacus, from north to south, into the Padus ; but originally rising in the Rhetian Alps. Now Mincio or Menzo, running through the duchy of Mantua into the Po.

MIND, a thinking intelligent being, otherwise called spirit, in opposition to matter or body. See ME-TAPHYSICS, Part III.

MINDANAO, or MAGINDANAO, a large island of Asia in the East Indies, and one of the Philippines; 160 miles in length, and 120 in breadth. The interior parts contain several chains of lofty mountains, between which are extensive plains, where vast herds of cattle roam at large in the most delicious pastures. Several deep valleys also intersect, as it were, certain parts of the country, through which, during the rainy seasons, vast torrents pour from the mountains, and force their impetuous way to the sea. The rains and vapours which lodge in the plains diffuse themselves into meandering rivulets, and, collecting a variety of small streams in their course, approach the sea in the form of considerable rivers .- The sovereign of Magindanao is a powerful prince, and has several inferior chiefs, who acknowledge him as their head. Nevertheless, there are others of them who refuse submission to him, and are consequently in a continual state of war; so that peace, at least, does not appear to be one of the blcssings of this island. The Spaniards, indeed, assert their right to the entire dominion of Magindanao; but it is mere assertion; for though they have forts, &c. on the island, it is by no means in a state of subjection to their nation.

The air is esteemed salubrious, particularly in the vicinity of the sea. The heat there is not, in any degree, so intense as might be expected in a country which is situated on the very verge of the torrid zone. The prevalence of the easterly winds, in that part of the coasts which is washed by the Pacific ocean, renders the air cool and pleasant, the trade wind blowing

incessantly on its shores. It acts, indeed, with so Mindan much power as to sweep the whole breadth of the island; and though in its passage it loses much of its Minder strength, it retains a sufficient degree of force to afford refreshing breezes to the inhabitants of the western shore. The interior parts are much colder, from a very cloudy atmosphere, which frequently hangs over the summits of the mountains in thick and humid vapours. The soil, which is very exuberant, is suited to the cultivation of the whole vegetable tribes. Ricc is produced in the greatest abundance; a pecul, or 133 pounds, may be purchased for a Spanish dollar. Every part of the island abounds with buffaloes, cows, hogs, goats, &c. It affords also great variety of fowls, and a species of duck, whose head is of a fine scarlet colour. Here is also a small breed of horses, remarkable for their spirit. The natives, however, principally employ buffaloes in the various branches of husbandry and agriculture.

The city of Magindanao is situated on the southeast side of the island, has a river capable of admitting small vessels, and carries on a considerable trade with Manilla, Sooloo, Borneo and the Moluccas. Their exports are rice, tobacco, bees wax, and spices; in return for which they receive coarse cloths of Coromandel, China ware, and opium. The village or town of Samboingan is situated on the banks of a small rivulet, which empties itself immediately into the sea, and is agreeably shaded by groves of cocoa trees. The number of its inhabitants is about 1000, among which are included the officers, soldiers, and their respective families. In its environs there are several small look-out houses, erected on posts of twelve feet high, in all of which a constant guard is kept; so that it appears as if the Spaniards were in a continual state of enmity with the natives. The houses are built of those simple materials which are of very general use in the eastern seas. They are erected on posts, and built of bamboo, covered with mats; the lower apartments serve for their hogs, cattle, and poultry, and the upper oncs are occupied by the family.

MINDELHEIM, a town of Germany, in the circle of Suabia, and in Algow, with a castle. It is capital of a small territory between the rivers Iller and Lech, subject to the house of Bavaria. It was taken by the Imperialists after the battle of Hochstet, who erected it into a principality in favour of the duke of Marlborough; but it returned back to the house of Bavaria by the treaty of Rastadt. It is 33 miles south east of Ulm. E. Long. 10. 40. N. Lat 48. 5.

MINDELHEIM, a district of Germany, in Suabia, lying between the bishoprick of Augsburg and the abbacy of Kempten, which is 20 miles in length and 16 in breadth.

MINDEN, a considerable town of Germany, in the circle of Westphalia; and capital of a territory of the same name; seated on the river Weser, which renders it a trading place. It formerly belonged to the king of Prussia, who secularized the bishoprick. It is 27 miles east by south of Osnaburg, and 37 west of Hanover. E. Long. 9. 5. N. Lat. 52. 22.

MINDEN (the principality of), in Germany, lies in the circle of Westphalia, to the north of the county of Ravensburg, and along each side of the river Weser. It

Minden

Mine

It is about 22 miles square, and Minden and Petershagen are the principal places. It was formerly a bishoprie, but is now secularized ; was afterwards ceded to the elector of Brandenburg, and is now annexed to the new kingdom of Westphalia.

MINDORA, an island of Asia, in the East Indies, and one of the Philippines, 50 miles in circumference, and separated from Luconia by a narrow channel. It is full of mountains, which abound in palm trees and all sorts of fruits. The inhabitants are idolaters, and pay tribute to the Spaniards, to whom this island belongs

MINE, in Natural History, a deep pit under ground, from whence various kinds of minerals are dug out; but the term is more particularly applied to those which yield metals. Where stones only are procured, the appellation of quarries is universally bestowed upon the places from which they are dug out, however deep they may be.

The internal parts of the earth, as far as they have been yet investigated, do not consist of one uniform substance, hut of various strata or beds of substances, extremely different in their appearances, specific gravities, and chemical qualities, from one another. Neither are these strata similar to one another either in their nature or appearance in different countries; so that even in the short extent of half a mile, the strata will be found quite different from what they are in another place. As little are they the same either in depth or solidity. Innumerable craeks and fissures, by the miners called lodes, arc found in every one of them; but these are so entirely different in size and shape, that it is impossible to form any inference from their size in one place to that in another. In these lodes or fissures the metallic ore is met with; and, considering the great uncertainty of the dimensions of the lodes, it is evident that the business of mining, which depends on that size, must in like manner be quite uncertain and precarious. Mr Price, in his treatise on the Cornish mines, observes, that " the comparative smallness of the largest fissures to the bulk of the whole earth is really wonderful. In the finest pottery we can make, by a microscopic view, we may discover numerous cracks and fissures, so small as to be impenetrable by any fluid, and impervious to the naked eye; as, by the laws of nature originally imposed by the Creator, it happens that matter cannot contract itself into solid large masses, without leaving fissures between them, and yet the very fissures are as necessary and useful as the strata through which they pass. They are the drains that carry off the redundant moisture from the earth; which, but for them, would be too full of fens and bogs for animals to live or plants to thrive on. In these fissures, the several ingredients which form lodes, by the continual passing of waters, and the menstrua of metals, are brought out of the adjacent strata, collected and conveniently lodged in a narrow channel, much to the advantage of those who search for and pursue them; for if metals and minerals were more dispersed, and scattered thinly in the hody of the strata, the trouble of finding and getting at them would be endless, and the expence of procuring them exceed the value of the acquisition.

The insides of the fissures are commonly coated

over with a hard, crystalline, earthy substance or Mine. rind, which very often, in the breaking of hard ore, comes off along with it, and is commonly called the capels or walls of the lode : but Mr Price is of opinion, that the proper walls of the lode are the sides of the fissure itself, and not the coat just mentioned, which is the natural plaster upon those walls, furnished perhaps by the contents of the fissures, or from oozings of the surrounding strata.

The breadth of a lode is easily known by the distance betwixt the two incrusted sides of the stones of ore; and if a lode yields any kind of ore, it is a better sign that the walls be regular and smooth, or at least that one of them be so, than otherwise; hut there are not many of these fissures which have regular walls until they have been sunk down some fathoms.

Thus the inner part of the fissure in which the ore lies, is all the way bounded by two walls of stone, which are generally parallel to one another, and include the breadth of the vein or lode. Whatever angle of inclination some fissures make in the solid strata at their beginning, they generally continue to do the same all alone. Some are very uncertain in their breadth, as they may be small at their upper part and wide underneath, and vice versa. Their regular breadth, as well as their depth, is subject to great variation; for though a fissure may be many fathoms wide in one particular place, yet a little further east or west it may not perhaps be one inch wide. This excessive variation bappens generally in very compact strata, when the vein or fissure is squeezed, as it were, through hard rocks which seem to compress and straiten it. A true vein or fissure, however, is never entirely obliterated, but always shows a string of metallic ore or of a veiny substance; which often serves as a leader for the miners to follow, until it sometimes leads them to a large and richly impregnated part. Their length is in a great measure unlimited, though not the space best fitted for yielding metal. The richest state for copper, according to Mr Price, is from 40 to 80 fathoms deep; for tin, from 20 to 60: and though a great quantity of either may be raised at 80 or 100 fathoms, yet, "the quality (says our author) is often too much decayed and dry for metal."

Mr Price informs us, that the fissures or veins of the Cornish mines extend from east to west; or, more properly, one end of the fissure points west and by south, or west and by north; while the other tends east and by south, or east and by north. Thus they frequently pass through a considerable tract of country with very few variations in their directions, unless they be interrupted by some intervening cause.---But, besides this east and west direction, we are to consider what the miners call the underlying or hade of the vein or lode; viz. the deflection or deviation of the fissure from its perpendicular line, as it is followed in depth like the slope of the roof of a house, or the descent of the steep side of a hill. This slope is generally to the north or south; but varies much in different veins, or sometimes even in the same vein ; for it will frequently slope or underlie a small space in different ways, as it may appear to be forced by hard strata on either side .- Some of the fissures do P 2 net

Mine. Bot vary much from a perpendicular, while some devi-- ate more than a fathom; that is, for every fathom they descend in perpendicular height, they deviate likewise as much to the south or north. Others differ so much from the perpendicular, that they assume a position almost horizontal; whence they are also called horizontal or flat lodes, and sometimes lode plots. Another kind of these has an irregular position with regard to the rest; widening horizontally for a little way, and then descending perpendicularly almost like stairs, with only a small string or leader to follow after; and thus they alternately vary and yield ore in several flat or horizontal fissures. This, by the Cornish tinners, is called (but in Mr Price's opinion erroneously) a floor or squat; which, properly speaking, is a hole or chasm impregnated with metal, making no continued line of direction or regular walls. Neither docs a floor of ore descend to any considerable depth; for underneath it there appears no sign of a vcin or fissure, either leading directly down or any other way. This kind of vein is very rare in Britain. The fissures most common in Britain are the perpendicular and inclined, whether their direction be north or south, east or west.

The perpendicular and horizontal fissures (according to our author) probably remain little altered from their first position, when they were formed at the induration of the strata immediately after the waters left the land. The perpendicular fissures are found more commonly situated in level ground, at a distance from hills, and from the sea shore; but with regard to the latter, we find that the upper and under masses of strata differ in their solidity and other properties. " Hence, (says our author) it is very plain, that inelined fissures owe their deflection or underlie to some secondary cause, violence, or subsidence, of the earth : for though perpendicular fissures are seldom to be seen, yet such as are inclined at very considerable depths, become more and more perpendicular, as the more central strata by reason of the vast superincumbent weight, do not seem so likely to be driven out of their position as those which lie nearer the surface."

The fissures are often met with fractured as well as inclined; the reason of which, in Mr Price's opinion, has been a subsidence of the earth from some extraordinary cause. " The original position (says be) must have been horizontal, or parallel to the surface of the earth : but we often find these strata very sensibly declined from that first position ; nay, sometimes quite reversed, and changed into perpendicular. When we see a wall lean, we immediately conclude that the foundation has given way, according to the angles which the walls make with the horizon; and when we find the like declination in strata, we may conclude, by parity of reason, that there has been a like failure of what supported them, in proportion to that declination ; or that whatever made the strata to fall so much awry, must also cause ever thing included in those strata to fall proportionally. Wherever the greatest subsidence is to the north, the top of the lode or fissure will point to the north, and of conscquence underlie to the south, and vice versa: the slide or heave of the lode manifests the greater subsidence of the strata; but the same lode is frequently fractured and heaved in several places, all of which,

by due observation, will show us they were occasioned Mine. by so many several shocks or subsidencies, and that the strata were not unfooted, shaken, or brought to fall only once or twice, but several times."

Mr Price, in the course of his work, observes, that, though the metallic veins generally run from east to west, they are frequently intersected by veins or lodes, as he calls them, of other matters, which run from north to south. Some of these cross veins contain lead or antimony, but never tin or copper. Sometimes one of these unmetallic veins intersects the true one at right angles, sometimes obliquely; and sometimes the mixture of both is so intimate, that the most expert miners are at a loss to discover the separated part of the true vein. When this last is intercepted at right angles, it is moved either north or south, a very little way, perhaps not more than one fathom; in which case, the miners having worked to a small distance in one of these directions, if they find themselves disappointed, turn to the other hand, and seldom fail of meeting with what they expected. Sometimes they are directed in their search by the pointing of a rib or string of the true vein; but when the interruption happens in an oblique direction, the difficulty of finding the vein again is much greater.

When two metallic veins in the neighbourhood of each other run in an oblique direction, and of consequence meet together, they commonly produce a body of ore at the place where they intersect ; and if both are rich, the quantity will be considerable ; but if one be poor and the other rich, then both are either enriched or impoverished by the meeting. After some time they separate again, and each will continue its former direction near to the other; but sometimes, though rarely, they continue united.

It is a sign of a poor vein when it separates or diverges into strings; but on the contrary, when several of them are found running into one, it is accounted a promising sign. Sometimes there are branches without the walls of the vein in the adjacent strata, which often come either obliquely or transversely into it. If these branches are impregnated with ore, or if they underlie faster than the true vein, that is, if they dip deeper into the ground, then they are said to overtake or come into the lode, and to enrich it; or if they do not, then they are said to go off from it, and to impoverish it. But neither these nor any other marks either of the richness or poverty of a mine are to be entirely depended upon; for many mines, which have a very bad appearance at first, do nevertheless turn out extremely well afterwards; while others, which in the beginning seemed very rich, turn gradually worse and worse : but in general, where a vein has a bad appearance at first, it will be imprudent to be at much expence with it.

Veins of metal, as has been already observed, are frequently, as it were, so compressed betwixt hard strata, that they are not an inch wide : nevertheless, if they have a string of good ore, it will generally be worth while to pursue them : and they frequently turn out well at last, after they have come into softer ground. In like manner, it is an encouragement to go on if the branches or leaders of ore enlarge either in width or depth as they are worked; but it is a bad sign if they continue horizontal without inclining downwards; though it is not proper always to discontinue the work-

line.

4

ing of a vein which has an unfavourable aspect at first. Veins of tin are worth working when only three inches wide, provided the ore be good ; and copper ores when six inches wide will pay very well for the working. Some of the great mines, however, have very large veins, with a number of other small ones very near each other. There are also veins, crossing one another sometimes met with, which are ealled contras, vulgarly caunters. Sometimes two veins run down into the ground in such a manner that they meet in the direction of their depth; in which case the same observations apply to them which are applicable to those that meet in a horizontal direction. Sometimes a vein will suddenly disappear without giving any warning, by becoming narrower, or of worse quality; which by the miners is called a start or leap, and is very common in the mines of Cornwall. In one day's time they may thus be disappointed in the working of a rich vein of tin, and have no further sign of any thing to work upon. At the fractured extremity of their vcin they perceive a body of clay or other matter; and the method of recovering their vein is to drive on the work in the direction of the former part, so that their new work shall make the same angle with the clay that the other part of the vein does. Sometimes they sink a shaft down from the surface; but it is generally a matter of difficulty to recover a vein when thus lost.

The method of discovering mines is a matter of so much difficulty, that it seems surprising how those who were totally unacquainted with the nature of metals first eame to think of digging them out of the earth. According to Lucretius, the discovery was made by the conflagration of certain woods, which melted the veins of metal in the earth beneath them; but this seems rather to be improbable. Aristotle, however, is of the same opinion with Lucretius, and tells us, that some shepherds of Spain having set fire to the woods, the earth was thus heated to such a degree that the silver near the surface of it melted and flowed into a mass; and that in a short time the metallic mass was discovered by the rending of the earth in the time of an earthquake : and the same story is told by Strabo, who ascribes the discovery of the mines of Andalusia to this accident. Cadmus is said by some to have been the first who discovered gold : while others ascribe this to Thoas the Thracian, to Mercury the son of Jupiter, or to Pisus king of Italy; who having left his own eountry, went into Egypt, where he was elected king after the death of Mizraim the son of Ham; and, on account of his discovery, was called the Golden God. Others say, that Eaclis or Cæacus the son of Jupiter, or Sol the son of Oceanus, was the first discoverer ; but Eschylus attributes the discovery not only of gold, but of all other metals, to Prometheus. The brass and copper mines in Cyprus were first discovered by Cinyra the son of Agryopa; and Hesiod ascribes the discovery. of the iron mines of Crete to the Cretan Dactyli Idai. The extraction of lead or tin from its ore in the island of Cassiteris, according to several ancient authors, was discovered by Midacritus .- The Scripture, however, ascribes the invention of brass and iron, or at least of the methods of working them, to Tubal Cain before the flood.

In more modern times, we know that mines have been frequently discovered by accident; as in sea cliffs,

among broken eraggy rocks, by the washing of the Mine. tide or floods, also by irruptions and torrents of water issuing out of hills and mountains, and sometimes by the wearing of high roads. Mr Price mentions another way by which mines have been discovered, viz. by fiery coruscations; which, he says, he has heard from persons whose veracity he is unwilling to ques-" The tinners (says he) generally compare tion. these effluvia to blazing stars or other whimsical likenesses, as their fears or hopes suggest ; and search with uncommon eagerness the ground over which these jack-a-lanterns have appeared and pointed out. We have heard but I'tle of these phenomena for many years : whether it be, that the present age is less eredulous than the foregoing, or that the ground, being more perforated by innumerable new pits sunk every year, some of which, by the stannary laws, are prevented from being filled up, has given these vapours a more gradual vent, it is not necessary to inquire, as the fact itself is not generally believed."

Mines, however, are now most commonly discovered by investigating the nature of such veins, ores, and stones as may seem most likely to turn to account : but there is a particular sagacity, or habit of judging from particular signs, which can be acquired only by long practice. Mines, especially those of copper, may also be discovered by the harsh and disagreeable taste of the waters which issue from them; though it is probable that this only happens when the ore lies above the level of the water which breaks out; for it does not seem likely that the taste of the ore could ascend, unless we were to suppose a pond or lake of water standing above it. The presence of copper in any water is easily discovered by immerging in it a bit of polished iron, which will thus instantly be turned of a copper colour, by reason of the precipitation of the metal upon it. A candle, or picce of tallow put into water of this kind, will in a short time be tinged of a green colour.

Another and still more remarkable method of discovering mines is said to be by the virgula divinatoria, or " divining rod ;" which, however incredible the storics related concerning it may be, is still relied on by some, and among others by Mr Price. It is not known who was the inventor of this method; but Agricola supposes that it took its rise from the magicians, who pretended to discover mines by enchantment. No mention is made of it, however, before the 11th century, since which time it has been in frequent use ; and the Corpuscular Philosophy has even been called in to account for it. But before we pretend to account for phenomena so very extraordinary as those reported of the virgula divinatoria, it is necessary, in the first place, to determine whether or not they exist. Mr Price, as has been already hinted, believes in it, though he owns that by reason of his constitution of mind and body, he is almost incapable of co-operating with its influence. The following account, however, he gives from Mr William Cookworthy of Plymouth, a gentleman of known veracity and great chemical abilities.

He had the first information concerning this rod from one Captain Ribeira, who deserted from the Spanish service in Queen Anne's reign, and became captain-commandant in the garrison of Plymouth; in which Mine.

10

MIN

Mine.

which town he satisfied several intelligent persons of the virtues of the rod, by many experiments on pieces of metal hid in the earth, and by an actual discovery of a copper mine near Oakhampton, which was wrought for some years. This captain very readily showed the method of using the rod in general, but would not by any means discover the secret of distinguishing the different metals by it : though, by a constant attention to his practice, Mr Cookworthy discovered it. Captain Ribeira was of opinion, that the only proper rods for this purpose were those cut from the nut or fruit trees; and that the virtue was confined to certain persons, and those, comparatively spc.tking, but few: but Mr Price says, that the virtue resides in all persons and in all rods under certain circumstances. "The rod (says he) is attracted by all the metals, by coals, limestone, and springs of water, in the following order: 1. Gold; 2. Copper; 3. Iron; 4. Silver; 5. Tin; 6. Lcad; 7. Coals; 8. Limestone and springs of water. One method of determining the different attractions of the rod is this: Stand, holding the rod with one foot advanced; put a guinea under that foot, and an halfpenny under the other, and the rod will be drawn down; shift the pieces of money, and the rod will be drawn towards the face, or backwards to the

"The rods formerly used were shoots of one year's growth that grew forked; but it is found, that two separate shoots tied together with packthread or other vegetable substance answer rather better than such as are naturally forked, as the shoots of the latter are seldom of an equal size. They are to be tied together by the greater ends, the small ones being held in the hands. Hazle rods cut in the winter, such as are used for fishing rods, and kept till they are dry, do best; though, where these are not at hand, apple-tree suckers, rods from peach trees, currants, or the oak, though green, will answer tolerably well."

gold, which proves the gold to have the stronger at-

Our author next proceeds to describe the manner of holding the rod; of which he gives a figure, as he says it is difficult to be described. The small ends being crooked, are to be held in the hands in a position flat or parallel to the horizon, and the upper part in an elevation not perpendicular to it, but at an angle of about 70 degrees. " The rod (says he) being properly held by those with whom it will answer, when the toe of the right foot is within the semidiameter of the piece of metal or other subject of the rod, it will he repelled towards the face, and continue to be so while the foot is kept from touching or being directly over the subject ; in which case it will be sensibly and strongly attracted, and be drawn quite down. The rod should be firmly and steadily grasped; for if, when it has begun to be attracted, there be the least imaginable jerk or opposition to its attraction, it will not move any more till the hands are opened, and a fresh grasp taken. The stronger the grasp the livelier the rod moves, provided the grasp be steady and of an equal strength. This observation is very necessary, as the operation of the rod in many hands is defeated purely by a jerk or counteraction; and it is from thence concluded, that there is no real efficacy in the rod, or that the person who holds it wants the virtue;

I

whereas, by a proper attention to this circumstance in using it, five persons in six have the virtue, as it is called; that is, the nut or fruit-bearing rod will answer in their hands. If a rod, or the least piece of one of the nut-bearing or fruit kind, be put under the arm, it will totally destroy the operation of the *virgula divinatoria*, in regard to all the subjects of it, except water, in those hands in which the rod naturally operates. If the least animal thread, as silk, or worsted, or hair, be tied round or fixed on the top of the rod, it will in like manner hinder its operation; but the same rod placed under the arm, or the same animal substances tied round or fixed on the top of the rod, will make it work in those hands, in which without these additions it is not attracted."

Such are the accounts of this extraordinary rod, to which it is probable that few will assent; and we believe the instances of mines having been discovered by it are but very rare. Another and very ancient mode of discovering mines, less uncertain than the divining rod, but extremely difficult and precarious, is that called shoding; that is, tracing them by loose stones, fragments, or shodes, which may have been separated or carried off to a considerable distance from the vein, and are found by chance in running waters, on the superficies of the ground, or a little under .-... "When the tinners (says Mr Price) meet with a loose single stone of tin ore, either in a valley or in ploughing or hedging, though at 100 fathoms distance from the vein it came from, those who are accustomed to this work will not fail to find it out. They consider, that a metallic stone must originally have appertained to some vein, from which it was severed and cast at a distance by some violent means. The deluge, they suppose, moved most of the loose earthy coat of the globe, and in many places washed it off from the upper towards the lower grounds, with such a force, that most of the backs or lodes of veins which protruded themselves above the fast were hurried downwards with the common mass: whence the skill in this part of their business lies much in directing their measures according to the situation of the surface." Afterwards, however, our author complains that this art of shoding, as he calls it, is in a great measure lost.

The following account of a method of finding silver mines by Alonzo Barba seems to be similar to that of shoding just now mentioned. " The veins of metal (says he) are sometimes found by great stones above ground; and if the veins be covered, they hunt them out after this manner; viz. taking in their hands a sort of mattock, which has a steel point at one end to dig with, and a blunt head at the other wherewith to break stones, they go to the hollows of the mountains, where the current of rain water descends, or to some other part of the skirts of the mountains, and there observe what stones they meet with, breaking in pieces those that seem to have any metal in them; whereof they find many times both middling sort of stones and small ones also of metal. Then they consider the situation of that place, and whence these stones can tumble, which of necessity must be from higher ground, and follow the track of them up the hill as long as they can find any of them," &c.

"Another way (says Mr Price) of discovering lodes

is by working drifts across the country, as we call it, that is, from north to south, and vice versa. I tried the experiment in an adventure under my management, where I drove all open at grass about two feet in the shelf, very much like a level to convey water upon a mill wheel; by so doing I was sure of cutting all lodes in my way: and I did accordingly discover five courses, one of which has produced above 180 tons of copper ore, but the others were never wrought upon. This method of discovering lodes is equally cheap and certain; for 100 fathoms in shallow ground may be driven at 50s. expence."

In that kind of ground called by our author feasible, and which he explains by the phrase tenderstanding, he tells us, that " a very effectual, proving, and consequential way is, by driving an adit from the lowest ground, cither north or south ; whereby there is a certainty to cut all lodes at 20, 30, or 40 fathoms deep, if the level admits of it. In driving adits or levels across, north or south, to unwater mines already found, there are many fresh veins discovered, which frequently prove better than those they were driving to."

After the mine is found, the next thing to be considered is, whether it may be dug to advantage. In order to determine this, we are duly to weigh the nature of the place, and its situation, as to wood, water, carriage, healthiness, and the like; and compare the result with the richness of the ore, the charge of digging, stamping, washing, and smelting.

Particularly the form and situation of the spot should be well considered. A mine must either happen, I. In a mountain; 2. In a hill; 3. In a valley; or, 4. In a flat. But mountains and hills are dug with much greater ease and convenience, chiefly because the drains and burrows, that is, the adits or avenues, may be here readily cut, both to drain the water and to form gangways for bringing out the lead, &c. In all the four cases, we are to look out for the veins which the rains or other accidental thing may have laid bare; and if such a vein be found, it may often be proper to open the mine at that place, especially if the vein prove tolerably large and rich; otherwise the most commodious place for situation is to be chosen for the purpose, viz. neither on a flat, nor on the tops of mountains, but on the sides. The best situation for a mine is a mountainous, woody, wholesome spot; of a safe easy ascent, and bordering on a navigable river. The places abounding with mines are generally healthy; as standing high, and everywhere exposed to the air; yet some places where mines are found prove poisonous, and can upon no account be dug, though ever so rich. The way of examining a suspected place of this kind, is to make experiments upon brutes, by exposing them to the effluvia or exhalations, to find the effects.

Devonshire and Cornwall, where there are a great many mines of copper and tin, is a very mountainous country, which gives an opportunity in many places to make adits or subterraneous drains to some valley at a distance, by which to carry off the water from the mine, which otherwise would drown them out from getting the ore. These adits are sometimes carried a mile or two, and dug at a vast expense, as from 2000l. to 4000l. especially where the ground is rocky;

and yet they find this cheaper than to draw up the Mine. water out of the mine quite to the top, when the water runs in plenty, and the mine is deep. Sometimes, indeed, they cannot find a level near enough to which an adit may be carried from the very bottom of the mine ; yet they find it worth while to make an adit at half the height to which the water is to be raised, thereby saving half the expence.

Mr Costar, considering that sometimes from small streams, and sometimes from little springs or collections of rain water, one might have a good deal of water above ground, though not a sufficient quantity to turn an overshot wheel, thought that if a sufficient fall might be had, this collection of water might be made useful in raising the water in a mine to the adit, where it may be carried off.

But now the most general method of draining mines is by the steam engine. See STEAM-Engine.

MINE, in the military art, denotes a subterraneous canal or passage, dug under the wall or rampart of a fortification, intended to be blown up by gunpowder.

The alley or passage of a mine is commonly about four feet square; at the end of this is the chamber of the mine, which is a cavity of about five feet in width and in length, and about six feet in height; and here the gunpowder is stowed. The saucisse of the mine is the train, for which there is always a little aperture left.

Two ounces of powder have been found, by experiment, capable of raising two cubic feet of earth; consequently 200 onnces, that is, 12 pounds 8 ounces, will raise 200 cubic feet, which is only 16 feet short of a cubic toise, because 200 ounces, joined together, have proportionably a greater force than two ounces, as being an united force.

All the turnings a miner uses to carry on his mines, and through which he conducts the saucisse, should be well filled with earth and dung; and the masonry in proportion to the earth to be blown up, as 3 to 2. The entrance of the chamber of the mine ought to be firmly shut with thick planks, in the form of a St Andrew's cross, so that the enclosure be secure, and the void spaces shut up with dung or tempered earth. If a gallery be made below or on the side of the chamber, it must absolutely be filled up with the strongest masonry, half as long again as the height of the earth; for this gallery will not only burst, but likewise obstruct the effect of the mine. The powder should always be kept in sacks, which are opened when the mine is charged, and some of the powder strewed about : the greater the quantity of earth to be raised is, the greater is the effect of the mine, supposing it to have the due proportion of powder. Powder has the same effect upon masonry as upon earth, that is, it will proportionably raise either with the same velocity.

The branches which are carried into the solidity of walls do not exceed three feet in depth, and two feet six inches in width nearly : this sort of mine is most excellent to blow up the strongest walls.

The weight of a cubic foot of powder should be 80lb.; I foot I inch cube will weigh 100lb. and I foot 2 inches and 11 150lb.; and 200lb. of powder will

Min

Mine. be I foot 5 inches cube ; however, there is a diversity in this, according to the quantity of saltpetre in the gunpowder.

If, when the mines are made, water be found at the bottom of the chamber, planks are laid there, on which the powder is placed either in sacks or barrels of 100lb. each. The saucisse must have a clear passage to the powder, and be laid in an auget or wooden trough, through all the branches. When the powder is placed in the chamber, the planks are laid to cover it, and others again aeross these; then one is placed over the top of the chamber, which is shaped for that purpose; between that and those which cover the powder, props are placed, which shore it up; some inclining towards the outside ; others to the inside of the wall; all the void spaces being filled with earth, dung, brick, and rough stones. Afterwards planks are placed at the entrance of the chamber, with one across the top, whercon they buttress three strong props, whose other ends are likewise propped against another plank situated on the side of the earth in the branch; which props being well fixed between the planks with wedges, the branch should then be filled up to its entrance, with the forementioned materials. The sancisses which pass through the side branches must be exactly the same length with that in the middle, to which they join : the part which reaches beyond the entrance of the mine is that which conveys the fire to the other three; the saucisses being of equal length, will spring together.

From a great number of experiments, it appears, 1. That the force of a mine is always towards the weakest side; so that the disposition of the chamber of a mine does not at all contribute to determine this effect. 2. That the quantity of powder must be greater or less in proportion to the greater or less weight of the bodies to be raised, and to their greater or less cohesion; so that you are to allow for each cubic fathom

Of loose earth,	9 or 10lb.
Firm earth and strong sand,	II or I2
Flat clayey carth,	15 or 16
New masonry, not strongly bound,	15 or 20
Old masonry, well bound, -	25 or 30

3. That the aperture, entonnoir of a mine, if rightly charged, is a cone, the diameter of whose base is double the height taken from the centre of the mine. 4. That when the mine has been overcharged, its entonnoir is nearly cylindrical, the diameter of the upper extreme not much exceeding that of the chamber. 5. That besides the shock of the powder against the bodies it takes up, it likewise crushes all the earth that borders upon

it, both underneath and sidewise. To charge a mine so as to have the most advantageous effect, the weight of the matter to be earried must be known; that is, the solidity of a right cone, whose base is double the height of the earth over the centre of the mine : thus, having found the solidity of the cone in cubic fathoms, multiply the number of fathoms by the number of pounds of powder necessary for raising the matter it contains, and if the cone contains matters of different weights, take a mean weight between

them all, always having a regard to their degree of cohesion.

As to the disposition of mines, there is but one gene- Miner ral rule, which is, That the side towards which one would determine the effect be the weakest; but this varies according to occasions and circumstances.

The calculation of mines is generally built upon this hypothesis, That the entonnoir of a mine is the frustum of an inverted cone, whose altitude is equal to the radius of the excavation of the mine, and the diameter of the whole lesser base is equal to the linc of least resistance; and though these suppositions are not quite exact, yet the calculations of mines deduced from them have proved successful in practice ; for which reason this calculation should be followed till a better and more simple be found out.

M. de Valliere found that the entonnoir of a mine was a paraboloid, which is a solid generated by the rotation of a semiparabola about its axis; but as the difference between these two is very insignificant in practice, that of the frustum of a cone may be used.

MINEHEAD, a town of Somersetshire, 166 miles from London. It is an ancient borough, with a harbour in the Bristol channel, near Dunster castle, much frequented by passengers to and from Ireland. It was incorporated by Queen Elizabeth, with great privileges, on condition the corporation should keep the quay in repair; but its trade falling off, the quay was neglected, and they lost their privileges. A statute was obtained in the reign of King William, for recovering the port, and keeping it in repair, by which they were to have the profits of the quay and pier for 36 years, which have been computed at about 2001. a year; and they were at the expence of new-building the quay. In pursuance of another act, confirming the former; a new head has been built to the quay, the heach cleared, &c. so that the biggest ship may enter, and ride safe in the harbour. The town in 1811 contained 1037 inhabitants. It was formerly governed by a portreeve, and now by two constables chosen yearly at a court leet held by the lord of the manor. Its chief trade is with Ireland, from whence about 40 vessels used to come hither in a year with wool; and about 400 chaldrons of coals are yearly imported at this place, Watchet, and Poriock, from South Wales, which lies directly opposite to it about seven leagues over, the common breadth of this channel all the way from Holmes to the Land's End. Here are several rich merchants, who have some trade also to Virginia and the West Indies; and they correspond much with the merchants of Barnestaple and Bristol in their foreign commerce. Three or four thousand barrels of herrings, which come up the Severn in great shoals about Michaelmas, are caught, chired, and shipped off here every year, for the Mediterranean, &c. The market here is on Wednesday, and fair on Whitsun-Wednesday.

MINERAL, in Natural History, is used in general for all fossil bodies, whether simple or compound, dug out of a mine; from whence it takes its denomination. See MINERALOGY.

MINERAL Waters. All waters naturally impregnated with any heterogeneous matter which they have dissolved within the earth may be called mineral waters, in

Mineral. in the most general and extensive meaning of that name; in which are therefore comprehended almost all those that flow within or upon the surface of the earth, for almost all these contain some earthy or saline matter. But, strictly speaking, those waters only which hold in solution such a quantity of foreign ingredients as to give them properties which are easily recognised by the taste

or smell come under the denomination of mineral wa- Mineral. ters. For the methods of analyzing mineral waters, see CHEMISTRY Index in this work, and DECOMPOSITION CHEMICAL, SUPPLEMENT.

Here we shall give a tabular view of the more cmarkable mineral waters which have been discovered and examined.

An ALPHABETICAL TABLE of the most noted Mineral Waters in Europe, exhibiting their Medicinal Properties and Contents.

,Names of	Countries in which	Contents and Quality of the	Medicinal Virtues.
Abcourt,	Near St Germains in France.	A cold chalybeate water, containing besides the iron a small quantity of fossil alkali saturated with fixed	Diuretic and purgative. Internally used in dropsies, jaundice, and obstructions of the viscera; externally in scorbutic cruptions, ulcers, &c.
Aberbrothick,	County of Forfar in Scotland.	air. A cold chalybeate. Con- tains iron dissolved in fix- ed air.	Diuretic and corroborative. Used in indigestions, nervous disorders, &c.
Acton,	Middlesex county, England.	Contains Epsom and sea salt.	Strongly purgative, and causes a soreness in the fundament.
Aghaloo,	Tyrone, Ireland.	Sulphur, fossil alkali, and some purging salt. Cold.	Alterative and corroborant. Useful in scrofulous disorders, worms, and cu- taneous diseases.
Aix-la-Cha- pelle,	Juliers in Germany.	Sulphureous and hot. Con- tain aerated calcareous earth, sea salt, fossil al- kali, and sulphur.	Diaphoretic, purgative, and diuretic. Used as baths as well as taken in- ternally. Useful in rheumatisms, and all diseases proceeding from a debility of the system.
Alford or Aw-	Somersetshire, Eug-	A purging salt along with sea salt. Cold.	Strongly purgative.
Askeron,	Yorkshire, in Eng- land.	Contains Epsom salt, aerat- ed calcareous carth, and sulphur. Cold.	Diurctic. Useful when drunk in leprosy, and other cutancous discases.
Antrim,	Ireland.		Similar to Borrowdale water, but weak-
Baden,	Swabia in Germany.	Hot and sulphureous springs and baths, resembling those of Aix-la-Chapelle.	See AIX-LA-CHAPELLE, and BADEN, in the order of the Alphabet.
Bagnigge,	Middlesex, near London.	Epsom salt and muriated magnesia. Cold. Anc- ther spring contains iron and fixed air	Strongly purgative, three half pints be- ing a dose. The chalybeate spring also proves purgative when the bowels contain any vitiated matter.
Balimore,	Worcestershire in England.	A fine cold chalybeate, con- taining iron rendered so- luble by fixed air, along with some other salt sup- posed to be fossil alkali.	Corroborative, and good in obstructions of the viscera. Drank from two to three pints in a morning.
Ball or Baud- well,	Lincolnshire in Eng- land.	A cold petrifying water; contains aerated calcare- ous earth or magnesia.	Corroborative and astringent. Drunk to the quantity of two pints, or two and a half.
Balaruc,	Languedoc in France.	Hot, and contain some pur- ging salts.	Drank as purgatives, and used as hot baths. Useful in scrofulous and cuta- neous disorders.
Ballycastle,	Antrim in Ireland.	Chalybeate and sulphureous. Cold.	Resembles that of Balimore in virtue.
Ballynahinch,	Down in Ireland.	Iron, fixed air, and sulphur. Cold.	Useful in scorbutic disorders and diseases of indigestion.
Ballyspellan	Ncar Kilkenny in Ireland	Iron, fixed air, and proba- bly fossil alkali.	Similar in virtue to that of Balimore.
VOL XIV P	ort 1	+	Q. Bagneres,

	MIN	[122]	MIN
Names of	Countries in which	Contents and Quality of the	Medicinal Virtues.
Springs. Bagneres,	they are found. Bigorre in France.	Earth and sulphur. Hot.	The waters used in baths, like those of Aix-la-Chapelle. Some of the springs purceative, others diuretic.
Bareges,	Bigorre in France.	Sea salt, fossil alkali, calca- reous earth, selenites, sul- phur, and a fine bitumi- nous oil. Hot.	Diuretic and diaphoretic. Useful in ner- vous as well as cutaneous disorders, in old wounds and some venereal com- plaints. Used as baths, as well as taken internally to the quantity of a quart or there wints.
Barnet and	Hertfordshire in.	Epsom salt, and aerated cal-	Purgative.
North-hall,	England.	careous earth.	Demonfully correspondive and very use-
Bath,	Somersetshire in England.	earth, selenite, Glauber's salt, and sea salt. Hot.	ful in all kinds of weaknesses. Used as a bath, and taken internally.
Bandola,	Italy.	Iron, fixed air, fossil alkali, and a little sulphur.— Cold.	Gently laxative, diuretic, and diaphore- tic.
Borrowdale,	Cumberland in Eng- land.	A great quantity of sea salt, aerated calcareous carth, and some bittern. Cold.	Strongly emctic and cathartic. Some- times useful in the jaundice and dropsy, scorbutic disorders, and chro- nic obstructions. Used likewise as a bath in cutaneous diseases. Taken in the dose of a pint, containing only about seven drachms and a half of sea salt; so that a great part of the virtue must reside in the aerated calca- reous earth
Brentwood,	Essex in England.	Epsom salt, and aerated cal-	Purgative.
Bristol,	Somersetshire in England.	Calcareous earth, sea salt, Epsom salt, Glauber'ssalt, and selenites. Hot.	Used as a bath; and drank from four to eight ounces at a time, to two quarts per day. Useful in consumptions, dia- betes, fluor albus, &c.
Bromley, Broughton,	Kent in England. Yorkshire in Eng- land.	Iron and fixed air. Cold. Sulphur, sea salt, Epsom salt, and aerated earth. Cold.	Diuretic and corroborative. Similar to Harrowgate.
Buxton, *	Derbyshire in Eng- land.	A small quantity of sea salt, fossil alkali, Epsom salt, and aerated calcare- ous earth. Hot. Herc is also a fine cold chaly-	Useful in gout, rheumatism, and other disorders in which tepid baths are serviceable. Used as baths, and drank to the quantity of five or six pints per day.
Caroline baths	, Bohemia.	beate spring. Iron, fixed air, aerated earth, sea salt, fossil alkali, Ep- som salt, and Glauber's solt. Hot	Purgative, and used as baths. Of service in disorders of the stomach and bowels, scrofula, &c.
Carlton,	Nottinghamshire in England.	Iron dissolved in fixed air, along with a bituminous oil, which gives it the smell of horse dung.— Cold.	Dinretic and corroborative.
Carrickfergus,	Antrim in Ireland.	Seems from its bluish colour to contain a very small quantity of conver Cold	Weakly purgative.
Carrickmore,	Cavan in Ireland.	Fossil alkali, fixed air, and some purging salt. Cold.	Purgative and diuretic.
Cashmore,	Waterford in Ire- land.	Green vitriol.	Purgative, diuretic, and sometimes eme- tic.
Castle-Connel,	, Limerick in Ireland.	Iron dissolved in fixed air, &c. Cold.	Resembles the German Spaw, and is in considerable repute.
Castle-Leod,	Ross-shire in Scot- land.	Aerated earth, selenites, Glauber's salt, and sul-	, Diuretic, diaphoretic, and corroborant; - useful in cutaneous diseases.
3	1.1	phur. Cold.	Castlemain

	MIN	[123]	MIN
Names of	Countries in which	Contents and Quality of the Water	Medicinal Virtues.
Castlemain,	Kerry in Ireland.	Iron, sulphur, and fixed air. Cold.	Corroborant and diuretic.
Cawley,	Derbyshire in Eng- land.	Epsom salt, aerated calca- reous earth, and sulphur. Cold.	Gently purgative.
Cawthorp,	Lincolnshire in Eng- land.	Iron, fixed air, and proba- bly fossil alkali. Cold.	Purgative, and corrects acidities.
Chadlington,	Oxfordshire in Eng- land.	Fossil alkali, sea salt, and sulphur. Cold.	Purgative.
Chaude Fon- taine,	Liege in Germany.	Aerated earth, fossil alkali, and fixed air. Hot.	Resembles those of Aix-la-Chapelle and Buxton.
Cheltenham,	Gloucestershire in England.	Calcareous earth, iron, Ep- som salt, and common salt. Cold.	Purgative and corroborant; taken in the quantity of from one to three or four pints. It is useful in cases of in- digestion and seorbutic disorders; also in the gravel.
Chippenham,	Wiltshire in Eng- land.	Iron dissolved in fixed air.	Diurctic and corroborative.
Cleves,	Germany.	Iron, fixed air, and other ingredients of Pyrmont water.	Diuretic and corroborant.
Clifton,	Oxfordshire in Eng- land.	Fossil alkali and aerated cal- careous earth or selenite. Cold.	Gently laxative, and used as a bath for cutaneous disorders.
Cobham,	Surry in England.	Iron, and some purging salt.	Purgative, diuretic, and corroborant.
Codsalwood,	Staffordshire in Eng- land.	Sulphur, fixed air, and ae- rated earth.	Resembles the Askeron water.
Colehester,	Essex in England.	Epsom salt, and aerated cal- careous earth.	Strongly purgative.
Colurian,	Cornwall in Eng- land.	Iron, fixed air, and aerated earth.	Corroborative and diuretie.
Comner, or Cumner,	Berkshire in Eng- land.	Some purging salt, and pro- bably aerated earth; the water is of a whitish co-	Purgative, in the quantity of one, two, or three quarts.
Coolauran,	Fermanagh in Ire-	Iron, fixed air, and aerated	Diuretic.
Corstorphine,	land. Mid Lothian in Seot- land.	earth. Sulphur, sea salt, clay, and Ensom salt. Cold.	Diurctic and laxative.
Coventry,	Warwickshire in England.	Iron, fixed air, and some	Purgative, diuretic, and corroborant.
Crickle Spaw,	Lancashire in Eng- land.	Sulphur, sea salt, and acrated earth.	Purgative, and resembling Harrowgate water.
Croft,	Yorkshire in Eng- land.	Aerated earth, vitriolated magnesia, and sea salt.	Purgative, and resembling Askeron wa- ter.
Crosstown,	Waterford in Ire- land.	Martial vitriol.	Diuretic, purgative, and sometimes eme- tic.
Cunley-house,	Lancashire in Eng- land.	Sulphur, aerated earth, and fixed air.	Purgative, and resembling the Askeron water.
Das Wild Bad,	Nuremberg in Ger- many.	Iron, fixed air, and some sa- line matter.	Corroborant. Useful in obstructions of the viscera, and female complaints.
D' ax en Foix,	1 5 leagues from Thou- louse in France.	Similar to Aix-la-Chapelle. Hot.	Used as a bath, and also drank, like the Aix-la-Chapelle waters.
Deddington,	Oxford in England.	Iron, sulphur, aerated earth, sea salt, or fossil alkali.	Alterative, purgative in large quantity, and useful in scorbutic and cutaneous disorders.
Derby,	Near the capital of Derbyshire in England	Iron dissolved by fixed air.	Corroborant.
Derryinch,	Fermanagh in Ire-	Sulphur and fossil alkali.	Diuretic and diaphoretic.
Derrindaff,	Cavan in Ireland.	Sulphur and purging salt.	Similar to the Askeron water. Q 2 Derrylester,

	MIN	[I24]	MIN

MIN

Medicinal Virtues.

Useful in the scurvy, leprosy, cutaneous disorders, & c.

Useful in disorders of the eyes, scrofula, &c.

Emetic and cathartic. Useful in old sores, and cures mangy dogs.

Similar to Swadlingbar water.

Emetic, cathartic, and diuretic.

Used only for washing mangy dogs and scabby horses.

Similar to Ilmington water. Similar to Borrowdale water. A hot water, similar to that

of Bristol.

Iron and fixed air in considerable quantity. Iron. Two springs. Similar to Scarborough water, but is sometimes apt to vomit.

Diuretic and cathartic; used also externally. Recommended as excellent in diseases of the skin; in leprosies, scorbutic complaints, scrofula, old sores, &c. Also serviceable in inflammations and other diseases of the eyes; in the gout and stone, in bilious and paralytic cases, and in female obstructions. The external use is by washing the part at the spout several times a-day, and afterwards covering it with cloths dipt in the water and kept constantly moist; also by general bathing.

land.

land.

Similar to Islington. Warm springs, of the nature of the Bristol water, except that they are very slightly impregnated with iron, but contain a great quantity of aerated earth. They are colder than the Buxton; but their virtues similar to those of the two places mentioned. Sulphur and sea salt.

Sulphur and fossil alkali.

Similar to Tunbridge.

Sulphurated hydrogen, carbonic acid and azotic gases, with common salt.

Similar to Islington water.

Alterant, diuretic, and sometimes purgative. Is used as a bath, and the steam of the hot water has been found serviceable in relaxing hard tumors and stiff joints.

Similar to the waters of Drumgoon,

Purges strongly.

Similar to Harrowgate.

Moss-house,

Moreton,

Lancashire in England. Shropshire in England.

Similar to Holt water.

	MIN	[127]	MIN
Names of	Countries in which	Contents and Quality of the	Medicinal Virtues.
Mount D'Or,	France.	Warm, and similar to the waters of Aix-la-Cha-	Diuretic, purgative, and diaphoretic.
Nevil Holt,	Leicestershire in England.	selenite or aerated earth, and Epsom salt.	Purgative, diurctic, and diaphoretic Powerfully antiseptic in putrid dis- cases, and excellent in diarrhœa, dy- senteries, &c.
New Cartmall,	Lancashire in Eng- land.	Sea salt and aerated earth.	Purgative.
Newnham Re-	Warwickshire in England.	Similar to Scarborough wa- ter.	
Newtondale,	Yorkshire in Eng-	Aerated calcareous earth or magnesia.	Astringent or tonic.
Newton-Stew-	Tyrone in Ireland.	Similar to Tunbridge.	
Nezdenice,	Germany.	Fixed air, fossil alkali, iron, and earth.	Diuretic, diaphoretic, and tonic.
Nobber, Normanby,	Meath in Ireland. Yorkshire in Eng- land.	Martial vitriol. Sulphur, much fixed air, some sea salt, and Epsom	Similar to Hartfell. Similar to Askeron water.
Nottington,	Dorsetshire, Eng-	Sulphur, fossil alkali, and	Useful in cutaneous diseases.
Orston,	Nottingham, Eng- land.	Much fixed air, Epsom salt, and a little sea salt, with some iron.	Purgative.—It intoxicates by reason of the great quantity of air contained in it.
Oulton, Owen Breun,	Norfolk, England. Cavan, Ireland.	Similar to Islington. Sulphur, Epsom salt, and	Similar to Askeron water.
Pancras,	Near London.	Epsom salt, and aerated earth.	Diuretic and purgative.
Passy, Peterhead,	Near Paris. Aberdeen county, Scotland.	Similar to Pyrmont water. A strong chalybeate, but of which no analysis has been published.	Similar to Islington, but more power- ful.
Pettigoe, Pitkeathly,	Donnegal, Ireland. Perthshire,Scotland.	Sulphur and purging salt. Sea salt, a small quantity of muriated and likewise of aerated carth.	Similar to Askeron water. Gently purgative. Very useful in scrofu- lous and scorbutic habits.
Plombiers,	Lorraine, France.	Saline matter, probably fos- sile alkali, with a small portion of oil.—Warm.	Used as a bath, and for washing nleers. Inwardly taken it cures complaints from acidity, hemorrhagies, &c.
Pontgibault,	Auvergne, France.	Fossil alkali and calcarcous earth.	Diuretic and laxative.
Pougues,	Nivernois, France.	Calcareous earth, magnesia, fossil alkali, sea salt, earth of alum, and siliccous carth.	Diuretic and laxative.
Pyrmont,	Westphalia, Germa- ny.	Aerated iron, calcareous carth, maguesia, Epsom salt, and common salt.	Diuretic, diaphoretic, and laxative. Re- commended in cases where the con- stitution is relaxed; in female com- plaints, in cutaneous diseases, in ner- vous disorders, in the gravel and uri-
			nary obstructions; and considered as among the best restoratives in decayed and broken constitutions.
Queen Camel,	Somersetshire, Eng- land.	Sulphur, sea salt, fossil al- kali, calcareous carth, and bituminous oil.	Used in scrofulous and cutaneous disor- ders.
Rippon,	Surry in England. Yorkshire, England.	Similar to Acton water. Sulphur, sca salt, and aerat- ed earth.	Diaphoretic and alterant.

Tilbury,

	MIN	[120]	MIN
Names of Springs.	Countries in which they are found.	Contents and Quality of the Water.	Medicinal Virtues.
Tilbury,	Essex in England.	Fossil alkali.	Diuretic and diaphoretic.
Tober Bony,	Near Dublin in Ire- land.	Fossil alkali, earth, and bi- tuminous oil.	Similar to Tilbury.
Tonstein,	Cologne in Germany.	Fossil alkali.	Similar to Seltzer, but more purgative.
Tralee,	Kerry in Ireland.	Similar to Castle Connel.	, in his has have
Tunbridge,	Kent in England.	Iron, some sea salt, with a little selenites and calca- reous earth.	An excellent chalybeate, useful in all diseases for which the Spaw is recom- mended
Upminster,	Essex in England.	Sulphur, fossil alkali, and purging salt.	Purgative and diuretic.
Valils,	Dauphiny in France.	Fossil alkali.	Diuretie and laxative.
Wardrew,	Northumberland.	Sulphur, earth, and sea salt.	Similar to Harrowgate water,
Weatherstack,	Westmoreland in England.	Iron, sea salt, and a small quantity of hepatic gas.	Purgative.
Wallenfrow,	Northamptonshire in England.	Similar to Islington water.	
West Ashton,	Wiltshire in Eug- laud.	Similar to Islington.	
Westwood,	Derbyshire in Eng-	Green vitriol.	Similar to Shadwell. Used for washing
Wexford.	Treland	Similar to Islington	ulcers of the legs.
Whiteacre,	Lancashire in Eng- land.	Aerated iron, and probably calcareous earth.	Somewhat astringent.
Wigglesworth,	Yorkshire in Eng- land.	Sulphur, earth, and common salt.	Emetic in the quantity of two quarts, and said to be eathartic in the quantity of
Wildungan,	Waldech in Germa-	Similar to the waters of Bath.	Useful in scorbutic and gouty diseases.
Windgate Spaw,	Northumberland.	Carbonate of iron, green vi- triol, alum, common salt, caleareous earth.	Corroborant and diuretie; and useful in stomach complaints and scrofula.
Witham,	Essex in England.	Aerated iron, and common salt.	Diuretic, alterative, and corroborant.
Wirksworth,	Derbyshire in Eng- land.	Sulphur, purging salt, and aerated iron.	Useful in scrofulous and entaneous diseases.
Zahorovice,	Germany.	Similar to Nezdenice water.	Much esteemed in scrofulous cases.

MINERALOGY.

MINERALOGY is that branch of natural history which has for its object the description and discrimination of inorganized or mineral substances, as they are found in the earth or on its surface.

The knowledge of some mineral bodies may be considered as eoeval with the earliest ages of the world. The rudest and most barbarous nations could not be ignorant of some of the properties of the substances which were most familiar to their observation; and mankind have made little progress in eivilization, when they are entirely unacquainted with the nature of those matters from which some of the metals are extracted.

Precious stones, it seems not at all improbable, first attracted the notice of mankind. The richness of colour, brilliancy, lustre, and durability of these bodies, could not fail to excite admiration, and make them be sought after as ornaments, even by the least civilized people, and in countries where they are most abundant. They were well known, it would appear from the sacred

I bry.

writings, among the Jews and Egyptians in the time of Moses. At this period, however, both the Jews and Egyptians had advanced far in refinement.

But this knowledge was too limited to be dignified with the name of *Mineralogy*. It wanted that comprehensive, connected, and scientific view which could entitle it to that denomination. And indeed it may be said to be only of modern date that the knowledge of minerals rose to the rank of science, and assumed any thing like a regular and connected form.

Dioscorides and Theophrastus among the Greeks, and Writers on Pliny among the Romans, have, it is true, described a minerals. few mineral bodies; and Avicenna, an Arabian philosopher and physician, who flourished in the end of the 10th and beginning of the 11th century, arranged those objects into four great classes, viz. 1. Stony bodies. 2. Saline bodies. 3. Inflammable bodies; and, 4. Metals —au arrangement which, it is eurious to remark, must be well founded; for it has been adopted, sometimes indeed with slight deviations, by almost all mineralogical R writers MINERALOGY.

History.) writers since that period. But still the knowledge of minerals was bounded by very narrow limits.

Agricola.

have thus rendered this knowledge of more interest and importance than in any other country. To Germany indeed it must be acknowledged that mineralogy is indebted in a great measure for its origin, and for a very ample share of its progressive improvement. George Agricola, a native of Misnia, in which country he settled as a physician, lived during the first half of the 16th century. Being strongly attached by inclination to the study of minerals, he removed to Chemnitz in Hungary, where he might have an opportunity of prosecuting his favourite studies; and there, by the most unwearied application to mineralogy, and particularly to the various operations on the metals, he became the most celebrated metallurgist of his time. He is supposed to be the first German author who professedly wrote on mineral substances. The following titles chiefly comprchend the various heads into which his works on metallurgy and mineralogy are divided, De Ortu et Causis Subterraneorum ; De Natura eornm quæ afflunnt ex Terra; De Natura Fossilium; de Medicatis Fontibus; De Subterraneis Animantibus ; De Veteribus et Novis Metallis ; and De Re Metallica. His arrangement of minerals is into two great divisions. 1. Simple or Homogeneous Minerals; and, 2. Heterogeneous Minerals. The first, or simple minerals, includes four subdivisions, viz. 1. Terra ; 2. Succus Concretus ; 3. Lapis ; 4. Metallum. The second great division, the heterogeneous minerals, comprehends two subdivisions, viz. 1. Compound minerals; 2. Mixed minerals. Several writers on mineralogy appeared in the course

of the 17th century; and about the beginning of the

18th Beccher proposed an arrangement of bodies on

The variety and value of mineral productions in Ger-

many have excited more attention to these studies, and

Beccher.

6 Linnæus.

chemical principles, or according to their constituent parts. In the year 1736, Linnæus published a system of mineralogy, in which mineral bodies are divided into three classes, viz. 1. Petræ ; 2. Mineræ ; 3. Fossilia. These are subdivided into orders : the first containing three, Vitrescentes, Calcareæ, Apyræ; the second containing three, Salia, Sulphurea, Mercurialia; and the third also containing three, Concreta, Petrifacta, Terræ. Three years afterwards the system of Cramer appeared, according to which all mineral substances are arranged into seven classes, of which the following are the titles. 1. Metals; 2. Semimetals; 7 3. Salts; 4. Inflammable substances; 5. Stones; 6. Walleriu. Earths; and, 7. Waters. About 10 years after the first publication of the mineral system of Linnæus, Wallerius professor of mineralogy at Upsal, and his cotemporary, communicated to the world a more enlarged and improved arrangement of mineral bodies than any which had hitherto appeared. According to the system of Wallerius, all minerals arc distributed into four classes, each of which is subdivided into four orders. The first class, Terræ, includes the orders Macræ, Pingnes, Minerales, and Arenaceæ ; to the second class, Lapides, belong the orders Calcarei, Vitrescentes, Apyri, Saxa; the third class, Mineræ, comprehends the orders Salia, Sulphurea, Semimetalla and Metalla; and the fourth, Concreta, is composed of the orders Pori, Petrifacta, Figurata, and Calculi.

Of the systematic writers on mineralogy from the

4

time of Linnæus, which have now been mentioned, and History of others which the limits of this historical sketch do not permit us to notice, it is to be observed, that by all of them, although the general arrangement of Avicenna was not followed, yet in the subordinate divisions his classes were adopted, and constituted some of their orders. The classes of Avicenna were not restored till the time of Cronstedt, a Swedish mineralogist, in whose Cronstell system, which was published in the year 1758, they re-sumed the place which they formerly held. The system of Cronstedt is divided into four classes, Terræ, Salia, Phlogistica, and Metalla. The first class, Terræ, includes 9 orders, Calcarea, Silicea, Granatina, Argillaceæ, Micaceæ, Fluores, Asbestinæ, Zeoliticæ, and Magnesiæ. To the second class, Salia, belong two orders, Acida and Alkalina. The third class, Phlogistica, consists only of one order; and the fourth class, Metalla, is composed of two orders, Metalla perfecta and Semimetalla. The system of Cronstedt, the most complete which had yet been offered to the world, and which, by comparing it with the systems accounted by some the most perfect of the present day, will be found not much different in its arrangement, continued to be read and studied for more than twenty years, and was translated into different languages. This arrangement is founded on chemical principles. The first class, for instance, is divided into nine orders already enumerated, and corresponding, as he supposed, to nine earths, of one of which the stones included in each order are chiefly composed. But as the improvements in chemical analysis led to greater accuracy of investigation, the earths which Cronstedt supposed to be simple were found to be compound. The number of simple or primitive earths was then diminished to five; and thus the number of genera, as they appeared in the Sciagraphia Regni Mineralis of Bergman, published in 1782, was Bergman also five. At that period five earths only were known. The same method of constructing the genera is still followed, so that the number of genera has increased in proportion to the number of earths which have been since discovered.

In the year 1780, a translation of Cronstedt's mineral system appeared in Germany, accompanied with notes 10 by Werner, the celebrated professor of mineralogy at Werne Freyberg in Saxony. Six years before this time Werner had published a separate treatise on the classification of minerals, in which he exhibited his method of describing them by means of external characters. The notes on Cronstedt's system are to be considered as a farther illustration of this method, as well as a catalogue of minerals. belonging to Pabst Von Ohain, which was drawn up by the same naturalist and published in 1791. In Germany the method of Werner, we believe, is almost exclusively adopted; and it is chiefly followed in most other countrics, France excepted, where mineralogical knowledge is also greatly cultivated.

Mr Kirwan first introduced the knowledge of this Kirwa system into Britain, in his treatise on mineralogy published in 1784; and about ten years afterwards it was still farther elucidated by the same author in an improved and enlarged edition of that work. In preparing the latter edition, Mr Kirwan enjoyed the peculiar advantage of consulting one of the completest and best arranged collections of minerals which had yet been Lesket made in any country. This is the Leskean collection collect of of min

of fossils, which Mr Kirwan pronounces to be the most perfect monument of mineralogical ability now extant. " That the possession of this cabinct, Mr Kirwan proceeds to state, should escape the vigilance of the most learned nations, and fall to the lot of Ireland, hitherto so inattentive to matters of this nature, was little to be expected. Through the active zeal, however, of two of its most chlightened patriots (A), and the influence secured to them by former services of the most cssential nature, the sums requisite for its purchase, and for building a repository to receive it, were obtained *." This splendid and extensive collection, we are farther informed, was made by Lesko, whose name it now hears, and who was one of the earliest and most eminent of the disciples of Werner. It was arranged between the years 1782 and 1787, according to the principles of Werner, and with his assistance. After the death of Mr Leske, a catalogue was drawn up by Karsten, another of Werner's disciples. This catalogue in its arrangement corresponds to the arrangement of the cabinet, which is divided into five parts.

story.

reface

Mine-

The first part, which is denominated the characteristic part, consists of 580 specimens. These are in-tended for the illustration of the external characters, or the principles of the classification.

The second, which is the systematic or oryctognostic part, comprehends all simple minerals distributed according to their genera and species agreeable to the method then followed by Werner. This part contains 3268 specimens.

The third part, which is called the geognostic or geological, includes the substances found in the different kinds of rocks, as they are divided into primitive, transition, stratiform, alluvial, and volcanic mountains. This part of the collection is peculiarly rich in petrifactions; and the whole number of specimens which it contains extends to 1100.

The fourth part is intended to illustrate the mineralogy of every country on the globe, by exhibiting its mineral productions. The order of arrangement of this part is from America to Asia, Europe, and Africa. As there are many countries yet unexplored, it is the most imperfect division of the whole collection ; and, indeed, as Mr Kirwan observes, it can only be completed by national opulence.

The fifth part is called the economical collection. It is formed of 474 specimens of minerals which are cmployed in arts and manufactures, as in architecture, sculpture, agriculture, jewellery, colouring, dyeing, clothing, pottery, glazing, enamelling, polishing of metals, furnace-building, medicine, metallurgy, &c. The whole cabinet consists of 7331 specimens.

Such is the valuable source from which Mr Kirwan derived the information detailed in his system of mineralogy. And here we are led to throw out a hint that the friends of this science could not more effectually promote its knowledge, and encourage its progress, than by establishing similar collections wherever it is taught and studied. But patriotism and power are unfortunately oftener directed to deeds of splendour and History. magnificence, than they are occupied in forming and accomplishing the humbler and more permanent plans of national utility.

But to resume our narrative of the history of mineralogy, we cannot help expressing our regret that Mr Kirwan has never found it convenient to revise and improve his system as he might have done, aided by the immense stock of mineralogical knowledge which has been accumulated since its first publication. This is the more to be regretted, because, notwithstanding the rapid progress of the science, and the great improvements which the system of Werner has received, no good or even tolerable account of it has yet appeared in the English language.

France, where many branches of natural history have long flourished, has contributed largely to the science of mineralogy. Even the period of war, which at first sight would appear to be extremely adverse to the tranquil pursuits of knowledge, has in this case proved peculiarly favourable to the study of mineralogy in that kingdom. The knowledge of minerals has not only been encouraged and promoted in France, by being forced to direct her attention to her own resources, while her intercourse with other countries from which she derived various commodities indispensably necessary for economical purposes was interrupted; but also by the subjugation to her overgrown power, of those parts of Europe where mineralogy has been most cultivated and improved, thus affording every facility of correspondence, and rendering accessible those mineral treasures which exhibit the best and fullest illustration of the science. The French government, indeed, whatever form it may have assumed, has invariably been impressed with the importance of mineralogy; and even during the horrors of revolution, has never failed to promote its progress, by forming and supporting extensive collections, and establishing able and enlightened teachers at the expence of the nation.

Of the works on mineralogy which have appeared in France, we shall only mention the treatises of Brochant, Hauy, and Brongniart. They are the sources from which the information in the following treatise is chiefly derived, and they may be recommended as the best guides to the study of this department of natural history. The system of Brochant is formed entirely on the prin-Brochant ciples of Werner's classification, and is undoubtedly the most perspicuous account of the system of the German mineralogist which has yet been published. The principles on which the elaborate and ingenious method of arrangement proposed by the celebrated Hauy have been already detailed. (See CRYSTALLIZATION). Here we shall only remark that the study of the regular forms of minerals with a view to methodical arrangement, was successfully prosecuted by Bergman and Romé de Lisle ; but has been extended and carried to the highest degree of perfection by the sagacity, profound physical knowledge, and mathematical address of the Abbe Hany. But although the mineral system of Hauy R 2 this

(A) The Right Honourable John Forster, late Speaker of the Irish House of Commons, and the Right Honourable W. B. Cunningham.

History. this distinguished philosopher be founded on characters the most certain and the most uniformly permanent, yet it may be doubted whether the previous knowledge necessary to understand it, and in some cases the difficulty of applying its principles in ascertaining some of the most essential characters, may not preclude this work from being so generally and practically useful as other systems. The scientific mineralogist, however, will always regard it as a monument of indefatigable industry and patient research which has rarely been equalled, and will derive from it the most material aid in his studies.

The system of Hauy consists of four classes. I. The first class consists of substances which are composed of an acid united to an earth or an alkali, and sometimes to both; and it contains three orders: 1. Earths combined with an acid; 2. Alkalies combined with an acid; and, 3. Earths and alkalies combined with an acid. II. This class includes only earthy substances, but sometimes combined with an alkali. It constitutes the siliceous genus of other systems. III. The third class comprehends combustible substances which are not mctals. It is divided into two orders; the first containing simple, and the second compound combustibles. IV. The metals form the fourth class. It is divided into three orders, which are characterized by different degrees of oxidation. Besides these classes there are three appendices. The first contains those substances whose nature is not sufficiently known to have their places accurately assigned in the system. The second appendix includes aggregates of different mineral substances. It is divided into three orders. The first treats of primitive rocks; the second of secondary and tertiary rocks; and the third of breccias. The third appendix is devoted to the consideration of volcanic products. This is divided into six classes ; but it is

to be observed, that the volcanic products of this mine- History ralogist comprehend, not only such substances as are universally allowed to have a volcanic origin, but also basalts, traps, and other minerals, the origin of which is still questioned.

The system of Brongniart takes a wider range than Brongnia other systems, including substances which are not treated of by writers on mineralogy. It is divided into five classes. The first contains those substances, excluding the metals, which are combined with oxygen. It contains two orders; the first including air and water, and the second the acids. The second class, which treats of saline bodics, is divided into two orders : the first comprehends the alkaline salts, and the second the carthy salts. The third class, containing the stones, is divided into three orders : the first, hard stones; the second magnesian; and the third argillaccous. The fourth class contains the combustible substances, which are divided into two orders; first compound, and se-cond, simple combustibles. The fifth class includes the metals, which are divided into two orders; first, the brittle, and second the ductile metals. The treatise of Brongniart, notwithstanding some peculiarities in the classification which are not quite familiar to us, will be found one of the most useful that has hitherto appeared, not only on account of the accuracy of the descriptions, which arc divested of every kind of rcdundancy, but also on account of the interesting geological discussions which are introduced, as well as numerous and important practical details in metallurgy and other useful arts.

The following treatise will be divided into two parts. The first part will contain the classification and description of minerals; and the second part will be destined to the analysis of minerals and to metallurgy, or the method of extracting metals from their ores.

PART I. OF THE CLASSIFICATION OF MINERALS.

THE method to be followed in this treatise is nearly that of Werner, all the material parts of which we shall freely borrow from the work of Brochant already noticed, as the best on the subject which we have had an opportunity of consulting. We shall, however, occasionally avail ourselves of any useful information which may be derived from the mineralogy of Kirwan, Brongniart, and Hauy; and in particular we shall insert the essential characters of the species given by the latter. The universal characters employed by Werner in the description of minerals arc seven in number: I. Colour; 2. Cohesion; 3. Unctuosity; 4. Coldness; 5. Weight; 6. Smell; 7. Taste. The table and the illustrations which follow are chiefly taken from Weaver's translation of Werner's treatise on that subicct.

In the following table is exhibited the arrangement of the generic external characters of fossils.

EXTERNAL CHARACTERS of Minerals arranged according to their respective generic characters, and illustrated by appropriate examples.

Common Generic External Characters.

I. THE COLOUR.

The most obvious of the external characters of minerals, is colour; it is also one of the most certain characters, and often serves as the principal distinguishing mark of many mineral substances. In deriving the characters of minerals from colour, three things are considered: r. The several principal colours, with their varieties. 2. The shade of colour. 3. The tarnished colours.

I. Principal Colours.

The several principal colours are not derived from the division of the solar ray by means of the prism, but are such as are considered simple in common life. The principal colours are the eight following; viz. white, gray, black, blue, green, yellow, red, and brown.

gray, black, blue, green, yellow, red, and brown. A. WHITE is the first principal colour, and it includes the following eight varieties.

1. Snow white, as snow white quartz, white lead ore, Carrara marble.

2. Reddish

art I.

Classifica- 2. Reddish white, as porcelain earth, reddish white tion. quartz.

3. Yellowish white, as white amber, zeolite, chalk.

4. Silver white, as native silver, native bismuth, and arsenical pyrites.

5. Grayish white, as several kinds of gypsum, quartz, and foliated granular limestone.

6. Greenish white, as white amianthus, talc, and calcareous spar.

7. Milk white, as calcedony, opal, and milk white quartz.

8. *Tin white*, as native quicksilver, native antimony, and white cobalt ore.

B. GRAY is the second principal colour, and its varieties are the following.

1. Lead gray, as in common galena, compact galena, gray antimonial ore, and vitreous copper ore.

2. Bluish gray, as in bluish gray clay, bluish gray marble, and bluish gray limestone.

3. Pearl gray, as in quartz, calcedony, and porcelain jasper.

4. Reddish gray, as in granular limestone and feldspar.

5. Smoke gray, as in gray hornstone, and in dark gray flint.

6. Greenish gray, as in cat's eye, prehnite, and some varieties of argillaccous schistus.

7. Ycllowish gray, as in yellowish gray calcedony, yellowish gray tripoli.

8. Steel gray, as in specular iron ore, gray copper ore, striated gray ore of mangauese.

9. Ash gray, as in quartz, wacken, and some varieties of argillaceous schistus.

C. BLACK, which is the third principal colour, is divided into the six following varieties.

I. Grayish black, as in basalt, black limestone, and black flint.

2. Brownish black, as in black blende, tiu-stone crystals, black cobalt ore, and bituminous shale.

3. Dark black, or velvet black, as in Iceland agate or obsidian, schorl, and jet.

4. Iron black, as in micaceous iron ore, magnetic iron stone, and sometimes in antimoniated silver ore.

5. Greenish black, as in pitchstone, hornblende, and serpentine.

6. *Bluish black*, as in aluminous shale, black cobalt ore, dull black lead ore.

D. BLUE is the fourth principal colour, including seven varieties.

1. Indigo blue, as in blue martial earth.

2. Prussian blue, as in the sapphire and blue rock salt.

3. Azure blue, as in lapis lazuli, and azure copper ore.

4. Violet blue, as in fluor spar, amethyst, and in rock salt.

5. Lavender blue, as in a variety of porcelain, jasper, and lithomarga.

6. Smalt blue, as in light azure copper ore, and blue martial earth.

7. Sky blue, as in light azure copper ore, blue native vitriol, and sky blue fluor spar.

E. GREEN is the fifth principal colour, of which there are the following varieties.

1. Verdigrease green, as in green copper ore, green Classificut fluor spar.

2. Celadon green, as in the Brasilian beryl, and in pure green earth.

3. Mountain green, as in actynolite, hornstone, and in most beryls.

4. Emerald green, as in fibrous malachite and fluor spar.

5. Leek green, as in actynolite, jade, and prasium.

6. Apple green, as in chrysolite, prehnite, and nickel ore.

7. Grass green, as in some varieties of chrysoprase and some green lead ores.

8. *Pistachio green*, as in chrysolite, iron shot green copper ore.

9. Asparagus green, as in chryso beryl, and some varietes of green lead ore.

10. Olive green, as in green lead ore, serpentine, pitchstone, and garnet.

11. Blackish green, as in dark green serpentine.

12. Canary green, as in green lead ore, micaceous uranitic orc, and green steatites.

F. YELLOW is the sixth of the principal colours. It includes 12 varieties, which are the following.

1. Sulphur yellow, as in native sulphur and some varieties of serpentine.

2. Lemon yellow, as in yellow orpiment, and some yellow lead ores.

3. Gold yellow, as in native gold.

4. Bell metal yellow, as in iron pyrites.

5. Straw yellow, as in calamine and bismuth ochre.

6. Wine yellow, as in Saxon topaz and yellow calcareous spar.

7. Isabella yellow, as in calamine and sparry iron ore. 8. Ochre yellow, as in iron ochre, yellow jasper, and

calamine. 9. Orange yellow, as in red orpiment and red lead ore.

10. Honey yellow, as in amber fluor spar and calcedony.

11. Wax yellow, as in yellow lead ore, common opal, and calcedony.

12. Brass yellow, as in copper pyrites, and native gold.

G. RED is the seventh principal colour, and it includes the following 15 varieties.

1. Morning or aurora red, as in red lead ore, red orpiment.

2. Hyacinth red, as in the hyacinth, and a variety of brown blende.

3. Brick red, as in porcelain jasper.

4. Scarlet red, as in light red cinnabar.

5. Copper red, as in native copper.

6. Blood red, as in Bohemian garnet, and red carnelian.

7. Carmine red, as in red copper ore, and clear red cinnabar.

8. Cochineal red, as in cinnabar, sometimes jasper, and red quartz.

9. Crimson red, as in ruby, oriental garnet, and red cobalt ore.

10. Columbine red, as in precious garnet, and red cobalt ore.

11. *Flesh red*, as in feldspar, red gypsum, red quartz, and flesh red barytes.

12. Rose

Part

assificaruby. tion.

13. Peach blossom red, as in striated and earthy red cobalt ores.

14. Cherry red, as in red antimony ore and ruby.

15. Brownisk red, as in red argillaceous iron stone, and red earthy iron stone.

H. BROWN is the eighth and last of the principal colours. It is divided into the eight following varieties.

1. Reddish brown, as in brown tin stone, and brown blende.

2. Clove brown, as in rock crystal, brown iron ore, and thumerstone.

3. Hair brown, as in wood tin ore from Cornwall.

4. Yellowish brown, as in brown iron ochre and jasper.

5. Tombac brown, or pinchbeck brown, as in brown mica.

6. Wood brown, as in bituminous wood, a variety of asbestus.

7. Liver brown, as in brown cobalt ore, and brown iasper.

8. Blackish brown, as in lowland argillaceous iron ore, mineral pitch, and bituminous wood.

II. Shade or Intensity of Colour.

Colours may be determined by the relation in which they stand to each other with regard to intensity or shade. Thus among the principal colours, there are some which are light, as white and yellow; and some which are dark, as blue and black; and besides, the varieties of the principal colours differ from each other in respect to shade. Thus among the blue colours, indigo blue is dark, azure blue clear, and sky blue light; and even the varieties may afford a diversity of shade, as, for instance, clear canary green, light canary green.

Here it ought to be remarked, that the peculiar shade of colour in a mineral is frequently owing to its greater or less transparency, the paleness being in proportion to the degree of transparency, and the darkness to the de-gree of opacity. The degree of lustre also in minerals produces great variety in the shade of colour.

In discriminating the shade or intensity of colour, four degrees have only in general been adopted. These are the following. 1. Dark. 2. Clear. 3. Light. 4. Pale.

1. Dark, as in Bohemian garnet, which is dark blood red.

2. Clear, as in green hornstone, which is clear mountain green.

3. Light, as in red carnelian, which is light blood red.

4. Pale, as in aquamarine, which is pale mountain green.

III. Tarnished Colours.

Tarnished colours afford peculiar characteristic marks of many minerals. By tarnishing, is meant a difference in the colour of the surface after exposure to the air from what the fresh fracture of the mineral exhibits.

Some minerals are always found tarnished in their natural position in the earth, as in common galena, gray ore of antimony and blende: some tarnish on every fresh fracture being made, as in native arsenic and copper pyrites ; while others are tarnished in both cases, Classificaas in native arsenic, and purple copper ore. tion.

The colours of tarnished minerals are divided into, I. Simple, and 2. Variegated.

I. SIMPLE TARNISHED COLOURS afford five varieties. a. Gray is the tarnished colour of white cobalt ore, and steel gray of brown hematites.

b. Black is the tarnished colour of native arsenic, brown hematites, and gray cobalt ore.

c. Brown is the tarnished colour of native silver, which is white.

d. Reddish, of native bismuth, the fresh fracture of which is silver white.

e. Yellowish, of white cobalt ore, and argentiferous arsenical pyrites.

2. VARIEGATED TARNISHED COLOURS include four varieties.

a. Pavonine tarnished, as in copper pyrites, purple copper ore and common pyrites.

b. Iridescent tarnished, as in gray antimonial ore, galena, specular iron ore.

c. Columbine tarnished, as in copper pyrites.

d. Steel-coloured tarnished, as in gray cobalt ore.

IV. The Play of Colour.

The play of colour in a mineral can only be observ ed in sunshine or in a strong light. By this is understood that property which some minerals possess of refracting from particular spots the different rays of light. This effect is produced by the peculiar association of the molecules of the mineral, and the various degrees of its transparency. Accidental causes, however, produce a similar effect, such as slight rifts, cracks, &c.

The play of colour is remarkable in the diamond and in the opal, and sometimes in rock crystal.

V. The Mutable Reflection of Colour.

This is distinguished from the play of colour by the mineral exhibiting in the same spot a change of colour according to the position of its surface being varied, producing a different angle with the incident rays of light. This change takes place, 1. On the surface; 2. Internally.

1. The superficial mutable reflection is finely exemplified in Labrador stone, and in a variety of marble which contains petrified shells.

2. The internal mutable reflection of colour appears in cat's eye, precious opal, and moonstone.

VI. The Mutation of Colour.

This is distinguished from the tarnish; in which latter the surface only undergoes a change of colour, but in the mutation of colour, the effect penetrates the mineral, and sometimes pervades the whole. This affords two varieties.

1. The fading of colour.-By this is meant that the colour of a mineral becomes paler when it is exposed to the light, heat, or is undergoing decomposition. Examples of these changes may be observed in striated red cobalt ore, which exposed to the air becomes pale brownish ; blue fluor spar becomes green ; chrysoprase becomes light green; pearl gray silver ore becomes clear brown.

2. The perfect change of colour is often the consequence of fading, when one colour is lost, and a new one

Classifica- one appears, as in light-coloured sparry iron ore; eartion. thy gray, ore of manganese, and argillaceous iron stone.

VII. Delineations of Colours.

The delincations of colours are observed on simple minerals, the same specimen containing several colours, which pass through its interior, according to certain delineations. Of these delineations the following nine varieties are described.

1. Dotted, when fine points of another colour are dispersed over the surface, as in scrpentine, and some varieties of jasper.

2. Spotted, when the points or spots are of the size of a lentil to that of a sixpence, or from one-fourth to one inch in diameter. The spots are round and regular, or irregular.

a. Regular, as in some varieties of serpentine, and in argillaceous schistus.

b. Irregular, as in a variety of marble from Bayreuth.

3. Nebulous or cloudy, when the spots are large and irregular, forming with the ground colour the appearance of clouds, as in calcedony and jasper.

4. *Flamy*, when the spots are large, and drawn in one direction to a sharp point, as in striped jasper and some marbles.

5. Striped, when large spots are drawn in the same direction, and run parallel through the whole specimen. There are two varieties.

a. Straight or curved striped, as in straight striped jasper.

b. Broad or linear, as in linear striped agate, calcedony, &c.

6. Annular, when the stripes form concentric circles, as in jasper, carnelian, and flints.

7. Dendritic, when the delineation resembles the trunk of a tree separating into ramifications, as in steatites, some limestones, Egyptian marble, and calcedony.

8. Ruinous, when the delineation presents the appearance of ruins, as in Florentine or landscape marble.

9. Veined, when the delineation consists of variously coloured narrow stripes, crossing each other in different directions, forming sometimes the appearance of a net, as in marble, serpentine, and jasper.

II. THE COHESION OF THE PARTICLES.

The cohesion of the particles in minerals is the second common generic character, which is observed by the sight, and also by the touch. According to this property, minerals are divided into solid, friable, and fluid; but these properties also belong to the particular generic characters of minerals, to be afterwards described.

Particular Generic External Characters of Solid Minerals.

I. THE EXTERNAL APPEARANCE.

In the external appearance of a mineral, three things are to be observed, the external form, the external surface, and the external lustre.

4. The external form of a mineral is that figure or

shape of the natural surface, which its primitive individuals are found to possess. The external forms of solid minerals are distinguished into common, particular, regular or crystallized, and extraneous.

1. Common External Shape.

When a mineral exhibits no resemblance to any known substances in common life, it is said to be of a common form. Of common forms there are six kinds.

A. Massive, when a mineral is of an indeterminate form, or amorphous, and of nearly equal dimensions, from the size of a hazel nut to the greatest magnitude, and when it is incorporated with another solid mineral, it is said to be massive. Solid minerals are most frequently found of this external form, and some are never found otherwise, as in steatites, common pit-coal, galena, and copper pyrites.

B. Disseminated, or interspersed, when a mineral, without any particular form, is in small pieces not exceeding the size of a hazel nut, incorporated with another solid mineral. This affords three varieties.

a. Coarsely interspersed, in size of a hazel nut to that of a pea, as in copper pyrites.

b. Finely interspersed, from the size of a pea to that of a grain of millet, as in tinstone, in granular quartz.

c. Minutely interspersed, from the size of a grain of millet till it is scarcely perceptible to the eye, as in interspersed native gold.

C. In angular pieces, of which there are two varieties.

a. Sharp-cornered, as in calcedony and in quartz.

b. Blunt-cornered, as in common opal.

D. In grains. Detached minerals, from the size of a hazel nut to that which may be distinguished by the cye, are said to be in grains. These are distinguished, *a*. According to size, into

«. In gross grains from the size of a hazel nut to that of a pea, as in lowland argillaccous iron ore.

S. Large grains, from the size of a pea to that of a hemp seed, as in precious garnet, magnetic iron sand.

7. Small grains, from the size of hemp seed to that of millet, as in the above minerals.

3. In minute or fine grains, such as are smaller than millet seeds, as platina, native gold, tinstone.

b. According to the form, which is in

a. Angular grains, as in magnetic iron sand.

B. Rounded grains, as in platina and native gold.

c. According as they inhere in other minerals. In this respect they are, &. Loose, B. Partially, or γ .

Wholly. E. In plates, distinguished into

L. In plates, distinguished into

a. Thick plates, as in rcd silver ore.b. Thin plates, as in vitreous silver ore.

F. In membranes or flakes, when the thickness does

not much exceed that of paper, divided into

a. Thick, as in native silver.

b. Thin, as in iron pyrites.

c. Very thin, as in vitreous silver ore.

2. Particular External Forms.

The forms which come under this denomination exhibit a greater or less resemblance, both to natural and artificial objects. They are called particular, because, like the former, they are not usual or common. There

136

assifica. There are five kinds of particular external forms, viz.

irt I.

A. ELONGATED. Of this there are eleven varietics. a. Dentiform, as in native silver, and dentiform vitreous silver ore.

b. Filiform, as in native silver, and vitreous silver ore.

c. Capillary, resembling hairs, as in native gold and native silver.

d. Reticnlated, as in native silver, native copper, and a variety of galena.

e. Dendritic, which is either regular or irregular, as in native silver and native copper.

f. Coralliform, as in calcareous stalactites, commonly known by the name of *flos forri*, and brown hæmatites.

g. Stalactitiform, as in calcareous sinter, brown iron stone, and calcedony.

h. Tubuliform, as in compact brown iron stone, and galena.

i. Fistuliform, as in martial pyrites.

k. Frutescent, or arbustiform, as in black iron stone, and compact gray ore of manganese.

1. Matrasiform, having the figure of a chemical matrass, as in black hæmatites, and gray ore of manganese.

B. ROUNDED, of which there are five varieties.

a. Botryform, resembling a bunch of grapes, as in black cobalt ore, malachite, and copper pyrites.

b. Globular, of which there are five varieties.

a. Perfectly globular, as in pisolite, and white cobalt ore.

B. Elliptical, as in quartz and flint.

y. Amygdaloid, as in zeolite and green earth.

S. Spheroidal, as in Egyptian jasper and calcedony.

s. Imperfectly globular, as in carnelian and calcedony.

c. Kidneyform, as in red hæmatites, native arsenie, and malachite.

d. Bulbous or nodular, as in nodular flint and martial pyrites.

e. Liquiform, as in a singular variety of galena, from Freyberg.

C. FLATTENED. Of the particular forms of this denomination there are three kinds.

a. Specular, as in compact galena, and compact red iron stone.

b. In *laminæ* or *leaves*, which form is peculiar to metals, as in native gold and silver.

c. Pectinated, as in quartz from Schemnitz.

D. IMPRESSED. Particular forms of these afford six varieties.

a. Cellular, of which there are several kinds, as,

a. Straight cellular, which presents two varieties. J. Hexahedral, as in quartz; 2. Polyhedral, as in cellular quartz and calcareous spar.

β. Round cellular, as, I. Parallel round, as in quartz;
2. Spongiform, as also in quartz;
3. Indeterminate, as in brown iron stone;
4. Double, as in quartz and hepatic pyrites;
5. Veiny, as in white cobalt ore.

b. With impressions, which are,

a. Cubical, as in quartz and fluor spar.

B. Pyramidal, as in quartz, fluor spar, and vitreous silver ore.

y. Conical, as in native arsenic and quartz.

3. Tabular or prismatic, as in quartz.

s. Globular, as in vitreous silver ore.

VOL. XIV. Part I.

c. Perforated, as in lowland argillaceous iron orc. d. Corroded, as in quartz, galena, and vitreoussilver ore. e. Heteromorphous, as in native iron, swampy iron ore, and native arsenic.

f. Vcsicular, as in lavas, pumice stones, basalt, and wacken.

E. CONFUSED, of which there is only one variety.

a. Ramose, as in native iron, sometimes native copper, and vitreous silver ore.

3. Regular External Forms or Crystallizations.

In describing crystallizations or regular forms of minerals, four things are to be considered; the essential quality of the crystals; the form, aggregation, and magnitude.

A. THE ESSENTIAL QUALITY OF CRYSTALS, WHICH IS EITHER GENUINE OR SPURIOUS.

a. Genuine or true crystals, which are the most common, as in calcareous and fluor spars.

b. Spurious or after crystals, which are distinguished from true crystals by being hollow, having a rough or drusy surface, and the solid angles or edges never sharp or well defined. Examples are found in quartz of the spurious crystals of the cube, and of the octahedron of fluor spar.

B. FORM OF CRYSTALS. This is the most conspicuous property of crystals, and commonly serves as a distinctive character of those minerals which have regular forms. The form of crystals is composed of planes; of edges formed by the junction of two planes; of determinate angles, and of solid angles formed by the union of three or more planes in one point.

«. In the form of crystals, the primary or fundamental forms are first to be considered, and then the variations or modifications of these forms.

I. THE PARTS OF THE PRIMARY FORM ARE,

I. Planes, which are either

a. Lateral planes, forming the confines of the body towards its smallest extent; or, b. Extreme or terminal planes, which form the confines of the body towards its greatest extent.

2. Edges, which are,

+

.a. Lateral edges, or, b. Extreme edges.

3. Solid angles, which have been defined above.

II. KINDS OF PRIMARY FORMS, which are the seven following.

I. The Icosahedron, which is composed of 20 equilateral triangular planes, united under equal angles, as in iron pyrites.

iron pyrites. 2. The Dodecahedron, which is composed of twelve regular, pentangular planes, united under equal obtuse angles, as in iron pyrites, and white cobalt ore.

3. The Hexahedron, including the cube and the rhomb, is composed of six quadrilateral planes, as in calcareous spar, fluor spar, iron pyrites, galena, &c.

careous spar, fluor spar, iron pyrites, galena, &c. 4. *The Prism*, which is one of the most common crystallizations among minerals, is composed of an indeterminate number of quadrangular lateral planes, having the same direction, and all terminating in two extreme planes, each of which has as many sides as the crystallization possesses lateral planes; as in various lead ores, rock crystal, topaz, and shorl.

5. The Pyramid is composed of an indeterminate number of triangular lateral planes, converging to a S point,

137

Classification. Classifica- point, and of a base having as many sides as the crytion. stallization has lateral planes; as in quartz, calcareous spar, and amethyst.

6. The Table, which is composed of two parallel lateral planes, much larger in comparison than the other planes; the extreme planes being indeterminate in number, small, and narrow; as in tabular crystallized specular iron ore, calcareous spar, and heavy spar.

7. The Lens, consists of two lateral planes only, differing according as the lateral planes are differently curved. Of this there are two kinds: 1. The common lens, composed of two convex lateral planes; and, 2. The selliform, consisting of one convex and one lateral plane, somewhat resembling a saddle. Crystals of both kinds are observed in sparry iron ore and calcareous spar.

III. DIFFERENCES IN EACH KIND OF PRIMARY FORMS.

These primary forms differ from each other according to simplicity, position, number of planes, size of the planes, angles under which they meet, direction of the planes, and fulness of the crystal.

1. Simplicity. This distinction is confined to the pyramid, which is either,

A. Simple, as in light red silver orc, gray copper orc, quartz, amethyst; and

B. Double, in which those of the one pyramid are either,

a. Set on the lateral planes of the other, and this w. directly, or β obliquely; or b. on the lateral edges of the other. Examples of this are observed in double pyramidal vitreous silver ore, galena, rock crystal, ruby, and diamond.

2. Position, which is either,

A. Erect, which is very common; or, B. Inverted, which has only been observed in simple hexahedral pyramidal crystals of calcareous spar.

3. Number of Planes, in the primary form, is in some determinate, and in the others variable. Here are to be considered,

A. The kind of planes, as

a. In the prism and pyramid, in which the lateral planes vary; and, b. In the table, in which the extreme planes vary.

treme planes vary. B. The number of planes, which in the prism and pyramid are found,

a. Trihedral, having three planes, as in the trihedral prism of shorl, and the trihedral pyramid of gray copper ore.

b. Tetrahedral, having four planes, as in the tetrahedral prism of arsenical pyrites, and in the double tetrahedral pyramid of ruby and galena.

c. Hexahedral, as in the hexahedral prism and pyramid of calcareous spar.

d. Octahedral, as in the octahedral prism of topaz; and in the double octahedral pyramid of garnet and zeolite.

The table occurs,

a. Quadragonal, having four extreme planes, as in heavy spar, yellow lead ore, and calamine.

b. Hexagonal, having six extreme planes, as in mica and heavy spar.

c. Octagonal, or with eight extreme planes, as in yellow lead ore and heavy spar.

4. The size of the planes, in relation to each other, Classific which are said to be,

A. Equal, or

B. Unequal; and this latter is either indeterminate, or determinate.

a. Indeterminate, which is observed in the lateral planes of the hexahedral prism of rock crystal.

b. Determinately unequal, as in prismatic white lead ore, and hexahedral prismatic calcareous spar. In this latter the following varieties are observed.

a. Alternately broad and narrow. B. The two opposite broader; and, y. The two opposite narrower.

5. Angles under which the planes are associated. These are angles of the lateral edges, of the extreme edges, and of the summit.

A. Angles of the lateral edges. These are,

a. Equiangular, as in the icosahedral crystals of ironpyrites.

b. Rectangular, as in cubical fluor spar.

c. Oblique angular, as in rhomboidal calcareous spar.

d. Unequiangular, as in the hexahedral prism of rock crystal, and in the octahedral prism of topaz.

A. Angles of the extreme edges are,

a. Equiangular, as in the hexagonal table of mica.

b. Rectangular, as in the quadragonal table of heavy spar.

c. Oblique angular, which is either, α . Parallel, as in the tetrahedral prism of feldspar; or, β . Alternate oblique angular, as in copper pyrites.

d. Unequiangular, as in the hexagonal table of prehnite.

C. Angles of the summit, which are confined to the pyramid, and present the following varieties.

a. Very obtuse, when the angle is from 150° to 130°, as in tourmalin.

b. Obtuse, when the angle is from 130° to 110°, as in calcareous spar.

c. Rather obtuse, from 110° to 90°, as in honey stone.

d. Rectangular, as in zircon.

e. Rather acute, from 90°, to 70°, as in quartz.

f. Acute, from 70° to 50°, as in calcareous spar.

g. Very acute, from 50° to 30°, as in sapphire.

6. The direction of the lateral planes. These are either straight or curvated.

A. Straight planes are even surfaces, and are the most common.

B. Curvated planes are distinguished according to position and form.

a. Position, which is, α . Inwardly curvated or concave; or, β . Outwardly curvated or convex; and, γ . Inwardly and outwardly curvated, or concave and convex. The first is observed in fluor spar, the second in diamond, and the third in sparry iron stone.

b. The form is either, α . Spherical, as in brown spar; β . Cylindrical, in which the curvature runs, 1. Parallel to the sides, as in iron pyrites, or, 2. Parallel to the diagonal, as in fluor spar; and, γ . Conical, as in gypsum.

7. The fulness of the crystal. Crystals are either full and perfect, or hollowed at the extremity, or throughout.

A. Full or perfect crystals, which is most commonly the case.

B. Hollowed

B. Hollowed at the extremity, as in calcareous spar, lassificagreen lead ore, &c.

C. Hollow through the whole crystal, as in prismatic beryl.

β. Modifications of the primary form.

The changes or alterations which take place on the principal or fundamental form, are three; truncation, bevelling, and acumination.

I. TRUNCATION. In the truncation are to be considered the parts and the determination.

1. The parts of the truncation arc the planes, the edges, and the angles.

2. The determination of the truncation relates to,

a. The situation as it occurs at the angles or edges of the primary form.

b. Its magnitude, which, in relation to the planes of the primary form, is small or large : in the one case the angles or edges are said to be slightly, in the other deeply truncated.

c. The application of the truncation, which is either direct or oblique. The edges of cubical iron pyrites afford an example of oblique truucation.

d. The direction of the truncation, which presents either an even or a curvated surface.

Cubical galena, with truncated angles; tetrahedral prismatic tin stone crystals, with truncated edges; double tetrahedral pyramidal tin stone crystals, with truncated edges, are instances of truncation.

II. BEVELLING, in which the parts and determination are also to be considered.

1. The parts of the bevelling are, the planes, the edges, and the angles. The bevelling edges are distinguished into the proper bevelling edge, which is formed by the conjunction of the bevelling planes, and the bevelling edges formed by the junction of the bevelling planes with the lateral planes of the primary form. 2. The determination of the bevelling, in which is

to be observed,

A. Its situation as it takes place, a. At the extreme planes, which is confined to the prism and table; b. At the edges, which is mct with in the hexahedron, prism, pyramid, and table : and, c. At the angles, which is a very rare occurrence.

B. Its magnitude, which is said to be slight or deep. C. The angle under which the bevelling planes con-

join, which is said to be, a, Acutely, b. Rectangularly, or, c. Obtusely bevelled.

D. The continuation of the bevelling, which is either uninterrupted, or interrupted. Of the latter case there are two varieties, when it is once or twice interrupted. The lateral edges of double trihedral pyramidal calcareous spar are once interruptedly bevelled; and the obtuse extreme edges of quadrangular tabular heavy spar, are twice interruptedly bevelled.

E, The application, a. Of the bevelling itself, which is either direct or oblique (the former is the most common, and the latter occurs in prismatic basaltic hornblende); and, b. Of the bevelling planes, which are set, either on the lateral planes, or on the lateral edges.

III. THE ACUMINATION, in which are also to be considered the parts of the acumination and the determination.

1. The parts of the acumination consist of,

A. The acuminating planes. B. The acuminating edges ; which are distinguished into, a. Proper edges of acumination, formed by the junction of the acuminat- Classificaing planes; b. The extreme edges of acumination; tion. The edges between the acuminating and lateral c. planes. C. The angles of acumination.

2. The determination of the acumination relating to,

A. Its situation, as it occurs at a. The solid angles; or, b. At the extreme planes of the primary form. The acumination of the prism is always at the extreme planes; of the cube usually at the angles, and of the pyramid generally at the summit.

B. The planes themselves, in which are to be observed,

a. Their number, which is either equal to, or fewer than thoso of the primary form. In the hexahedral prism of calcareous spar and garnet, and in the trihedral prism of tourmaline, the acumination is by three planes; in the tetrahedral prism of jargon and hyacinth, by four planes; in the hexahedral prism of calcareous spar and rock crystal, by six planes; and in tetrahedral prismatic topaz, by eight planes.

b. Their relative size, which is either equal or unequal. In quartz and rock crystal, the planes of acumination aro generally indeterminately unequal; and in heavy spar they are determinately equal.

c. Their form, which is determinate, as in hyacinth and calcareous spar; or indeterminate, as in jargon and wolfram.

d. Their application, which is either on the lateral planes of the primary form, as in jargon and hyacinth, or on the lateral edges, as in calcareous spar and garnet.

C. The summit of the acumination, which is, a. Obtuse, as in hexahedral prismatic garnet; b. Rectangular, as in tetrahedral prismatic jargon; or, c. Acute, as in hexahedral prismatic calcareous spar.

D. The magnitude of the acumination, which is said to be, a. Slightly acuminated, as in gray copper ore and copper pyrites; or, b. Deeply, as in fluor spar, with the angles acuminated by 6 planes.

E. Determination of the acumination; which is either a point or a line. The first is the most common ; and the last is met with in prismatic white lead ore and heavy spar.

y. Manifold modifications of the primary form.

In these modifications crystals are cither, 1. Situated beside each other; or, 2. Placed the one above the other.

But in describing a crystallization, the number of its planes in general, and of each kind in particular, and their figure, if determinate, may be noticed, to render the description more accurate. As, for instance, cubical galena, with truncated angles, consist of 6 octangular and 4 triangular planes.

And still farther, in explaining the form of crystallizations, by way of addition may be mentioned,

1. The different modes of determination of which they are capable. Two different modes may in some cases be adopted.

a. The representative, by which is understood the description of a crystallization according to its apparent form; or,

b. The derivative, which is founded on the consideration of its derivation, and its relation to the other crystals of the same mineral. The prismatic crystallization of the tourmaline is representatively an enneahe-S 2 dral

tion.

Classifica- dral prism, and derivatively a trihedral prism, with the tion. three lateral sides bevelled.

But, in general, the chief or cssential form of a crystallization is determined by, a. The largest planes; b. The greatest regularity; c. The most frequent occurrence of the crystallizations; d. The affinity to the other primary forms; c. The suitableness and peculiarity of its modifications; and, f. The greatest simplicity in the mode of determination.

2. The transitions from one primary form into another. These arise,

a. From the gradually increased extent of the modifying planes, and the decreased extent of the primary planes; or,

b. From a change in the relative size of the planes; or,

c. From a change in the angles under which the planes are associated; or,

d. From the convexity of the planes; or,

e. From the aggregation of crystals.

3. The difficulties which are opposed to the exact determination of crystals. These proceed, *a*. From their compression, some planes being uncommonly large or small; or, *b*. From their penetrating each other, as in tin-stone crystals; or, *c*. From their partial concealment, as in feldspar, hornbleude, and garnet; or, *d*. From their being broken, as often happens in the crystallization of precious stones; or, *e*. From their extreme minuteness.

C. The aggregation of crystals. According to this, crystals are either,

a. Single, in which case they are, ω . Loose or detached, as in precious stones, cubical iron pyrites, &c.; β . Inhering or inlaying in another mineral, as feldspar in porphyry; or, γ . Adhering, as in quartz crystals; or,

b. Aggregated, which are either regular or irregular.

«. Regular or determinate; such are, 1. Twin crystals, as in staurolite or cross stone; and, 2. Triple crystals, as in calcareous spar and ruby: but this is very rare.

β. Many singly aggregated crystals, are such crystals as are, 1. Heaped upon one another, as in calcareous and fluor spars; 2. Adhering laterally, as in amethyst crystals; and, 3. Implicated one in the other, as in gray antimonial ore, and in the hexahedral prisms of calcareous spar.

v. Many doubly aggregated crystals are distributed according to the form they assume ; such as the following, are enumerated.

1. Scopiform, when aggregated, needle-like, and capilliform crystals diverge from a common centre, as in zeolite, striated red cobalt ore, and capilliform pyrites.

2. Fasciform, which is composed of double scopiform, with a common centre, as in calcareous spar, zeolite, and prehnite.

3. Acicular or columnar. Elongated, equally thick prisms adhering laterally together, are of this description, as in acicular heavy spar, and a variety of white lead ore.

4. In a row, like a string of pearls, as in pyramidal crystals of quartz.

5. Bud-like, in simple pyramids whose bases are con-

nected, and whose joints are directed towards each Classific other, as in bud-like drusen of quartz.

6. Globular, a casual aggregation, consisting mostly of tables or cubes, arranged in a globular form, as in octahedral iron pyrites.

7. Amygdaloid, when the tables are externally accumulated, smaller upon smaller, as in heavy spar.

8. *Pyramidal*, which takes place chiefly in prisms nearly parallel, the summits inclining to each other; the central prism being the highest, as in calcareous spar.

9. Rose-like, composed of thin tables, on whose lateral planes others are assembled, and arranged in a roselike appearance.

D. The magnitude of crystals, which is determined,

a. According to the greatest dimension, as α . Of an uncommon size, in crystals which exceed two feet, as in quartz and rock crystal; β . Very large, from two feet to six inches, as in rock crystal and calcareous spar; γ . Large, from six to two inches, as in iron pyrites, fluor spar, and garnet; δ . Of a middling size, from two inches to half an inch, which are very common; ϵ . Small, from half an inch to one-eighth of an inch, also very common; ζ . Very small, from one-eighth of an inch to such as may be distinguished by the naked eye, as in corneous silver ore, and very small tin stone crystals; n. Minute, whose form cannot be distinguished by the naked eye, as in native gold and green lead ore.

b. According to relative dimensions, when compared with others; and this is distinguished into α . Short or low, and long or high; β . Broad and narrow, or longated; γ . Thick and thin, or slender; δ . Needle-like and capilliform; ϵ . Spicular, and ζ . Globular or tessular.

4. Extraneous external forms, or petrifactions, which are divided into petrifactions of animals, and petrifactions of vegetables.

A. Petrifactions of animals, or zoolites, as

a. Of the class mammalia, the parts of which commonly found are the bones, the teeth, horns, and skeletons. Such are the bones of the elephant and the rhinoccros, which are found in Siberia, and the bones of the mammoth from North America.

b. Of birds, petrifactions of which are very rare. Some skeletons of aquatic birds have been met with in limestone near Oening.

c. Of amphibious animals, such as those of the tortoise, found in the same vicinity as the bones of the elephant; of frogs and toads, in the swinc stone of Oening; and of an animal resembling a crocodile in aluminous shale near Whitby in Yorkshirc.

d. Of fishes, of which whole fishes, skelctons, and impressions, have been found in different places.

c. Of insects, petrifactions of which are not very common, excepting insects, such as crabs, which have been frequently observed.

f. Of vermes, of which numerous petrifactions are found belonging to the orders *testacea*, *crustacea*, and *corallina* or corals.

B. Petrifactions of vegetables, which are less numerous in the mineral kingdom than those of animals. These are distinguished into,

a. Petrified wood, the most usual of which are pctrifactions of the trunk, branches, or roots of trees, and commonly nrt I.

assifica- commonly consisting of siliceous substances, as woodtion. stone, jasper, horn stone.

b. Impressions of leaves and plants, which are not uncommon in the strata of coal countries, particularly in the shale, sand stone, the argillaccous iron stone, and the coal itself.

II. THE EXTERNAL SURFACE, which is the second particular generic character of solid minerals; and this is,

1. Uneven, having irregular elevations and depressions, as in calcedony.

2. Granular, when the elevations are small, round, and nearly equal, as in stalactitical brown laematites.

3. Drusy, having minute, prominent, equal crystals on the surface, as in iron pyrites and quartz crystals.

4. Rough, when the elevations are minute and almost imperceptible, as in cellular quartz.

5. Scaly, when the surface is composed of slender splinters like scales, as in chrysolite.

6. Smooth, as in hæmatites and fluor spar.

7. Streaked, which is either singly or doubly streaked.

A. Singly streaked surfaces are,

a. Transversely, as in rock crystals; b. Longitudinally, as in topaz and prismatic shorl; c. Diagonally, as in specular iron ore; and d. Alternately, as in iron pyrites.

B. Doubly streaked, which is,

a. *Plumiformly*, or like a feather, as in native silver and native bismuth; and,

b. Retiformly, as in gray cobalt ore.

8. Rugose. Of slight linear elevations, as in calcedony.

III. THE EXTERNAL LUSTRE, in which are to be determined,

1. The intensity of the lustre, which is distinguished into different degrees, as

A. *Resplendent*, which is the strongest kind of lustre, as in native quicksilver, galena, and rock crystal.

B. Shining, as in gray copper ore, heavy spar, and pitch-stone.

C. Weakly shining, as in iron pyrites, fibrous gypsum, and garnet.

D. Glimmering, as in earthy tale, in the fracture of flint, and of steatites.

E. Dull, as in most friable minerals, as in earthy lead ore, monntain-cork, chalk, &c.

2. The kind of lustre, which is either common or metallic.

A. The common lustre belongs chiefly to earthy stones and salts. It is distinguished into

a. Glassy, as in quartz and rock crystal.

b. Waxy or greasy, as in opal, and in yellow and green lead ores.

c. Pearly, as in zeolite.

d. Diamond, as in white lead ore and diamond.

e. Semimetallic, as in mica and hæmatites.

B. Metallic lustre, which is peculiar to metals and most of their ores, as native gold and native silver, copper pyrites, and galena.

Appearance of the fracture..

Here, as in the external appearance, three kinds of

characters present themselves; I. The internal lustre; Classifica-II. The fracture; III. The form of the fragment.

I. The internal lustre, the characters of which are to be determined in the same manner as the external lustre.

II. The *fracture*, which is either compact or jointed. I. The compact fracture, which is distinguished into

splintery, conchoidal, uneven, earthy, and hackly.

A. Splintery, which is either

a. Coarse splintery, as in quartz, prase, and jade; or b. Fine splintery, as in hornstone and fine splintery limestone.

B. *Even*, which happens in minerals that are usually opake, and have only a glimmering lustre, as in compact galena, calcedony, and yellow carnelian.

C. Conchoidal, which is distinguished,

a. According to the size, into large and small.

b. According to the appearance, into perfect and imperfect; and

c. According to the depth, into deep and flat.

Flint, opal, jasper, and obsidian, afford examples of the conchoidal fracture.

D. Uneven, which is either,

a. Of a coarse grain, as in copper pyrites.

b. Of a small grain, as in gray copper ore, and

c. Of a fine grain, as in arsenical pyrites.

E. Earthy, which is the common fracture in earths and stones, as in marl, chalk, limestone.

F. Hackly, in which the fracture exhibits sharp points, which is peculiar to the metals, as in native gold and native copper.

2. The jointed fracture. This is divided into the fibrous, striated, foliated, and slaty.

A. The fibrous fracture, in which are to be observed,

a. The thickness of the fibres, as they are coarse, fine, or delicate, as gypsum, fine fibrous malachite, and in wood-tin-ore.

b. The direction of the fibres, which are straight, as in red hæmatites, and gray antimonial ore; or curved, as in black hæmatites, and fibrous rock salt.

c. The position of the fibres, which is ∞ . Parallel, as in rock salt and amianthus : β . Diverging, which is, 1. Stelliform, as in black hæmatites, and fibrous zcolite ; or, 2. Scopiform, as in fibrous malachite : or γ . Promiscuous, as in gray antimonial ore.

d. The length of the fibres, which is α . Long, as in gypsum and amianthus; or β . Short, as in red hæmatites.

B. Striated, in which are to be considered,"

a. The breadth of the striæ, which are, ∞ . Narrow, as in azure copper ore; β . Broad, as in actynolitc and hornblende; or γ . Very broad, as in sapphire and zeolite.

b. The direction of the striæ, which is either, ω . Straight, as in gray ore of manganese; or, β . Curved, as in zeolite and actynolite.

c. The position of the striæ, which is α . Parallel, as in asbestus and hornblende; β . Diverging, which is distinguished into stelliform, as in iron pyrites and zeolite, or scopiform, as in actynolite and limestone; or γ . Promiscuous, as in gray antimonial ore and actynolite.

d. Length of the strice, as being α . Long striated, as in asbestus and gray antimonial ore; or β . Short striated, as in actynolite.

Classifica- C. The foliated fracture, in which are to be detertion. mined,

a. The magnitude of the folia, as being a. Large foliated, as in mica and specular gypsum. β . Scaly foliated, which is distinguished into 1. Coarse, 2. Small, and 3. Fine scaly foliated, as in micaceous iron ore and gypsum. γ . Granularly foliated, which is distinguished into 1. Gross, 2. Coarse, 3. Small, and 4. Fine granularly foliated, as in sparry iron ore, blende, and calcareous spar.

b. The perfectness of the folia, as being α . Perfectly foliated, as in feldspar; β . Imperfectly foliated, as in topaz; or, γ . Concealed foliated, as in emcrald.

c. The direction of the folia, which is α . Straight, as in large foliated blende; or β . Curved foliated. The latter is distinguished into 1. Spherically curved, as in heavy spar; 2. Undularly curved, as in tale; 3. Petaloidally curved, as in galena; or, 4. Indeterminately curved, as in mica and specular gypsum.

d. The passage or cleavage of the folia, which is,

«. According to the angle which one passage forms with another; and this is either, 1. Rectangular, or, 2. oblique angular; or,

β. According to the number of the cleavages, and is either,

1. A single cleavage, as in mica and talc; 2. A double cleavage, as in feldspar and hornblende; 3. A triple cleavage, as in calcareous spar and sparry iron ore; 4. A quadruple cleavage, as in fluor spar; 5. A sextuple cleavage, as in yellow, brown, and black blende.

D. The slaty fracture, in which are to be determined the thickness and direction of the lamellæ.

a. The thickness of the lamellæ, which is either, α. Thick, or β. Thin slaty.

b. The direction of the lamellæ, as being either, w. Straight, or β . Curved slaty; the latter being distinguished into 1. Undularly, or 2. Indeterminately curved.

In some minerals which possess distinct parts, two kinds of fracture may be observed. Thus, in fibrous gypsum, and in red and brown hæmatites, both the fibrous and foliated fracture appear; the fibres are then intersected by the folia under a certain angle. In topaz, the transverse fracture is foliated, and the longitudinal fracture is conchoidal.

III. The form of the fragments, which is either regular or irregular.

1. Regular fragments, as when they are,

A. Cubical, as in galena and rock salt.

B. Rhomboidal, in which case the fragments are

a. Specular on all the planes, as in heavy spar;

b. On four planes, as in feldspar and hornblende; and,

c. On two planes, as in specular gypsum.

C. Trapezoidal fragments, &c.

D. Trihedral pyramidal fragments are rarely to be seen distinctly, excepting in fluor spar.

D. Dodecahedral fragments, as in blende.

2. Irregular fragments, as when they are,

a. Cuneiform, as in wood-tin-ore, and malachite.

B. Specular, as in amianthus.

C. Tabular, as in mica and talc.

D. Indeterminate, which are the most common among solid minerals, and are distinguished into

a. Very sharp edged, as in obsidian, common opal, Classifie and rock crystal.

b. Sharp edged, as in hornstone and quartz.

c. Moderately sharp edged, as in limestone.

d. Rather blunt edged, as in steatites ; and

c. Blunt edged, as in chalk and fullers earth. 3. The appearance of the distinct concretions.

In determining this character, the form of the distinct concretions, the surface of separation, and the

I. The form of the distinct concrctions, which is either granular, lamellar, columnar, or pyramidal.

1. Granular, distinct concretions are distinguished,

A. With respect to the form, into

a. Round granular, which is either α . Spherically round, as in roc stone and pisolite; or β . Lenticularly granular, as in argillaceous iron stone; or γ . Elongated round granular, as in quartz: and,

b. Angularly granular, which is either α . Common, as in galena and calcareous spar; or β . Elongated annularly granular, as in hornblende and granular limestone.

B. With regard to the size of the concretions. These are,

a. Gross granular, as in zeolite and blende.

b. Coarse granular, as in mica, galena, and pisolite.

c. Small granular, as in roe stone and garnet; and

d. Fine granular distinct concretions, as in granular limestone and galena.

2. Lamellar distinct concretions. The differences to be observed here are, with respect to the direction or form, and the thickness.

A. With respect to the direction or form, they are either,

a. Straight lamellar: and again either quite straight, as in some galena and heavy spar; or fortification-like, as in some amethyst and calcedony.

b. Curved lamellar, which is either indeterminate, as in galena and specular iron ore; reniform, as in fibrous malachite and native arsenic; or concentric, which is either spherical concentric, as in calcedony and pisolite, or conically concentric, as in some stalactites and hæmatites.

B. With regard to the thickness, as being

a. Very thick, the concretions exceeding one-half inch, as in amethyst and heavy spar.

b. Thick, the concretions being between one-half and one-fourth inch, as in heavy spar and native arsenic.

c. Thin, between one-fourth and one-half inch, as in calcedony.

d. Very thin, from a line to a thickness just perceptible to the maked eye, as in specular iron.

3. Columnar distinct concretions, which are distingnished with regard to the direction, thickness, form, and position.

A. The direction, which is either,

a. Straight columnar, as in schorl and calcareous spar, and.

b. Curved columnar, as in argillaceous iron stone, and specular iron ore.

B. The thickness is distinguished into,

a. Very thick, when the diameter exceeds two inches, as in basalt and quartz.

3

lustre of separation, are to be considered.
b. Thick columnar, from two inches to one-fourth ssificainch, as in amethyst and calcareous spar. ion.

c. Thin, from one-fourth to one-half inch, as in calcareous spar and argillaccous iron stone.

d. Very thin, the thickness being less than a line, as in schorl and columnar argillaceous iron stone.

C. The form of the concretions being either

a. Perfectly columnar, as in argillaceous iron stone.

b. Imperfectly, as in amethyst.

c. Cuneiform columnar, as in calcareous spar and arsenieal pyrites.

D. The position of the concretions, which is either

a. Parallel columnar, as in schorlite, or

b. Diverging or promiscuous columnar, as in schorl and arsenical pyrites.

4. Pyramidal distinct concretions. This form of conerction is very rare, and has been observed only in the basalt of Iceland, Faro, and Bohemia.

II. The surface of separation, which is distinguished into

1. Smooth, as in wood tin ore.

2. Rough, as in native arsenic.

3. Uneven, as in galena and blende; and

4. Streaked, which is either,

A. Longitudinally streaked, as in schorl and schorlite. B. Transversely and fortification-like, as in amethyst and specular iron ore.

III. The lustre of separation. This character is to be determined in the same manner as the external lustre.

4. The General Appearance.

This comprchends three particular generic characters, the transparency, the streak, and the stain.

1. The transparency, which is distinguished into the following five degrees.

1. Transparent, which is either,

A. Common, as when objects appear single through a transparent mineral; or,

B. Doubling, when objects appear double, as in caleareous spar, or double refracting spar, jargon, and chrysolite.

2. Semitransparent, as in opal and ealcedony.

3. Translucent, as in flint, cat's eye, and fluor spar. 4. Translucent at the edges, as in hornstone and foliated gypsum.

5. Opake, which is peculiar to minerals of a metallic lustre, as in malachite and jasper. II. The streak, which is either,

1. Of the same colour, or,

2. Different from that of the mineral, and whose lustre is the same; or,

B. More or less different.

In red silver ore the streak is a dark crimson red; in einnabar, scarlet red; in green lead ore, greenishwhite; in red lead ore, clear lemon yellow.

III. The stain. With respect to this character, minerals are distinguished into such as,

1. Simply stain, and this either strongly or weakly, as gray ore of manganese, and red sealy iron ore; and into such as

2. Both stain and mark, as chalk and plumbago; and

3. Such as do not stain.

Characters for the Touch.

Characters of this description are, hardness, soli-

dity, frangibility, flexibility, and adhesion to the Classificatongue. tion.

I. The hardness, which is determined by the following degrees.

1. Hard, as when a mineral gives fire with steel, but eannot be seraped with the knife. This character is distinguished into,

A. Hard, when the file makes a considerable impression, as in feldspar and schorl.

B. Very hard, on which it makes a weak impression, as in rock erystal and topaz.

C. Extremely hard, on which the file makes no impression, as diamond and emery.

2. Semihard may be slightly seraped with a knife, but gives no fire with steel, as red copper ore, blende, limestone.

3. Soft, easily scraped with the knife, as in galena, mica, asbestus.

4. Very soft, which receives an impression from the nail, as in gypsum, chalk, talc.

II. The solidity, according to which solid minerals -are distinguished into,

1. Brittle, when the particles are in the highest degree coherent and immoveable, as in quartz, gray copper ore, and copper pyrites.

2. Sectile, when the particles are coherent but not perfectly immoveable among one another, as in plumbago and galena.

3. Malleable, when the integrant particles are coherent and also more or less moveable among one another, as in the most of the native metals.

HI. The frangibility, with regard to which solid minerals are either,

1. Very difficultly frangible, as native metals, and massive common hornblende.

2. Difficultly frangible, as in prase, massive quartz, and asbestus.

3. Rather easily frangible, as iron pyrites, vitreous copper ore.

4. Easily frangible, as in galena, opal, and heavy spar.

5. Very easily frangible, as in amber and pitcoal. IV. The *flexibility*, according to which solid minerals are.

1. Flexible, which is distinguished into,

A. Common, as in malleable minerals, amianthus, gold ore.

B. Elastic, as in mica, elastic mineral pitch from Dcrbyshire.

2. Inflexible, such minerals as break when the direction of the fibres is changed.

V. The adhesion to the tongue, according to which some minerals possess this property

1. Strongly, as in hydrophane.

2. Rather strongly, as in bole and lithomarga.

3. Weakly, as talc.

4. Very weakly, as in elay.

5. No adhesion at all, as is the case with most minerals.

Characters for the Hearing.

I. The sound, which is distinguished into

1. Ringing or sounding, as in native arsenic and common slate.

2. Creaking, as in native amalgam when pressed with the finger.

3. Rustling,

Classifica- 3. Rustling, as in passing the finger over mountain cork and farinaceous zeolitc. tion.

2. Particular generic characters of friable minerals. The characters included under this title are the external form, the lustre, the appearance of the particles, the stain and the friability.

1. The external form, which is either massive, as in percelain earth; interspersed, as in black silver ore; as a thick or thin crust, as in black copper ore; spumiform, as in red and brown scaly iron ores ; dendritie, as gray ore of manganese; or reniform, as pure clay and earthy talc.

II. The lustre, which is determined as in solid minerals; but here it is distinguished,

1. With regard to intensity, as

A. Glimmering, as in earthy talc and scaly iron ore; and,

B. Dull, as in earthy lead ore and lithomarga.

2. With regard to the kind, as it is common or metallie.

111. The appearance of the particles, which is either, 1. Dusty, as in black copper ore, iron ochres.

2. Scaly, as in earthy tale.

IV. The stain is distinguished in friable minerals as being either

1. Strong, as in scaly iron ore.

2. Weak, as in earthy lead orcs.

V. The friability, with regard to which friable minerals are either,

1. Pulverulent, as earthy lead ores, and blue martial earth.

2. Loosely coherent, as scaly iron ore and clays.

3. Particular generic characters of fluid minerals. These characters relate to the external form, the lustre, the transparency, the fluidity, and the wetting of the fingers.

I. The external form, which is either,

1. In globules; and, 2. Liquiform; both which characters belong to native mercury.

II. The lustre, which is determined as formerly explained, and is either, 1. Common ; or, 2. Metallic, as in native mercury.

III. The transparency, of which three degrees are distinguished in fluid minerals : 1. Transparent, as in naphtha; 2. Turbid, as in petroleum; 3. Opake, as in native mercury.

IV. The fluidity, which is characterised by being, 1. Perfectly fluid, as mercury, and, 2. Cohesivc, as in mineral tar.

V. The wetting of the fingers. 1. Some fluid minerals wet the fingers, as mineral tar; and, 2. Some do not, as native mercury.

Remaining Common Generic External Characters.

The remaining common generic characters are the unctuosity; the coldness; the weight; the smell; and the taste.

III. The unctuosity, of which there are four degrees.

. r. Meagre, as is the case with most minerals.

2. Rather greasy, as pipe clay.

3. Greasy, as fullers earth and steatites.

4. Very greasy, as talk and plumbago.

IV. The coldness, which includes three degrees.

1. Cold, having the coldness of quartz, as hornstone, jasper, marble.

2. Rather cold, as serpentine, gypsum,

3. Slightly cold, as amber, pitcoal, and chalk.

By this character cut and polished stones may be distinguished, where some of the other characters are lost; and by it also natural gems may be distinguished from those which are artificial.

V. The weight .- This character is most accurately discovered by taking the specific gravity of a mineral by means of a hydrostatic balance. See HyDRODYNA-MICS. But when this cannot be had recourse to, a mineral is examined by lifting it in the hand, and comparing its weight, thus estimated by the feeling, with its volume, by which means an approximation may be made to its specific gravity. Five degrees of this mode of estimating the weight of minerals have been assumed.

1. Supernatant, such minerals as swim in water, as naphtha, mountain cork.

2. Light, such minerals as have a specific gravity between 1.000 and 2.000, (taking water at 1.000) as amber, mineral pitch, and pitcoal.

3. Rather heavy, are such minerals as have a specific gravity between 2.000 and 4.000, which is the case with most kinds of stones, as amianthus, rock crystal, mica, fluor spar, diamond.

4. Heavy, when the specific gravity is from 4.000 to 6.000, as in most metallic ores, such as gray copper ore, red hæmatites, white lead ore, and in some others as heavy spar.

5. Extremely heavy, when the specific gravity exceeds 6.000, which includes the native metals, as native gold, native copper, and native silver, and some others, as galena, tinstone crystals, sulphurated bismuth, and vitreous silver ore.

VI. The smell is characteristic of only a small num-, ber of minerals. It is observed either,

1. Of itself without addition, and is,

A. Bituminons, as mineral pitch and naphtha.

B. Slightly sulphureous, as in native sulphur and gray antimonial ore.

C. Bitterish, as in ochre kept close shut up for some time.

D. Clayey, as in yellow chalk.

2. After breathing on a mineral, which should be cold and breathed upon strongly and quickly, when the smell perceived is,

A. Clayey bitter, as in hornblende and some sienites.

3. After rubbing or striking, when the smell emitted is,

A. Urinous, as in swinestone after rubbing.

B. Sulphureous, as in pyrites.

C. Garlic, as in arsenical pyrites and white cobalt ore.

D. Empyreumatic, as in quartz and pitcoal.

VII. The taste, which is characteristic of one class of minerals, only, viz. the salts; and it is either,

1. Swectish saline, as rock salt.

2. Sweetish astringent, as native alum.

3. Sourish astringent, as native vitriol.

4. Bitter saline, as native Epsom salt.

5. Cooling saline, as native nitre.

6. Lixivious, as native alkali.

7. Urinous, as native sal ammoniac.

Beside the characters which we have now illustrated, some others are occasionally and successfully employed in the description of minerals. These have been brought under

144

tion.

lassifica- under the denomination of physical, chemical, and emtion. pirical characters.

1. Physical. The most common of the physical characters is the property which some minerals possess of exhibiting signs of electricity and magnetism. Some minerals become electric by being heated, and others by friction; and the electricity thus excited is in some vitreous or positive, and in others resinous or negative. Some minerals, too, and particularly some varieties of iron ore, are distinguished by being attracted by the magnet. Such arc magnetic pyrites, and magnetic iron sand. By filing a mineral so fine that the particles shall swim on water, and then applying a magnet, the slightest degree of magnetic effect may be observed. Among the physical properties of minerals also, may be reckoned the phosphorescence, which is produced by friction, as in some varieties of blende ; or by exposure to heat, as fluor spar, and some calcareous spars. To these characters also belongs the peculiar property of Lemnian earth and some other boles, which being thrown into water split into pieces with a crackling noise; and the property of some opals and other stones. of acquiring a higher degree of transparency when they are immersed in water, hence called hydrophanes.

2. Chemical characters .- By some simple experiments, the nature of many mineral substances may be easily and quickly ascertained, and particularly by means of acids. Thus, the nitrous acid is employed to discover whether a mineral effervesces, from which character the nature of the mineral can be more certainly known than by any other. Ammonia, or the volatile alkali, dissolves copper, and assumes a blue colour. Acetic acid is successfully employed as a test of lead, which communicates to the acid a sweetish taste. By means of heat, and particularly by the use of the blowpipe, much knowledge may be obtained of the nature of minerals. Some are volatilized; in others the colour is changed; and while some are nearly fused at different temperatures, others burn with a flame of peculiar colours.

3. Empirical characters.—Among these characters, the most common is the peculiar efflorescence which takes place in some ores. In copper ores the efflorescence is green or blue; in iron ores, brown, yellow, or red; in cobalt, peach blossom red; and in arsensic, white.

Characters for the distinction of minerals may be obtained from the circumstance of certain minerals being found generally accompanying others; as native arsenic with orpiment; gray copper ore with copper pyrites, and gray silver ore; red copper ore with native copper : Classificawhite cobalt ore is rarely found without nickel; and tion by attending to this circumstance, it will not be mistaken for arsenical pyrites. For the sake of brevity, Mr Kirwan, and others

For the sake of brevity, Mr Kirwan, and others after him, have adopted a method of expressing some of the characters by means of numbers. The following table exhibits some of these characters and corresponding numbers.

Resplendent, denoted by the number	4.
Shining	3.
Weakly shining	2.
Glimmering	1.
Dull	0.

Fragments, when the form is indeterminate.

Very sharp-edged	1.
Sharp-edged	4.
Rather sharp-edged	
Rather blunt	I.
Perfectly blunt	
	.

Transparency.

Transparent	4.
Semitransparent	3.
Translucent	2.
Onake	1.
opune	0.

Hardness.

Of chalk, denoted by	2
Yielding to the nail	3.
May be scraped with a knife	4.
Yields more difficultly to the knife	6.
Scarcely yields to the knife	7.
Does not give fire with steel	8.
Gives feeble sparks with steel	0.
Gives lively sparks	10.

But it is obvious that this abridged mode of expressing these characters, by means of numbers, can only be advantageously employed by those who have made themselves quite familiar with the different numbers corresponding to the different shades of character, and who can thus recollect them with facility and precision. To others this method of description, by requiring constant reference to the explanation, may prove rather embarrassing, so that what is gained in brevity may be lost in perspicuity. We propose, therefore, still to retain the verbal mode of expression in preference to the numerical.

TABLE OF MINERALS arranged in the order of their Genera and Species, each Genus being divided into Families or Groupes, the characters of which latter are derived from their external properties according to the method of Werner.

FIRST CLASS.	III. SILICEOUS Genus.	Garnet Family.	Ruby Family	1.1.4

I. GENUS. DIAMOND.

One Species. DIAMOND.

Id. Kirwin, I. 393. Le Diamant, Brochant, II. 153. Hauy, III. 287.

Essential character .- Scratches all other minerals.

External characters .- Its most common colours are gravish white and yellowish white; smoke gray and yellowish gray; clove brown; sometimes asparagus green, passing to pistachio green and apple green; sometimes a wine yellow and citron yellow, and also blue and rose red.

When the diamond is cut, it presents a splendid and varied play of colours, which is one of its most striking characters.

It is found sometimes in rounded grains, which are supposed to have been crystals with the edges worn; but it is most frequently met with crystallized.

The primitive form is a regular octahedron, the integrant molecule a regular tetrahedron; but the form which it commonly assumes is the spheroidal, with 48 curvilineal faces, six of which correspond to the same face of the primitive octahedron. Besides this form there are various others, as the double three-sided pyramid, the dodecahedron, &c. All the modifications of the crystals of the diamond, Hauy observes, seem to be the effects of its tendency to crystallize in a regular figure of 48 plane faces, which, if it ever has existed, has not yet been discovered; and it is easy to conceive that this form would be produced by intermediate decrements on all the angles of the nucleus; but the deviations from this form scem to have been occasioned by its precipitate formation.

The external lustre is from four to one; internal four. The fracture is straight foliated, with a fourfold cleavage, parallel to the faces of the octahedron; transparency four to three; hardness ten; brittle; specific gravity 3.518 to 3.600. Becomes positively electric by friction, even before it is polished.

Chemical character .--- When exposed to a sufficient temperature, it is entirely consumed. This has been fully ascertained by the experiments of modern chemists, from which it is concluded, that the diamond is entirely composed of pure carbone. See CHEMISTRY.

Mr Boyle was the first, according to Henckel, who subjected the diamond to the action of heat, and in his experiments he found that it exhaled very copious and acrid vapours. This was about the year 1673; but in the year 1694 the experiment was repeated by the order of Cosmo III. grand duke of Tuscany. Diamonds were exposed to the heat of the powerful burning glass of Tschirnhausen, the action of which was even aided by means of another burning glass; and about the end of 30 seconds a diamond of 20 grains lost its transparency, separated into small pieces, and was at last entirely dissipated. The same experiment was repeated on other diamonds, always with the same result, and without exhibiting the least sign of fusion. Newton, in his treatise on Optics, has placed the diamond among combustibles, supposing that it is a coagulated unctuous substance. He had been led to this by observing its extraordinary refractive power, which in combustible bodies he found to be in a ratio considerably higher

I

than their density. According to this general law he Classific. concluded, that the diamond as well as water contained an inflammable principle, both of which have since been verified. Newton's treatise was not published till 1704; but it appears that part of it was composed and read to the Royal Society in the year 1675, nearly 20 years before the Florentine experiments were made.

But nearly 70 years before this latter period, Boetius de Boodt, in his History of Stones, appears to have been perfectly satisfied, from an experiment which he describes, that the diamond was of an inflammable nature. This document, which we presume will gratify the curiosity of many of our readers, is too singular to be omitted. "Mastix deinde calefieri parum, quemadmodum et adamas debet, idque, ut impositus ac supra positus mastici statim illi unione vera uniatur, ac vivos undique radios a se jaceat. Hanc unionem respuunt aliæ omnes gemmæ diaphanæ-cur vero legitimus adanias solus tincturam illam recipiat, aliæ gemmæ non, difficile est scire. Existimo mutuum illum et amicum. amplexum propter similitudinem aliquam quam habent in materia et qualitatibus; hoc est, tota utriusque natura fieri, quod itaque mastix quæ igneæ naturæ est adamanti facile jungi possit, signum est; id propter materiæ similitudinem fieri, ac adamantis materiam igneam, et sulphuream esse, atque ipsius humidum intrinsicum et primogenium cujus beneficio coagulatus est, plane fuisse oleosum et igneum, aliarum vero gemmarum aqueum .- Non mirum itaque si pinguis, oleosa, et ignea masticis substantia illi absque visus termino adpingi et applicari, aliis vero gemmis non possit." Boetius de Boodt, Gem. et Lapid. Hist. Hanoviæ, 1609. 4to. lib. ii. cap. I.

For the sake of the English reader we shall translate this curious document. " If mastich and the diamond be exposed to heat, and brought into contact, they enter into perfect union, and emit a very lively flame, which docs not take place in any other gem. But what is the reason that the diamond alone possesses this property? I am of opinion that this mutual combination arises from a certain resemblance which each of the substances possesses in its nature and properties : on this account, therefore, the mastich, which is of a combustible nature, may be united to the diamond from a similarity in their nature, which shows that the diamond is composed of combustible and sulphureous matter; and that the humid and original particles of its composition, by means of which it was coagulated, or assumed a solid form, have been decidedly of an oily and inflammable nature, while those of other gems have been of an aqueous nature. It is not, therefore, surprising that the fat, oily, and combustible substance of mastich may enter into intimate union with the diamond, but cannot be combined with other gcms."

Localities, &c .- The diamond is found in various places of the East Indics, as in the provinces of Golconda and Visapour, in the peninsula of Hither India; and in the kingdoms of Pegu and Siam, in the peninsula of Farther India, and nearly, it is observed, in the same degree of latitude. In 1728 the diamond was discovered in Brasil, in the district of Serro-do-Frio, which is situated in the same southern latitude as the countrics which produce the diamond on the north side of the equator. The native repository of the diamond, so far as is known, is a ferruginous soil, but whether it

Part

assifica- he produced on the spot where it is discovered, or have been transported from the place of its origin, has not been ascertained. It is found also in veins filled with soil of a similar nature. We shall here add a short history of the diamond mines.

art I.

tion.

15

mond

The diamond mines are found only in the kingdoms of Golconda, Visapour, Bengal, the island of Borneo, and Brasil. There are four or five mines, or rather three mines and two rivers, whence diamonds arc obtained. The mines are, I. That of Raolconda, in the province of Carnatica, five days journey from Goleonda, and cight from Visapour. It has been discovered about 200 years. 2. That of Gani, or Coulour, seven days journey from Golconda eastward. It was discovered 150 years ago by a peasant, who digging in the ground found a na-tural fragment of 25 carats. 3. That of Soumelpour, a large town in the kingdom of Bengal, near the Diamond-mine. This is the most ancient of all: it should rather be called that of Goual, which is the name of the river, in the sand whereof these stones are found. 4. The fourth mine, or rather the second river, is that of Sueeudan, in the island of Borneo; and, 5. That of Serro-do-Frio in Brasil.

Diamond-mine of Raoleonda .- In the neighbourhood of this mine the earth is sandy, and full of rocks and copse-wood. In these rocks are found several little veins of half and sometimes a whole inch broad, out of which the miners, with a kind of hooked irons, draw the sand or earth wherein the diamonds are; breaking the rocks when the vein terminates, that the track may be found again, and continued. When a sufficient quantity of earth or sand is drawn forth, they wash it two or three times, to separate the stones. The miners work quite naked, except a thin linen cloth before them; and besides this precaution, have likewise inspectors, to prevent their concealing diamonds, which, however, they frequently find means to do, by watching opportunities when they are not observed, and swallowing them.

Diamond-mine of Gani or Coulour.-In this mine are found a great number of diamonds from 10 to 40 carats, and even more. It was here that the famous dia-mond of the Great Mogul, which before it was cut weighed 793 carats, was found. The diamonds of this mine are not very clear: their water is usually tinged with the quality of the soil; being black where that is marshy, red where it partakes of red, sometimes green and yellow, if the ground happen to be of those colours. Another defect of some consequence is a kind of greasiness appearing on the diamond, when cut, which takes off part of its lustre .- There are usually no less than 60,000 persons employed in this mine.

When the miners have found a place where they intend to dig, they level another somewhat bigger in the neighbourhood thereof, and inclose it with walls about two feet high, only leaving apertures from space to space, to give passage to the water. After a few su-perstitious ceremonics, and a kind of feast which the master of the mine makes for the workmen, to eneourage them, every one goes to his business, the men digging the earth in the place first discovered, and the women and children carrying it off into the other walled round. They dig a few fect deep, and till such time as they find water. Then they cease digging; and the water thus found serves to wash the

earth two or three times, after which it is let out at Diamond an aperture reserved for that end. This carth being genus. well washed, and well dried, they sift it in a kind of open sieve, and lastly, search it well with the hands to find the diamonds. This mine is in a plain of about onc league and a half in extent, bounded on one side by a river, and on the other by a range of lofty mountains, which form a semicircle. It is said that the nearer the digging is carried to the mountains, the diamonds are the larger.

Diamond-mine of Soumelpour, or river Goual .---Soumelpour is a considerable town near the river Goual, which runs into the Ganges. It is from this river that all our fine diamond points, or sparks, called natural sparks, are brought. They never begin to seek for diamonds in this river till after the great rains are over, that is, after the month of December ; and they usually even wait till the water is grown elear, which is not before January. The season at hand, eight or ten thousand persons, of all ages and sexes, come out of Soumelpour and the neighbouring villages. The most experienced among them search and examine the sand of the river, and particularly where it is mixed with pyrites, going from Soumelpour to the very mountain whence it springs. When all the sand of the river, which at that time is very low, has been well examined, they proceed to take up that wherein they judge diamonds likely to be found ; which is done after the following manner: They dam the place round with stones, earth, and faseines, and throwing out the water, dig about two feet deep: the sand thus got is earried into a place walled round on the bank of the river. The rest is performed after the same manner as at other mines.

Diamond-mine in the island of Borneo, or river of Suecudan .- We are but little acquainted with this mine ; strangers being prohibited from having access to it: though very fine diamonds have been brought to Batavia by stealth. They were formerly imagined to be softer than those of the other mines; but experience shows they arc in no respect inferior.

Diamond-mine of Serro-do-Frio .- A description of this mine was given by D'Andrada in 1792, to the Natural History Society of Paris. The mine is situated to the north of Villa Rica, in the 18th degree of south latitude. The whole country in which the diamonds are found abounds with ores of iron ; and the stratum of soil, immediately under the vegetable soil, contains diamonds disseminated in it, and attached to a gaugue or matrix which is more or less ferruginous; but they are never found in veins.

When this mine was first diseovered, the searching for diamonds was so successful, that the Portuguese fleet which arrived from Rio de Janeiro in 1730 brought no less than 1146 ounces of diamonds. This unusual quantity introduced into the market immediately reduced the price; and to prevent this circumstance recurring, the Portuguese government determined to limit the number of men employed in the mines.

As the diamond is the hardest of all substances, it Method of can only be cut and polished by itself. To bring it cutting and to that perfection which augments its price so consi-polishing derably, the lapidaries begin by rubbing several against diamonds each other, while rough; after having first glued them to the ends of two wooden blocks, thick enough to be held

149

Diamond held in the hand. It is this powder thus rubbed off genus the stones, and received in a little box for the purpose, that serves to grind and polish them.

> Diamonds are cut and polished by means of a mill, which turns a wheel of soft iron sprinkled over with diamond-dust mixed with oil of olives. The same dust, well ground, and diluted with water and vinegar, is nsed in the sawing of diamonds; which is performed with an iron or brass wire, as fine as a hair. Sometimes, in lieu of sawing the diamonds, they cleave them, especially if there be any large shivers in them.

> The method of cutting and polishing the diamond was not discovered till the 15th century. The diamonds which were employed as ornaments before that period, were in their rough and natural state. The invention is ascribed to Louis Berguen, a native of Bruges, who in the year 1476, cut the fine diamond of Charles the Bald, duke of Burgundy, which he lost the same year at the battle of Morat. This diamond was then sold for a crown, but afterwards came into the possession of the duke of Florence.

> The first water in diamonds means the greatest purity and perfection of their complexion, which ought to be that of the purest water. When diamonds fall short of this perfection, they are said to be of the second or third water, &c. till the stone may be properly called a coloured one.

17 Of estimating.

The value of diamonds is estimated by Mr Jefferies by the following rule. He first supposes the value of a rough diamond to be settled at 21. per carat, at a medium; then to find the value of diamonds of greater weights, multiply the square of their weight by 2, and the product is the value required. E.g. to find the value of a rough diamond of two carats: $2 \times 2 = 4$, the square of the weight; which, multiplied by two, gives 81. the true value of a rough diamond of two carats. For finding the value of manufactured diamonds, he supposes half their weight to be lost in manufacturing them ; and therefore, to find their value, we must multiply the square of double their weight by 2, which will give their true value in pounds. Thus, to find the value of a wrought diamond weighing two carats; we first find the square of double the weight, viz. $4 \times 4 \equiv 16$; then $16 \times 2 \equiv 32$. So that the true value of a wrought diamond of two carats is 32l. On these principles Mr Jefferics has constructed tables of the price of diamonds from I to 100 carats.

13 Celebrated diamonds.

The greatest diamond ever known in the world is one belonging to the king of Portugal, which was found in Brasil. It is still uncut : and Mr Magellan informs us, that it was of a larger size; but a piece was cleaved or broken off by the ignorant countryman, who chanced to find this great gem, and tried its hardness by the stroke of a large hammer upon the anvil.

This prodigious diamond weighs 1680 carats : and although it is uncut, Mr Romé de l'Isle says, that it is valued at 224 millions sterling; which gives the estimation of 79,36 or about 80 pounds sterling for each carat : viz. for the multiplicand of the square of its whole weight. But even in case of any error of the press in this valuation, if we employ the general rule above mentioned, this great gem must be worth at least 5,644,800 pounds sterling, which are the product of 1680 by two pounds, viz. much above five millions

and a half sterling. But this gem is supposed by some Classific to be a white topaz.

The famous diamond which adorns the sceptre of the empress of Russia under the eagle at the top of it weighs 770 carats, and is worth at least 4,854,728 pounds sterling, although it hardly cost 135,417 guineas. This diamond was one of the eyes of a Malabarian idol, named Scharingham. A French grenadier, who had deserted from the Indian service, contrived so well as to become one of the priests of that idol, from which he had the opportunity to steal its eye : he run away to the English at Trichinopoly, and thence to Madras. A ship-captain bought it for twenty thonsand rupces: afterwards a Jew gave seventeen or eighteen thousand pounds sterling for it : at last a Greek merchant named Gregory Suffras, officiend it to sale at Amsterdam in the year 1766 : and Prince Orloff made this acquisition for his sovereign the empress of Russia. This diamond is of a flattened oval form and of the size of a pigeon's egg.

The diamond of the Great Mogul is cut in rose; weighs $279\frac{1}{90}$ carats, and it is worth 380,000 guineas. This diamond has a small flaw underneath near the bottom : and Tavernier, page 389, who examined it, valued the carat at 150 French livres. Before this diamond was cut, it weighed $793\frac{5}{8}$ carats, according to Romé de l'Isle : but Tavernier, page 339, of his second volume, says that it weighed 900 carats before it was cut. If this be the very same diamond, its loss by being cut was very extraordinary.

Another diamond of the king of Portugal, which weighs 215 carats, is extremely fine, and is worth at least 369,800 guineas.

The diamond of the grand duke of Tuscany, now of the emperor of Germany, weighs $139\frac{1}{2}$ carats; and is worth at least 109,520 guineas. Tavernier says, that this diamond has a little hue of a citron colour; and he valued it at 135 *livres tournoises* the carat. Robert de Berquen says, that this diamond was cut into two: that the grand Turk had another of the same size: and that there were at Bisnagar two large diamonds, one of 250 and another of 140 carats.

The diamond of the late king of France, called the *Pitt* or *Regent*, weighs $136\frac{3}{4}$ carats: this gem is worth at least 208,333 guineas, although it did not cost above the half of this sum. Patrin says, that it is believed to be at Berlin, (I. 226.) and we may add, that it has probably been carried back to France among other spoils.

The other diamond of the same monarch, called the Sancy, weighs 55 carats; it cost 25,000 guincas: and Mr Duten says, that it is worth much above that price.

Brilliant DIAMOND, is that cut in faces both at top and bottom; and whose table, or principal face at top, is flat. To make a complete square brilliant, if the rongh diamond be not found of a square figure, it must be made so; and if the work is perfectly executed, the length of the axis will be equal to the side of the square base of the pyramid.—Jewellers then form the table and collet by dividing the block, or length of the axis, into 18 parts. They take $\frac{1}{\sqrt{8}}$ from the upper part, and $\frac{1}{\sqrt{8}}$ from the lower. This gives a plane at $\frac{4}{\sqrt{8}}$ distance from the girdle for the table; and a smaller plane at $\frac{1}{\sqrt{8}}$ distance from the collet; the breadth of which will be

150

ssifica- be $\frac{1}{3}$ of the breadth of the table. In this state the stone is said to be a complete square table diamond.-The vion. brilliant is an improvement on the table-diamond, and was introduced within the 17th century according to Mr Jefferies.

II. GENUS. ZIRCON.

1. Species. ZIRCON.

Jargon, Kirw. I. 257. Zircon, Hauy. II. 465. Id. Brochant, I. 159.

Essen. Char .- Its specific gravity about 4.4; the joints natural, some of which are parallel, and others are oblique to the axis of the crystals.

Exter. Char -Colours reddish and yellowish, greenish, greenish yellow, and whitish. The colour in general varies from green to gray, and is most commonly pale; and the polished stone exhibits in some degree the play of colours of the diamond.

It is found in rounded, angular, or flattened grains, or in small angular fragments with notched edges, and also crystallized. The primitive form is an octahedron with isosceles triangles, and the integrant molecule is an irregular tetrahedron. The following are the most common forms of its crystals.

1. A prism with four rectangular faces, each base of which has a pyramid with four faces placed on the four lateral faces, which terminates sometimes in a line, but most frequently in a point.

2. The preceding crystal, in which the opposite lateral edges of the prism are truncated.

3. The crystal (1.) in which the edges of the faces of the pyramid are bevelled.

4. The crystal (1.) having the lateral edges of the prism, and the summit of the pyramid truncated

5. The crystal (1.) in which the angles between the prism and the pyramid are bevelled.

6. A prism with four faces, having the two opposite narrow, and the two others broad.

7. A double pyramid with four faces, with the edges of the common base truncated.

8. The perfect octahedron with obtuse angles.

The crystals are commonly small; the surface smooth, but that of the angular fragments is rough. Lustre, 3 and 4; internal lustre 4 and 3; somewhat vitreous, or approaching to that of the diamond. Fracture imper-fect or flat conchoidal; fragments, 3. Transparency, 4, 3. Causes double refraction. Hardness, 9; brittle. Spec. grav. 4.416 to 4.4700.

Chem. Char .--- Infusible by the blow-pipe without addition, but with borax it forms a transparent colourless glass. The following are its constituent parts.

Zirconia,	70
Silica,	26
Iron,	I
Loss,	3
	-
	100

Localities .- The zircon was first found in Ceylon, accompanied with crystals of spinelle and tourmaline, in a river near the middle of the island; and more lately it has been found in Norway, in a rock composed of feld- Zircon spar and hornblende.

Uses.-The zircon is employed as a precious stone. and particularly as an ornament in mourning.

2. Species. HYACINTH.

Id. Kirw. I. 257. Zircon, Hauy, II. 465. L'Hyacinthe, Brochant, I. 163.

Essen. Char.-The same as the first species.

Exter Char .- The most common colour is what is called hyacinth red, blood red, and yellowish brown.

It is found in rounded grains, and frequently in crystals, the primitive form of which is the same as the first. species. The crystals are,

I. A prism with four faces.

2. The same slightly truncated on its edges.

3. The double pyramid with four faces, or a very obtuse octahedron, which is a rare variety.

4. A prism with six faces, each base of which is terminated by an acumination with three faces, placed alternately on the three lateral edges, forming the rhomboidal dodecahcdron.

The crystals are commonly small, the surface smooth; external lustre, 3, 4; internal, 4; greasy, fracture straight foliated; cleavage double, rectangular; fragments, 3; transparency, 4, 2; causes double refraction; hard and brittle; unctuous to the touch when cut; spec grav. 4.385 to 4.620.

Chem. Char .- By the action of the blow-pipe the hyacinth loses its colour, but retains its transparency. It is infusible without borax, which converts it into a transparent colourless glass.

Constituent Parts.

From	Ceylon.	From Exp	ailly.
Zirconia,	70	64.5	66
Silica,	25	32	31
Oxide of iron,	0.5	2	2
Loss,.	4.5	1.5	I
		Ship Scholarsenpered	

100 Klap. 100 Vauq. 100 Vauq.

Localities .- It is found in Ceylon in similar situations with the former; in Brazil, Bohemia, and in the rivulet Expailly, in Velay in France; and also in the neighbourhood of Pisa in Italy.

Uses .- As it is susceptible of a fine polish, the hyacinth has been ranked among precious stones.

Remarks .- The analogy between the crystalline forms of the zircon and hyacinth; their double refraction; the similarity of their other characters, and particularly the results of chemical analysis, have led Hauy to form them into one species.

A variety, under the name of cinnamon stone, has been considered as a distinct species; but the differences are so very slight, that it may be included in the description of the preceding.

III. GENUS. SILICEOUS.

1. Species. CHRYSOBERYL.

Id. Emm. Wid. Lenz. Kirw. Chrysopale, Lam. Cymophane, Hauy.

Exter. Char .- The colour is an asparagus green; passing

genus.

art I.

genus.

152

Siliccous passing sometimes to a greenish white, and sometimes to an olive green; sometimes bright brown and yellowish brown, passing to yellowish gray; affords a feeble change of colour from bluish to milky white.

It is found in angular or rounded grains, which appcar to have been water worn; and in crystals, exhibiting, I. A table with six faces, elongated, of various thickness, truncated on the terminal edges. 2. A prism with four rectangular faces. 3. A prism with six faces, of which four are broader and two are narrower opposite to each other.

The grains are slightly rough, and have a considerable external lustre. The crystals arc striated lengthwise on their lateral faces; the other faces are smooth; lustre external very shining-internal the same, intermediate between that of the diamond and the vitreous lustre.

The fracture is in all directions perfectly conchoidal; the fragments are indeterminate with sharp edges. It has little transparency, but a considerable degree of hardness. Spec. grav. 3.698 to 3.719 Wern. 3.710 Klap. 3.796 Hauy.

Chem. Char .- It is infusible without addition by the action of the blow-pipe. By Klaproth's analysis, the following are its constituent parts.

Alumina,	71.5
Silica,	18
Lime,	6
Oxide of iron,	1.5
Loss,	3

Localities .- Brazil, Ceylon, Siberia.

Uses .- The hardness of the chrysoberyl, and change of colour which it exhibits, have procured it a place among precious stones of inferior value. It is known in commerce under the name of changeable opal or oriental chrysolite.

2. Species. CHRYSOLITE.

Id. Emm. Wid. Lenz. Mus. Lesk. Kirw. Peridot, Daub. Hauy.

Exter. Char.-The most common colour is a bright pistachio green, passing to an olive green; sometimes of a bright asparagus or clear meadow green ; rarely the green approaches to brown and almost to a cherry red.

It is found in angular fragments with the edges a little notched, or in rounded grains, or in crystals hav-ing the angles and cdges a little notched. The forms of its crystals are, 1. A large rectangular prism having its lateral edges truncated and sometimes bevelled, and terminated by a six-sided prism, of which two opposite sides are placed on the small lateral faces of the prism. The four others on the lateral truncated faces, the latter forming a more acute angle than the two former.

2. The next form varies from the preceding, in having two additional terminating faces, placed on the broad faces of the prism, each of which is consequently situated between two of the planes corresponding to the truncated planes.

3. In another variety the summit of the pyramid is Classific truncated by a convex cylindrical plane, the convexity of which passes from one of the small opposite lateral plancs towards the other.

4. In some instances the crystals are so small, that the same lateral faces almost entirely disappear, while the two larger assume a curved form, giving such crystals a tabular appearance.

The external surface of the angular fragments and of the rounded crystals is scaly, which affords an essential character to this mineral. The small lateral planes are smooth, the broad ones are distinctly striated lengthwise. Externally the surface is shining; internally shining and vitreous.

The fracture in all directions is perfectly conchoidal; the form of the fragments is indeterminate, with very sharp edges. It is almost always transparent, and refracts double; it is not so hard as quartz. Brittle. Spec. grav. 3.340 to 3.420 Wern. 3.428 Hauy.

Chem. Char.-By the action of the blow-pipe it is fused with borax without effervescence, and affords a greenish, transparent glass.

Constituent parts.

C	rystallised.	Cut.	Crystallised.
Silica,	38	39	38
Magnesia,	39.5	43.5	50.5
Oxide of iro	n, 19.	19	9.5
Loss,	3.5		2.
			7 37

100 Klap. 100.5 Vaug. 100 Vaug.

Localities, &c .- This mineral is brought from the Levant, but it is not known whether it is found in Asia or Africa. It has been discovered in Bohemia; and crystallised specimens included in a kind of lava have been brought from the isle of Bourbon. As it is usually found in rounded fragments, in the midst of earthy substances, its relative situation is scarcely known.

Uses .- The chrysolite has been often employed for various purposes as a precious stone, but as it possesses no great degree of hardness, it is not much esteemcd.

Substances of a very different nature have been, at different times, described under the name of Chrysolite. It appears that the yellow chrysolite of the ancients is the same with our topaz, and that their green topaz is our chrysolite. Plin. lib. xxxvii. cap. 8.

3. Species. OLIVINE.

Id. Emm. Wid. Lenz. Kirw. Lameth. Chrysolite en grains irreguliers, De Born. Peridot Granuliforme, Hauy. Chrysolith des Volcans, of many mineralogists.

Exter. Char .- The most common colour is a bright olive green, sometimes of an apple green, pistachio, or mountain green; a wine, honey, or orange yellow, and sometimes also a reddish brown, and brownish black; but these latter varieties are rare. It is found in rounded pieces, from the size of the head to that of a grain of millet, most commonly included, and disseminated in basalt. It has been found crystallized.

assifica-Internally, this mineral varies in its lustre between shining and weakly shining; in the yellow varieties the lustre is between vitreous and resinous.

> The fracture is more or less conchoidal; sometimes uneven; the shape of the fragments is indeterminate, with sharp edges. The rounded pieces of a certain size are composed of distinct granular concretions, with small grains.

> It is sometimes transparent, and varies to semitransparent and translucent. It is brittle, and not so hard as quartz. Spec. grav. 3.225 to 3.265.

> Chem. Char.-Olivine is infusible by the action of the blow-pipe; in nitric acid it loses its colour, giving to the liquid a pale yellow colour.

	Constituent	Parts. Klaproth.

Magnesia, Lime,	37	38.5	37.75
Oxide of iron	1, 12.5	12.	10.75
Loss,	2.25		

100.75 100.00-102.75

Localities, &c .- Olivine is found in different countries, as in Bohemia and Saxony, and in Vivarais in France, and most commonly in rounded pieces in the cavities of basalt. Brochant says that it has not been discovered in the basalts of Ireland, England, Sweden, Norway, and Italy. We have, however, collected specimens of olivine among the basaltic rocks of the Giant's Causeway in Ireland.

Olivine and chrysolite are considered by Hauy as one species, and described under the name peridot.

4. Species. CoccolITE.

Coccolithe, Brochant, ii. 504. Haiiy, iv. 355. D'Andrada. Nich. 4to. Jour. v. 495.

Exter. Char.-Colour, meadow green, olive, or blackish green. It is found in masses which are composed of separate pieces, granular, in small grains, which may be easily separated; these grains are angular, and discover some appearance of tendency to crystallization.

Lustre, resplendent, vitreous; fracture foliated; cleavage double, as examined by Haüy, but single according to D'Andrada : it is hard, scratches glass; the grains are often translucent. Spec. grav. 3.316 to

3.373. Chem Char.—Coccolite is infusible without addition before the blow-pipe. With borax it melts into a pale yellow transparent glass, and with carbonate of potash into an olive green vesicular glass.

to

Localities .- It is found in the iron mines of Hel- Siliceous lesta and Assebo in Sudermania, at Nerica in Sweden, genus. and near Arendal in Norway.

5. Species. AUGITE.

Octahedral Basaltine, Kirw. i. 219. L'Augite, Brochant, i. 179. Pyroxene, Hauy, iii. 80.

Essen. Char .- Divisible, parallel to the sides of an oblique rhomboidal prism, of about 92° and 88°, which is subdivided in the direction of the great diagonals of the bases.

Exter. Char .- Colour, olive green, black, white, and gray. It is found sometimes in rounded pieces, and in grains, but most frequently crystallized. The primitive form is an oblique-angled prism, the bases of which are rhombs : the integrant molecule is an oblique triangular prism. The form of the crystals is generally a six and eight sided prism, which is terminated by a two-sided summit. The crystals are commonly small, smooth, and brilliant, sometimes a little shining. Internal lustre shining, and almost resplendent, resinous. Fracture perfectly foliated ; cleavage double ; translucent at the edges; harder than olivine; gives lively sparks with steel, and scratches glass; rather brittle;

spec. grav. 3.226 to 3.777. Chem. Char.—Fusible before the blow-pipe with difficulty, and only in small fragments, which melt into a black enamel.

Localities, &c.-Augite is found in basalt along with olivine and hornblende, in Bohemia, Hungary, and Transylvania; in the basalt of Arthur's seat near Edinburgh.

6. Species. VESUVIAN.

La Vesuvienne, Brochant, i. 184. Idocrase. Hauy, ii. 574.

Essen. Char .- Divisible parallel to the faces and diagonals of a rectangular prism, with square bases; melts into a yellow glass.

Exter. Char .- Colour brown, orange, dark green, and yellowish green.

This mineral is found massive, disseminated, or crystallized. Primitive form, a rectangular prism, little different from a cube; integrant molecule a triangular prism. The forms of its crystals are, a rectangular prism, with four sides, truncated on all its edges, or truncated on its lateral edges; or a six-sided prism truncated on all its edges. The crystals are usually small, single sometimes, and sometimes in groups. Lateral planes longitudinally streaked. Some are TT smooth;

tion.

Siliceous smooth; lustre resplendent, vitreous; internal lustre genus. shining, resinous. Fracture imperfectly conchoidal, sometimes uncven, often also foliated. Fragments indeter-

minate, with rather sharp edges. Translucent, and almost semitransparent; hard, brittle; specific gravity 3.365 to 3.420.

Chem. Char .-- Fusible without addition into a yellow glass.

Constituent Parts. Klaproth.

	From Vesuvius.	From Siberia.

Localities, &c.-It is found in the neighbourhood of Vesuvius, accompanied by limestone in small grains, foldspar, mica, hornblende, and calcareous spar; and it is supposed to have been thrown out of the volcano unchanged. In Siberia it is found in steatites, sometimes mixed with crystals of magnetic iron.

Uses .- At Naples it is employed as a precious stone.

7. Species. LEUCITE.

La Leucite, Brochant, i. 188. Vesuvian, Kirwan, i. 285. Amphigene, Haüy, ii. 559.

Essen. Char.—Divisible, parallel to the faces of a cube, and at the same time to those of a rhomboidal dodecabedron.

Exter. Char .-- Colour grayish or yellow white.

It is rarely found massive or in grains, but most frequently crystallized. The primitive form of its crystals is the cube; the integrant molecule an irregular tetrahedron; the most common form of the crystals is a short double pyramid with eight faces opposed base to base, cach summit of which is surmounted by an obtuse acumination with four faces, corresponding alternately to the four lateral edges of the pyramid, and thus producing a figure of twenty-four trapezoidal faces; the crystals are commonly small, the surface rough and dull, or at most feebly shining. Internal lustre shining, vitreous. Fracture foliated, sometimes conchoidal. Fragments indeterminate with sharp edges. Semitransparent or translucent. Scarcely scratches glass. Brittle. Spec. grav. 2.455 to 2.490.

Chem. Chat. .-. Infusible before the blow-pipe, but with borax gives a transparent glass.

Localities, &c.-Leucite is found in the lavas of Vesurvius, and in the basalts of Italy; in basalts and other

rocks of Bohemia, and also, it is said, in a granitic Classifica rock in the Pyrenees.

8. Species. MELANITE, or Black Garnet.

La Melanite, Brochant, i. 191.

Exter. Char.—Colour velvet black, or brownish or grayish black. It is most commonly found crystallized, in six-sided prisms, terminated at each extremity by an obtuse acumination, with three planes placed alternately on three of the lateral edges; the prisms are sometimes truncated on all the edges, and sometimes only the lateral edges. The surface is smooth and shining. Internal lustre shining. Fracture imperfect, flat, conchoidal. Fragments indeterminate, sharp-edged, opaque, hard, and rather brittle. Spec. grav. 3.691 to 3.800.

Constituent Parts. Vauquelin.

Silica,	35

Localities.--It has been found only at Frescati and St Albano near Rome.

9. Species. GARNET.

Le Grenat, Brochant, i. 193. Garnet, Kirwan, i. 238. Grenat, Haüy, ii. 540.

Essen. Char.-Specific gravity at least 3.5. The forms derived from the rhomboidal dodecahedron.

The primitive form is a rhomboidal dodecahedron. The inclination of each rhomb to the two adjacent is 120° , the plain angles $109^{\circ} 28' 16''$ and $70^{\circ} 31' 44''$. The integrant molecule is the tetrahedron, whose faces are isosceles triangles equal and similar.

The garnet is divided into three subspecies, the precious, common, and Bohemian garnet.

Subspecies 1. PRECIOUS GARNET.

Exter. Char.— Colour red, of which there are several varieties, as blood red, cherry red, hyacinth rcd, sometimes brown and even black.

The garnet is rarely found massive or disseminated, but sometimes in rounded grains, and most frequently crystallized, of which the following are the forms.

1. A prism with six sides terminated by a double obtuse summit with three faces, corresponding alternately to the three lateral edges at each end of the prism, and thus forming a rhomboid of twelve faces.

2. The same crystal truncated on all its edges, forming a figure of 36 faces. The faces of the truncations are elongated bexagons.

3. A short double pyramid, with eight faces opposed base to base, the summits of cach of which are surmounted by an obtuse acumination, corresponding alternately to the four lateral edges of one of the pyramids. assifica- mids, forming a crystal of 24 sides, which are pretty equal trapezoids. tion.

4. The preceding form with twelve truncations ; eight on the eight acute alternating angles of the two summits, and four on the obtuse angles of the common base of the two pyramids, making in all 36 faces.

The surface is a little unequal in the grains, smooth in the crystals, and almost always streaked diagonally. The lustre varies from shining to resplendent, and is vitreous. Fracture more or less perfectly conchoidal, sometimes uneven or splintery, and sometimes foliated. Fragments indeterminate with sharp edges. Transparent or translucent. Scratches quartz. Refraction simple. Brittle. Spec. grav. 4.085 to 4.352.

Chem Char .- Before the blow-pipe it is fusible into a dark enamel.

Localities, &c.-The garnet is not uncommon in most countries of the world, and it is usually found in primitive rocks.

Uses .- It is employed as a precious stone.

The precious garnet is supposed to be the carbuncle of the ancients.

Subspecies 2. COMMON GARNET.

Essen. Char.-The same as the precious garnet. Exter. Char.--- It is found massive and disseminated,

and also sometimes crystallized. The forms of the crystals arc the same as those of precious garnet. The surface of the crystals is diagonally streaked.

Colour brown, green, greenish black, brownish red, and orange yellow. Lustre shining, resinous, or vitreous. Fracture uneven, sometimes splintery. Fragments sharp-edged. Rarely transparent, sometimes translucent, and commonly at the edges; not so hard as the precious garnet. Brittle. Spec. grav. from 3.668 to 3.757.

Chem. Char.-Melts before the blow-pipe into a dark enamel, and easier than the former.

Constituent Parts. Vauquelin.

Localities, &c.-This mineral is found in serpentine in Saxony; the most beautiful are from Bohemia, where it is found in alluvial land.

Uses .- It is employed in jewellery. The small grains are used as a substitute for emery in polishing.

This mineral is formed into a separate species by some, and is distinguished from the garnet by its colour, want of crystallization, and transparency; but these differences in the external characters Hauy considers as insufficient to constitute a different species of two minerals which agree in a greater number of other characters. Magnesia indeed has been detected in the latter as one of its constituents, no trace of which has been yet discovered in the former.

10. Species. GRENATITE.

Grenatite, Brochant, ii. 496. Id. Saussure, § 1900. Staurotide, Hauy, iii. 93. Pierre de Croix, De Lisle, ii. 434.

Essen. Char.-Divisible parallel to the sides of a rhomboidal prism, whose angles are equal to 129° 30', and 50° 30', which may be subdivided in the direction of the short diagonals of the bases.

Exter. Char.-Grenatite is always found crystallized. The primitive form is a rectangular prism with rhomboidal bases, having the angles inclined, as mentioned in the essential character. The integrant molecule is a triangular prism. It is frequently met with in double crystals, crossing each other in the form of a cross, from which the name is derived, sometimes at right angles, and sometimes obliquely; sometimes also there are ob-lique triple crossings. The surface is smooth and shining, or uneven and dull.

The colour is reddish or blackish brown; internal lustre shining, between vitreous and resinous. Fracture U 2 imperfectly genus.

art I.

tion.

Siliccous imperfectly foliated, in the direction of the axis; in genus. other directions uneven, small grained, or sometimes a -little conchoidal; often opaque, sometimes translucent.

Scratches quartz feebly; specific gravity 3.2861.

Chem. Char.-Before the blow-pipe it becomes brown without fusion, and is then converted into a fritty substance.

II. Species. CEYLANITE.

Pleonaste, Hauy, iii. 17. Spinelle Pleonaste, Brongniart, i. 438.

Essen. Char .- Scratches glass slightly, and is divisible into a regular octahedron.

Exter. Char .- This mineral is found in rounded masses, and also crystallized. Primitive form of the crystals, a regular octahedron. The integrant molecule a regular tetrahedron. The edges of the octahedron are sometimes truncated, and form a regular 1 2-sided rhomboid. The crystals are small; the fracture is conchoidal; the lustre shining and vitreous.

The colour is sometimes perfectly black, brown, bright blue, purplish red, or dark green. It is hard, but not very brittle. Spec. grav. 3.76 to 3.79.

Chem. Char .- Infusible before the blow-pipe.

Localities, &c .- This mineral is met with in the island of Ceylon, along with tourmaline and other crystallized substances, which have been carried from their native repositories by means of water. It has been found also in disseminated crystals in the cavities of the lava of Vesuvius; and very small blue crystals of ceylanite have been observed in the volcanic (basaltic) rocks at Closterlach on the banks of the Rhine.

12. Species. SPINELLE.

Spinel and Balas Ruby, Kirw. i. 253. Le Spinel, Brochant, i. 202. Spinelle, Hauy, ii. 496.

Essen. Char .- Scratches quartz strongly; the primitive and common form, a regular octahedron.

Exter. Char.-Spinelle is found in rounded grains, or Classificu crystallized : the primitive form of the crystals is a regular octahedron ; the integrant molecule the regular tetrahedron. Its usual forms are a double pyramid with four faces applied base to base, constituting a perfect octahedron; or it is truncated on all its edges, or only on those of the common base of the two pyramids. It is met with also in the form of a double crystal, composed of two octahedrons, which are often flattened.

Colour usually red, of various shades, from carmine red to rose red; sometimes reddish white, and orange yellow. Faces of the octahedron smooth, those of the truncations longitudinally streaked. Lustre resplendent, vitreous; fracture conchoidal; the longitudinal fracture is foliated; fragments indeterminate, sharp-edged; semitransparent, and sometimes transparent. Scratches quartz; is scratched by sapphire. Spec. grav. 3.570 to 3.645.

Chem. Char.-Before the blow-pipe it is infusible; but with borax it melts, and without frothing up.

Constituent Parts.

Localities, & c.-Crystals of spinelle are found in Ceylon, in a river which comes from the high mountains in the middle of that island : they are accompanied with zircon, tourmaline, and different other stones. It is found also in Pegu.

Uses .- Spinelle is ranked among precious stones, and is greatly esteemed when it is of a certain size. It is said that a fine spinelle ruby, whose weight exceeds four carats, is worth half the price of a diamond of the same weight.

13. Species. SAPPHIRE.

Oriental Ruby, Sapphire, and Topoz, Kirwan, i. 250. Le Saphir, Brochant, i. 207. Telesie, Hauy, ii. 480.

Essen. Char .- Specific gravity about 4; natural joints very distinct, and perpendicular to the axis of the crystals.

Exter. Char .- Sapphire is found in fragments, in rounded pieces, and also crystallized. The primitive form of the crystal, according to Hauy, is a regular six-sided prism, and the integrant molecule is a triangular, equilateral prism; but, according to Bournon, the primitive form is a rhomboid, whose angles are 96° and 84°. The usual forms of the crystals are, 1. A small six-sided prism. 2. A pyramid with six faces, very sharp, double, the two pyramids applied base to base. 3. The same crystal with the summit truncated. 4. A pyramid with six faces, double; the two pyramids applied base to base, but less sharp than the second form. The surface of the crystals is smooth, and often streaked transversely.

The

The principal colour is blue, varying between Prussian and indigo blue; other varieties are of a deep violet blue. Sapphires are also found red, yellowish, and greenish. Two or three colours appear in the same crystal, sometimes in bands and sometimes in concentric circles. Externally, the lustre of the sapphire is shining; internally, resplendent and vitreous. Fracture perfectly conchoidal. Fragments sharp-edged; transparent or semitransparent, sometimes only translucent. Scratches all other earthy substances. Brittle. Spec. grav. 3.991 to 4.283.

Chem. Char. — Infusible before the blow-pipe. Melts with borax without intumescence. The blne variety, exposed to a strong heat, loses its colour, Haüy.

Localities, &c.—The finest sapphires are brought from Pegu and the island of Ceylon. The sapphire is also found in Bohemia, accompanied with zircon, Bohemian garnet, and magnetic iron; and in the river Expailly in France.

Expailly in France. Uses.—The sapphire, next to the diamond, is the most highly valued of precious stones.

14. Species. CORUNDUM.

Corindon, Hauy, iii. 1. Adamantine Spar, Kirw. i. 335-Le Spath Adamantin, Broch. i. 356.

Essen. Char.-Scratches quartz; divisible into a rhomboid somewhat acute.

Exter. Char.—This mineral is found massive, disseminated, and crystallized; 1. In six-sided prisms, having the extremities broken, and the faces sometimes unequal. 2. A six-sided prism, terminated by a sixsided pyramid. 3. A pyramid with six short faces, whose summit is strongly truncated; and, 4. The preceding crystal terminated by a three-sided pyramid. From the investigations of Count de Bournon and Mr Greville, it appears that the crystallization of corundum is similar to that of the sapplire*. Lustre, which is intermediate between resinous and vireous, shining or weakly shining; cross fracture uneven, or splintery, sometimes foliated; fragments rhomboidal, sometimes sharp-edged.

The colour is greenish white, greenish gray, and asparagus green, translucent at the edges; refraction double. Extremely hard. Spec. grav. 3.710 to 3.873.

Chem. Char.-Entirely infusible before the blow-pipe.

	100 *

Localities, &c .- This mineral is found in Saxony, disseminated in a bcd of indurated steatites, mixed with common tale; also in the island of Naxos in the Archipelago; and in Italy, Spain, and Peru.

Uses.-Emery, as well as the two former species, is employed, when reduced to powder, in cutting and polishing hard stones, glass, and metals.

Not only the external characters, but also the near approach in the proportion of their constituent parts, of the three species last described, would lead to consider them as the same species, or at least as varieties. Emery is by some mineralogists arranged among the ores of iron.

17. Species. TOPAZ.

Occidental Topaz, Kirw. i. 254. La Topaze, Broch. i. 212. Topaze, Hauy, ii. 504.

Essen. Char .- Refraction double; joints very distinct; perpendicular only to the axis of the crystals.

Exter. Char.-The topaz is sometimes found massive, sometimes disseminated, and sometimes in rounded fragments; but it is most commonly crystallized. The primitive form of its crystals is a right-angled prism, whose bases are rhombs, and having the large angle 124° 22'; the integrant molecule is the same. The most common forms of the topaz are,

1. A prism with eight sides, terminated at the one end by a four-sided summit, and at the other (which but rarely happens), by one of a different form. In a variety of the Brazilian topaz, the one summit presents six sides, and the other ten; and the electricity exhibited by the latter by means of heat, is negative, while that of the former is positive. This difference in the two opposite summits of a crystal, as has been observed by Hauy, is a peculiarity in all crystals which acquire by means of heat two kinds of electricity.

2. The next common form of the topaz is an eightsided prism, whose base is horizontal, and bordered with a row of six oblique faces. This variety, which is found in the mines of Saxony, becomes readily electric by friction, but not by heat.

The prevailing colour of the topaz is yellow of various shades. The crystals are of middling size ; their lateral faces are sometimes convex and cylindrical ; the surface of the same face is longitudinally striated, while that of the other faces is smooth. Lustre vitreous; cross fracture perfectly foliated; longitudinal fracture conchoidal; fragments indeterminate; transparent; sometimes semitransparent or translucent; refraction double; scratches rock-crystal. Spec. grav. 3.464 to 3.564.

Chem. Char .- Infusible before the blow-pipe, but melts with borax without intumescence. The Brazilian topaz heated in a crucible assumes a rose red colour, Classific when it is called by the jewellers ruby of Brazil. The Saxon topaz becomes white when exposed to heat; and thus deprived of colour, is sold for the diamond. According to Vauquelin, all the varieties of topaz reduced to powder, and added to syrup of violets, at the end of two or three hours communicate a green colour.

Constituent Parts.

According to Klaproth and Vauquelin.

Alumina,	47	to	50
Silica,	28	to	30
Fluoric acid,	17	to	20
Iron,	0	to	4

Localities, &c .- The topaz is found in different parts of Saxony, particularly in the mountain Schneeckenstein, which is denominated topaz rock, and is arranged with the primitive mountains. In this rock the topaz. is mixed with quartz, schorl, mica, and lithomarga. Near Zinnwald it is found in granite. It is also found mixed with ores of tin. In Siberia the topaz is found in graphic granite, accompanied with beryl, quartz, and garnet. Topaz is also met with in Brazil and Asia Minor.

Uses .- The topaz is employed for the purposes of jewellery as a precious stone, but it is not considered of very great value.

18. Species. PYROPHYSALITE.

This mineral which was described and analysed by Hisenger and Berzelius, is of a greenish white colour. When thrown on hot coals it becomes phosphorescent, and gives out a greenish flame. When it is strongly heated by the action of the blow-pipe, the surface is covered with small vesicles which explode. These phenomena are ascribed to the fluate of lime which forms one of its constituent parts, and which sometimes appears surrounding it with a crust.

Localities, &c .- Gahn found this stone at Finbo near Fahlun in Sweden, in nodules imbedded in a granite, composed of white quartz, feldspar, and silvery mica. The nodules are separated from the rock by a greenish yellow talc +.

+ Bronghi art, ii. 401

19. Species. EUCLASE.

Id. Hauy, ii. 531. Id. Brochant, ii. 508.

Essen. Char .- Divisible by two longitudinal lines perpendicular to each other.

Exter. Char .- This mineral has only been found crystallized. The primitive form of the crystals is a rectangular prism with square bases, and that of the integrant molecule is the same. The most common form under which it appears is an oblique four-sided prism, with the edges truncated in various ways. The cry-stals are streaked longitudinally. The lustre is resplendent and vitrcous. Longitudinal fracture foliated; cross fracture conchoidal.

Colour, bright sea green. Transparent, and refracts double. Scratches quartz. Very frangible ; hence its name signifying easily broken. Spec. grav. 3.062.

Chem. Char.-Loses its transparency before the blow-pipe, and melts into a white enamel.

		offer u		

Localities.—This mineral was brought from Peru, and has never been found any where else. It was in single crystals, so that its repository is unknown. It is by some mineralogists arranged among the ores of iron.

20. Species. EMERALD.

Id. Kirw. i. 247. L'Emeraude, Brochant, i. 217. Emeraude, Hauy. ii. 516.

Essen. Char.—Scratches glass easily; divisible, parallel to the faces, and to the bases of a regular hexaliedral prism.

Exter. Chav.—The emerald is only found crystallized, and the primitive form of its crystals is a regular six-sided prism; the integrant molecule is a triangular prism, the sides square, and the bases equilateral triangles. The usual forms are, I. A perfect six-sided prism; 2. Truncated on its lateral edges; 3. Truncated on its terminal edges; 4. Truncated on its terminal angles; and, 5. Having the terminal edges bevelled. The crystals are seldom large. Their surface is smooth and shining; internal lustre shining and resplendent; vitreous; fracture conchoidal or unequal, sometimes transversely foliated; fragments indeterminate, sharp edged.

Colour emerald green of all shades; most commonly transparent, sometimes only translucent : refraction double; with difficulty scratches quartz. Spec. grav. 2.600 to 2.775.

Chem. Char.-Fusible before the blow-pipe, but with difficulty; melts readily with borax.

Localities, &c.—Thefinest emeralds are brought from Peru, where they are found in veins or cavities of the granite mountains. They are also found in Upper Egypt, Ethiopia, and in the island of Ceylon. The emerald is accompanied by calcareous substances, as carbonate of lime and gypsum.

Uses.—The rich green of the emerald has obtained for it a high rank among precious stones, and it is employed for similar purposes.

21. Species. BERYL.

Aqua Mavina et Samaragdus, Beryllus, Wallerius, i. 254. Aigue Marine de Siberie, Romé de Lisle, ii. 252. Id. De Born, i. 71. Beryl, Kirw. i. 248. Le Beril Noble, Brochant, i. 220. Emeraude Limpide, vert-bleuatre, jaune-verdatre, &c. Hauy, ii. 521.

Essen. Char.-The same as the cmerald.

Exter. Char.—The beryl is sometimes found in rounded fragments, but most commonly crystallized, and the forms of its crystal are the same as the emerald. The lateral faces of the crystals are deeply striated.

The colours of the beryl are usually a pale or yellowish green; external lustre shining; internal resplendent, vitreous; longitudinal fracture conchoidal, or foliated. Cleavage fourfold. Fragments indeterminate and sharp-edged; often transparent, sometimes semitransparent, and translucent. The latter variety is distinguished by transverse rents. Refraction in a slight. degree double; nearly as hard as topaz; brittle; spec. grav. 2.65 to 2.75. Becomes electric by friction. *Chem. Char.*—Before the blow-pipe it is fusible, but

Chem. Char.—Before the blow-pipe it is fusible, but with difficulty, and yields a white, scarcely translucent glass.

Localities, &c.—The beryl is brought from the East Indies, and from Brazil; but the finest and purest are found in Daouria, on the frontiers of China, in the neighbourhood of Nertschink; and the matrix of these beryls is said to be an indurated clay, resembling jasper. The beryl is also found in Siberia, where it is usually accompanied with quartz, feldspar, garnets, tourmaline, mica, and fluor spar, in the veins of primitive mountains. The beryls from Siberia are almost all found in graphic granite. Beryl is also found in Saxony, and lately in France, in a large vein of quartz traversing graphic granite. Dolomicu found the beryl perfectly transparent and colourless, in the granite of the island of Elba.

Uses .- The beryl is employed as a precious stone, but is not greatly esteemed.

Remarks.—The emerald and the precious beryl approach so nearly to cach other, not only in the forms of their crystals, which are almost the same, and in their constituent parts, which afford but slight variations, but also in their other characters, that they ought to be considered, as has been done by Hauy, as varieties of the same species. The only differences which exist between them scen. to be accidental. These are chicfly in the colour, and in the crystallization; the former of which is a finer green, and the latter is more perfect in the emerald than in the beryl. The colouring matter of the emerald is oxide of chromium, while that of the beryl I 59 Siliceous genus.

rt I.

ion.

Siliceous ryl is oxide of iron. In all the other characters they genus. are nearly the same.

22. Species. SCHORLITE, or Schorlous Beyrl.

Schorlite, Kirw. i. 286. Le Beril Schorliforme, Brochant i. 224. Leucolite and Pycnite, Hauy, iii. -236.

Essen. Char .- Infusible. Original form of the crystals a regular hexahedral prism.

Exter. Char .- This mineral is usually found crystallized, in longish masses, mixed with other substances, and generally imbedded in granite; the form of the crystals, when they are regular, is a six-sided prism, which is sometimes truncated on its terminal edges, and sometimes the form disappears from its being deeply and longitudinally striated. The crystals are generally large.

Colour white, straw yellow, or reddish. Translucent or nearly opaque. External lustre shining between vitreous and resinous. Cross facture imperfectly foliated, longitudinal, imperfectly conchoidal. Scratches quartz slightly. Brittle. Spec. grav. 3.514 to 3.530.

Chem. Char .- Infusible with the blow-pipe; with borax yields a transparent glass.

Localitics, &c .- This mineral is generally found imbedded in granite; sometimes it is met with in gneis, accompanied with lepidolite. It enters into the composition of a rock formed of quartz and gray mica at Altenberg in Saxony. A red variety of this mineral was formerly considered by mineralogists as a crystallized lepidolite. Schorlous beryl has been arranged as a subspecies of beryl; but its specific gravity, different degree of hardness, and especially its composition, are characters sufficiently distinct to constitute a separate species.

23. Species. SCHORL.

This species is divided into two subspecies ; 1. Black or common schorl, and 2. Tourmaline.

Subspecies I. BLACK SCHORL.

Schorl, Kirw. i. 265. Le Schorl Noir, Brochant, i. 226. Tourmaline, Hauy, iii. 31.

Essen. Char .- Electric by heat in the two opposite extremities; forms of the crystals derived from a rhomboid.

Exter. Char .- This mineral is found in masses, and disseminated, but most frequently crystallized. The primitive form of its crystals is an obtuse rhomboid;

the integrant molecule is a tetrahedron. Its usual forms Classifica are, 1. A three-sided prism, with the lateral edges either truncated or bevelled ; 2. The same prism having a three-sided obtuse summit, the sides corresponding to the lateral edges. The truncations and bevelments of the lateral edges vary in the size of the faces, thus producing prisms of six and nine sides. The lateral faces of the three-sided prism are often convex. The lateral surfaces are longitudinally and dceply striated. The lustre, both external and internal, which is vitreous, varies between shining and weakly shining. The frac-ture is imperfectly conchoidal or uneven; cross fracture is sometimes convex on the one side and concave on the other. When black schorl is massive, it is found in separate pieces, thin, and apparently fibrous, parallel, or interwoven and divergent. The faces of these separate pieces are striated lengthwise. The fragments are indeterminate.

Colour velvet black of various shades. Commonly opaque, rarely translucent, except in small crystals. Streak gray. Inferior to quartz in hardness. Specific gravity 3.092 to 3.212.

Chem. Char .- Under the blow-pipe it froths up, and melts into a grayish white enamel.

, Constituent Part	s. Wiegleb.
Alumina,	A0.83
Silica,	33.33
Iron,	20.41
Manganese,	3.33

Physical Char .- Black schorl becomes electric by heat ; and the electricity of one extremity of the crystal is positive, while that of the other is negative; but when it cools, it is said, that the nature of the electricity is reversed ; the positive extremity becomes negative, and the negative becomes positive.

Localitics, &c .- Black schorl is usually found in granite, gneis, and the other primitive rocks; in veins of tin and ores of iron; in the topaz rock of Schneeckenstein in Saxony, of which it constitutes a part. It is also met with in Switzerland, Spain, Hungary, and Britain.

Subspecies 2. TOURMALINE.

Id. Kirw. i. 271. Le Schorl Electrique, Brochant, i. 229. Tourmaline Verte, Hauy, iii. 41.

Essen. Char .- The same as black schorl.

Exter. Char .- The tourmaline is found sometimes in masses and grains, but most commonly crystallized. The form of its crystals is a regular three-sided prism, with the edges, I. Either truncated or bevelled. 2. A regular three-sided prism with the lateral faces convex, and terminating in an obtuse, three-sided prism, the sides of which correspond to the lateral faces at one extremity, and to the lateral edges at the other. 3. An obtuse, double, three-sided pyramid, the faces of the one corresponding to the edges of the other. 4. A six-sided prism with equal angles. 5. A six-sided prism, the sides meeting two and two alternately under three obtuse angles. 6. A nine-sided prism, having three lateral angles acute, and six obtuse alternately. 7. The same crystal having the three acute lateral edges truncated, and thus forming a twelve-sided prism. The surface of the crystals is sometimes smooth, but most

160

tion.

assifica- most frequently striated longitudinally. Lustre shining and vitreous. Longitudinal fracture conchoidal; cross fracture foliated. The direction of the plates is inclined to the axis of the prism. Fragments indeterminate ; the erystals are usually opaque, when seen laterally.

The colour of the tourmaline is greenish, of various shades, yellowish brown, and very rarely indigo blue. The colours are usually very dcep, and at first sight appear black. It is usually translucent, and sometimes approaching to transparent, particularly when it is seen in a direction perpendicular to the axis of the prism; but it appears opaque when it is seen in a direction perpendicular to the basis of the prism, even when the height of the prism is less than its thickness. It is harder than quartz. Brittle. Spee. grav. 3.086 to 3.363.

Chem. Char .- With the blow-pipe the tourmaline melts into a grayish white, porous enamel.

Bergman's analysis is of the tourmaline of Ceylon, Vauquelin's is that of the green tourmaline of Brazil.

Physical Char.-The property of the tourmaline, of becoming electric by heat, has been already noticed as one of its distinctive characters. This physical property has occupied the attention of philosophers for a long time. It was observed by Lemery in 1719, and examined by Epinus in 1770. Pliny indeed mentions a reddish or purple-eoloured stone, which being heated or rubbed, attracts light bodies. This is supposed to have been the tourmaline. This property is susceptible of various modifications. The electricity of the tourmaline may be conveniently exhibited by heating two crystals, suspending the one by a thread, and presenting successively to its extremities the extremities of the other erystal. The extremities which possess the same kind of electricity will be repelled, while those which possess a different kind will be attracted. If a crystal of tourmaline be broken while it is electrified, the fragments immediately present electrical poles, situated in the same direction as those of the entire erystal.

The extremity of the crystals of tourmaline which has the greatest number of faces, exhibits positive electricity, while the extremity having the smaller number of faces exhibits negative electricity. The proper degree of heat for exciting the electricity of tourmaline is from 100° to the boiling point of Fahrenheit. When heated beyond this point, it is deprived of its electricity, and recovers it only in eooling; but if the temperature be increased still more, the crystal becomes again electric, but the poles are reversed. The electric poles may be also reversed, by heating a crystal of tourmaline unequally, by means of a burning glass.

Localitics, &c.-The tourmaline is found in almost all primitive mountains; the finest crystals are brought from Ceylon, Madagasear, Saxony, the Tyrol, Spain, YOL. XIV. Part I.

and Brazil. The tourmaline of the Tyrol is found in Siliceous a talcky rock, mixed with chlorite, mica, and horn- genus. blende. Those of Saxony and Spain are found imbeded in gneis, but those of Brazil and Ceylon are in separate erystals. In Bohemia they are found in mines. The tourmaline is also a native of France, Sweden, Norway, and Britain.

24. Species. PISTAZITE.

Glassy actynolite, Kirwan, i. 168. Delphinite, Saussure Voyages, Nº 1918. Acanticone, Arendalite, D'Andrada, Nich. Jour. 4to. v. 193. La Rayonnante Vitreuse, Broehant, i. 310. Epidote, Hauy, iii. 102.

Essen. Char.-Divisible parallel to the faces of a rhomboidal prism of 1142°, and 652°.

Exter. Char .- Pistazite is found massive or crystallized in flattened four-sided prisms, terminated by foursided pyramids, and also sometimes in regular six-sided prisms; the summit of the pyramid almost always truncated, as well as the lateral edges. The erystals are sometimes acicular and streaked longitudinally. Internal lustre shining. Fracture foliated or radiated. Fragments wedge-shaped and splintery.

Colour deep green, olive green, or greenish yellow. Translucent, sometimes transparent. Hard, easily seratches glass, and is brittle. Spee. grav. 3.45. Powder greenish yellow or whitish.

Chem Char.-Fusible by the blow-pipe, and is eonverted into a brown slag, which blackens by continuing the heat.

Localities, &c .- Pistazite is found in Dauphiny, on the surface and in the fissures of an argillaecous rock, accompanied by quartz, amianthus, and feldspar, and in the Pyrenees in limestone; near Arendal in Norway; and in argillaceous schistus, north end of the island of Arran in Scotland.

25. Species. ZOYSITE.

This mineral, which was discovered by Baron de Zoys, and therefore bears his name, is considered by Hauy as a variety of Epidote.

It appears in prisms which are deeply furrowed or rhomboidal, and very much flattened. They are of a gray colour, or grayish yellow, with a pearly lustre.

Localitics .- Zoysite is found particularly in Carinthia, and also in the Tyrol and in the Valais*.

26. Species. AXINITE, or THUMERSTONE.

Id. Kirw. i. 273. La Pierre de Thum, Brochant, i. 236. Axinite, Hauy, iii. 22.

Essen. Char.-Divisible parallel to the faces of a rhomboidal prism of $101\frac{10}{2}$, and $78\frac{10}{2}$.

Exter.

* Brongni-

art, ii. 400,

Part I

tion

Exter. Char .- Thumerstone is found in masses, disseminated and crystallized. The primitive form of its crystals is a right-angled prism, whose bases are oblique-angled parallelograms, having their angles of 101° 32', and 78° 28'. The integrant molecule is an oblique triangular prism. The most common form of its crystals is a quadrangular prism, so oblique and flattened, that its angles become as sharp as the cutting part of a hatchet. The faces of the crystals are longitudinally striated, but the truncated faces are smooth. Externally lustre splendent; internal shining and vitreous. Fracture vitreous, sometimes rough and splintery. Fragments indeterminate, sharp edged. Massive thumerstone is composed of separate testaceous, thin, and slightly curved concretions, with a smooth surface, which is somewhat irregularly striated.

The colour is clove brown, varying to violet bluc, yellowish, and greenish gray. Massive thumerstone is only translucent. The crystals are semitransparent, and sometimes transparent. It is harder than feldspar, but less so than quartz; gives fire with steel, and diffuses an odour similar to what is produced by flint. Brittle. Spec. grav. 3.213 to 3.30C.

Chem. Char .- Thumerstone froths up under the blowpipe, and is converted into a grayish enamel, and with borax into a finc olive green enamel.

Cons	tituent Parts.

Lime,	9.39	19
Oxide of iron,	8.63	14
manganese,	I.	4
Loss,	2.49	1
	100.00	100.

Localities. &c.-Thumerstone, which is hitherto a rarc mineral, has been only found in veins and fissures of primitive rocks, and chiefly in rocks with a base of serpentine. It is usually accompanied with asbestus, rock crystal, and sometimes calcareous spar. It was first discovered at Thum in Saxony, from which it derives its name; but has been since found in the Pyrenees, in France, at Mount Atlas in Africa, in Norway, and in Cornwall in Britain.

27. Species. QUARTZ.

Essen. Char .- Divisible into a rhomboid, which is slightly obtusc.

Quartz, which is found, either massive, crystallized, or in rounded pieces, is one of the most abundant mineral substances. The primitive form of its crystals is a slightly obtuse rhomboid, of 94° 4', and 85° 56'. The integrant molecule is a regular tetrahedron.

On account of the variety of forms and appearances, quartz has been divided into subspecies; into five by Werner; by others only into two, viz. rock-crystal and common quartz. We shall nearly follow the former subdivisions, which are, amethyst, rock-crystal, milk-quartz, common quartz, and prase, including also ferruginous quartz.

Subspecies I. AMETHYST,

Id. Kirw. i. 264. L'Amethyste, Quartz-hyalin Violet, Hauy, u. 417.

Exter. Char .- The amethyst is found frequently cry- Classifica. stallized, but it is also found massive and in rounded pieces. I. The form of its crystals is a regular six-sided prism, terminated by a six-sided pyramid, the sides of which correspond to those of the prism. 2. A double six-sided pyramid. Fracture conchoidal, rarely splintery or fibrous. Fragments indeterminate, sometimes wedge-shaped. Massive amethyst is composed of separate pieces, which are sometimes granulated, sometimes scopiform when the crystals are combined together.

The colour is commonly violet blue of various shades, blackish brown and greenish white. External lustre resplendent; internal resplendent and shining vitreous. It varies between transparent and translucent. Scratches glass. Brittle. Spec. grav. 2.653 to 2.750.

Chem. Char.-Entirely infusible under the action of the blow-pipe.

Constituent Parts. Rose.

Silica,	97.50
Alumina,	.25
Oxide of iron and manganese,	.50

98.25

Localities, &c .- Amethyst is found in Bohemia, Saxony, Siberia, very abundant in the Uralian mountains, Hungary, and Auvergne in France. It is usually met with in the veins of metalliferous mountains, very rarely in granitic mountains. It is frequently met with crystallized, lining the cavities of balls of agate ; in amygdaloid and porphyry rocks.

Uses .- When the amethyst is cut and polished, it assumes an agreeable colour and lustre, so that it is employed in jewellery.

Werner has divided the amethyst into two varieties, the common and fibrous; the latter being chiefly characterized by its fibrous fracture and resinous lustre. This latter variety too, is only found massive.

Subspecies 2. ROCK CRYSTAL.

Mountain Crystal, Kirw. i. 241. Le Cristal de roche, Brochant. i. 243. Quartz-hyalin Limpide, Hauy, n. 417.

Exter. Char .- Rock crystal is usually found crystallized, sometimes in rounded pieces, but rarely massive. The form of its crystals is, I. A six-sided prism, having one of its bases or both surmounted by a sharp pointed pyramid; the sides of the pyramid and prism corresponding. This is its most usual form ; but it exhibits many apparent varietics, arising from modifications in the magnitude of one or several of the faces at the expence of the others, 2. A double six-sided pyramid, which is sometimes perfect, and sometimes truncated on the edges of the common base; and sometimes too, three alternating faces on each pyramid are larger than the others, giving to the crystal the appearance of a cube. 3. A simple, very acute pyramid with six sides, having its summit, and often also its base, acuminated with six faces: but this is rather an irregularity in the crystallization than a new form.

The crystals of this mineral are sometimes very large, and they are also found very small. In the rounded pieces the external surface is rough, but in the perfect crystals

Siliceous

genus.

ssifica- crystals the faces of the prism are striated transversely; but those of the pyramids and acuminations are smooth. The lustre is resplendent and vitreous; fracture perfectly conchoidal, sometimes, however, foliated ; fragments indeterminate, very sharp edged.

Tt I.

Colours of rock-crystals are grayish white, yellowish white, pearl gray, yellowish and blackish brown. Internally it is sometimes iridescent. It is transparent, sometimes semitransparent. By looking across one of the faces of the pyramid, and the opposite face of the prism, double refraction is produced. Scratches glass, and gives sparks with steel. Somewhat frangible; spec. grav. 2.650 to 2.888.

Chem. Char .- Entirely infusible before the blowpipe.

> Constituent Parts. Bergman. Silica, 93 Alumina, Lime, I 100

Physical Char.-It is sometimes phosphorescent; two crystals, by being rubbed together, exhibit a little light in the dark, and give out a peculiar odour, which is somewhat empyreumatic.

Localities, &c.-Rock-erystal is most commonly found in veins of primitive rocks, and particularly in granite; in druses lining the cavities of these rocks. The finest crystals are now brought from Madagascar, but it is a very frequent mineral in most countries, as in the mountains of Switzerland, where it was formerly dug out of the faces of lofty precipices by the inhabitants. It is also found in Bohemia, Saxony, Hungary, and in Cornwall in England, and different parts of Scotland, as in the island of Arran, in the cavities of the granite mountains, and in Cairngorm in Aberdeenshire, the two latter, which are well known by the name of Arran stones and Cairngorms, are usually of a smoky colour, owing, it is supposed, to iron or manganese ; probably to the latter, for from some experiments which we have made, the colour entircly disappears by exposing the crystal to a strong heat, and from other observations it appears that the colouring matter is also destroved by the action of light.

Rock crystal sometimes contains schorl, amianthus, actynolite, mica, and titanium. Crystals are also sometimes met with in cavities containing a drop of water, and a small quantity of air.

Uses .- Rock crystal, on account of its lustre and transparency, is employed in jewellery, and particularly when it is coloured, as those from Cairngorm in the north of Scotland, many of which are held in high estimation.

Subspecies 3. ROSY RED or MILKY QUARTZ.

Rosy Red Quartz, Kirw. i. 245. Quartz, laiteux, Brochant, i. 246. Quartz-hyalin laiteux, Hauy, ii. 420.

Exter. Char.__This mineral is always found massive. It is indeed said by Emmerling, that it has been found erystallized, in small six-sided prisms, terminated by a six-sided pyramid, at Rabenstein in Bavaria. Internally, its lustre is shining, rarely resplendent ; resinous ; fracture perfectly conchoidal, and fragments indeterminate. Siliceous It varies between semitransparent and translucent.

genus.

The colour is sometimes milk white; but its principal colour, it is said, is pale rose red. In its other characters it agrees with rock crystal.

It is suspected that this mineral is composed of silica and oxide of manganese, to the latter of which the colour is owing.

Localities, &c .- Milk quartz forms beds in primitive mountains; at Rahenstein in Bavaria it is met with in a large grained granite. It is also found in Finland, Greenland, Saxony, Siberia, and the western part of Inverness-shire in Scotland.

Uses .- The semitransparence, the fine colour, and the polish of which it is susceptible, have introduced this mineral to be employed in jewellery.

Subspecies 4. COMMON QUARTZ.

Quartz, Kirw. i. 242. Le Quartz commune, Brochant, i. 248. Quartz hyalin amorphe, Hauy, ii. 425.

Exter. Char.-Common quartz is found in various forms, massive, disseminated, in grains, and rounded pieces. It is sometimes stalactitical, globular, kidneyform, tuberculated, cellular, perforated, and correded; sometimes also it is crystallized, and the crystals are either true or supposititions. The true crystals are grouped together in reniform, rounded, or radiated masses; the form is the same as that of rock crystal. The pscudo crystals derive their figure from the substances on which they are formed, as the cube from fluor spar, the octahedron from the same, the six-sided table from barytes, the acute six-sided pyramid from calcareous spar. The surface of the true crystals is similar to that of rock crystal, but that of the pseudo crystals is rough, and the lustre is dull. Fracture of common quartz is small, conchoidal; sometimes large, splintery, and sometimes imperfectly foliated, or fibrous, with large parallel fibres. Fragments indeterminate, with sharp edges, very rarely rhomboidal. It is commonly translucent, rarely semitransparent. The colour is milk white, snow white, reddish white, and blood and flesh red, with many shades of these colours. Scratches glass. Spec. grav. 2.040 to 2.654.

Chem. Char.-Infusible before the blow-pipe. Silica. forms the principal constituent part; but among the numerous varieties of common quartz, there are no doubt slight differences in the nature and quantity of the materials which enter into its composition. The different shades of colour are owing to different portions and different states of metallic substances.

Localities, &c .- Common quartz is one of the substances of most frequent occurrence in all kinds of rocks, forming one of the chief component parts of primitive mountains, sometimes in entire beds, or whole mountains, as in the islands of Isla and Jura in Scotland. It is also frequent in veins, very common in stratiform rocks, where it constitutes the base of sandstone: in alluvial rocks it is met with in rounded pieces, or in the form of sand.

Uses .- Common quartz is employed in the manufacture of glass instead of sand; in the fabrication of smalt, and as a flux for calcareous ores of iron.

A variety of this, called aventurine, is sometimes held in considerable estimation. It is the quartz hyalin X 2 aventurine

Siliceous aventuriné of Hauy, and the natural aventuriné of De Lisle. It is of a deep red, gray, green, or blackish colour, marked with spots sometimes of a yellowish, and sometimes of a silvery appearance, which proceed from very thin pieces of pure quartz disseminated in the mass. It ought not to be confounded with quartz mixed with mica, or micaceous quartz, which is a com-pound rock. On the contrary, the diversity of colours seems to be owing to numerous fissures which are arranged nearly in the same direction.

Aventurine is found near Vasles, in the department of Deux Sevres in France, in the form of rounded stones, which are reddish; at Cape de Gates in Spain, of a whitish colour, with silvery spots; in Arragon, which affords several varieties ; near Madrid, among rounded fragments of granite; at Facebay in Transvlvania, where it is of a black colour, with very small golden spots; and in the neighbourhood of Catharineburg in Siberia.

The name aventurine is derived from the following circumstance. A workman having dropped by chance, par aventure, some brass filings into a vitreous matter in the state of fusion, gave the mixture this name, of which was afterwards made vases and other ornamental objects. Mineralogists gave the same name to natural substances which have a striking resemblance to this artificial production. Hauv, ii. 422.

Subspecies 5. PRASE.

Prasium, Kirw. i. 249. La Prase, Brochant, i. 252. Quartz Hyalin Vert obscure, ii. 419. Quartz Prase, Brongniart, i. 280.

Exter. Char .- This mineral possesses all the characters of quartz in general. It is most commonly found massive, and very rarely crystallized. The crystals, which are usually small, have the form of rock crystal.

The colour is usually leek green; the external surface is rough and glistening; the internal shining and vitreous; it is translucent; the fracture imperfectly conchoidal, and sometimes coarse splintery; fragments sharp-edged. When it is massive, it is composed of distinct concretions, which are granulated prismatic, or cunciform, the surface of which is rough and transversely striated.

Localities, &c .- Prase is found at Brietenbrunn near Schwartzenberg in Saxony, in a metallic vein, accompanied with magnetic pyrites, galena, blende, calcareous spar, and actynolite. It is also found in Bohemia, in Finland, near lake Onega, and in Siberia.

Uses.-As it is susceptible of a fine polish, prase is employed in jewellcry.

This mineral ought not to be confounded with quartz coloured by means of chlorite, which latter is of a brighter green, but opaque.

Subspecies 6. FERRUGINOUS QUARTZ, or Iron Flint.

Le Caillou Ferrugineux, Brochant, i. 248. Quartz Rubigineux, Brongniart, i. 281. Quartz Hyalin hematoide, Hauy, ii. 420. Eisenkiesel of the Germans.

Exter. Char.-The peculiar character of this mineral seems to be owing to a large proportion of oxide of iron, which renders it opaque. It is usually found massive, but it sometimes also assumes a crystalline form, which is a prism with six equal sides, acuminated at each extremity with three planes. The colour is of a

yellowish brown, sometimes of a brownish red, and of Classifica a bright blood red. It is usually opaque, or only transparent at the edges. External lustre resplendent; internal shining and vitreons. Fracture imperfectly conchoidal; fragments angular, but not very sharp-edged. Concretions small grained and distinct. It is harder than common jasper. Not very brittle.

Localities .- This mineral is found in veins of ironstone in Saxony, and in England, where it is accompanied with sulphate of barytes.

Forruginous quartz is distinguished from jasper, to the red variety of which it has a striking resemblance, by its shining fracture, which is also vitreous and conchoidal; its property of crystallizing; and according to Brongniart, by having no alumina in its composition, which he properly considers as an essential characteristic.

28. Species. HORNSTONE.

Hornstoue, Kirw. i. 303. La Pierre de Corne, Brochant, i. 254. Petrosilex, Hauy, iv. 385.

This mineral is met with in masses and also in rounded balls. The colour is usually gray; it is translucent at the edges, the fracture splintery or conchoidal; it has little lustre; is so hard as to scratch glass, and give fire with steel; and its spec. grav. is from 2.699 to 2.708.

The diversity of fracture which has been observed in hornstone, has led to the subdivision of this species into three subspecies, viz. splintery hornstone, conchoidal hornstone, and woodstonc.

Subspecies 1. SPLINTERY HORNSTONE.

Hornstone Ecailleux, Brochant, i. 255. Petrosilex Squamosus, Wallerius, i. 280.

Exter. Char .- This mineral is found massive, or in rounded pieces. It has scarcely any lustre; the fracture is fine, splintery; fragments sharp-edged; translucent at the edges. It is scarcely so hard as quartz; it is brittle.

The colour is bluish gray, smoke and pearl gray, sometimes greenish and yellowish gray, more rarely olive and mountain green. Sometimes there is a mixture of these colours, arranged in spots and stripes. Spec. grav. 2.654. Kirw.

Chem. Char .- According to some mineralogists, this variety of hornstone is fusible before the blow-pipe, but according to others it is infusible without the addition of borax.

The following are the constituent parts of a hornstone analyzed by Kirwan.

Silica, Alumina.			72
Carbonate	of	Lime,	6
			100

Localities, &c.-This variety of hornstone is chiefly found in voins in primitive mountains. It is also found in rounded pieces in alluvial rocks, and it constitutes the chief basis of hornstone porphyry, as at Dannemora and Garpenberg in Sweden. It is met with in veins at Freyberg, Schneeberg, Johann-Georgenstadt, and Gersdorf in Saxony.

tion.

Subspecies 2. CONCHOIDAL HORNSTONE.

Petrosilex Equabilis, Wallerius, i. 281. Le Hornstein Conchoide, Brochant, i. 258.

Exter. Char .- This mineral is always found massive, and seems to approach in its characters very nearly to the preceding variety or subspecies, excepting in the fracture, which is perfectly conchoidal.

Localities, &c .- This subspecies is found in beds and veins, when it is sometimes accompanied with agate. It has been found accompanying gneis at Goldberg in Saxony, and fine specimens of both subspecies are met with in the island of Rona near Sky in Scotland, where it seems to form a considerable vein, traversing a gneis rock.

Subspecies 3. WOODSTONE, or Petrified Wood.

Woodstone, Kirw. i. 215. Le Holzstein, Broehant, i. 259. Quartz Agathe Hyloide, Hauy, ii. 439.

This subspecies possesses more distinctive characters than the former; and as it seems to be wood, retaining its original texture, converted into hornstone by some petrifying process, it is usually found in insulated masses, or in rounded picces. It has the external appearance of wood, for the surface is rough and uneven, or longitudinally striated ; internally it is glistening, but sometimes dull, having a vitreous lustre. The fracture most frequently exhibits the fibrous texture of the wood. The cross fracture is sometimes splintery or imperfectly conchoidal. The fragments are indeterminate, and slightly sharp-edged. The most common colour is dark gray, ash gray, grayish white, and sometimes cochineal and blood red. Different colours appear in the same mineral, forming spots, clouds, or stripes. It is commonly translucent at the edges, sometimes entirely translucent, and sometimes opaque. It is hard and brittle.

Localities .- Woodstone is met with in Bohemia, Saxony, and Siberia, and on the banks of Loch Neagh in the north of Ireland, particularly, as we have been informed, near places where some of the rivers discharge their waters into the lake.

Uses .- This mineral is generally susceptible of a fine polish, and is therefore employed in jewellery.

29. Species. FLINTY SLATE, or Siliceous Schistus.

This species is divided into two subspecies or varieties, viz. common siliceous schistus, and Lydian stone.

Subspecies I. COMMON SILICEOUS SCHISTUS.

Siliceous schistus, Kirw. i. 306. Schiste silicieux commun, Brochant, i. 283.

Exter. Char.-This mineral is found in masses or rounded pieces, and it is frequently transversed by veins of quartz of a grayish white, or coloured red by means of iron. This, it is said, is a distinguishing characteristic of siliceous schistus which it rarely wants (Brochant). Internally it is dull, very rarely a little glimmering. The fracture in the small is compact, sometimes splintery, and sometimes imperfectly conchoidal; but in the great or large masses it is slaty, a character which almost always disappears in the small fragments. The fragments are sharp edged. The colour is blackish, greenish, or smoke gray. It is commonly opaque, rarely translucent at the edges. It is hard and brittle.

Chem. Char .- Before the blow-pipe, gray siliccous Siliceous schistus becomes white and friable; the black assumes genus. a darker colour, and is a little vitrified at the edges.

Constituent Parts. W	Vicgleb.
Silica, Magnesia, Lime, Iron, Inflammable matters, Loss,	75 4.58 10. 3.54 5.02 1.86
	100.00

Localities, &c .- Siliceous schistus is met with in Bohemia, Saxony, Switzerland, and Siberia; at Leadhills in Seotland, and also at Carlops near the termination of the great coal field to the south of Edinburgh.

The geological position of this stone is not pre-cisely determined. In Scotland it is connected with those rocks which come under the denomination of transition rocks; but according to different descriptions it seems to have been confounded with argillaceous sehistus, with which indeed it possesses some common properties; and some mineralogists regard it as an argillaceous schistus, having a larger proportion of siliceous earth. In support of this opinion, silieeous schistus has been found in situations where it is subordinate to argillaceous schistus.

Subspecies 2. LYDIAN STONE.

Basanite, Kirw. i. 307. La Pierre de Lydie, Brochant, i. 286. Roche Corneenne, Hauy, iv. 434.

This stone, which is of a grayish, bluish, or velvet black, is found in masses, and in rounded pieces of a trapezoidal form, which are also traversed with veins of whitish quartz. The external surface is smooth and weakly shining ; the internal is glimmering. The fracture is even, sometimes slightly conchoidal or uneven, rarely splintery; in large masses it is slaty. The fragments are sharp-edged, and sometimes assume a cubical form. It is commonly opaque, and rarcly translucent at the edges. It is seratched by quartz ; brittle. Spec. grav. 2.415 to 2.880.

Localities .- Lydian stone is found in similar places with the former variety.

Uses .- This stone has been long known under the name of *touchstone*, because it is employed to ascertain the purity of gold. From this use it obtained the name of Baraves or the trier, and it was called Lydian stone, because it was found in Lydia. When it is employed as a touchstone, the gold to be tried is rubbed on its polished surface; on the metallic trace which remains nitrie acid is poured, and the quantity of alloy is judged of by the degree of change which takes place, this being compared with traces made and treated in the same way with needles differently alloyed and prepared for the purpose. This test, it is to be observed, is not perfectly accurate, but is sufficiently so for those who are much employed in the use of it. "The property which renders this mineral fit for the above purpose depends on its degree of hardness, while it presents at the same time a smooth and even fracture without being perfectly smooth. Other stones possessing similar properties.

166

Siliceous ties, such as several varieties of basalt, are convenientgenus. , ly employed for the same purpose.

30. Species. FLINT.

Flint, Kirw. i. 301. Pierre à fusil, Broehant, i. 263. Quartz-Agathe Pyromaque, Havy, ii. 427.

Fater. Char .- Flint is found massive, disseminated, in angular fragments, in globular masses, tuberculated, and perforated. The surface is sometimes rough, sometimes uneven, and sometimes smooth. The white crust with which it is often covered, is considered by some mineralogists as an incipient decomposition. The external lustre is dull or a little glimmering; the internal is weakly shining; the fracture is perfectly conchoidal, the fragments sharp edged. The colour is usually gray, smoke gray, sometimes perfectly black. Various colours appear in the same mineral, presenting spots, stripes, and clouds. Commonly translucent at the odges ; scratches quartz : spec. grav. 2.58 to 2.99.

Chem. Char .- Entirely infusible before the blowpipe.

Physical Char .- Two pieces of flint rubbed together in the dark, give out, like quartz, a phosphoric light.

Localities, &c .- Flint is never found in primitive mountains, excepting in very small quantity, and very rarely, in some veins; in alluvial rocks it is sometimes met with in rounded pieces ; but it is most abundant in stratified mountains, particularly in beds of limestone, marl and chalk, in which it is disposed in parallel layers. It is met with in Saxony, Denmark, Sweden, Poland, and Spain, and is very abundant in chalk beds in the north of France, and also in different parts of England. It is also met with distributed in layers in the white limestone rocks, on the north coast of Ireland. In the department of Jura in France, globular masses of flint have been found with cavities containing sulphur.

19 Formation of flints,

The singular geological relations of this mineral have greatly puzzled naturalists, who are fond of such speculations, and are never satisfied till they have accounted for every thing, however seanty and defective the data may be on which their hypotheses are formed. It is on this account that the theories which have been proposed, to explain the formation of flint, offer nothing more than the silliest and most groundless conjectures; and indeed the same remark is equally applicable to theories of the earth in general. It has been already observed that flint is regularly disposed in layers, in the beds of chalk or limestone in which it is found. In an insulated mass of white limestone near Port Rush on the north coast of Ireland, which we had an opportunity of examining, the balls of flint were disposed in this way with great regularity. When the bed of lime-stone is of no great thickness, it contains only one layer of flints, but in thicker beds there are two layers of

flints, the one near the top, and the other near the bot- Classifie tom of the bed. Those layers of flint, too, it is to be observed, have exactly the same inclination as the strata of limestone. According to one set of theorists, the by fire, flint being in a state of fusion, was ejected from the bowels of the earth, and deposited in the places where it is now found. This opinion carries along with it its own absurdity; for admitting that the flinty matter has been in a state of fusion, it is impossible to suppose that it could be deposited with so much uniformity and regularity, by being projected according to the conjecture of the philosophers who maintain this opinion. Had this been the mode of its formation, masses of flint would have been found throughout every part of the chalk or limestone beds, and not in regular layers, as is really the case.

According to another opinion, by which the forma- by water tion of flint is proposed to be accounted for, cavities were produced, while the chalk and limestone were yet in a soft state, in consequence of the air extricated during the evaporation of the water ; and the flinty matter in solution was introduced into these eavities by infiltration from above. But the same argument is equally forcible against this opinion. It is impossible to conceive that the cavities could be so regularly and uniformly produced by the extrication of the air. They would have been found through every part of the beds of ehalk and limestone where flint is met with. And besides, even allowing that this flinty matter was held in solution by water, it might naturally be asked, why the greatest proportion of it was not deposited near the surface, when it first came in contact with the chalk or limestone, rather than to have continued to pass through the different beds, and form masses of solid flints at the greatest depths, in as great quantity as near the surface.

A third opinion, which some imagine to be less im- by marin probable than either of the former, supposes that flints animals. have been entirely produced by marine animals deposited during the formation of the strata in which they are contained. This opinion seems to derive some support from the remains of marine animals, which are not unfrequently found included in nodules of flint. It is no rare occurrence to meet with shells thus attached to these nodules, and converted into flinty matter, but at the same time retaining their original form and appearance in the most perfect manner.

Uses .- The extensive use of this mineral, in consequence of its property of striking fire with steel, as gun flints, is well known. Flints are employed also as a substitute for quartz in the manufacture of glass and porcelain, and in the fabrication of smalt. The coarser kinds, or such as are perforated and carious, are applied to the purposes of building and millstones. Sometimes the colours and the polish of fiint are so fine as to have brought it into use in jewellery.

As flints are found in greatest abundance in France Manufacand England, the principal manufactures of gun flints ture of gu are carried on in these countries. A particular account fints. of this manufacture in France has been given by Do-lomieu and Salivet, Jour. des Mines, Nº 33, pp. 693 and 713. The whole process, which according to the description of Dolomieu is divided into four stages, is very simple.

I. After having fixed upon a mass of stone fit for

tion.

4

ssifica- for the purpose, the first part of the operation is to break the stone into pieces of convenient size. With this view the workman, seated on the ground, places the stone on his left thigh, and strikes it with small strokes, to divide it into pieces of a pound or a pound and a half weight, having large surfaces and smooth fractures, and at the same time he avoids splitting or shaking the stone by too feeble or too violent strokes.

2. In the next part of the operation the nicest management and dexterity of hand are required; for by repeated strokes splinters of the proper size to form gun flints are detached; one is separated at every stroke. During this operation he holds the mass of stone in his left hand. The splinters are about $I\frac{\pi}{2}$ inch broad, $2\frac{\pi}{2}$ long, and two lines thick in the middle. They are slightly convex above, and concave below; thick at one edge, and thin at the opposite edge.

3. The flint is brought to a regular shape during this part of the operation ; and,

4. The edge of the gun flint which strikes fire, is brought to a straight line by placing it on a sharp iron instrument, and giving it five or six small strokes with a eircular hammer (roulette). This finishes the operation, and the whole time of making a flint is not equal to a minute. With masses of stone that work easily, an expert workman will prepare 1000 good splinters in a day. It requires another day to bring to the proper shape 500; so that in three days he can split off from. the mass and completely finish 1000 gun flints.

31. Species. CALCEDONY.

This species has been divided into two subspecies or varieties; common ealcedony and carnelian.

Subspecies I. Common CALCEDONY.

Id. Kirw. i. 298. La Calcedoine Commune, Brochant, i. 268. Quartz Agathe Calcedoine, Hauy, ii. 425.

Exter Char.—This mineral is found massive, in rounded pieces, which arc globular, reniform, botryoidal, stalactitical, cellular; and sometimes also it is crystallized in the form of a cube, rhomboid, a simple pyramid with three and six faces; but these are supposed to be pseudo crystals, or merely a crust of calcedony on the crystals of other substances. The external surface is most commonly uneven, sometimes rough, and rarely smooth. External lustre is accidental; internal glimmering, rarely a little shining; fracture even, sometimes imperfectly conchoidal or splintery; fragments. sharp edged.

Colour white, grayish or bluish white, yellowish or blackish: various colours appear in spots, elouds, stripes, and veins. Sometimes when it is cut it is irideseent; commonly translucent, rarcly semitransparent. Harder than flint. Brittle. Spee. grav. 2.600 to 2.700.

Chem. Char .- Before the blow-pipe it is infusible.

Constituent Parts.

100

Silica,	Bergman. 84
Alumina, A trace of iron,	16
() () () () () () () () () ()	-

Localities, &c.—Calcedony is most usually met with in globular masses in amygdaloid, as at Oberstein, in the duchy of Deux Ponts. It is found also in Saxony, Silesia, and Siberia, in Iceland and the Faro islands; in the north of Ireland; and in several of the western islands of Seotland. The cavities of the balls of ealeedony are often lined with crystals of quartz and amethyst.

Uses.—Calcedony takes a fine polish, and is thereforeemployed in jewellery.

2. Subspecies. CARNELIAN.

Id. Kirw. i. 300 La Cornaline, Brochant, i. 272: Quartz-Agathe Cornaline, Hauy, ii. 425.

This mineral is found in masses, or disseminated, but most frequently in rounded pieces of a globular, kidney form, or stalactitical shape. External surface rough and uneven; internal lustre glimmering, or slightly shining; fracture perfectly conchoidal; fragments very sharpedged; most common colour blood red of various shades, and sometimes reddish brown or wax and honey yellow; semitransparent, hard, and brittle. Spec. grav. 2.59 to 2.73.

Chem. Char.-Carnelian is infusible before the blowpipe, but loses its colour, and becomes white.

Localities, &c.—Carnelian is found in similar cireumstances, and in similar places with common ealcedony, but is of less frequent occurrence. The fuest carnelians are brought from the east, and thence they are denominated oriental.

Uses.—The carnelian is employed for the same purposes as common calcedony.

Observations on Agate.—As common calcedony and carnelian, along with jasper, constitute the base of the greater number of agates, it may be here proper to introduce a few remarks on the mineral substances which are included under this name, and on the theories of their formation.

The term agate is of very general application, com- varieties. prehending numerous varieties, which are chiefly distin- of agate. guished by the arrangement and disposition of the colours with which they are marked, and from which they have derived particular names. The following are some of the principal varieties of agate. 1. Eortification agate, in which the different coloured stripes are arranged in a zigzag manner, presenting something of the appearance of a fortified town. 2. Landscape agate, in which the colours and shades arc so arranged as to exhibit the appearance of a landscape. 3. Band or ribbon agate, in which the various colours are disposed in stripes or zones, which are usually in straight lines, but sometimes concentric. To this variety of agate, when the zones or stripes are arranged parallel to each other, and distinctly marked, the name of onyx was given by the ancients. The name onyx, which signifies the nail of the finger, is derived from the whitish colour resembling that part of the body. They also gave the name of sarde to a variety of the same stone, of a flesh colour, and afterwards the compound name sardonyx was given to another variety, in which a whitish layer of the onyx, having some degree of transparency, covered another layer of a flesh red, the colour of which latter appeared through the former in the same manner as the colour of the flesh appears through the nail. But in

rt I.

Siliccous in the end, the name of onyx seems to have been applied to all stones formed of lavers of different colours. 4. Moss agate. In some varieties of agate filaments of a greenish or other colour, having the appearance of some species of confervæ or musci, are observed, and these have been denominated moss agates. Some have supposed that these filaments have been real mosses or confervæ, enveloped by the siliceous matter. In some also delineations of a brown or black colour, exhibit the appearance of trees or shrubs. This dendritical appearance is ascribed by some to the infiltration of iron or manganese into the natural fissures of the stone. The finest agates of this variety, it is said, are brought from Arabia, by the way of Mocha, on the coast of the Red sea; and hence they are known by the name of Mocha stones. Besides these varieties, there are several others, as tubular agate, when it is composed of calcedony, which seems to have been in the form of stalactites, and afterwards filled up with a different mineral substance, or at least of a different colour; clouded agate, presenting the appearance of clouds; radiated or stellated, when the different colours are arranged in rays; breccia agate, composed of fragments of different kinds of agate, and cemented together by siliceous matter, and eonstituting a real breccia; spotted agate, when the colours are disposed in points or spots; petrified agate, which seems to have been wood penetrated with the matter of agate; coral agate, having the appearance of coralloid; jasper agate, in which the predominant part of its composition is jasper.

25 Formation of agate,

26

by fusion.

The formation of agate has been the subject of much controversy among contending theorists; for while one party conceives that it affords the strongest proofs of being produced by means of heat, or from a state of fusion, another party seems to be equally convinced that it supplies them with the most certain evidence of having been formed from an aqueous solution.

Besides other strong objections that might be urged against the opinion of agate being formed from a state of fusion, the uniformity and regularity in the arrangement of the different kinds of matter of which it is composed, scem quite hostile to it, and, excepting to those who are previously prepossessed with such an opinion, will, we presume, appear altogether insurmountable; for it is inconceivable, that a mass of mclted matter, whether it have been in a state of fusion in the place where it is now found, or projected from the bowels of the earth into the strata which are now its repository, while in a soft state, could arrange itself into layers, some of them often extremely thin, and disposed in stripes, concentric circles, spots, while these various kinds of matter exhibit very slight shades of difference in their constituent parts. It cannot even be imagined that all this could have been effected, even by the slowest and most gradual process of cooling.

27 by aqueous

In accounting for the formation of agate hy solution infiltration in water, it is said that the cavities in the rocks which contain agate, were formed in consequence of the evolution and extrication of air, while those rocks were in a state of softness; and that the matter of which agate is composed, was introduced in the state of an aqueous solution by means of infiltration. But objections, equally insurmountable, might easily be adduced against this theory : and one of the first that presents itself is dezived from the diversity of matter deposited in masses of I

agate. This objection, indeed, is attempted to be ob- Classific viated by supposing that the agate composed of different kinds of matter was derived from different kinds of snc. cessive solutions : but this is only removing the diffieulty a step farther ; for, can it easily be conceived, that a very thin layer of one kind of matter being deposited, and this, let it be supposed, of a white colour, the solution was changed, from which proceeded another thin layer; that the solution was again changed, and deposited a third kind of matter; and after another change, a fourth kind, or perhaps that the deposition of the first kind of matter again commenced. But if infiltration from an aqueous solution have really been the mode of formation of this mineral, how comes it, it may be fairly asked, that the depositions from the different kinds of solution have not been arranged, at least in the larger cavities, in strata or zones parallel to the horizon; because it seems natural to suppose that the deposition of stony matter, from a state of solution in water, would be influenced by gravitation, and thus be horizontally arranged ? We are aware, indeed, of an objection which may be made to this observation. It will be said that the influence of gravity has in this case been counteracted by the action of affinity between the stony matter in solution, and the sides of the cavity in which the agate is formed; but whatever effect this might have in the smaller eavities, its influence would be diminished in those of larger capacity.

To what we have now said on this subject, which, it must be acknowledged, is more curious than useful, we shall only add a circumstance which, so far as we know, has not been noticed by geologists; but it seems to be of considerable importance to the establishment or subversion of the theory of the formation of agate by means of infiltration in the state of aqueous solution. It will be allowed, we presume, that all agates found in the same horizontal position, or at the same depth from the surface, from which the aqueous solution is understood to have proceeded, were formed from the same solutions; at least those agates which are contiguous to each other, that is, within the space of a few yards, or even of a single yard. Now, if this be admitted, all the agates which have derived their materials from the same solutions, ought to be exactly of the same kind, because their origin is cotemporaneous, and it is derived from the same solutions. To ascertain this point with precision, it will be necessary to examine agates in their native repositories; and although we shall not pretend confidently to decide the question, because our observations with this view have not been sufficiently varied and extensive, yet we strongly suspect, that it will appear, from future investigations, that agates, and even such as are almost contiguous to each other, have been formed of very different materials, or of similar materials arranged in a very different manner. To those who are fond of such speculations we recommend this as a subject of investigation.

Localities .- Agates are found in great abundance in different parts of the world. They are sometimes distributed indiscriminately with the rocks which contain them, sometimes in beds or layers, in interrupted masses, and sometimes in thin beds, where there is scarcely any interruption of continuity. This last mode of arrange-ment, however is rare. Agates are sometimes found in metallic veins, or are mixed with metallic substances, 28

Part

n die

seum

111.

MINERALOGY.

ssifica- as the sulphurets of lead and silver. It would appear, too, that agates also exist in primitive rocks. Saussure has observed them in granite, containing nodules of the same granite, and penetrated with iron pyrites. He has observed also at the same place, near Vienne, in the department of Iserc, thin layers of calcedony alternating with gneis; but porphyries and similar rocks are the usual repositories of agate. These stones are found in great variety and abundance at Oberstein, in the department of Mont-Tonerre, in France, in a rock of amygdaloid of a peculiar nature, and full of cavities of all sizes. This rock is considered by Dolomieu as a volcanic tufa; but according to other mineralogists, and particularly Faujas de St Fond, who has given a minute description of it*, it is considered as a porphyry or amygdaloid, with a basis of trap, which is very subject to decomposition. The globular masses of agate are disposed in this rock without any order, and are usually enveloped with a peculiar greenish carth, but which contains no copper. In the geodes of agate found at Oberstein, jasper, amethyst, carbonate of lime in crystals, chahasie, a species of zeolite, and some portion of titanium, have been observed ; but not the least trace of any organized body. Digging, polishing, and forming into a great variety of ornamental objects, constitute the chief employment of the inhabitants of Oherstein.

Agates are found in abundance in different parts of Scotland : but the largest and finest are met with in the neighbourhood of Montrose and Stonchaven; in the rocks near Dunbar on the east coast, and in the rocks about Dunure, on the shore of Carrick in Ayrshire.

32. Species. HYALITE.

Id. Kirw. i. 296. Muller's glass of the Germans. Lava glass of many.

Exter. Char .-- This substance is found in grains or masses, or in thin layers on other minerals. It has much the appearance of gum, and is usually cracked. The lustre is shining and vitreous; fracture conchoidal, sometimes foliated; fragments sharp-edged.

Colour grayish white or yellowish; and, according to Kirwan, pure white. Translucent, sometimes semitransparent; has considerable hardness, and is brittle. Spec. grav. 2.110.

Chem. Char .- Infusible at 1 50° Wedgwood, but melts with soda.

Constituent Parts.		
Silica,	.57	•
Alumina,	18	
Lime,	15	
With some traces of iron.		

Localitics, &c .- Hyalite is found in rocks of amygdaloid, or wacken, near Franckfort on the Maine.

33. Species. OPAL,

This species is divided into four subspecies or varieties.

Subspecies I. PRECIOUS OPAL.

Opal, Kirw. i. 289. L'Opale Noble, Brochant, i. 341. Quartz-resinite Opalin, Hauy, ii. 434. Vol. XIV. Part I.

Exter. Char .- This mineral is found massive or disse-"Siliceous minated, and sometimes in veins; internal lustre splen- genus. dent and vitreous; fracture perfectly conchoidal; fragments sharp-edged.

Colour milk-white, clear or pale, and sometimes bluish gray; and by holding it in different lights, a very bright and varied play of colours, the principal of which are golden yellow, scarlet red, bright blue, green and gray, is seen. It is commonly translucent, rarely semitransparent; pretty hard and brittle. Spee. grav. 2.114

Chem. Char .- The precious opal treated with the blow-pipe splits and cracks, and loses its transparency, but is not melted.

Constituent Part.	s. Klaproth.
Silica,	90
Water,	10
and the second sec	
	100

Localities .- The finest opals arc found at Czerwenitza net far from Caschau in Upper Hungary, in an argillaceous decomposed porphyry, which according to some mineralogists is a gray stone (graustein of the Germans), and are disposed in veins, nests, and grains. When the opal adheres in small particles closely together in the stone, it forms what is called mother of opal. It is found in the same manner in a kind of breccia of this decomposed porphyry. (Townson's Travels in Hungary, p. 307.). It is found also at Eibenstock, Johann-Georgenstadt, and Freyberg in Saxony. At this latter place the repository of the opal is porphyry. The opal also is met with in Iceland.

The opal mines described by Dr Townson are situatcd in a hill of some miles in extent not far from the village of Czerwenitza. This hill has been opened in several places, but in three with the greatest success. Guards are placed upon it to prevent any person from digging this precious stone; for as it is situated in part of the royal domain, the peasants who were formerly permitted to search for it on their own account arc now prohibited by the emperor. But even at the time Dr Townson visited the mines the work had been discontinued for three or four years as unprofitable. The usual mode of conducting the operations in searching for the opal is by quarrying to the depth of three or four yards, rarely deeper. The rock is thus thrown out, broken to pieces, and afterwards examined. In one place the search had been made by mining; but the gallery was only a few yards in length. From this account it appears that the rock containing the opal lies near the surface, and seldom, it is said, extends deeper than a few fathoms. The opals denominated oriental by the lapidaries, a term expressive of their value rather than of their origin, are supposed to be from these mines, in which, according to records still in existence, 300 men were employed not less than 400 years ago.

Uses .- On account of the fine play of colours, the opal is held in great estimation for the purposes of jewellery, and the opals which reflect green colours in most abundance are most highly valued. The finest opals are called oriental; but this epithet is given by the lapidarics to the more perfect precious stones, and is not to be understood as denoting that they have been, brought from eastern countries.

160

Siliceous genus.

170

The ancients, it would appear from the account of Pliny, attached an immense value to this stone; for he informs us that a senator called Nonius rather submitted to banishment than give up an opal which he had in his possession to Mark Anthony. This opal was estimated at 20,000 sesterees. Lib. xxxvii. cap. 6.

Subspecies 2. COMMON OPAL.

Semi-opal, Kirwan, i. 290. L'Opale Commune, Brochant. i. 344. Quartz resinite Hydrophane et Quartz resinite Girasol, Hauy, ii. 433.

Exter. Char.—Common opal is found in masses, or disseminated, sometimes in rounded or angular pieces, and sometimes kidney-shaped or botryoidal. Internal fustre splendent, and intermediate between vitreous and resinous. Fracture conchoidal, but sometimes uneven. Fragments sharp-edged.

Colour milk-white, and varieties of this colour held in certain directions appear of a wine yellow. The other shades of colour are yellowish or reddish white, and wax or honey yellow. Semitransparent and sometimes transparent. Specific gravity from 1.958 to 2.015. In other characters the same as the precious opal.

Chem. Char.-Infusible before the blow-pipe, but melts with borax, and without swelling up.

Constituent Parts. Klaproth.

Fro	m Kozemutz.	From Telkoba	anya.
Silica, Alumina, Oxide of iron, Loss,	98.75 0.10 0.10 1.05	Siliea, Oxide of iron, Water Loss	93.50 1.00 5.00
	100.00		100,00

Localities, &c.—The common opal is found in veins, chiefly in amygdaloid rocks, and sometimes also, it is said, in granites and porphyries. It is of most frequent occurrence in Bohemia; in Saxony, as at Freyberg, Eibenstock, &c.; in Hungary, in Poland, in Scotland, and the Faroe islands. The amygdaloid rocks in the vicinity of the Giants Causeway in the north of Ireland also afford a repository for this mineral.

Uses.—It is employed as well as the former for the purposes of jewellery, but is esteemed of inferior value.

It has been observed of some varieties of common opal that they are hydrophanous, that is, they possess the property of becoming transparent when immersed in water, a property which it is supposed depends on the absorption of the water in the pores of the opal. When similar varieties of opal are dipped in melted wax, they are impregnated with it, and become in like manner transparent, but on cooling resume their opacity. To such varieties De Born has given the name of *Pyrophane*.

Subspecies 3. SEMI-OPAL.

Id. Kirwan, i. 290. La Demi-opale, Brochant, i. 347. Quartz Resinite Commune, et Menilite, Hauy, ii. 433.

Exter. Char.—This mineral is found in masses or disseminated, in angular fragments, stalactitical, botry-

oidal, or in superficial layers. Lustre glimmering or Classifica. shining, and intermediate between vitreous and resinous. Fracture conchoidal, and frequently even. Fragments sharp-edged.

Colours extremely various, but in general duller and less vivid than common opal. The most predominant are yellowish, grayish and reddish white, more rarely milk white. Various colours are sometimes disposed in spots, stripes, and clouds. Translucent at the edges, and sometimes, but rarely, semitransparent. Pretty hard and brittle. Spee. grav. 2.540.

Chem. Char.-Infusible before the blow-pipe, but melts with borax and without frothing up.

Constituent Parts.	Klaproth.

	I Haland high

100.00

Localities, &c.—The seni-opal is found in the same places and in similar rocks with the common opal, as in basalt and amygdaloid, but chiefly in granite and perphyry, and particularly in the veins of such rocks containing silver.

Some varieties of pitch stone have been ranked with semi-opal by mineralogists; and menilite, a mineral to be afterwards described, has been also considered merely as a variety of it.

Subspecies 4. WOOD OPAL.

Ligniform Opal, Kirwan, i. 295. Opale Ligniforme, Broehant, i. 350. Quartz resinite Xyloide, Hauy, ii. 439.

Exter. Char.—This variety of opal is found in masses of different sizes, retaining the form and texture of the wood which is supposed to be penetrated with the stony opaline matter. Lustre interally weakly shining, between vitreous and resinous. Transverse fracture conchoidal, longitudinal fracture shows the woody texture. . Fragments sharp-edged.

Colours grayish and yellowish white, yellowish brown and ochre yellow. Different colours are sometimes arranged in concentric circles, in spots, and stripes. Often opake, but rarely translucent except at the edges. Intermediate between hard and semi-hard. Brittle. Spec. grav. 2.600.

Localities, &c.-The wood opal is found at Pornick near Schemnitz in Hungary, and at Telkobanya in the same country.

34. Species. MENILITE.

Pitchstone, Kirwan, i. 292. Variety of flint of some, and Semi-opal of Klaproth.

Exter. Char.—This mineral is found in tuberose masses, which have a smooth ribbed surface, and are sometimes covered with a whitish crust. Internal lustre weakly shining. Transverse fracture flat, conchoidal; longitudinal, coarse, splintery. Fragments sharp-edged.

Chesnut brown colour, and marked with alternating stripes of pearl gray and reddish brown. Translucent. Pretty hard and brittle. Spec. grav. 2.185.

Localities, &c....This mineral is found at Menil-Montant, from which it derives its name, near Paris, in nodules disposed in interrupted strata, in the middle of a foliated, argillaceous schistus, which is interposed between the beds of gypsum.

35. Species. JASPER.

Jasper has been divided into six subspecies, 1. Egyptian; 2. Striped; 3. Porcelain; 4. Common; 5. Agate; and, 6. Opal.

Subspecies 1. EGYPTIAN JASPER.

Egyptian Pebble, Kirwan, i. 312. Le Jaspe Egyptien, Brochant, i. 332.

Exter. Char.—This variety of jasper is found in rounded pieces, which are generally spherical, and have a rough surface. External lustre glimmering or weakly shining; internal weakly shining. Fracture perfect conchoidal; fragments sharp-edged.

The colours of this variety are disposed in zones or irregular stripes, which are nearly concentric. These colours are yellowish brown on a ground of chesnut brown; usually opaque, or slightly translucent at the edges. Spec. grav. 2.56 to 2.6.

Chem. Char .- Infusible before the blow-pipe.

Localities, &c.—This mineral, as its name imports, is brought from Egypt, where, as was observed by Cordier, it constitutes part of a breccia which is entirely composed of fragments of siliceous stones, immense strata of which abound in that country, and the deserts of Africa in the vicinity. The masses of jasper are found among the sand which has been derived from the decomposition of this breccia, and particularly near Suez.

Uses.—This variety, on account of its hardness and beautiful colours, is in considerable estimation for ornamental purposes.

Subspecies 2. STRIPED JASPER.

Id. Kirw. i. 312. Le Jaspe Rubané, Broch. i. 334. Quartz-Jaspe Onyx, Hauy, ii. 436.

Exter. Char.—This variety of jasper is found massive, and sometimes forms entire beds. It has no lustre, except from the mixture of extrancous substances. Fracture conchoidal, sometimes splintery or carthy. Fragments sharp-edged.

To the variety of colours of this mineral it owes its name. These are pearl gray, yellowish and greenish gray, with shades of red and blue, and these different colours are arranged in straight or curved lines; generally opaque, translucent only at the edges. Localities, &c. This variety of jasper abounds in Siberia : it is found also in Saxony, in the Hartz, where it reposes on gray wacken; in Sicily; and in the hills in the vicinity of Edinburgh.

Subspecies 3. PORCELAIN JASPER.

Porcellanne, Kirw. i. 313. Le Jaspe Porcelaine, Broch. i. 336. Thermantide Porcellanite, Hauy, iv. 510.

Exter. Char.—Usually found in masses or angular pieces, in which rents or fissures are often observed, and also in whole beds. Internal lustre glimmering or weakly shining; resinous. Fracture imperfect conchoidal or uneven. Fragments sharp-edged.

The colour exhibits great variety; pearl, ash, yellowish and bluish gray, with shades of yellow, red, and rarely green. The colour is generally uniformly the same, but sometimes it is striped and dotted, flamed and clouded; impressions of vegetables of a red colour are observed on the blue varieties, and the rents or fissures are of a red colour in the grayish specimens; is entirely opaque; pretty hard, and easily frangible.

Chem. Char .- Melts before the blow-pipe into a black slag.

Constituent Parts	. Rose.

Localities, &c.—This mineral is abundant in different parts of Bohemia; it is met with also in Saxony, in the rocks in the vicinity of Edinburgh, and on the coast of Fife near Dysart in Scotland.

This jasper derives its name from its fracture, which resembles that of porcelain; and as it is frequently found in places where subterraneous fires have existed, such as beds of coal which have been kindled by accident, it is ascribed to their action; and according to Werner, it is nothing more than a slaty clay altered by fire,

Subspecies 4. COMMON JASPER.

Id. Kirw. i. 310. Jaspe Commun, Broch. i. 338.

Exter. Char.—This variety is usually found massive, sometimes disseminated, or alternating in thin layers with other stones. Lustre glimmering or shining,' between vitreous and resinous. Fracture more or less perfectly conchoidal, sometimes splintery or earthy. Fragments sharp-edged.

Colours extremely various, exhibiting different shades of red, yellow, and black; and several of these are united together, presenting clouds, spots, and stripes. Usually opaque, or slightly translucent at the edges. Is scratched by quartz. Easily frangible. Spec. grav. 2.3 to 2.7.

Chem. Char,-Entirely infusible before the blow-Y 2 pipe. Siliceons pipe. Its constituent parts are extremely variable. The genus. following were obtained by the analysis of Kirwan.

Siliea,	75
Alumina,	20
Oxide of iron,	in i

100

Localitics, &c.—This jasper is very common in different parts of the world; in Saxony, Bohemia, Hungary, France, Spain, Italy, Siberia, and also in Scotland, as among the basaltic rocks in the vicinity of Edinburgh, and at Dunbar. It is usually found in veins, especially such as contain ores of iron. It is often traversed with veins of quartz, or mixed with pyrites, lithomarga, semiopal, brown spar, native and vitreous silver. It has been taken for the basis of some porphyries, but these turn out to be indurated elay, pitch stone, and horn stone.

Subspecies 5. JASPER AGATE.

Exter. Char.—This variety seems to be the same as that already mentioned under the name of *agate jasper*, in speaking of agates at the end of the description of caleedony. It is found massive, and possesses no lustre. Fracture conchoidal, generally opaque, pretty hard, and sometimes adheres to the tongue. The colours are yellowish or reddish white, which are disposed in stripes and circles.

Localities, & e.--It is met with in many places in agate balls, in amygdaloid rocks.

Subspecies 6. OPAL JASPER.

Exter. Char.—This variety of jasper seems to possess many common characters with some varietics of opal. It is found massive. Internal lustre between vitreous and resinous, is shining or resplendent. Fracture conchoidal. Fragments very sharp-edged.

Colours searlet red, blood red, brownish red, more rarely yellow. Colours disposed in veins, spots, and clouds. Opaque, or translucent at the edges. Brittle, and easily frangible.

Localities, &c.—This mineral is found in Hungary, in Siberia, and other places, and is usually in nests in porphyry.

Beside the localities of the different varieties of jasper already mentioned, we may notice that it is met with in Siberia of a white and bluish colour. The hill on which the fortress of Orskaia stands on the left bank of the river Jaik, in the government of Orembourg, is entirely composed of a pale green and deep red jasper, disposed in inclined beds; and on the most elevated parts of the Altaian mountains, near the source of the river Korgou, a jasper has been discovered of an ivory white colour, which is remarkable for being penetrated with black dendrites.

Uses of Jasper.—It is valued according to its hardness, the degree of polish of which it is susceptible, and the beauty and variety of its colours; and it is employed in forming vases, handles for swords and knives, and other smaller ornamental purposes.

36. Species. HELIOTROPE, or Bloodstone.

Heliotropium, Kirw. i. 314. L'Heliotrope, Broch. i. 276. Quartz jaspe Sanguin, Hauy, ii 436.

Exter. Char.—Heliotrope is found massive or in an- Classific gular pieces; external lustre glimmering or shining, tion. and resinous; fracture conchoidal, sometimes uneven. Fragments very sharp-edged.

Colour chiefly deep green, but of various shades, with spots of olive and yellow, but most frequently scarlet or blood red: translucent at the edges: hard, easily frangible. Spec. grav. 2.62 to 2.7.

Chem. Char.—Entircly infusible before the blow-pipe. Localities, & e.—This mineral was originally brought from the east, but it has since been found in Siberia, in Bohemia, where it is met with in a vein, and in Iceland.

Uses.—It is employed for similar purposes with jasper or agate.

By many mineralogists this mineral is considered as a variety of jasper; hence it has been called oriental jasper; and it is supposed by some to be a calcedony penetrated with green earth.

37. Species. CHRYSOPRASE.

Chrysoprasium, Kirw. i. 284. La Chrysoprase, Broch. i. 280. Quartz Agathe Prase, Hauy, ii. 426.

Exter. Char.—This mineral is found massive, or in angular fragments : internal lustre rarely glimmering; fracture even, sometimes splintery; fragments sharpedged.

Colour apple-green, greenish gray, or leek-green; translucent, sometimes semitransparent; less hard than ealcedony and flint. Spee. grav. 2.25.

Chem. Char.-Infusible before the blow-pipe, but loses its transparency, and becomes white.

Constituent Parts.	Klaproth.

Alumina,	.08
Lime,	.82
Oxide of iron,	.08
Oxide of nickel,	1.00
Loss,	1.86
	AND DESCRIPTION
	100.00

Localities, &c.—Chrysoprase is found at Kosemutz, in Upper Silesia, in a mountain composed of serpentine, asbestus, indurated tale, and lithomarga.

Uses.—It is employed for similar purposes as jasper, and it is greatly esteemed when it is of a fine applegreen colour. It is said that some varieties of this mineral lose their colour by being exposed to moisture, so that the jewellers, before using them, put them to the test, by keeping them for some time in a moist place.

38. Species. PLASMA.

Id. Broch. i. 278. Silex Plasme, Brongniart, ii. 398.

Exter Char.—This mineral is found disseminated, in rounded pieces, and also in angular pieces. Internal lustre glimmering or weakly shining; resinous. Fracture conchoidal, even, and sometimes splintery. Translucent, and sometimes even transparent in thin pieces.

Colour various shades of green; and sometimes different colours are disposed in spots, stripes, and points. Nearly

172

Part

MINERALOGY.

assifica- Nearly equally hard with calcedony. Brittle, and easily tion. frangible.

Chem. Char.-It is infusible before the blow-pipe, but becomes white.

Localitics, &c.—It is said by some, that this mineral has only been found among the ruins of Rome, but according to Brongniart and others, it has been found in the Levant, in Upper Hungary, and in Moravia, in a mountain of serpentine, where it is accompanied with flint.

Uses.—It appears that this mineral was much employed by the ancients for ornamental purposes.

39. Species. CAT'S EYE.

Id. Kirw. i. 301. L'Ocil de Chat, Brochant, i. 292. Quartz-Agathe Chatoyant, Hany, ii. 427.

Exter. Char.—This mineral, as it is brought from its native country, is usually cut and polished, so that its natural form is unknown; but it is supposed that it is met with in grains or rounded pieces. A mass described by Klaproth, which seemed to be in its natural state, had a quadrangular form, a rough surface, and considerable brilliancy. The lustre is resplendent and resinous. The cross fracture is uneven, the longitudinal fracture imperfectly foliated. Fragments more or less sharpedged.

The colour is greenish yellow and smoke gray, of various shades, and sometimes, but rarely, grayish or silvery white. It is translucent, rarely semitransparent. When it is cut, it reflects different rays of light by changing its position, a character by which it is easily known. This is ascribed to small parallel fibres which appear in the interior of the stone. It is hard, easily frangible. Spec. grav. 2.625 to 2.660.

Chem. Char.—It melts with great difficulty by the action of the blow-pipe. Klaproth subjected it to the heat of a porcelain furnace, but it was not melted; it only lost its hardness, lustre, and transparency, and the colour became of a pale gray.

Constituent Parts. Klaproth.

Silica,	95.00	94.50
Alumina,	1.75	2.00
Lime,	1.50	1.50
Oxide of iron,	0.25	0.25
Loss,	1.50	1.75
	100.00	100.00

Localities.—Cat's eye is brought from Ceylon and the Malabar coast, and also, it is said, from Egypt and Arabia; but always in the polished state. The only one known in its natural state was that above mentioned, which was presented to Klaproth by Mr Greville of London.

Uses.—This mineral is in great estimation as a precious stone, and it is usually cut for ring-stones.

The name is derived from its possessing the property of reflecting the light similar to the eye of the cat, and hence the term *chatoyant* among jewellers, which is expressive of that effect.

49. Species. OBSIDIAN.

Id, Kirwan, i. 265. Iceland agate vulgo. L'Obsidienne,

Brochant, i. 288. Lave vitreuse Obsidienne, Hauy, Siliceous iv. 594.

Exter. Char.—This mineral is found in masses, and sometimes in rounded pieces. Lustre resplendent, vitreous; fracture perfectly conchoidal; fragments very sharp-edged.

The most common colour of obsidian is perfectly black, sometimes greenish and grayish, black, blueish, greenish and smoke gray, and yellow and red, according to Humboldt: most commonly opaque, but sometimes translucent on the edges. It is hard and easily frangible. Spec. grav. 2.348.

Chem. Char.—Before the blow-pipe obsidian melts into an opaque porous glass, of a grayish white colour.

Localities, &c.—This mineral is found in Iceland, in Siberia, in the Lipari islands, in Hungary, in Madagascar, the island of Teneriffe, in Mexico, Peru, and some of the South sea islands. Humboldt discovered a variety of obsidian in New Spain, which was chatoyant in a considerable degree. The obsidian from Hungary is found in insulated pieces among detached masses of granite, gneiss, and decomposed porphyry. Obsidian was long supposed to have a volcanic origin; but it appears, from the accounts of those who have visited Iccland, that it is not only found in the vieinity of Hecla, but everywhere, distributed like quartz and flint; and besides it is not unfrequent in countries where volcandes were never known to exist.

Uses.—The fine colour and hardness of this stone have brought it into use for ornamental purposes. Among the ancient Mexicans and Peruvians it was employed as mirrors, some of which, it is said are sometimes still found in the tombs of their ancient sovereigns (Faujas Miner. des Volcans, p. 308.); and also for cutting instruments as knives and even razors. Hernandez saw the Mexican cutlers make a hundred knives of obsidian in the course of an hour. Obsidian, it is said, has also been used as mirrors for telescopes.

41. Speeies. PITCHSTONE.

Id. Kirwan, i. 292. La pierre de poix. Brochant, i. 353. Petrosilex resiniforme, Hauy, iv. 386.

Exter. Char.-Pitchstone, which has received its name

art I.

174

genus.

Siliceons name from its resemblance to pitch, is found massive sometimes in extensive beds and veins, and also forming entire mountains. Internal lustre shining and resinous. Fragments sharp-edged. In coarse and frequently small granular distinct concretions which have a . smooth surface.

> The colours are various shades of black, green, brown, red, and gray. Translucent, but commonly at the edges only. Brittle, and rather easily frangible. Spec. grav. of pitchstone from Saxony, 2.314; of black pitchstone from Arran, 2.338; of pitchstone from Meissen 1.645, Klaproth.

Chem. Char.-Fusible by the blow-pipe, and is converted into a white porous enamel.

Constituent Parts of pitchstone from Meissen of an olive green colour. Klaproth, Transl. ii. 207.

Loss,	1.5
	100.00

Localitics, &c.-Pitchstone is found in great abunance in Saxony, in Hungary, and also in Siberia. It abounds also in Scotland, particularly in the island of Arran, where it is met with in beds, but chiefly in veins traversing the strata in the less elevated parts of the island. Pitchstone also forms the basis of a porphyry.

42. Species. PEARLSTONE.

Obsidienne Perlée, Brongniart, ii. 340. Lave Vitreuse Perlée, Hauy, iv. 495. Volcanic Zeolite, Fichtel. Zeolitic Pitchstone of others. See Klaproth, Transl. ii. 263.

Exter. Char .- Pearlstone almost always forms the ground or basis of a species of porphyry which contains roundish or longish vesicular cavities. Lustre pearly. Fracture seems imperfectly conchoidal; but is not very perceptible. Fragments blunt-edged.

Colour bluish, ash, greenish gray. Translucent at the edges. When breathed upon, gives out the argillaceous odour. Not brittle, but easily frangible. Soft. Spec. grav. 2.340 to 2.548.

Chem. Char.-Before the blow-pipe froths up like zeolite, but is not fused.

Constituent Parts. Klaproth, ii. 267.

100.00

Localities, &c .- Pearlstone is found near Tokay in Classific Hungary, in strata alternating with those of argilla- tion. ceous porphyry, and containing in its vesicles uodules of obsidian; it is also met with in Iceland, and in the north of Ireland.

43. Species. PUMICE.

Id. Kirwan, i. 415. La Pierre ponce, Brochant, i. 443. Ponce, Brongniart, i. 332. Lave vitreuse pumicée, Hauy, iv. 495.

Exter. Char .- This mineral is found massive or disseminated, and it is always of a porous or vesicular texture.

Lustre glimmering, or a little shining and silky. Fracture fibrous; fragments blunt-edged.

Colour grayish white, bluish, or yellowish gray. Opaque, rarely translucent at the edges, sometimes semihard, but generally soft, very brittle, and very easily frangible. Spec. grav. 0.914. Chem. Char.—Fusible before the blow-pipe, and is

converted into a white glass.

Constituent Parts. Klaproth, ii. 208.

Silica,	77.50
Alumina,	17.50
Oxide of iron,	1.75
Soda of potash,	3.
Loss,	.25
	100.00

Localities, &c.-Pumicestone has been supposed to be a volcanic production, because it is found in the vicinity of volcanoes; the Lipari islands are almost entirely composed of it, and there it is accompanied with obsidian. It is also found in Iceland and Teneriffe; in Hungary; and on the banks of the Rhine between Andernach and Coblentz.

Uses .- Pumice is very much employed in polishing stones, metals, glass, ivory, and in the preparation of parchment.

A rare variety of pumice is described by Brongniart in the form of vitreous filaments as fine as hair; the colour is a deep bottle green, and it melts by heat into a white enamel. This pumice is supposed to be projected from the volcano in the isle of Bourbon.

44. Species. PREHNITE.

Id. Kirwan, i. 274. La Prehnite, Brochant, i. 295. Prehnite, Hauy, iii. 67.

Essen. Char .- Divisible by one distinct line only, and pretty clean; electric by heat.

Exter. Char .-- Prehnite is found either massive or crystallized. The principal form of its crystals is a four-sided rhomboidal table, which is either perfect or truncated on all its edges, or a table with six faces, and an equal angle, or a large rectangular prism terminated by a bevelment which is somewhat obtuse. The crystals are usually grouped together, and united by their lateral faces; face of the crystals smooth; external lustre shining; internal weakly shining and pearly; principal fracture foliated, cross fracture fine-grained uneven; fragments but little sharp-edged. Colour

Part

С

Colour green, olive green, mountain green, and sificagreenish white; scmitrausparent, and sometimes transparent. Scratches glass slightly. Brittle, and easily frangible. Spec. grav. 2.609 to 2.696.

Localities .- Prehnite was brought first from the Cape of Good Hope, by Colonel Prehn, whose name it now bears. It is also found in France, as in Dauphiny, where it exists in veins. It is not unfrequent in different parts of Scotland, as among the porphyry rocks six miles to the south of Paisley; in the neighbourhood of Dunbarton; and in the rocks round Edinburgh.

45. Species. ZEOLITE.

This species has been divided into four subspecies.

Subspecies I. MEALY ZEOLITE.

Zeolite, Kirwan, i. 278. La Zeolite Farineuse, Brochant, i. 298. Mesotype, Hauy, iii. 151.

Exter. Char .- This variety is found massive or disseminated, and sometimes it is branched or coralloidal, and sometimes also it envelopes other zeolites with a thin crust. It is dull; fracture earthy; fragments blunt-edged.

Colour usually reddish or yellowish white, or flesh red, opaque, very brittle; does not adhere to the tongue. When scratched with the finger nail it gives out a dull sound.

Constituent Parts.	Pelletier.
Silica,	50
Alumina,	20
Lime,	8
Water,	22
	100

Localities, &c .- This variety of zeolite is found in Ireland, the Faro islands, and Sweden. It is frequent in different parts of Scotland, as at Dunbar, and several of the Western islands.

Subspecies 2. FIBROUS ZEOLITE.

Zeolithe Fibreuse, Brochant, i. 299. Mesotype, Hauy, i. 151.

Essen. Char.-Divisible parallel to the faces of a rectangular prism; electric by heat in two opposite points.

Exter. Char .- This variety is found massive, but most frequently crystallized : the primitive form is a. rectangular prism with square bases ; its common forms are a rectangular prism, truncated at each extremity by a four-sided pyramid, corresponding to the lateral faces ; a four-sided rectangular prism with two broad and two narrow sides, and also terminated by four-sided pyramids, or a four-sided prism, nearly rhomboidal, the two sharp lateral edges of which, as well as the two obtuse terminal angles, are truncated. The crystals are united together in bundles; so that the acuminations only can be seen; the crystals are commonly smooth and shining ; the internal lustre is weakly shining and pearly; fracture radiated : the rays broad or narrow; fragments wedge-shaped.

Colour yellowish, grayish, reddish, and snow-white; translucent, sometimes transparent; semiliard; scratches calcareous spar; brittle, and easily frangible. Spec. grav. 2.0833.

Chem. Char .- Before the blow-pipe it froths up, gives out a phosphorescent light, and is converted into a porous enamel. With acids it forms a gelatinous substance.

Subspecies 4. FOLIATED ZEOLITE.

Zeolithe Lamelleuse, Brochant, i. 302. Stilbite, Hauy, iii. 161.

Essen. Char .- Fusible into a spongy enamel, but not electric by heat.

Exter. Char .- This variety of zeolite is usually found Exter. Char .- This variety is found massive, and in amygdaloidal or globular pieces, and also crystallizstals, divergent and radiating; internal lustre glimmer- with rectangular bases: the usual forms of its crystals

genus.

are,

176

genus.

Siliceous are, a short equiangular six-sided prism with two broad, two narrower, and two very narrow faces; a table with six equal faces, and a rhomboidal prism. Surface of the crystal smooth and shining; internal lustre shining and pearly; fracture foliated; the plates most frequently curved with a simple cleavage.

Colour similar to the former; it is translucent er semitransparent; semihard, and easily frangible. Spec. grav. 2.5.

Chem. Char.-Froths up and phosphoresces, under the blow-pipe; placed on hot coals, it becomes white and is easily reduced to powder. It is not converted into a jelly by acids.

Localities, &c .- The different varieties of zeolite are usually found in amygdaloid rocks; basalts, porphyry, slate, wacken, and green stone. They often line the sides of fissures passing through these rocks, and are accompanied with calcareous, spar, calcedony, sometimes with native copper and native silver, as in Iceland. The finest zeolites are brought from the islands of Faroe, Iceland, Ædelfors in Sweden. The different varieties, are, not unfrequent in Scotland. The fibrous and radiated kinds are met with extremely beautiful in the islands of Cannay and Skye; the foliated or stilbite in the island of Staffa, in Skye, and in the lead yeins at Strontian.

46. Species. CUBIZITE.

La Zeolithe Cubique, Brochant, i. 304. Analcime, & Chabasie, Hauy. iii. 180.

Essen. Char .- Original forms of the cube, fusible into a glass.

Exter. Char .- This-mineral is found massive or crystallized; the form of the crystals is a perfect cube, which is its primitive form. This is sometimes truncated on all its angles by three small triangular faces, or with twenty-four equal and similar trapezoids like the garnet. The external lustre is resplendent, vitreous, or pearly. Internal shining or weakly shining. Fracture imperfectly foliated, almost uneven. Fragments imperfect cubes.

Colour white, yellowish, grayish, or reddish white. It is translucent or opaque. Semihard. Spec. grav. about 2 (Hauy). Difficult to produce any signs of electricity; hence the name analcime, signifying want

of power, given to it by Hauy. Chem. Char.—Froths up before the blow-pipe, and melts into a porous glass.

Localities, &c .- Cubizite is found in Skye, in Staffa, and in the Salisbury rocks near Edinburgh. Fine specimens of cubizite are abundant at the Giants causeway in the north of Ireland. Chabasie is found also at Oberstein in Germany.

VID ML 10 Pagrot Isters 2

By many mineralogists chabasie and analcime are Classific considered as one species; but more nearly investigated, as has been done by Hauy and others, they must ap-pear very different. The preceding description refers chiefly to analcime. We shall shortly state the principal characters of chabasie from Hauy, iii. 176.

Essen. Char .- Divisible into a rhomboid slightly obtuse, and easily fusible by heat.

Exter. Char.-Chabasie is commonly crystallized. Primitive form of the crystals is a slightly obtuse rhomboid, whose plane angle at the summit is about 93^{to}, so that it approaches nearly to the cube; integrant molecule is the same. Six of the edges are truncated, the truncations uniting three and three at the two opposite angles, and the remaining six angles are also truncated. It appears also in the form of double six-sided pyramids applied base to base, having the six angles at the base, and the three acute edges of each pyramid truncated.

Colour whitish, sometimes reddish, but this seems to be owing to a superficial crust. Lustre shining or re-splendent and vitreous. Transparent or translucent.

Chem. Char .- Is easily fusible before the blow-pipe. and melts into a whitish spongy mass.

47. Species. CROSS-STONE.

Staurolite, Kirwan, i. 282. Pierre Cruciforme, Brochant, i. 311. Harmotome, Hauy, iii. 191.

Essen. Char .- Divisible into a rectangular octahedron, which may be subdivided on the angles contiguous to the summits.

Exter. Char .- This mineral is always crystallized. Its usual forms are, a double crystal composed of two broad prisms, with four rectangular faces, and terminated at each extremity by a four-sided obtnsc pyramid placed on the lateral edges. These two prisms cross each other by their broader faces, so that the faces of the acumination meet together, and the double crystal thus formed having four right-angled re-entering angles, resembles a cross. The crystals are obliquely streaked. External lustre shining and resplendent, vitreous. Internal weakly shining. Fracture foliated.

Colour grayish or milky white, translucent, sometimes semi-transparent. Semi-hard, scratches glass slightly. Spec. grav. 2.333 to 3.61.

Chem. Char .- Before the blow-pipe it is fusible, and froths up. The powder thrown on hot coals is phosphorescent, giving out a greenish yellow light.

Localities .- This mineral has been found in veins at Andreasberg in the Hartz, accompanied by carbonate of lime, from which it is sometimes called andreolite. It is also found in the lead veins at Strontian in Scotland, and in balls of agate at Oberstein. In the latter place, crystals are single.

48. Species

48. Species. LAUMONITE.

rt I.

sifica-

ion.

Zcolithe Efflorescente, Hauy, iv. 410. Id. Brochant, ii. 530.

Exter. Char.—This mineral is found in masses which are composed of irregular groups of crystals crossing each other in all directions. Form of the crystals is a four-sided prism, nearly rectangular, and terminated by a base inclined to one of the lateral edges under an angle of 133° ; frequently the acute angle is truncated, and thus terminating in a bevelment placed on the acute lateral edges. The lateral faces are longitudinally streaked, and the lustre is shining. The faces of the summit are also shining, but smooth. Fracture foliated, and parallel to the lateral faces.

Colour grayish white, somewhat pearly. Is translucent, rather soft; sectile, and easily frangible.

But all these characters are considerably different by the action of the air. The whole mass is gradually separated, and the crystals become opaque, falling into triable folia, which are in a short time reduced to a snow-white powder, from which it derives the name given to it by Hauy.

Chem. Char.—Fusible before the blow-pipe, without frothing up, into a white enamel, and forms a jelly with acids.

Localities.—This mineral was found in 1788 by Gillet Laumont, in the lead mines of Huclgoët in Brittany in France, and from him it derives its name. It forms a small vein contiguons to the vein of galena. We have collected specimens of a mineral, whose characters correspond with laumonite, in a vein traversing a basaltic rock in the island of Skyc. After being kept for some years it appeared equally liable to disintegration by exposure to the air.

49. Species. DIPYRE.

Id. Brochant, in 508. Id. Hauy, iii. 242.

Essen. Char.—Divisible parallel to the faces of a regular 6-sided prism. Fusible with intumescence.

Exter. Char.—This n.ineral is found in small fascicular masses or crystals. Lustre shining, vitrcous. Longitudinal fracture foliated.

Colour grayish or reddish white, and sometimes pale rose red. Semi-hard; scratches glass, and is easily frangible. Spec. grav. 2.630.

Chem. Char.—Fusible. The powder thrown on hot woals produces phosphorescence.

Constituent Parts.	Vauquelin.

Water,	2
Loss,	4
	001

Localities, &c.—This mineral has only been found at Mauleon, in the Pyrenees, in a rock of steatites. It was discovered by Lelievre and Gillet Laumont, in 1786.

Vol. XIV. Part I.

50. Species. NATROLITE.

Id. Klaproth. Id. Brongniart, i. 370.

Exter. Char.—This mineral is found in masses, in a rock of amygdaloid. External surface somewhat rough; internal lustre glimmering; fracture fibrous and radiated.

Colour brownish yellow, inclining to olive, and different colours appear in parallel and waved zones; is translucent at the edges; scarcely scratches glass; is easily frangible. Sp. grav. 2.16.

Chem. Char.—Is reduced by the blow-pipe to a white glass. Nitric acid produces no effervescence, but converts it in a few hours to a thick jelly.

Constituent Parts.	Klaproth.

Oxide of iron,	1.75
Loss,	1.75
	Contrain Descentioned
	100.00

Localitics, &c.-Natrolite has been found only at Roegau, near the lake of Constance in Switzerland, in the cavities of an amygdaloid rock. The name is derived from natron or soda, of which it contains so large a proportion.

51. Species. AZURITE.

Lazulite, Klaproth, Analyt. Essays, i. 170. Le Lazulithe, Broch. i. 315.

Exter. Char.—This mineral has been found disseminated, massive, and crystallized in rectangular foursided prisms. Lustre glimmering and shining. Fracture imperfectly conchoidal.

Colour indigo, Prussian, or deep smalt blue; streak lighter blue; nearly opaque, or translucent at the edges; hardness, nearly that of quartz. Brittle and casily frangible.

Chem. Char.—Infusible before the blow-pipe, but loses its colour, becomes earthy, and of a clear gray. With borax it produces a bright yellow glass. Acids have a very feeble action upon it. Klaproth ascertained that it is composed of silica, alumina, and oxide of iron; but the quantity which he operated on was too small to ascertain the proportions.

Localities, &c.—This mineral has been found at Vorau in Styria, in a rock of micaceous schistns, where it forms, along with grayish quartz and silvery white mica, a vein of about half an inch thick.

52. Species. LAZULITE.

Lapis Lazuli, Kirw. i. 283. La Pierre d'Azure, Broch. i. 313. Lazulite, Hauy. iii. 145.

Exter. Char.—This mineral is found massive, disseminated, and in rounded fragments; internally dull, and rarely glimmering. Fracture earthy, or fine-grained uneven; fragments sharp-edged.

Colour

Siliceous Colour azure blue; opaque, or translucent on the cdges; hard, or semihard; brittle and easily frangible. Spec. grav. 2.76 to 2.94.

Chem. Char.—It retains its colour at the temperature of 100° Wedgewood; but with a stronger heat froths up into a yellowish hard coloured mass. By increasing the heat, it changes to a white enamel; with acids after calcination, forms a jelly.

Constituent Parts.

100.0

Localities, &c.—This mineral is found in Persia, Natolia, and China, and it is supposed that its repository is among granite. It has been found also in Siberia, near the lake Baikal, where it forms a voin along with garnets, feldspar, and pyrites. It is frequently mixed with pyrites, and a grayish white feldspar.

Uses.—This stone, when it is of a fine blue colour, and free from white spots, is held in great estimation for various ornamental purposes; but it derives its greatest value from its use in painting. The colour which it furnishes is called *ultramarine*. To prepare it, the stone is first calcined, and then reduced to an impalpable powder, which is mixed with a paste composed of resinous matters, of wax and linseed oil. From this mixture a powder is obtained by washing, which being dried affords the colouring matter. This colour, when used in painting, is not susceptible of change.

53. Species. HYDRARGILLITE.

Wavellite of Dr Babington and others.

Exter. Char.—This mineral is found crystallized. The crystals are very minute, and are attached to quartz, in tufts or bundles, which diverge from a common centre. It is also found closely compacted together, in the form of mammillary protuberances of the size of small peas, and adhering to each other. The crystals, when magnified, appear to be four-sided, and, when broken, the section secms to be rhomboidal. The crystals have sometimes the appearance of fine down, and sometimes are of the size of a hair. Lustre silky.

The colour is white, with a shade of gray or green; usually opaque, and sometimes semitransparent. The texture is loose; but the small fragments are so hard as to scratch agate. Spec. grav. 2.25 to 2.70.

Chem. Char.-Infusible before the blow-pipe; but the crystals, exposed suddenly to strong heat, decrepitate.

Localities, &c.—This mineral was first discovered by Dr Wavell, in a quarry near Barnstaple. Mr Hatchett found it, in 1796, filling the cavities and veins of a soft argillaceous schistus. It has since been found in Stenna-Gwyn mine, in the parish of St Stephen's, Cornwall, where it is accompanied with sulphuret of tin, copper, and iron.

54. Species. ANDALUSITE.

Adamantine Spar, Kirwan, i. 337. Spath Adamantin, Bournon, Jour. dc Phys. 1789. Teldspath Apyre, Hauy, iv. 362.

Exter. Char.—This mineral is found massive, and crystallized in rectangular four-sided prisms, the summits of which are obliterated. Lustre weakly shining and resinous. Longitudinal fracture foliated. Cross fracture a little splintery. Colour reddish brown or violet; translucent at the edges. Very hard; scratches quartz, and sometimes even spinelle. Difficultly frangible. Spec. grav. 3.165.

Chem. Char .- Infusible before the blow-pipe.

Localities, &c.—This mineral was first discovered by Bournon in the granitic rocks of Forez, where it occupies a vein of common feldspar. It has been found also in Spain, where it enters into the composition of a granite. It is also met with in Aberdcenshire. When first discovered it was supposed to be a variety of adamantine spar, or corundum; but its inferior spec. grav. and the difference in the structure of its crystals, afford sufficient characteristic differences.

55. Species. FELDSPAR.

This species is divided into the five following subspecies: 1. Adularia. 2. Labradore stone. 3. Common feldspar. 4. Compact feldspar. 5. Hollow spar.

Subspecies 1. ADULARIA.

Moonstone, Kirwan, i. 322. L'Adulaire, Brochant, i. 371. Feldspath Nacré, Hauy, ii. 606.

Exter. Char.—This mineral is found massive or crystallized. The forms of its crystals are, 1. A four-sided rhomboidal prism. 2. A perfect rhomb, more or less oblique. 3. A rectangular four-sided table, with oblique terminal faces. 4. A six-sided prism. 5. A sixsided table. Surface of the crystals smooth or longitudinally streaked. Lustre shining or resplendent. Internal lustre resplendent, vitreous, or pearly. Fracture foliated. Cleavage double. Fragments rhomboidal.

Colonr yellowish, greenish, or milk-white : is sometimes

tion.
sificatimes chatoyant. Is always translucent; sometimes semitransparent. Hard; scratches common feldspar. Brittle, and easily frangible. Spec. grav. 2.500 to 2.561.

Chem. Char.—Adularia before the blow-pipe cracks and splits, and then melts into a white glass.

Localities, &c.—This stone was first brought from the island of St Paul, near the coast of Labradore, whence its name. It has been since found in Bohemia, and near the lake Baikal in Siberia. It is rarely found in its native repository, but it is supposed to belong to primitive rock; for it is accompanied with schorl, mica, and hornblende.

Uses .--- The brilliancy of its colours, and particularly its chatoyant property, have brought it into use in jewellery.

Subspecies 3, COMMON FELDSPAR.

Id. Kirwan, i. 316. Le Feldspath Commun, Brochant, i. 362. Feldspath, Hauy, ii. 590.

Exter. Char.—Feldspar is found massive, disseminated, in rounded picces, or crystallized. Its forms are, I. A broad six-sided prism with unequal angles, terminated at each extremity by an obtuse bevelment, whose faces are placed on the two lateral edges. 2. A foursided rhomboidal prism. 3. A four-sided rectangular prism, having the lateral edges sometimes truncated; and, 4. A six-sided table. Double crystals are sometimes met with. Lustre shining; internal lustre also shining; sometimes resplendent, vitreous or pearly. Fracture perfectly foliated; fragments rhomboidal.

Colours milk-white, yellowish, grayish, reddish, and greenish. Translucent; scratches glass; brittle, and easily frangible. Spec. grav. 2.437 to 2.704.

Chem. Char.-Before the blow-pipe melts into a white glass.

Localities, &c.—Feldspar is one of the most common substances, and the most universally distributed in nature. It does not exist, however, in large masses. It forms one of the component parts of granite, gneis, syenite and porphyry.

When exposed to the action of the air, it is very liable to decomposition, and then it is converted into a white earthy mass, which is employed in the manufacture of porcelain. This is the kaolin of the Chinese.

Subspecies 4. COMPACT FELDSPAR.

Continuous Feldspar. Kirw. i. 323. Le Feldspath Compacte, Broch. i. 367. Feldspath Compacts Bleu, Hauy, ii. 605.

Exter. Char.—This variety is found massive, and also in rounded pieces. Lustre weakly shining, or only glimmering. Fracture imperfectly foliated, sometimes splintery. Fragments not very sharp edged.

Colour bluish white, greenish or yellowish ; translucent, but sometimes only at the edges. Streak white ; is scratched by quartz.

Chem. Char.-Fusible before the blow-pipe.

Localities, &c.—Compact feldspar is found in Saxony, and in the Tyrol. It is not uncommon in Scotland, as in the Grampian mountains, and on the Pentland hills in the neighbourhood of Edinburgh. The crystals of feldspar observed in antique green porphyry, are supposed to belong to this variety.

22

Subspecies

art I.

Subspecies 5. HOLLOW SPAR, or Chiastolite.

Macle, Broch. ii. 514. Id. Hauy, iii. 267.

Essen. Char.—Divisions parallel to the faces of a prism, slightly rhomboidal. A black substance surrounded hy another of a whitish colour.

Exter. Char .- This mineral has been found only crystallized in four-sided, nearly rectangular prisms. The summit is always broken, by which the arrangement of the two substances is observed. The white part is the outermost; the black matter forms in the centre a small prism, whose sides correspond with those of the outer crystal. From the angles of the central prism proceed four narrow lines, which extend to each of the angles of the outer prism; and sometimes this black substance forms at the extremity of these lines, or in the angles of the large prism, a similar small prism of black matter. The black matter is an argillaceous schistus, similar to the repository of the crystals. The white part is sometimes weakly shining ; internal lustre glimmering, resinous. The black part is nearly dull. Fracture foliated; the black part earthy.

The colour of the white part, yellowish, or grayish white; that of the black part, grayish, or bluish black. Opaque, or translucent. Semihard : scratching glass when foliated. Streak white. Brittle; not very frangible. Spec. grav. 2.944. Communicates to scaling wax, negative electricity by friction.

Chem. Char.-Before the blow-pipe, the white part melts into a whiter glass; the black part into a black glass.

Localitics, &c.—This mineral has been found in Brittany in France, imbedded in argillaceous schistus; in the Pyrences, in a similar rock, lying immediately on granite, near St Jacques de Compostella in Spain; and in the mountains of Cumberland, also imbedded in argillaceous schistus.

The name *chiastolite* is derived from the appearance of the section of the crystal, which is supposed to have some resemblance to the Greek letter \varkappa .

56. Species. SCAPOLITE.

Scapolithe, Brochant, ii. 526. Id. Hauy, iv. 493. Rapidolithe, Abilgaard.

Exter. Char.—This mineral has been found massive, but most frequently crystallized in rectangular, foursided prisms, having the lateral edges truncated. The crystals are small, sometimes acicular, commonly elongated and aggregated. Their surface is longitudinally streaked and glimmering. Internal lustre weakly shining, vitreous or resinous. Fracture foliated.

Colour grayish white; translucent, or rarely transparent. Scratches glass, and is brittle. Spec. grav. 3.68 to 3.70.

Chem Char.-Froths up before the blow-pipe, and melts into a white enamel.

Localities, &c.—This mineral has been found in the mines of iron ore near Arendal in Norway. The crystals are mixed with mica and calcarcous spar.

57. Species. ARCTIZITE.

Wernerite, Hauy, iii. 119. Id. Brochant, ii. 529.

Essen. Char.-Spec. grav. 3.6. Phosphorescent by heat, but not by percussion.

Exter. Char.—This mineral is found massive, or crystallized in four-sided rectangular prisms, terminated by an obtase four-sided pyramid. The lateral edges are truncated, so that the prism appears to be eight-sided. Crystals small; lustre resplendent, sometimes weakly shining, and pearly or resinous. Fracture foliated. Fohia curved in two directions.

Colour between pistachio green and isabella yellow. Translucent. Scratches glass, and strikes fire with steel. The powder thrown on hot coals phosphoresces in the dark.

Chem. Char.—Before the blow-pipe it froths up, and easily melts into an imperfect white, and opaque enamel. Insoluble in nitric acid.

Localities, &c.—This mineral is found in the iron mines of Northo and Ulrica in Sweden. Bouoen near Arendal in Norway, and at Campo Longo in Switzerland.

58. Species. DIASPORE.

Id. Brochant, ii. 507. Id. Hauy, iv. 358.

Exter. Char.—This mineral is of a gray colour. Lustre shining, pearly. Fracture foliated, with the folia a little curved; separates into rhomboids, with angles about 130° and 50° ; scratches glass. Spec. grav. 3.432.

Chem. Char.—A fragment of this stone heated for a little in the flame of a candle decrepitates and disperses in all directions; from this property is obtained its name, which signifies to disperse. Heated in a close crucible to prevent the fragments from flying off, they were reduced to white shining particles, somewhat resembling boracic acid.

Constituent Parts. Vauquelin.

Alumina,	80
Oxide of iron,	3
Water,	17
	100

Localities, &c.-The repository of this mineral is unknown. It was connected with an argillaceous. ochrey rock.

This mineral approaches nearly to hydrargillite or wavellite, described above, in its constituent parts; but the proportions and some of the external characters are different.

59. Species. SPODUMENE.

Id. D'Andrada, Jour. de Phys. an 8. p. 240. Triphane, Hauy, iv. 407. Id. Brochant, ii. 528.

Exter. Char.—This mineral is found in small masses, which present some appearances of crystallization. Luster shining, pearly. Fracture in the mass radiated, of single

180 Siliccous

genus.

~

assifica- single crystals foliated and divisible in three directions, which sometimes afford an oblique angled prism of about 100° and 80°. Cross fracture dull, rough, and splintery. In larger masses the fracture is radiated. Lustre shining pearly. Scratches glass. Colour greenish white or leek green. Translucent at

the edges. Brittle. Spec. grav. 3.192 to 3.218.

Chem. Char .- Before the blow-pipe it separates at first into small yellowish plates, and then melts into a grayish white transparent glass.

Constituent Parts.	Vauquelin.
Silica, Alumina, Lime, Oxide af iron, Loss,	56.5 24 5 5 9.5
a state of the second	100.0

Localities, & e .- This mineral has been found in the mines of Utoe near Dalero in Sweden. Its repository seems to be a vein, where it is accompanied with quartz. and black miea.

The name triphane has been given to this mineral by Hauy from its peculiar three-fold natural divisions. It received the name spodumene, which signifies covered with ashes from D'Andrada.

60. Species. MEIONITE.

Id. Hauy, ii. 586. Id. Brochant, ii. 519.

Essen. Char .- Divisible parallel to the faces of a prism with square bases. Easily fusible into a spongy white glass.

Exter. Char.-It is found crystallized in four-sided rectangular prisms whose lateral edges are always truneated. It is terminated by an obtuse four-sided pyramid set on the lateral edges. Sometimes the lateral edges are doubly truncated, thus forming a sixteen-sided prism. The crystals arc small, adhering laterally and arranged in rows to the matrix. Lustre shining, vitreous. Longitudinal fracture foliated, and parallel to the four faces of the prism. Cross fracture slightly conchoidal.

Colour grayish white. Semi-transparent. Seratches glass.

Chem. Char .- Melts very easily before the blow-pipe with considerable intumescence accompanied with a hissing noise.

Localities, &c .- This mineral has only been found on Vesuvius near Mount Somma. The crystals are usually attached to fragments of foliated limestone.

61. Species. SOMMITE.

Nepheline, Hauy, iii. 186. Id. Brochant, ii. 522.

Essen. Char.-Divisible parallel to the sides and bases of a regular six-sided prism. With difficulty seratches glass.

Exter. Char .- This mineral is found disseminated in grains or in small crystals, which are commonly perfect six-sided prisms. The lateral faces are smooth and shining with a vitreous lustre. Longitudinal fracture foliated. Cross fracture conchoidal and shining. Cofour grayish white. Translucent, rarely semitransparent. The sharp points seratch glass, the others leave Siliceous only a white trace. Easily frangible. Specific gravi- genus. ty 3.2441.

Chem. Char .- Fusible into a glass by long continued heat. Becomes opake in nitric acid, hence the name nepheline, signifying cloudy, given to it by Hauy.

Constituent Parts.	Vauquelin.
Silica,	46
Alumina,	49
Lime,	2
Oxide of iron,	I
Loss,	2
	ground and a state
	TOO

Localities, &c .- This mineral is found lining the eavities of rocks on Mount Somma, from whence its name sommite. It is accompanied with vesuvian and black schorl, all which are supposed by some to be ejected matters from Vesuvius.

62. Species. ICHTHYOPHTHALMITE.

Id. D'Andrada. Ichthyophthalme, Brochant, ii. 552. Apophyllite, Hauy. Id. Brongniart, i. 385.

Exter. Char. - This mineral is found massive, and erystallized in rhomboids which approach nearly to the cube; in thick six-sided tables, and in rectangular four-sided tables, with truncated edges. Lustre shining, pearly. Fracture foliated ; elcavage single ; cross fracture fine grained uneven, and weakly shining.

Colour yellowish or greenish white; translucent or semitransparent. Scratches glass; not easily frangible. Spec. grav. 2.46.

Chem. Char.- Exposed to the blow-pipe, is with difficulty reduced to a white enamel. In nitric and muriatie acids it forms a jelly.

Constituent Parts.	Foureroy and Vauquelin.
Silica,	51
Lime,	28
Totash, Water	4
vi acci,	1./
	100

Localitics, &e .- This mineral is found in the iron mine of Utoe in Sweden, imbedded in a violet-coloured limestone, and accompanied with greenish hornblende and oxide of iron.

IV. ARGILLACEOUS GENUS.

I. Species. NATIVE ALUMINA.

Native Argil, Kirw. i. 175. L'Alumine Pure, Brochant, i. 318.

Exter Char .- This mineral is found in kidney-form masses ; it has no lustre ; fracture earthy ; fragments blunt edged.

Colours snow or yellowish white; opaque; stains a little; tender or friable; adheres a little to the tongue, feels mcagre ; gives out an earthy smell when breathed on. Spec. grav. 1.305 to 1.66.

rt I.

Argillace- Chem. Char.-Before the blow-pipe is absolutely inous genus. fusible, but dissolves almost entirely in acids.

Constituent Parts.	Fourcroy.
Alumina,	45
Sulphate of Inne,	24
Water,	27
Lime and silica,	4
	descents second
	100

But according to the analysis of others, it is composed almost entirely of pure alumina, mixed only with a small proportion of lime and silica.

Localities, &c.—It is found at Halle in Saxony, in part of the garden belonging to the college, immediately under the soil; but being only in small quantity, and in the neighbourhood of a large laboratory, has led to the supposition that it is an artificial production. It is said that it has been also found at Magdeburg in Lower Saxony, in Silesia, near Verona, and in England.

2. Species. PORCELAIN EARTH.

Porcelain Clay, Kirw. i. 178. La Terra Porcelaine, Brochant, i. 320. Argile Kaolin, et Feldspath Argilliforme, Hauy, ii. 616.

Exter. Char.—This mineral is found massive, or disseminated; has no lustre; stains strongly; has little coherence; adheres a little to the tongue.

Colour reddish, yellowish, or grayish white.

Chem. Char.-Infusible in the strongest heat of a furnace.

Constituent Parts. Vauquelin.

Silica,	55.	71.15
Alumina,	27.	15.86
Lime,	2.	1.92
Oxide of	iron, .5

	100.0	100.00

Localities, &c.—This mineral is found in considerable abundance in bcds and vcins, in granite and gneis, especially when the proportion of feldspar is considerable. It abounds in China and Japan, where it is known by the name of kaolin; in Bohemia, Saxony, Denmark, and particularly in many places of France, as at Limoges and Bayonne, and in Cornwall in England. In many cases it seems to be owing to the decomposition of granite.

Uses.—Porcelain carth, as its name imports, is employed either as it is found native, or mixed in certain proportions with other earths, in the manufacture of porcelain. That from Limoges in France is employed without any addition.

3. Species. COMMON CLAY.

This species is divided into five subspecies : 1. loam; 2. pipe clay; 3. potters clay; 4. variegated clay; and, 5. slaty clay.

4

Subspecies 1. LOAM.

Exter Char.—This mineral is found massive and in great abundance; has no lustre; fracture uneven or fine carthy; fragments very blunt-edged; has little coherence; stains.

Colour yellowish-gray, or spotted with yellow and brown, feels somewhat greasy, and adheres strongly to the tongue.

Localities, &c.-Loam is found in great abundance every where, and perhaps it ought to be considered as a mixture of different substances, rather than as a simple mineral.

Subspecies 2. PIPE CLAY.

Exter. Char.—This variety is found in great masses; has scarcely any lustre; fracture fine earthy, or finc grained uneven; fragments sharp-edged; has some coherence.

Colour grayish or yellowish white; streak shining; feels greasy, adheres strongly to the tongue, and is easily frangible.

Localities, &c.-It is very abundant in most countries, and is usually found in alluvial land.

Subspecies 3. POTTERS CLAY.

Id. Kirw. i. 180. Argile à Potier, Brochant, i. 322.

Exter. Char.—This variety is also found massive, and in great abundance. It is intermediate between solid and friable; has no lustre; fracture fine grained earthy, sometimes coarse grained uneven; fragments bluntedged.

Colour yellowish, greenish, or grayish white; sometimes reddish or ochrcy yellow of various shades. It is opaque, stains a little; streak a little chining; very brittle, and casily frangible; is somewhat ductile; adheres a little to the tongue, and feels greasy.

Chem. Char.—Is differently affected by the blowpipe, according to the proportion of the different substances of which it is composed; but in general is difficult of fusion. Effervesces with acids when the proportion of lime is considerable.

Constituent Parts.	Vauquelin.
Silica,	43.5
Alumina,	33.2
Lime,	3.5
Oxide of iron,	Ia
Water,	18.
Loss,	.8
	100 0

The proportions of silica and lime vary considerably; the silica is very often the predominant ingredient. Kirwin examined a potters clay, in which he found 63 parts of silica.

Localities, &c.—Potters clay is found in great abundance in most countries, and in similar situations with the former. It often forms thick beds in alluvial land, alternating with beds of sand.

Subspecies 4. VARIEGATED CLAY.

Exter. Char.-This mineral is found massive. Has

Part]

assifica- an earthy fracture, a shining streak, and is soft or frition. able.

The colour is white, red, or yellow, and these different colours arc sometimes in stripes, veins and spots. Adheres a little to the tongue, and feels somewhat greasy. It is sectile and light.

As this variety of clay forms with water a less tenacious mass than some of the other varieties, it probably contains a greater proportion of siliceous earth.

Localities, &c.-This mineral is found in Upper Lusatia.

Subspecies 5. SLATY CLAY.

Slate Clay, Shale, Kirwan, i. 182. L'Argile Schistcuse, Brochant, i. 327. Argile Schisteuse Impressionée, Hauy, iv. 448.

Exter Char.—This subspecies is found massive ; internally dull, when free from mica ; fracture slaty or earthy ; fragments in tables.

Colour grayish, ycllowish, or blackish, sometimes reddish or brownish; opaque; soft, sectile, and easily frangible. Adheres to the tongue; feels meagre. Sp. grav. 2.6 to 2.68.

Localities, &c.—Usually accompanies coal, so that it abounds in all coal countries. It is sometimes mixed with sand, mica, and iron pyrites. It is known in this country under the name of *shale*, and in Scotland particularly by that of *till*, or described nuder the more general denomination of one of the coal metals. Slaty clay is still farther distinguished by impressions of ferns, reeds, or grasses. When it is of a black colour, it seems to be owing to a greater proportion of coaly matter.

4. Species. CLAY STONE, or INDURATED CLAY.

Indurated Clay, Kirwan, i. 181. L'Argile Endurcie, Brochant, i. 325.

Exter. Char.—Indurated clay is always found massive; it is dull; fracture compact, or finc earthy; but sometimes splintery or even, and also sometimes slaty. Fragments more or less sharp edged, and sometimes in tables.

Colour usually bluish, yellowish, or greenish gray, and sometimes pearl gray, grayish red, whitish, and brownish. These colours are often mixed, and are arranged in spots and stripes. Opaque, soft, rather brittle; casily frangible; adheres slightly to the tongue; feels greasy. Spec. grav. inconsiderable. Gradually falls to pieces in the water, or crumbles into powder. Has but little ductility.

Localities, &c.—Indurated clay is very common. It is found in veins, and sometimes in very extensive bcds. It constitutes the basis of many porphyries, especially in Saxony, where it is abundant. It is found in many parts of Scotland, as on the Pentland hills in the neighbourhood of Edinburgh.

Stourbridge clay, according to Mr Kirwan, may be included under this variety. It is of a gray colour; does not adhere to the tongue; part is soon diffused in water, and another part falls into powder. Mr Kirwan found it to contain 12.5 of moisture, 12 of a coarse white sand, 30 of a fine brownish sand, and even the remaining or argillaceous part was not entirely freed from sand but by boiling in acids.

5. Species. ADHESIVE SLATE.

Le Schiste à Polir, Brochant i. 376. Schiste à Polir, Hauy, iv. 449. Polishing Slate, Klaproth, i. 455. Analyt. Ess. Transl.

Exter. Char.—This mineral is found massive; is always internally dull; has a slaty or fine earthy fracture; fragments slaty or in tables.

Colour clear gray, whitish or reddish; opaque or slightly translucent at the edges; gives a shining streak; is sectile, soft, and very easily frangible; adheres strongly to the tongue: feels meagre. Specific gravity 2.08.

Chem. Char.—Immersed in water, adhesive slate absorbs it greedily, air bubbles being rapidly disengaged and with noise; but does not become tenacious. When reduced to powder and calcined, it loses about one-fifth of its weight. Exposed to strong heat, it is converted into a dark gray or yellowish and porous slag. (Brochant).

Constituent Parts. Klaproth.

	100.00	100.0

Localitics, &c.—Adhesive slate forms considerable beds at Menil-Montant near Paris. In these beds memlite already described is found.

6. Species. POLISHING SLATE.

Le Polierschiefer, Brochant, i. 376.

Exter. Char.—This mineral is found massive ; internally it is dull. Fracture slaty, but in some directions earthy. Fragments slaty or in tables.

Colour yellowish gray or white; and different colours appear disposed in stripes; is soft; adheres to the tongue; feels meagre, and is rather light.

Localities, &c.—This mineral has been found only, it is said, in Bohemia, near pseudo volcanoes, and it is supposed, that it is nothing more than indurated coal-ashes. It approaches so near in the characters that are given of it to the following, that it might be included under the same species, or considered as a variety of it.

7. Species. TRIPOLI.

Id. Kirw. ii. 202. Le Tripoli, Broch. i. 379. Quartz Aluminifere Tripolécn, Hauy, iv. 467.

Extcr. Char.—This mineral is found massive; is dull internally; has a coarse earthy fracture, sometimes slaty; fragments blunt-edged.

Colour yellowish gray, and sometimes brownish red. Is soft and somewhat friable; meagre to the feel, but does not adhere to the tongue.

Chem. Char.-It is almost infusible before the blowpipe.

art I.

ous genus. does not form a paste with water.

Constituent Parts.	Haasse.
Silica,	90
Oxide of iron,	3

Localities, & c .- This substance was formerly brought to Europe from Tripoli; hence the name; but it has since been found in many other places, as in Bavaria, Saxony, and Bohemia; in Russia and in England. It is found in the neighbourhood of basalts, sometimes forming veins; at Potschappel it is disposed in beds among the strata of coal, and near those places where strata of coal have been on fire.

Uses .- Tripoli is employed in polishing metals, precious stones, and glasses for optical instruments.

8. Species. FLOATSTONE.

Exter. Char .- This mineral has been found in tuberose porous masses ; it is dull, has an carthy fracture, and blunt-edged fragments.

The colour is yellowish gray or grayish white. It is soft and brittle; rough to the feel, and gives out a creaking sound. It is very light, from which it has its it name.

Localities, &c .- Has been only found at St Omers near Paris.

9. Species. ALUM STONE.

'La Pierre Alumineuse, Broch. i. 381.

Exter. Char .- This stone is found massive ; is generally dull, rarely a little glimmering; fracture uneven, sometimes splintery; fragments not very sharpedged.

Colour grayish or yellowish white: it is soft, and sometimes semihard; stains a little, and adheres to the tongue.

Chem. Char .- This mineral does not effervesce with acids ; but after being heated and dissolved in water, it affords alum. According to Bergman it contains 43 of sulphur, 35 of alumina, and 22 of silica; but the following is the result of Vauquelin's analysis.

Constituent Parts.

Alumina,	43.92
Silica,	24.
Sulphureous acid,	25.
Sulphate of potash,	3.08
Water,	4
	-
	100.00

Localities, &c .- This mineral has been long known under the name of the stone of Tolfa, from the name of the place where it is found near Rome, and where it forms a mountain which is traversed by vcins of whitish gray quartz. It is from this stone that the Roman alum, so celebrated in commerce, is manufactured; and it has

Argillace- pipe. It melts with borax without frothing up. It been supposed that the excelience of the alum is owing Classifica tion to the mineral containing within itself all the ingredients necessary in the formation of that triple salt.

10. Species. ALUMINOUS SCHISTUS.

This is divided into two varieties or subspecies; 1. common ; and, 2. shining.

Subspecies I. COMMON ALUMINOUS SCHISTUS.

Le Schiste Alumineux, Broch. i. 386.

Exter. Char .- This mineral is found in masses, which often contain pieces of a globular form. It is sometimes glimmering, amd sometimes dull; fracture commonly slaty, and sometimes a little carthy ; fragments in tables ; streak the same as the colour of the mineral, a little shining.

Colour grayish black or brownish; is soft; meagre to the feel, and casily frangible.

Chem. Char .- When exposed to the air for some time it separates and yields alum by lixiviation.

Localities, &c .- Aluminous schistus is abundant in Saxony, Bohemia, France, England, and some parts of Scotland. It is disposed in beds among stratiform rocks, and in transition rocks, and it is often traversed by veins of quartz. Being mixed with pyrites, the decomposition is thus promoted when exposed to the air.

Uses .- This mineral is dug out for the purpose of extracting alum, first by exposing it to the air or heat, and then by lixiviation.

Subspecies. I. SHINING ALUMINOUS SCHISTUS.

Le Schiste Alumineux Eclatant, Broch. i. 388.

Exter. Char .- This mineral approaches very nearly to the former in most of its characters, but in the direction of its principal fracture the external surface is smooth ; lustre shining, or resplendent, resincus, and even somewhat metallic; in the opposite directions it is dull. Fracture commonly slaty, and somewhat curved ; fragments in tables.

Colour intermediate between bluish and grayish black, and sometimes iron black. Colours in the rents iridescent.

In other characters and circumstances it resembles the former.

11. Species. BITUMINOUS SCHISTUS.

Le Schiste Bitumineux, Broch. i. 289. Bituminous Shale, Kirw. 183.

Exter. Char .- This mineral is found massive ; lustre glimmering; fracture most commonly thin, rarely thick; fragments in the form of tables, sometimes trapezoidal.

Colour brownish black, sometimes gray or blackish brown; soft and easily frangible; adheres slightly to the tongue; streak shining; feels greasy.

Chem. Char .- When placed on burning coals it gives out a pale flame with a sulphureous odour, becomes white, and loses a good deal of its weight.

Localities, &c .- This mineral is peculiar to coal countries, which it always accompanies, and alternates with

Part]

sifica- with slaty clay and coal. It is not unfrequent in Bolicion mia, Poland, England, and Scotland.

12. Species. DRAWING SLATE.

Black Chalk, Kirwan, i. 195. Le Schiste à Dessiner, Broch. i. 391. Argile Schisteuse Graphique, Hauy, iv. 447.

Exter. Char.—This mineral is found massive, usually dull; but in the direction of the principal fracture a little glimmering; fracture in certain directions curved slaty; in others fine grained earthy; fragments splintery or tabular.

Colour grayish or bluish black; opaque; stains black; soft; meagre to the feel.

Chem. Char.-Before the blow-pipe it becomes covered with a kind of varnish.

Constituent Parts.	Wiegleh.	
Silica,	64.50	
Alumina,	11.25	
Carbone,	II	
Oxide of iron,	2.75	
Water,	7.50	
Loss,	3	
	designed and the second	
	100.00	

Localities, &c.—Drawing slate frequently accompanies aluminous schistus. It forms along with it beds which are subordinate to clay slate. 'It is found in Italy, where it is an object of commerce. It is also found in Spain, France, and some parts of Scotland.

Uses.—As its name indicates, it is employed like black chalk in drawing.

13. Species. WHET SLATE.

Novaculite, Kirw. i. 238. Le Schiste à Aiguiser, Brochant, i. 393. Argile Schisteuse Novaculaire, Hauy, iv. 448.

Exter. Char.—This mineral is found massive; is scarcely glimmering; fracture in large masses slaty, in small pieces splintery; fragments tabular.

Colour commonly greenish gray, or smoke gray. Sometimes mountain green: translucent at the edges: semihard, but varying between hard and soft; rather easily frangible; streak grayish white; feels greasy; does not adhere to the tongue. Specific gravity 2.722.

Chem. Char.—Does not effervesce with acids, and is infusible before the blow-pipe.

Localities, &c.—Whet slate is found in primitive mountains, where it forms beds which are subordinate to clay slate. It was originally brought from the Levant; but has since been discovered in Bohemia, Saxony, in Bayreuth, where it is wrought, and in Siberia. An efflorescence has been observed on the surface, which is found to be sulphate of magnesia; from which it is naturally supposed that the base of that salt forms one of its constituent parts.

Uses.—Whet slate, as its name imports, is cut and polished for the purpose of sharpening knives and other Vol. XIV. Part I. + instruments; and, reduced to powder, is employed in Argillaceous genus.

14. Species. CLAY SLATE.

Argillite, or Argillaccous Schistus, or Slate, Kirwan, i. 234. Le Schiste Argilleux, Brochant, i. 395. Argile Schisteuse Tegulaire, Hauy, iv. 447.

Exter. Char.—Clay slate is found massive, or disseminated, or in rounded pieces; internally it is a little shining or glimmering; rarely dull; the more the structure is foliated, the greater is its lustre. Lustre sometimes silky, pearly, or semimetallic. Fracture more or less slaty, sometimes curved and waved, sometimes earthy or splintery; fragments tabular, rarely splintery; sometimes cubic or rhomboidal.

Colour chiefly gray of various shades ; but sometimes it is reddish, brownish, or yellowish, or reddish brown. Different colours are so disposed as to appear striped, waved, spotted, or dendritie. It is in general soft ; sometimes semihard, sectile, and easily frangible. Gives a grayish white streak ; feels greasy. Spec. grav. 2.67 to 2.88.

According to Kirwan, clay slate is composed of silica, alumina, lime, magnesia, and iron, with some bituminous particles.

Localities, &c.—Clay slate belongs equally to the primitive, transition, and stratiform rocks, and frequently forms entire mountains. Primitive clay slate is sometimes mixed with quartz, mica, hornblende, garnets, limestone, pyrites, cinnabar as at Idria; in general it abounds with metallic ores, either in veins or in beds.

Clay slate is very abundant in most countries; it is not unfrequent in many parts of Scotland; but the slate of Easdale, and the contiguous islands on the west coast, has long maintained a decided superiority and preference to all others in this country.

Uses.—Clay slate is in extensive use for covering houses, and then it is known in this country by the single word slate. It is also employed in large plates for writing on, or tracing characters that are afterwards to be effaced.

15. Species. LEPIDOLITE.

Id. Kirwan, i. 208. Id. Hauy, iv. 375. La Lepidolithe, Brochant, i. 399.

Exter. Char.—Lepidolite is found massive, and disseminated in small plates, which might be taken for mica. It is usually glimmering, rarely shining. Lustre semimetallic. Fracture fine grained uneven, rarely foliated. Fragments blunt edged.

Colour lilac blue, grayish and reddish brown; translucent. Semihard; sometimes soft; easily frangible; and feels meagre. It is easily scraped with the knife; but is with difficulty reduced to powder by trituration. The powder rubbed between the fingers has a greasy feel. Spec. grav. 2.816 to 2.854.

Chem. Char.—Froths up under the blow-pipe, and melts into a transparent colourless globule; but with the addition of a little nitre it becomes violet.

Potash,	4.	18
Fluate of lime,		4
Oxide of iron and man	ganese, .75	I
Water and loss,	2.5	3
	100.00	100

Localities, &c.—This mineral was first discovered in the mountain Gradisko near Rosena in Moravia, where it is found in considerable masses included in blocks of granite. It is found also in Sweden. Sometimes it is disseminated in quartz rock.

The name, from *Auric*, "a scale," is derived from its scaly structure. Lepidolite was at first taken for fluate of lime or zeolite. A red coloured variety of schorlite was also supposed to be crystallized lepidolite.

16. Species. MICA.

Id. Kirw. i. 21. Id. Broch, i. 402. Id. Hauy, iii. 208.

Exter. Char.—Mica is most commonly disseminated in thin tables, rarely massive or crystallized. The primitive form of its crystals is a rectangular prism, whose bases are rhombs with angles of 120° and 60° ; the integrant molecule is the same. The usual forms of its crystals are, a six-sided table with equal angles, sometimes very thick, which produces a six-sided prism, and the want of two of the faces produces the table with four rhomboidal faces; but the most common form of mica is in thin plates or scales of no determinate figure. The lateral faces of the basis of the tables are smooth and resplendent; lustre metallic; fracture foliated, sometimes curved or waved, and sometimes radiated; fragments in the form of plates.

Colour usually gray, ash, yellowish, greenish, and blackish gray; in thin plates semitransparent, or even transparent; otherwise, only translucent on the cdges; semihard, very easily frangible; flexible and elastic. Spec. grav. 2.79 to 2.93.

Physical Char.--Mica rubbed on Spanish wax communicates to it negative electricity.

Chem. Char.—Before the blow-pipe it is with difficulty fusible into a whitish gray or green enamel. Black mica yields a black enamel, which is attracted by the magnet.

Constituent Parts.

			Capital
	100.00	ICO	100

Localities, &c.-Mica is one of the most common Classific nincrals, forming one of the constituent parts of granite, gneis, micaceous schistus, and other primitive rocks, and in some of them sometimes forms particular small veins. Mica also enters into the composition of stratiform rocks, as green stone, basalt, wacken.

Cat gold and cat silver are varieties of mica of a gold or silver colour, which have a considerable lustre, but inferior to that of these metals. It may be easily distinguished by the streak, which in the mica affords a whitish powder without any lustre.

Uses.—When mica is obtained in large and thin plates, it is employed as a substitute for glass, and for this purpose it has been used for windows of men of war, as on account of its elasticity it is less subject to be broken from the concussion produced by the firing of canon.

17. Species. PINITE.

Micarelle, Kirw. i. 212. La Pinite, Broch. i. 456.

Exter. Char.—This mineral has been usually found crystallized in six-sided prisms, having all the lateral edges truncated, or only three alternating edges, or in four-sided rhomboidal prisms. The surfaces of the crystals smooth and a little glimmering; internally it is dull, sometimes a little shining in the cross fracture; the fracture is fine grained, uneven, or small conchoidal; fragments blunt-edged.

Colour reddish or blackish brown; opaque; the brown variety is slightly transparent; so soft as to be cut with a knife, when it becomes of a bluish black; powder bright gray; adheres a little to the tongue; feels greasy; sp. grav. 2.98.

Constituent Parts.	Klaproth.
Alumina, Sílica, Oxide of iron,	63.75 29.50 6.75
	100.00

Localities, &c.--Pinite is found only near Schnesberg in Saxony, in the mine called *Pini*; hence its name. It is accompanied by quartz, feldspar and mica, which constitute a small grained granite.

18. Species. POTSTONE.

Id. Kirw. i. 155. La Pierre Ollaire, Broch. i. 405. Tale Ollaire, Hauy, iii. 257.

Exter. Char.—Potstone is found massive; internally it is dull, sometimes glimmering or a little shining, pearly; fracture curved slaty, rarely foliated or waved; fragments blunt edged, in the form of tables or scales.

Colour greenish gray, sometimes reddish or yellowish; opaque, rarely translucent on the edges; soft, sectile, and mild; feels greasy; by being breathed upon it emits the argillaceous smell. Spec. grav. 2.76 to 2.86.

Chem. Char.-Infusible before the blow-pipe; some varieties absorb a little water.

Localities, &c .- Potstone is found at Chiavenna, in the Valteline, from which the specimen above analyzed was obtained; at Como, in Switzerland, hence ealled Como stone. It is also found in Saxony, Hungary, and on the banks of Loch Fine opposite to Inverary in Seotland. Potstone forms entire beds, and is usually accompanied by serpentine, or it is in nests; it is rarely pure, but mixed with chlorite, talc, asbestus, &e.

Uses .- On account of the refractory nature of this stone, it is employed in the construction of furnaces where great heat is required; and as it may be eut or turned on the lathe, it has been formed into utensils for the kitchen, and hence the name potstone.

19. Species. CHLORITE.

Id. Kirw. i. 147. La Chlorite, Broch. i. 408. Talc Chlorite, Hauy, iii. 257.

Chlorite is divided into four subspecies : 1. earthy; 2. common; 3. foliated; 4. schistose or slaty.

Subspecies 1. EARTHY CHLORITE.

Exter. Char.-This mineral is composed of small, scaly, thin, and slightly glimmering particles, cohering together, rarely in the form of powder.

Colour intermediate between mountain green and dark leek green; sometimes brownish; does not stain; feels greasy, but does not adhere to the tongue; gives an earthy smell by breathing on it.

Chem. Char .- Melts before the blow-pipe into a gray or black enamel.

Constituent Parts.	Vauquelin.

Localities, &c.-Common ehlorite is found in the same places with the former, and indeed it is supposed. to be earthy chlorite indurated. At Altenberg in Saxony, it is mixed with pyrites of copper and arsenic, and common hornblende.

Subspecies 3. FOLIATED CHLORITE.

Exter. Char .- This variety is found massive, disseminated, and crystallized in the form of a six-sided table somewhat elongated; several of these tables being united together, frequently form globular, kidney-form, or botryoidal groups. External lustre glimmering or weakly shining; internal shining, resinous, or pearly; fracture foliated; folia curved; cleavage simple; fragments in tables.

Colour intermediate between leek and dark green; opaque, or translucent at the edges ; streak light green ; is soft, sectile, easily frangible, and feels a little greasy.

Co

nstituent Parts.	Lampadu
-Silica,	35.
Magnesia,	29.9
Alumina,	18.
Oxide of iron,	9.7
Water,	2.7
Loss,	4.7
	100.0

Localities, &c .- This mineral has been only found on St Gothard in Switzerland; it lines the sides of a vein which traverses micaceous schistus. It is accompanied by crystals of green miea, adularia, and quartz.

Broehant suggests that foliated chlorite may perhaps be nothing else than a erystallized mica.

Subspecies 4. SCHISTOSE CHLORITE.

Exter. Char.-This variety is found massive; internal lustre weakly shining, sometimes shining, resinous ; fracture curved slaty, sometimes waved, or a little splintery; fragments tabular,

Colour green; is soft, seetile, and easily frangible; streak light green; feels a little greasy; gives the earthy

smell by breathing. Localities, &c.-Slaty chlorite is found in Norway, Sweden, Switzerland, in different parts of Scotland, as on the banks of Loch Lomond, and in the islands of Aa2 Bute

rt I. ssifica tion.

188

Argillace- Bute and Arran. Sometimes it forms very extensive ous genus. beds in mountains of clay slate, to which it is subordinate; and it is frequently accompanied by garnets and magnetic iron, crystallized in octahedrons. The name

is derived from the Greek word which significs green.

20. Species. HORNBLENDE.

This is divided into four subspecies; 1. common; 2. basaltic; 3. labradore; and, 4. schistose.

Subspecies 1. COMMON HORNBLENDE.

Hornblende, Kirw. i. 163. Hornblende Commune, Broch. i. 415. Amphibole, Hauy, iii. 58.

Exter. Char .- Hornblende is found massive or disseminated, and sometimes crystallized. The forms are a four-sided prism, of which the acute opposite lateral edges are strongly truncated; a six-sided prism with four broad and two narrow faces, slightly truncated on the lateral edges ; a similar six-sided prism, short, and having the extremities bevelled; an eight-sided prism, having at its extremities, a convex bevelment. Sometimes the crystals are acicular and in groups ; internal lustre shining, vitreous, or pearly; fracture foliated, sometimes radiated, and sometimes fibrous; surface of the fracture longitudinally streaked; fragments sharpedged, sometimes rhomboidal.

Colour deep black, greenish black, or greenish gray ; usually opaque. The green varieties translucent at the edges. Soft or semihard; not easily frangible; streak greenish gray; gives an earthy smell by breathing on it : sp. grav. 3.6 to 3.88.

Chem. Char .- Before the blow-pipe it melts easily into a grayish black glass.

Constituent Parts.

	Kirwan.	Hermann.
Silica,	37	37
Alumina,	22	27
Magnesia,	16	3
Lime,	2	5
Oxide of iron	, 23	25
Loss,		3
	-	
	100	100

Localities, &c .- Hornblende is one of the constituent parts of primitive rocks, as in sienite; and it seems also to be an accidental substance, as in gneiss, primitive limestone, porphyries, and micaceous schistus. It is found also in masses or entire beds, as in Saxony; and is very common in most countries, as in Norway, Hungary, and Britain.

Uses.-Sometimes employed as a flux for ores of iron.

Subspecies 2. BASALTIC HORNBLENDE.

Basaltine, Kirw. i. 219. Hornblende Basaltique, Roch. 1. 424.

Exter. Char.-This mineral is most frequently found crystallized in equal six-sided prisms, variously modified or with equal sides; having two narrow and four broad; or four narrow and two broad; or three broad and three narrow alternately. The crystals are imbedded, insulated, or grouped. Surface smooth, shining; internal lustre resplendent, in the cross fracture weakly

shining, vitreous; fracture foliated; cross fracture Classific small grained, uneven, er conchoidal. Fragments near- tion ly rhomboidal.

Colour velvet black, and sometimes with a shade of green ; opaque ; streak gravish white ; semihard ;

earthy smell by expiration. Spec. grav. 3.22 to 3.33. Chem. Char.-Before the blow-pipe melts less easily than the preceding, into a black glass.

Constituent Parts.	Bergman.
Silica,	58
Alumina,	27
Lime,	4
Magnesia,	I
Oxide of iron,	9
Loss,	I
	100

Localities, &c .- This mineral, as its name imports, is usually found in basalt. It is also met with in wacken, and in the lava of Vesuvius. It is not uncommon in the basaltic rocks of Silesia, Saxony, and Bohemia, as well as in those of this country. As it is less liable to decomposition than the rocks which contain it, detached crystals are frequently found among decayed basalt.

Subspecies 3. LABRADORE HORNBLENDE.

La Hornblende du Labrador, Broch. i. 419.

Exter. Char .- This mineral is found massive, disseminated, in rounded pieces, and very rarely crystallized in four-sided rectangular prisms. Internal lustre shining, somewhat metallic; fracture foliated, sometimes curved.

Colour blackish green, or greenish black ; sometimes bronze yellow; scarcely translucent at the edges; semihard; not difficultly frangible; streak greenish. Spec. grav. 3.38.

Localities, &c .- This mineral is found in the island of St Paul on the Labradore coast, but nothing is known of the nature of its repository.

Subspecies 4. SCHISTOSE HORNBLENDE.

Id. Kirw. i. 222. La Hornblende Schisteuse, Broch. i. 428.

Exter. Char.-This variety is found massive; internal lustre weakly shining; fracture in masses slaty; in small picces radiated, sometimes fibrous; fragments in plates.

Colour greenish, or grayish black; opaque; semihard; streak greenish gray; rather difficultly frangible; breathed on, gives the earthy smell.

Localities, &c .- Schistose hornblende forms extensive beds in primitive monntains, to which it is subordinate. It seems to be common hornblende more or less mixed with quartz. It is found in Bohemia, Norway, Sweden, in the isle of Skyc, and other places of Scotland.

21. Species. BASALT.

Figurate Trap, Trap, Whinstone, &c. Kirw. i. 225. -233. Le Basalte, Broch. i. 430. La Lithöide Prismatique, Hauy, iv. 474.

Part

Exter. Char,-Basalt forms entire mountains, in the neighbourhood of which it is found in rounded pieces, or in large globular masses; internally it is dull; sometimes glimmering from a mixture of hornblende; fracture uneven, sometimes fine splintery or conchoidal; fragments not very sharp-edged. It is most frequently in distinct concretions, which are prismatic or columnar, more or less regular; sometimes also in globular distinct concretions.

Colour gravish or bluish black, sometimes brownish on the surface; opaque; semihard; brittle, and very difficultly frangible; streak light ash gray; gives a ringing sound under the hammer. Spec. grav. 2.86

Chem. Char .- Melts very easily before the blowpipe into an opaque black glass which acts on the magnet.

Physical Char .- Many basalts affect the magnetic needle, reversing the poles when it is brought near them. This is ascribed to the great proportion of iron which enters into their composition.

Localities, &c. Basalt is not uncommon in every part of the globe, and in many places it is very abundant. It is found in regular columns in several of the Hebrides on the west coast of Scotland, as in Cannay, Eigg, the Schant isles, but particularly beautiful in Staffa. Pretty regular columns are observed also at Dunbar, and on the south-west side of Arthur's seat near Edinburgh ; but the Giant's causeway and the rocks about Fairhead on the north coast of Ireland, exhibit the finest and most extensive ranges of columnar basalt in the world.

Basalt, besides being in the columnar form, is often disposed in beds and veins; both of which are very common in different places in Scotland, particularly on the western coast, and in the western islands. See Dr Millar's edition of Williams's Mineral Kingdom.

No subject, in geological speculation, has produced more controversial discussion than the origin of basalt; one party asserting that it is the effect of fusion, while another contends that it must have been deposited from an aqueous solution. Our limits preclude us even from barely stating the arguments which have been proposed by naturalists in support of the theories which different parties have embraced. For an account of some of them, see GEOLOGY Index; and for the constituent parts of basalt, and some other facts connected with its natural history, see BASALT.

Uses .- Basalt is sometimes employed as a touchstone, as a flux for ores of iron, and in the manufacture of common bottles. It is also employed for millstones. The ancients employed it in sculpture, for it would appear that some of their vases and statues were formed of it.

22. Species. WACKEN.

Id. Kirw. i. 223. La Wakke, Broch. i. 434.

Exter. Char .- Wacken is found massive ; it is frequently vesicular, and the cavities are often filled with other minerals; internal appearance dull; fracture even or earthy; fragments rather blunt-edged.

Colour grayish green, grayish black, reddish, or brownish ; opaque ; streak a little shining ; soft or semiliard; casily frangible; feels a little greasy. Spec. Argillacegrav. 2.35 to 2.89.

Chem. Char .- Fusible like basalt.

Localities, &c .- Wacken belongs to the stratiform rocks. It contains sometimes petrified wood, and the bones of animals. It constitutes beds sometimes in the middle of basalt, but is oftener in the form of veins, and is the basis of amygdaloid, the cavities of which are filled with green earth, calcarcous spar, &c. Wackcn is met with in Saxony, Bohemia, Sweden, and many places of Scotland.

23. Species. PHONOLITE, or Clinkstone.

Id. Daubuisson, Jour. de Phys. lx. 74. La Pierre Sonnante, Broch. i. 437. Klingstein and Porphyrschiefer of the Germans.

Exter. Char .- This mineral is always found massive; internal lustre glimmering; fracture slaty, sometimes uneven or conchoidal; fragments sharp-edged; composed of distinct concretions, which are either in the form of tables, or are columnar, and somewhat regularly grouped together.

Colour gray, ash, greenish, or bluish gray; the colours sometimes have a dendritical appearance; opaque, or translucent at the edges; semihard, or hard; not difficultly frangible; in thin plates it emits a sound when struck with a hammer, and hence its name.

Spec. grav. 2.575. Chem. Char.-Melts before the blow-pipe into a colourless glass.

Consti	ituent Parts.	
	Klaproth.	Bergman.
Silica,	57.25	. 58.

Soda,	8.1	6.
Water,	3.	2.
Loss,	1.9	1.5
	Descention & second	
	100.00	100.0

The stone analyzed above by Bergman, was from Puy in Velay, in France, and is considered by Dolomieu as volcanic. The other by Klaproth, is from Bohemia. Excepting the small proportion of manganese detected in the latter, the coincidence of the two analyses is very striking.

Localities, &c .- Phonolite is not uncommon in many parts of the world. It is met with in Scotland, in the island of Lamlash near Arran; and it constitutes the greater part of Traprene Law in East Lothian ; in both places it is columnar.

24. Species. LAVA.

Id. Kirw. i. 400. La Lave, Broch. i. 440. La Scorifiee, Hauy, iv. 497.

Exter. Char .- This mineral is generally of a porous texture, with cavities of different sizes ; lustre glimmering

ous genus.

rt I.

ion.

Argillace- ing or a little shining, vitreous; fracture imperfectly ous genus conchoidal; fragments not very sharp-edged.

Colour blackish gray, perfect black, or brownish black, sometimes greenish, and rarely white; opaque;

semihard; brittle; not difficultly frangible; light. Chem. Char.—Lava is very fusible, and yields a compact black glass.

Constituent Parts.	Bergman.
Silica,	49
Alumina, Lime,	35
Oxide of iron,	12
	100

Localities, &c.-Lava being a volcanic product, is only found in the vicinity of volcanoes.

Uses.-Lavas are employed for the purposes of building; their lightness, arising from the numerous cavities, renders them proper for the construction of vaults.

25. Species. GREEN EARTH.

Id. Kirw. i. 196. La Terre Verte, Brochant, i. 445. Tale Chlorite Zographique, Hauy, iii. 257.

Exter. Char.—Green earth is found massive, or disseminated, or in superficial crusts on balls of agate; internally it is dull; fracture earthy; fragments bluntedged.

Colour celadon green, or blackish green; opaque; soft; feels slightly greasy; adheres a little to the tongue; streaks weakly shining.

Chem. Char.—Before the blow-pipe it becomes black, but is infusible. It is not acted on by acids, and absorbs water.

Constituent Parts.	\mathbf{K}	laprot	h.

Loss,	I.
	p

100.00

Localities, &c.—Green earth is found at Verona, where it is wrought, and constitutes an article of commerce; and it is met with in all amygdaloid rocks.

Uses.-Green earth is employed as a colouring matter in painting.

26. Species. LITHOMARGA.

Id. Kirw. i. 187. La Moelle de Pierre, Brochant, i. 447. Argile Lithomarge, Hauy, iv. 444.

This is divided into two subspecies, chiefly distinguished by their cohesion. These are, 1. friable; 2. indurated.

Subspecies 1. FRIABLE LITHOMARGA.

Exter. Char.—This is found massive or disseminated; is slightly glimmering; adheres strongly to the tongue; feels greasy.

Colour yellowish white, snow white, sometimes red- Classific dish; the particles have very little cohesion.

Subspecies 2. INDURATED LITHOMARCA.

Exter. Char.—This is also found massive or disseminated; is dull; has a fine grained earthy fracture, sometimes conchoidal; blunt-edged.

Colour white, yellowish, or reddish white; brownish red, and several shades of yellow. Different colours are disposed in spots, veins, dots, stripes; or clouds; opaque; very soft; streak shining; adheres to the tongue; feels greasy.

Chem. Char.—Infusible before the blow-pipe; falls to pieces in water without forming a paste. According to some analyses, it contains a large proportion of magnesia.

Physical Char.—Some varieties when rubbed with a feather in the dark, give a little light.

*Localities, &c.—Lithomarga or stone marrow, derives its name from its being found in nodules in amygdaloid rocks; it occupies veins or small fissures in porphyry, gneis, and serpentine. It is found in Bohemia, Saxony, France, England, and at the Giant's causeway in Ireland. A variety of lithomarga, which exhibits many fine colours, particularly violet or lavender blue, is found in beds reposing on coal at Planitz, near Zwickau in Saxony. It has been called, from its beautiful appearance, wonder earth of Saxony (Terra miraculosa).

27. Species. MOUNTAIN or ROCK SOAP.

Le Savon de Montagne, Brochant, i. 453.

Exter. Char.—This mineral is found massive; is dull internally; has an earthy, and sometimes an imperfectly conchoidal fracture; fragments blunt-edged.

Colour brownish black, spotted ochrey yellow. Opaque; very soft; casily frangible; streak shining, and resinous; stains and writes on paper; feels greasy, and adheres strongly to the tongue.

Localities, &c.—This mineral is rare; has been found at Olkutsch in Poland, and also, it is said, in England.

28. Species. UMBER.

Exter. Char.—This mineral is found massive; fracture conchoidal; fragments blunt-edged.

Colour brownish, of various shades; soft; adheres a little to the tongue, and has a meagre feel.

Localities, &c.—Umber is found disposed in beds, in the island of Cyprus; and it is employed as a pigment.

29. Species. YELLOW EARTH.

Id. Kirw. i. 194. La Terre Jaune, Broch. i. 455.

Exter. Char.—Yellow earth is found massive; it is dull, or in the principal fracture, which is slaty, glimmering; cross fracture earthy; fragments very bluntedged.

Colour ochrey yellow; very soft; streak shining; feels greasy, and adheres a little to the tongue.

Localities, & c.-It has only been found in small beds in stratified mountains, at Wehraw in Upper Lusatia,

Part

rt I.

MINERALOGY.

ssifica- satia, and it is said, in the cavities of gray wacken, and ion. in the fissures of a sandstone rock.

Uses .- It is employed in the arts as a pigment.

V. MAGNESIAN GENUS.

1. Species. NATIVE MAGNESIA.

Magnesie Native, Brochant, ii. 449.

Exter. Char .- Native magnesia is found massive, tuberous or carious. Surface uneven and dull. Fracture flat, conchoidal, splintery or earthy. Fragments sharpedged.

Colour yellowish gray, with spots and dendritic délineations of black or blackish brown. Opaque, soft and easily frangible. Feels greasy; adheres to the tongue, and is rather light.

Carbonic acid,	51.
Magnesia,	47.4
A trace of iron, Loss.	1.6.
	T00.0

Localities, &c .- This mineral was discovered by Dr Mitchell in a serpentine rock at Rouhschitz in Moravia.

A mineral in many respects similar to this has bur. de been analyzed by Giobert* .. It was long known uns. Ix. der the name of porcelain carth, and was successfully employed in that manufacture. Giobert supposes that the external characters, and particularly the colours, of the mineral found in Moravia, seem to indicate the existence of other substances beside those dctected by Dr Mitchell's analysis.

Exter. Char.-The mineral described by Giobert is found massive or in mammillary fragments, some of which are tuberculated. Surface dull. Fracture conchoidal or uneven.

Colour pure white. Opaque. Spcc. grav. variable. Hard, sometimes soft. Feels greasy ; adheres slightly to the tongue. The softer varieties absorb water greedily and with a hissing noise.

Chem. Char .- Infusible before the blow-pipe.

Constituent Parts.

Magnesia,	68:
Carbonic acid,	I2.
Silica,	15.6
Sulphate of lime,	1.6
Water,	3.
	Second
	700.0

Localities, &c .- This mineral is found at Baudissero, in a vein which traverses a steatitic rock of which the mountain is composed.

2. Species. BOLE.

Id. Kirw. i. 190. Le Bol, Broch. i. 459. Argile Ochreuse, Hauy, 445.

Exter. Char .- Found massive and disseminated ; surface dull, sometimes a little glimmering ; fracture conchoidal; fragments sharp-edged.

Colour yellowish brown or reddish, with spots and Magnesian dendritical figures of black ; opaque, rarely translucent genus. at the edges; very soft; easily frangible; adheres to the tongue; feels greasy; streak shining : sp. grav. I.4 to 2.

Chem. Char.-Before the blow-pipe it becomes black or gray, and melts into a greenish gray slag. Falls to pieces in water with a crackling noise, and without forming a paste.

Constituent Parts.	Bergman.
Silica,	47.
Alumina,	19.
Magnesia,	6.2
Lime,	5.4
Oxide of iron,	5.4
Water,	17.
	100.0

Localities, &c .- The chief places which yield bole are the island of Lemnos, hence called Lemnian earth ; Sienna in Italy, and Strigau in Silesia, in which latter place it is deposited on indurated clay; in Upper Lusatia it forms nests in basalt.

Uses .- Bole and similar earths were formerly employed in medicine; it is now only used in the preparation of colours.

CIMOLITE.

This is a mineral which in many of its characters is closely connected with the preceding.

Exter. Char.-It is found massive; fracture earthy uneven, or slaty; colour grayish white, pearl gray, and exposed for some time to the air, reddish; opaque; does not stain; adheres strongly to the tongue; is soft, and difficultly frangible : sp. grav. 2.

Chem. Char .- Before the blow-pipe it hecomes at first of a deep gray colour, but afterwards white.

Constituent Parts.	Klaproth.
Silica,	63.
Alumina,	23
Oxide of iron,	1.25
Water,	12.
Loss,	•75
	100.00

Localitics, &c.-This mineral was brought by Mr Hawkins from the island of Argentiers, formerly Cimolo, from whence it has its name. Olivier found a similar substance in the island of Milo, but which was very friable.

Uses .- This substance is employed in whitening woollen stuffs. It is described by Pliny under the name Cimolia, as being applied to the same purpose, and also as a medicine in his time.

It is to be observed that cimolite contains, according to the above analysis, no magnesia.

3. Species. SEA FROTH.

Kéffekill, Kirw. i. 144. L'Ecume de Mer, Broch. i. 462. Argile glaise, Hauy, iv. 433. Meerschaum of the Germans.

Extern

1.01

Magnesian genus.

Exter. Char .- This mineral is found massive, disseminated, or in superficial layers. Surface dull. Fracture fine earthy, sometimes slaty. Fragments sharp edged.

Colour ycllowish white. Opaque. Very soft. Easily frangible. Streak shining. Feels greasy ; and adheres to the tongue. Sp. gr. 1.6.

Chem. Char .- Infusible before the blow-pipe.

Consti	tuent Parts.	Klaproth.

	Break and the second	Construction of the second sec
	100.00	100.00

Localities, &c .- Sea froth is found in Natolia, in the Crimea, in Spain and some other places. It appears to be distributed in low grounds in thin beds; and it is said to be in the state of soft paste which hardens in the air.

Uses .- It is employed in Turkey, in the manufacturc of the heads of tobaeco pipes; and as a detersive substance, like fullers earth, by the Tartars.

4. Species. FULLERS EARTH.

Id. Kirw. i. 184. La Terre à Foulon, Broch. i. 464. Argile Smectique, Hauy, iv. 443.

Exter. Char .- Found massive. Surface dull. Fracture fine grained earthy, conchoidal or slaty. Fragments blunt edged.

Colour olive green, yellowish or reddish. Colours sometimes mixed and disposed in spots or stripes; opake; soft or friable. Streak somewhat shining. Sometimes adheres to the tongue ; feels greasy.

Chem. Char.-Does not effervesce with acids ; melts into a brown spongy clay; falls to pieces in water without forming a paste, and does not froth up like soap.

Constituent Parts. Bergman.

Silica,	51.8
Alumina,	25.
Lime,	3.3
Magnesia,	.7
Oxide of iron,	3.7
Water,	15.5
	T00.00

Localities, &c .- Fullers earth is found in Sweden, Saxony, and France, forming beds ; but the best fullers earth is found between strata of sandstone in Hampshire and some other places of England.

Uses.-Fullers earth is of great importance in woollen manufactures, on account of its detersive properties. It is extensively employed in the process of fulling or cleansing woollen stuffs from greasy matters.

5. Species. STEATITES.

La Pierre de Lard, ou Steatite, Broch. i. 474. Semiindurated and Foliated Steatites, Kirw. i. 151, and 154. Talc Steatite, Hauy, iii. 256.

Exter. Char .- Steatites is found massive, dissemina- Classific ted, and crystallized. Forms of the crystals, a six-sided prism terminated by a six-sided pyramid ; a rectangular and rhomboidal four-sided prism; and a double six-sided pyramid. The crystals are small, generally imbedded in the massive variety; but they are very rare; and it is supposed, with some probability, that they are pseudocrystals. Surface of the crystals smooth and shining. Internally dull; fracture coarse splintery, rarely earthy or slaty. Fragments blunt-edged.

Colour greenish, ycllowish, reddish or grayish. Colours sometimes mixed, and spotted or dendritical. Translucent at the edges. Soft, sometimes friable. Streak shining. Feels greasy. Sp. gr. 2.614. Chem. Char.—Infusible before the blow-pipe; but

becomes white and very hard.

	100.0	100.0

Localities, &c .- Steatites is found in primitive mountains, forming beds and veins in serpentine rocks ; sometimes in metallic veins, as in the tin mines near Freyberg. It is also imbedded in wacken, as in the island of Skye, and in veins of serpentine at Portsoy in Scotland. Steatites is also found in Cornwall in England, and in Sweden, Norway, Saxony, and France.

Uses .- Steatites is sometimes employed in the manufacture of porcelain, and some varieties of it answer for the same purpose as fullers earth.

6. Species. FIGURE STONE.

La Pierre à Sculpture, Broch. i. 451. Le Bildstein of the Germans.

Exter. Char .- This mineral is found massive. Internal lustre sometimes glimmering, sometimes dull, greasy. Fracture slaty ; cross fracture splintery.

Colour olive green, greenish gray, yellowish brown, sometimes reddish, and veined. Semitransparent, or translucent at the edges, and sometimes opake. Soft; sectile; feels greasy. Sp. gr. 2.78 to 2.81.

Constituent Parts. Klaproth.

Localities, &c.-This mineral is brought from China, and is always cut into various, often singular, figures; and hence the name bildstein, or sculpture stone.

MINERALOGY.

7. Species. NEPHRITE, or Jade.

Jade, Kirw. i. 171. Le Nephrite, Broch. i. 467. Jade, Hauy, iv. 368.

This species is divided into two subspecies.

Subspecies 1. COMMON NEPHRITE.

Exter. Char .- This variety is found massive, disscminated, or in rounded pieces. The surface is smooth, glimmering, and unetuous; internally it is dull; fracture slaty or coarse splintery, rarely fibrous ; fragments sharp-edged.

Colour leek green, sometimes inclining to blue, greenish or yellowish white; translucent, sometimes only at the edges ; hard ; very difficultly frangible ; feels greasy. Sp. grav. 2.97 to 4.38. Chem. Char.—Fusible before the blow-pipe, and melts

into a semitransparent white glass.

Constituent Parts.	Hoepfner.
Silica,	47
Alumina,	38 4
Lime, Oxide of iron.	2
- minagedue main	9
	100

Localitics, &c .- The repository of nephrite is unknown. It was originally brought from the Levant, East Indies, and China. It is found also in the Alps, in Switzerland, and in Piedmont. The water-worn pebbles which are collected on the banks of the lake of Geneva often contain this mineral. It is found also in a similar form at a particular place on the shores of Iona, one of the Hebrides, in Seotland.

Uses .- Oriental nephrite, long known under the name of Jade, is held in considerable estimation on account of its hardness and tenacity. It is employed by the Turks for the handles of knives and sabres, and frequently by others for various ornamental purposes.

The property of curing diseases of the kidneys is ascribed to this mineral by ancient authors, and hence the name nephritic stone, or nephrite.

Subspecies 2. AXE STONE.

La Pierre de hache, Brochant, i. 470. Beilstein of the Germans.

Exter Char .- This is also found massive, but most frequently in rounded pieces; lustre glimmering, or weakly shining; fracture in large masses, slaty; in small, splintery; fragments in the form of plates.

Colour deep meadow-green, sometimes olive green; translucent; semihard, and sometimes hard; not very brittle; more difficultly frangible than the preceding variety.

Localities, &c .- This mineral is found in China, the East Indies, and South America, on the banks of the river Amazons. It is found also in some of the islands in the South Sea, as well as in Corsica, Switzerland and Saxony.

Uses .- Axe stone is employed as hatchets and other VOL. XIV. Part I.

cutting instruments by the natives of those countries Magnesian where iron is little known. genus.

8. Species. SERPENTINE.

Id. Kirw. i. 156. La Serpentine, Brochant, i. 481. Roche Serpentineuse, Hauy, iv. 436.

This species is divided into two subspecies.

Subspecies 1. COMMON SERPENTINE.

Exter. Char .-- This mineral is found massive, very rarely disseminated ; internal lustre slightly glimmering, or only dull; fracture splintery, or fine grained uneven, rarely conchoidal; fragments sharp-edged.

Colour blackish green, leek green, grayish, greenish, or bluish gray; in some varieties, red of various shades. These colours are mixed and disposed in spots, stripes, veins, and dots. Translucent at the edges, or opaque; semihard ; not difficultly frangible ; feels greasy. Spec. grav. 2.57 to 2.7.

Chem. Char .- Infusible before the blow-pipe.

Constituent Parts.	Kirwan.

Water,	12

100

Localities, &c .- Serpentine belongs to the class of primitive rocks, and it constitutes entire mountains. It is found in Saxony, Bohemia, Italy, Corsica, and Siberia; in Cornwall in England, where it contains native copper, and at Portsoy in the north of Scotland, where it is known by the name of Portsoy marble. Common serpentine is frequently mixed with steatites, tale, asbestus, garnets, and magnetic iron, but never contains limestone. This variety, in the language of Werner, is of a newer formation than the following subspecies.

Uses .- Serpentine is susceptible of a fine polish; on account of which, and its beautiful colours, it is employed for various ornamental purposes.

Subspecies 2. PRECIOUS SERPENTINE.

Exter. Char .- This also is found massive or disseminated; internal lustre glimmering, rarely weakly shining, resinous; fracture conchoidal, even or splintery; fragments sharp-edged.

Colour dark leek green of various shades; translucent ; semi-hard ; easily frangible ; feels slightly greasy.

Localities, &c .- This subspecies is found in similar places with the preceding. It is distinguished from it by being always connected with limestone. The stones known in Italy by the name of *verde di Prato verde* Antico, verde de Suza, which are very often accompanied by limestone, may be included under precious serpentine.

9. Species. SCHILLER STONE.

Schillerspath, or Spath Chatoyant, Brochant, i. 421. Schiller Spar, Kirw. 221. Bb

tI. sifica-

inn.

194

Magnesiau

genus.

Exter. Char.—This mineral is found disseminated in thin plates, which assume a crystallized form, as in that of a table with six sides, or a short six-sided prism; lustre shining, sometimes resplendent, and semi-metallic; frac-

ture foliated. Colour olive green, bronze yellow, or silvery white; soft; casily frangible; somewhat elastic; feels greasy.

Chem. Char.-Before the blow-pipe it melts with borax, into a glass which becomes opaque on cooling.

Constituent Parts.	Heyer.
Silica, Alumina, Magnesia, Lime, Oxide of iron,	52 23.33 6 7 11.67
	100.00

Localitics, &c.—Schiller stone is found at Basta in the Hartz, in Moravia, the Tyrol, in Corsica, and in Cornwall. It is usually imbedded in serpentine, and is accompanied by quartz, mica, and copper pyrites. It is supposed by some to be crystallized serpentine.

10. Species. TALC.

This species is divided into three subspecies; 1. earthy, 2. common, and 3. indurated talc.

Subspecies 1. EARTHY TALC.

Talcite, Kirw. i. 149. Le Talc Terreux, Broch. i. 486. Talc Granuleux, Hauy, iii. 255.

 $E_{\text{Ater.}}$ Char.—Earthy talc is found disseminated in kidney-form masses, or in superficial layers; lustre glimmering, pearly; friable; the particles scaly, pulverulent, or slightly cohering.

Colour greenish, reddish, or silvery white; stains; fcels greasy, and is light.

Localities, & e.—This mineral is found in Piedmont, Saxony, Bohemia, and in the western parts of Invernessshire in Scotland, where it exists in veins or cavities of primitive rocks.

Subspecies 2. COMMON TALC.

Id. or Venetian Talc, Kirw. i. 150. Le Talc Commun, Broch. i. 487. Talc Laminaire, Hauy, iii. 255.

Exter. Char.—This mineral is found massive, disseminated, and rarely crystallized in very small six-sided tables; lustre shining or resplendent, pearly or metallic; fracture straight or curved foliated; fragments wedge-shaped.

Colour greenish white, pale apple green, reddish or yellowish white; translucent or semitransparent, in thin plates transparent, soft, flexible, but not elastic; feels greasy. Spec. grav. 2.7 to 2.8.

Chem. Char.-Infusible before the blow-pipe, which distinguishes it from chlorite; does not effervesce with acids.

Constituent Parts. Hoepfner.

Silica,	50
	5-
Magnesia,	44
A1	
Alumina,	0

¹⁰⁰

Localities, &c.—Common tale is always found in Classifi serpentine rocks, where it accompanies actynolite, steatites, and indurated tale. What is called Venetian tale is brought from the mountains of Saltzburg and the Tyrol.

Uses.—Talc is sometimes employed as a substitute for chalk, enters into the composition of crayons, and is mixed with some kinds of paint.

Subspecies 3. INDURATED TALC.

Le Talc Endurci, Broch. i. 489.

Exter. Char.--This is found massive, and sometimes, it is said, crystallized; lustre shining and resplendent, resinous or pearly; fracture curved foliated, or slaty; fragments blunt-edged, tabular.

Colour greenish white, snow white, or apple green; translucent; in thin plates semitransparent; very soft; smooth, and greasy to the feel.

Localities, &c.-Indurated talc forms beds in mountains of argillaceous schistus, gneis, and serpentine, in the Tyrol. Italy, and Switzerland, and also in the western parts of Scotland.

Uses.-It is applied to the same purposes as the preceding.

11. Species. ASBESTUS.

This is divided into four subspecies: 1. mountain cork; 2. amianthus; 3. common asbestus; and, 4. ligniform asbestus.

Subspecies 1. MOUNTAIN CORK.

Suber Montanum, Kirw. i. 163. Le Liege de Montagne, Broch. i. 492. Asbeste Tressé, Hauy, iii. 247.

Exter. Char.—This mineral is found massive, often in small plates, which are sometimes thin, and are then denominated *mineral paper*; sometimes thick, and then called *mineral leather*; more rarely in porous or cellular pieces, when they are denominated *mineral flesh*; sometimes it is marked with impressions; the lustre is weakly glimmering or dull; fracture to appearance compact and uneven, but it is fibrous, and the fibres are sometimes parallel, and sometimes interwoven; fragments very blunt-edged.

Colour yellowish or grayish white; opaque; very soft, extremely difficult to break; in thin plates flexible and elastic; creaks when handled; feels meagre. Spec. grav. 0.68 to 0.993.

Chem. Char .--- Melts before the blow-pipe with difficulty.

(Constituent Parts.	Bergman.
	Silica,	56.2
	Magnesia,	26.1
	Alumina,	2
	Lime,	12.7
	Oxide of iron,	3.

100.0

Localities, &c.—This mineral is found in thin veins in serpentine rocks: it is often mixed with quartz, tale, and silver ores, as in Saxony. It is also found in Sweden, Norway, Siberia, Hungary, and in the lead veins at Leadhills in Scotland.

MINERALOGY.

Subspecies 2. AMIANTHUS.

J. Id. Kirw. i. 161. L'Amianthe, Broch. i. 494. Asbeste Flexible, Hauy, iii. 247.

Exter. Char.—This variety is also found massive, more rarely disseminated, and in small detached bundles; lustre glimmering, or a little shining and silky; fracture fibrous straight or parallel.

Colour greenish or silvery white, yellowish white, or greenish gray; opaque; rarely translucent at the edges; very flexible, and even elastic in thin fibres; feels greasy.

Chem. Char.—Melts with difficulty before the blowpipe, into a white, gray, yellow, and sometimes black enamel.

Constituent	Parts.	Bergman.	Chenevix.
Silica,	64	64	59.
Magnesia,	17.2	18.6	25.

Oxide of iron,	.2.2	I.2	2.25
Loss,			1.50
	-		
	100.0	100.0	100.00

Localities, &c.—Amianthus is usually found in primitive rocks, but particularly those of serpentine. It is found in Saxony, Bohemia, Italy, Spain, France, Sweden, and in the western parts of Scotland; but the finest specimens of amianthus are brought from the island of Corsica.

Uses.—On account of the flexibility of this substance it is spun into threads; for this purpose it is mixed with lint, to render the threads less brittle in working them into cloth, which is afterwards passed through the fire that the vegetable matter may be consumed, and the amianthus, which is infusible, remains; and thus an incombustible cloth is obtained. The ancients manufactured this cloth for the purpose of wrapping round their dead bodies, that their ashes might be preserved unmixed with the wood employed in burning them.

Subspecies 3. COMMON ASBESTUS.

Asbestus, Kirw. i. 1 59. L'Asbeste Commune, Brochant, i. 497. Asbeste Dur, Hauy, iii. 247.

Exter. Char.—This also is found massive; lustre shining and weakly shining, silky or resinous; surface fibrous, the fibres being parallel, straight, or curved; the fibres arc more strongly united than in amianthus, and hence sometimes a splintery fracture.

Colour leek green, greenish, or yellowish gray; translucent at the edges; soft, or semihard; rather easily frangible; little flexible; feels greasy; spec. grav. 2.54 to 2.90.

Chem. Char.-Melts with difficulty before the blowpipe, into a dark gray slag.

Constituent Parts. Wiegleb.	
Silica, 46.66	
Magnesia, 48.45	
Oxide of iron, 4.79	
1.055, .I	
200.00	

Localities.—It is found in similar situations with the Maguesian preceding, in Saxony, Russia, Sweden, and in the western parts of Scotland.

Subspecies 4. LIGNIFORM ASBESTUS.

Id. Kirw. i. 161. Le Bois de Montagne, Brochant i. 499. Asbeste Ligniforme, Hauy, iii. 248.

Exter. Char.—This also is found massive; lustre glimmering, silky; fracture in large masses, curved slaty; in small pieces fibrous, and having the appearance of a woody texture; fragments in elongated plates.

Colour yellowish brown of different shades; opaque; soft; not difficultly frangible; in thin fragments a little flexible, but not elastic; feels meagre; adheres to the tongue; streak shining.

Chem. Char.-Before the blow-pipe is only fusible at the edges.

Localities, &c.—This variety is found in the Tyrol, where it is accompanied by galena, black blende, and a grayish white quartz.

12. Species. CYANITE.

Id. Kirw. i. 200. La Cyanite, Broch. i. 501. Sappare, Sauss. § 1900. Disthene, Hauy, iii. 220.

Exter. Char.—This mineral is found massive, disseminated, or crystallized, in four-sided prisms, of which two are broad and two narrow, and having the four lateral edges, or only the two opposite edges, truncated. This prism is often so flattened, as to have the appearance of a table. The broad faces of the crystals are smooth and shining, the narrow faces streaked and only glimmering, almost dull. Internal lustre shining and pearly; fracture curved radiated; that of the crystals foliated; fragments tabular, sometimes splintery, or imperfectly rhomboidal.

Colour blue of various shades, sometimes bluish and pearl gray; and different colours are arranged in stripes, spots, or clouds; translucent, or when crystallized semitransparent, or transparent; semihard, and sometimes soft; easily frangible; feels greasy. Spec. grav. 3.51 to 3.62.

Chem. Char.—Entirely infusible before the blow-pipe, on which account this mineral was employed by Saussure as a support for other substances in experiments with that instrument.

Constituent Parts.	Saussure.

Localities, &c.-Cyanite is found on St Gothard in Switzerland, in crystals mixed with quartz, garnets, and granitc, and imbedded in indurated talc. It is also found in Spain, France, Carinthia, Bavaria, Siberia, and in the north of Scotland, and always in primitive mountains.

13. Species.

irt I.

ion.

196 Magnesia genus.

13. Species. ACTYNOLITE.

This is divided into three species; 1. asbestous, 2. common, and 3. glassy.

Subspecies I. ASBESTOUS ACTYNOLITE.

Amianthinite, Kirw. i. 164. and Metalliform Asbestoid, ibid. 167. La Rayonnante Asbestiforme, Broch. i. 504. Actinote Aciculaire, Hauy, iii. 75.

Exter. Char.—This mineral is found massive, and rarely crystallized in rhomboidal six-sided prisms, two of which are about 124° 30′, and four about 117° 45′; lustre glimmering; internal lustre weakly shining, sometimes shining, pearly; fracture radiated; fragments wedge-shaped.

Colour white, or greenish, reddish, or yellowish gray; commonly opaque; sometimes translucent at the edges; streak greenish white; soft, rarely semi-hard; rather difficultly frangible. Specific gravity 2.58 to 3.33.

3.33. Chem Char.—Fusible before the blow-pipe into a black slag, or grayish white enamel.

Localities, &c.-Found in the neighbourhood of Bayreuth and the Bannat, in beds of serpentine and steatites.

Subspecies 2. COMMON ACTYNOLITE.

Asbestinitc, Common, Asbestoid, and Schorlaceous Actynolite, Kirw. i. 165–168. La Rayonnante Commune, Broch. i. 507. Actinote Hexaëdre, Hauy. iii. 74.

Exter. Char.—Massive, disseminated, crystallized in elongated, very oblique, six-sided prisms, having the acute lateral edges truncated. The crystals are acicular, and longitudinally streaked; lustre shining and vitreous; fracture radiated, parallel or divergent, stellated; fragments rather blunt-edged.

Colour olive green, pistachio green, reddish brown; crystals translucent or semitransparent; semihard; difficultly frangible; rarely fcels greasy. Spec. grav. 3. to 3.31.

Chem. Char.—Fusible before the blow-pipe into a black slag, a white transparent glass, or a grayish white enamel.

Constituent Parts.	Bergman.

	Construction of Immunol
	100.0

Localities, &c.—It is found in Saxony, Switzerland, Norway, and west side of Inverness-shire in Scotland. Its repository is in primitive mountains, where it is accompanied with ores of lead and iron, as well as with quartz and brown blende.

Subspecies 3. GLASSY ACTYNOLITE.

Id. Kirw. i. 168. La Rayonnante Vitreuse, Broch. i.

510. Thallite, Lametherie, ii. 319. Epidote, Hauy, Classifiii. 102.

Exter. Char.—Found massive or crystallized in thin six-sided prisms, whose surface is smooth and resplendent; internal lustre shining, vitreous; fracture radiated or wedge-shaped, fibrous; fragments splintery.

Colour olive green, leek green, and asparagus green; translucent, or semitransparent; semihard, or hard; very brittle, and very easily frangible. Spec. grav. 2.95 to 3.40.

Localities, &c.-This variety is found in similar repositories, and in similar places with the preceding.

14. Species. TREMOLITE.

This is also divided into three subspecies; 1. asbestous, 2. common, and 3. glassy.

Subspecies 1. ASBESTOUS TREMOLITE.

La Tremolithe Asbestiforme, Broch. i. 514. Grammatite. Hauy, 227.

Exter. Char.—Found massive, disseminated, and crystallized; and the crystals are capillary or acicular; lustre weakly shining, silky or pearly; fracture radiated or fibrous; fragments splintery and wedge-shaped.

Colour yellowish white, reddish, greenish, or grayish; opaque; translucent at the edges; very soft; casily frangible.

Subspecies 2. COMMON TREMOLITE.

La Tremolithe Commune, Broch. i. 515.

Exter. Char.—Massive, or crystallized in rhomboidal prisms, with angles of $126^{\circ} 52' 12''$, and $53^{\circ} 7' 48''$. The crystals are deeply striated longitudinally; external lustre resplendent; internal shining, pearly; fracture radiated, either parallel, divergent, or promiscuous; surfaces of the fracture longitudinally streaked; fragments splintery.

Colour greenish white, reddish, or yellowish; rarely pearl gray; always translucent; in crystals semitransparent; semihard; brittle; easily frangible; meagre to the feel.

Subspecies 3. GLASSY TREMOLITE.

La Tremolithe Vitreuse, Broch. i. 516.

Exter. Char.—Massive, or crystallized in long needle or awl-shaped prisms; internal lustre shining, and sometimes resplendent; vitreous or pearly; fracture radiated; cross fracture even, and a little oblique; fragments splintery.

Colour greenish or yellowish white; translucent; crystals sometimes transparent; semihard; brittle; easily frangible; feels meagre. Spec. grav. 2.90 to 3.2, Hauy.

Chem. Char.-Before the blow-pipe it melts into a porous white slag.

assifica-

tion.

Physical Char.—By percussion or friction in the dark, a reddish phosphorescent light appears; and the powder thrown on burning coals yields a greenish light.

Localities, &c., Tremolite is found imbedded in limestone, in primitive mountains. It was first discovered in the valley of Tremola by Pini, and hence its name. It is also found in Hungary, Bohemia, and Carinthia, and in the mountains six miles south of Paisley in Scotland, where it is accompanied with prchnite.

15. Species. SMARAGDITE.

Id. Saussure Voy. § 1313. Diallage, Hauy, iii. 125. Id. Brochant, i. 423. and ii. 506.

Exter. Char.—Smaragdite has been found massive and disseminated. Internal lustre shining. Fracture foliated. Cleavage single. Fragments rather sharp edged.

Colour, grass or emerald green. Slightly translucent. Semi-hard or soft. Brittle. Spec. grav. 3.

Chem. Char.—Before the blow-pipe melts into a gray or greenish enamel.

Localities, &c.—This mineral was found by Saussure in the vicinity of Turin, imbedded in nephrite clouded white and blue. It has also been found near the lake of Geneva among the rounded pebbles, and in Corsica in primitive rocks. In Italy, tables and ormamental pieces of furniture are made of smaragdite; and the Italian marble-cutters call it verde di Corsica.

16. Species. SAHLITE.

Id. D'Andrada, Jour. de Phys. An. 8. p. 241. Malacolithe, Hauy, iv. 379. Id. Brochant, ii. 518.

Exter. Char.-Found massive or crystallized in sixsided prisms, having two opposite lateral edges truncated. Lustre slightly glimmering, resinous. Fracture Calcareous. foliated. Cleavage threefold. Fragments sometimes genus. rhomboidal.

Colour grayish green or bluish gray. In thin plates translucent. Scarcely scratches glass. Very soft to the touch, from which it has the name *malacolite*. Spec. grav. 3.2307 to 3.2368.

Chem. Char.—Fusible before the blow-pipe into a porous glass.

Constituent Parts. V.	auquelin.

Localities, &c.—This mineral was discovered by D'Andrada in the silver mines of Sahla in Sweden, and hence it derived its name. It was found by the same naturalist at Busen in Norway. It appears from the observations of Hauy that sahlite and augite are very closely allied, not only in structure and external characters in general, but also in their constituent principles; the only difference in their composition is in the proportions of the lime and magnesia, which are smaller in augite than in sahlite; but the proportion of iron in the former is considerably greater than in the latter.

17. Species. SCHALSTONE, or TABULAR SPAR.

Exter. Char.—This mineral is found massive; lustre shining and pearly; fracture foliated or splintery, and coarse fibrous; consists of separate large-grained pieces implicated in each other; and according to Karsten, are very regular.

Colour milk white, yellowish or reddish white; translucent; semi-hard; brittle.

Constituent Part	s.
Silica,	50
Lime,	45
Water,	5.
	TOO

Localities, &c.—This mineral was first noticed by Stutz. It is found in the bannat of Temeswar, and is accompanied by crystallized garnets and calcareous spar.

VI. CALCAREOUS GENUS.

I. Species. AGARIC MINERAL, or Mountain Milk.

Id. Kirwan, i. 76. Id. Brochant, i. 519. Chaux Carbonaté Spongieuse, Hauy, ii. 167.

Exter. Char.—This mineral is composed of fine pulverulent particles, slightly united together, and nearly friable.

Colour yellowish white, or snow white ; stains strong-

ly;

Calcarcous ly; feels meagre; does not adhere to the tongue; neargenus. ly floats on water.

Chem. Char. — Effervesces with acids, and is entirely dissolved, so that it is chiefly composed of lime and carbonic acid.

Localitics, &c.—This mineral is found in the fissures and cavities of calcarcous mountains, and it is supposed that it originates from the destruction of the rocks, the particles of which are carried down to the fissures and cavities by rain water. Abundant in Switzerland.

2. Species. CHALK.

Id. Kirwan, i. 71. La Craie, Brochant, i. 521. Chaux Carbonaté Craycusc, Hauy, ii. 166.

Exter. Char.—Found massive; has a dull appearance; fracture earthy, and fragments blunt-edged.

Colour usually snow or yellowish white, sometimes gray or brown; opaque; stains and writes; very soft, and easily frangible; feels meagre; adheres a little to the tongue. Spec. grav. 2.31 to 2.65.

Chem. Char.—Effervesces with acids; before the blow-pipe is calcined, and converted to quicklime. It is almost entirely composed of lime and carbonic acid, with a mixture of a little oxide of iron and some other substances.

Localities, &c.—Chalk forms peculiar stratiform mountains which contain many petrifactions, the matter of which is almost always siliceous. They contain also flints arranged in regular strata. No metallic substances are found in chalk. A great body of chalk traverses France from south to north, extending from Champagny to Calais, and continued to England, in the south of which it forms extensive beds. Chalk is also found in the island of Zealand, in the Baltic, in Poland and many other places.

3. Species. LIMESTONE.

This is divided into four subspecies, which arc, 1. compact, 2. foliated, 3. fibrous, and 4. pea stone.

Subspecies I. COMPACT LIMESTONE.

This subspecies is again divided into two sections; the first including common compact limestone, and the second roe-stone.

A. Common Compact Limestone.

Id. Kirw. i. 82. Id. Broch. i. 523. Chaux Carbonaté Compacte, &c. Hauy, ii. 164.

Exter. Char.—Found massive; external form frequently figured from the numerous petrifactions which it contains; internally dull; rarely glimmering; fracture compact, splintery, uneven or earthy; fragments not very sharp-edged.

Colour usually gray, sometimes reddish or yellowish; different colours exhibit spots, stripes, veins, and dendritical figures; translucent at the edges; semihard; brittle; easily frangible; feels meagre; gives a grayish white streak. Spec. grav. 2.6 to 2.7.

Chem. Char .- Dissolves in acids with effervescence.

The constituents of limestone are carbonate of lime, with variable proportions of other earths, and particu-

larly alumina and silica. The following are the consti- Classifier tuent parts of magnesian limestone examined by Mr tion. Tennant.

Lime,	29.5
Magnesia,	20.3
Carbonic acid,	47.2
Alumina and oxide of iron,	.8
Loss,	2.2
	100 0

Localitics, &c.—Forms very extensive stratiform mountains, and is usually met with along with coal and sandstone. It is very abundant in Saxony, Bohemia, Sweden, France, Switzerland, and Britain. The magnesian limestone is abundant in Yorkshire and Nottinghamshire.

Uses.—The uses of limestone for the purposes of building, and when reduced to the state of quicklime, to form the basis of mortar, as well as in various arts, are well known.

This variety of limestone, when susceptible of a polish, furnishes *marbles*; which name, although it be applied to very different stones which are susceptible of a polish, and are fit for sculpture, or ornamental architecture, is frequently applied to limestone of this description.

B. OOLITE, or ROE STONE.

Id. Brochant, i. 529. Oviform Limestone, Kirw. i. 91. Chaux Carbonaté Globuliforme, Hauy, ii. 171.

Exter. Char.—This is found massive; internally dull; fracture compact; fragments blunt-edged.

Colour yellowish, smoke gray, hair, or reddish brown; opaque; rarely translucent at the edges; semihard; consists of small globular, distinct concretions: the size of the concretions are very various. Spec. grav. 2.4 to 2.5.

Localities, &c.-Roe stone is found in Sweden, Switzerland, Saxony, and in the south of England.

The ketton stone of England, and the celebrated Portland stone, belong to this variety. Of the latter some of the principal public buildings in England and Ireland are constructed.

Uses.—It is employed as a building stone; and when of a fine grain, it is polished and employed as marble.

Subspecies 2. FOLIATED LIMESTONE.

Of this there are two varieties, granularly foliated, and calcarcous spar.

A. GRANULARLY FOLIATED LIMESTONE.

Pierre Calcaire Grenue, Broch. i. 531. Chaux Carbonaté Saccharoïde, Hauy, ii. 164.

Exter. Char.—Found only massive; lustre shining, or strongly glimmering; between pearly and vitreous; fracture straight foliated; fragments rather bluntedged; in granular, distinct concretions, small or fine grained.

Colour usually snow white, grayish, yellowish, greenish, and rarely reddish white, and sometimes it is spotted, veined, or striped; usually translucent; semihard; feels meagre; brittle, and easily frangible. Spec. grav. 2.7 to 2.8.

198

Part

Part I.

lassifica-

Chem. Char.—Effervesces with acids, and is almost entirely dissolved. Some varieties, however, from an admixture of other substances, are very slowly acted on by aeids.

Localities, &c.—Granularly foliated limestone belongs almost exclusively to the primitive and transition mountains, reposing on gneis, micaceous schistus, and clay slate, containing, beside other mineral substances, various metallic ores.

It is found in Italy, Saxony, Bohemia, Sweden, Norway, France, and Britain.

Uses.—This variety of limestone is applied to the same purposes as the former.

Of MARBLES.—In the language of the architect and statuary, all stones come under the name of marble which are harder than gypsum, are found in large masses, and are susceptible of a good polish.

On this principle many varieties of limestone, granite also and porphyry, serpentinc, and even fine-grained basalts, are denominated marbles. But the word among mineralogists is taken in a more restricted sense, and confined to such varieties of dolomite, swinstone, and compact and granularly foliated limestone, as are capable of receiving a good polish. The most valuable of the calcareous marbles, for hardness, durability and colour, are brought from Italy, the Greek islands, and from Syria. When the ancient Romans were at the height of their civilized luxury, they obtained some varieties of marble from Numidia and other countries, which were very much esteemed.

The sculptors of ancient Greece and modern Europe have always held the white granularly foliated limestone in the highest estimation, both on account of its pure colour, delieate translueenee, and granular texture, which make it much easier to work than compact limestone. The species called dolomite is softer and of a finer grain, so that it is even more manageable under the chissel, and therefore many of the smaller works of the Greek sculptors are of this stone; but Paros and Carrara furnish Europe with the greatest quantity of statuary marble. The Parian marble, which consists almost entirely of carbonate of lime, is the purest, softest, and has some degree of transparency; that of Carrara is often mixed with granular quartz in considerable proportion. The following are the architectural marbles which are held in greatest estimation.

1. The marble called *bardiglio*, from Carrara, is of a deep blue colour, and seems to be the same with the white statuary marble of that place, with the addition of some colouring matter.

2. That variety of marble called *cipolin*, is statuary marble traversed by veins of mica.

3. Lumachella marble. This is a compact limestone of a brownish gray colour, containing shells which often retain the original pearly lustre. To this variety belongs the fire marble of Bleyberg in Carinthia, in which the imbedded shells are beautifully iridescent.

4. Florentine marble. This is a grayish, compact, argillaceous limestone, exhibiting designs of a yellowish brown colour, and resembling the ruins of houses : hence it is called *ruin marble*.

5. The marbles of Syria, Sienna, and Arragon, are of a yellow colour, and are in considerable estimation.

6. Brocatello marble. This is a breecia limestone, composed of fragments of a yellowish red and purple • 4 colour which are cemented by semitransparent, white Calcareous calcareous spar.

7. The marbles known by the names of verde antiche, verde di Corsica, are composed of limestone, calcareous spar, serpentine, and asbestus.

8. The British islands afford many fine marbles, of which that of Tiree is the finest and most beautiful. It has often a delicate flesh-coloured ground, spotted with green; but its colours, it is said, are apt to fade. Marbles have also been found in the island of Skye, and in the counties of Ross and Sutherland. For a particular account of these, see *Williams's Mineral Kingdom*. Marble is not uncommon in different parts of England; and in particular Devonshire and Derbyshire afford varieties which are held in considerable estimation on account of their beauty.

Elastic marble. Some varieties of granular limestone, when ent into thin plates, possess a certain degree of elastieity. The marble in which this property was observed, was in the Borghese palace at Rome. It was got from an ancient building. Dolomicu supposed that marble acquired this property by being deprived of moisture, and Fleuriau de Bellevue confirmed this opinion, by subjecting certain marbles to heat. He found also a natural elastic marble in Mount St Gothard.

B. CALCAREOUS SPAR.

Common Spar, Kirw. i. 86. Le Spath Calcaire, Broch. i. 536. Chaux Carbonatée, Hauy, ii. 127.

Essen. Char.—Divisible into a rhomboid of 101_{2}^{10} and 7.8_{2}^{10} : soluble with effervescence in nitric acid.

Exter. Char.—Calcareous spar is found massive, or disseminated in various forms, as globular, kidneyform, cellular, and stalactitical; but it is most frequently crystallized. The primitive form of its crystals is an obtuse rhomboid, whose angles are $101^{\circ} 32' 13$, ' and $78^{\circ} 27'$ 47''; integrant molecule the same. The variety of forms of calcareous spar is very great. Werner reduces them to three principal or prevailing forms, and from these he deduces the variations and modifications which take place. His principal forms are, 1. The six-sided pyramid; 2. The six-sided prism; aud, 3. The threesided pyramid. But according to others following the same method, the principal forms are the five following: 1. The six-sided pyramid; 2. The six-sided pyramid; and, 5. The bexahedron, including the rhomboid and cubc.

1. The six-sided pyramid is either simple or double. A. Simple. Simple pyramids are the summits of other pyramids, or of prisms, and they are variously modified in being equal sided, acute, or obtuse, having the angles at the base truncated, or having an obtuse three-sided summit slightly convex.

B. Double; in which two pyramids are obliquely united, and variously modified, by having the angles at the base truncated, or the faces of the summit a little convex.

2. The six-sided prism, is also variously modified, by having at each extremity a six-sided acute summit, or a second obtuse summit of three sides, placed alternately on three edges of the first.

3. A six-sided table, which is either perfect with equal or unequal sides, or rounded, or lenticular.

4. The

200

* *

Ma

290

Calcareous genus.

4. The three-sided pyramid, which is either simple or double, and is also variously modified.

5. The hexahedron, which includes the rhomboid, and this is either perfect, or has convex faces, or has six obtuse edges truneated ; and the cube, which is somewhat rhomboidal. But for a full account of all the varieties and modifications in the crystallization of caleareous spar, the reader is referred to the treatises of Hauy and Brochant.

The erystals of calcareous spar exhibit also a similarity of arrangement. The simple six-sided pyramids are frequently disposed in a globular, faseicular, or stellated form. The six-sided pyramids arc disposed in rows; the six-sided prisms are often disposed like steps of stairs, or are fascicular, or kidney-form; some acute three-sided pyramids of calcareous spar have been found hollow, and in some prisms the centre has been observ-ed of another colour. The surface of the crystals commonly smooth; lustre slining or resplendent; internal lustre resplendent or shining, vitreous, and sometimes pearly; fracture foliated; cleavage threefold; fragments always rhomboidal.

Colour usually white, grayish, reddish, greenish, or yellowish, white, rarely violet blue, or yellowish brown. Various degrees of transparency; when perfectly transparent, refraction is double. It was in this substance that the property of double refraction was first observed, and hence it was ealled double spar. This singular property engaged the attention and mathematical skill of Newton, Huygens, Buffon, and more lately the celebrated Hauy. Calcareous spar is semihard, brittle, and easily frangible. Sp. grav. about 2.7.

Chem. Char .- Soluble with effervescence in nitric acid, and reduced by calcination to quicklime.

hil.	Bergman.	Phillips
g. xiv. Lime,	55	55.5
· Carbo	nie aeid, 33	44.
Water	r, II	•5
	100	100.0

Physical Char .- Some varieties of caleareous spar, and particularly those from Derbyshire, give out, when heated, a phosphorescent light.

Localities, &c .- Calcareous spar is very common in all kinds of rocks, in veins and cavities, and particularly in mineral veins, accompanied with quartz, fluor spar, heavy spar, and metallic ore. The finest specimens of rhomboidal spar are brought from Iceland, Derbyshire, the Hartz, as well as Saxony, France, and Spain.

The erystallized sandstones of Fontainebleau are real rhomboidal crystals of caleareous spar, which, during the process of erystallization, have been penetrated with particles of sand.

Subspecies 3. FIBROUS LIMESTONE.

Id. Kirw. i. 88. La Pierre Calcaire Fibreuse, ou la Stalactite Calcaire, Broch. i. 549. Chaux Carbonatée Concretionnée, Hauy, ii. 168.

Of this subspecies two varieties have been formed, common fibrous, and caleareous sinter.

3

Exter. Char .- Found massive; lustre weakly shining and pearly; fracture fibrous, sometimes coarse and delicate, straight or parallel, and sometimes radiated ; fragments splintery.

Colour usually grayish, reddish, and yellowish white; generally translucent ; rarely semitransparent.

Localitics, &c.-This variety is found in veins; and some of it is susceptible of a fine polish, and was known to the ancients under the name of calcareous alabaster, to distinguish it from gypseous alabaster.

Sattin spar, a beautiful mineral, which is also susceptible of a fine polish, and has a siekly lustre, from which it derives its name, belongs to this variety. It was first discovered in Cumberland, and is but rarely met with in other places.

B. CALCAREOUS SINTER.

This variety is usually found stalactitical or tuberose, and also sometimes kidney-shaped, botryoidal, tubular, and eoralloidal. Surface usually rough, or drusy, rarely smooth ; internal lustre glimmering, sometimes weakly shining, silky, or pearly; fracture fibrous, which is either straight, scopiform, or stellular; fragments wedge-shaped and splintery.

Colour snow white, grayish green, or yellowish white, and these are sometimes arranged in stripes or veins ; translucent, sometimes only at the edges; rarely semitransparent; between semihard and soft; brittle and easily frangible. Sp. grav. 2.728.

Localitics, &c .- This mineral seems to be a deposition of caleareous particles, formed by the gradual infiltration of water into the eavities and fissures of limestone mountains. They are either deposited in layers on the floor, or suspended from the roof of those grottoes, and in this latter case they assume a great variety of initative forms. It is found therefore in the eelebrated grottoes of Auxelles, Arey, and Antiparos, and in the eavities of mineral veins at Leadhills.

The singular mineral substance, known by the name of flos ferri, belongs to this variety. This is found in the cavities of veins of spathose iron ore, from which it has derived its name. It is of a branched or coralloidal form.

Subspecies 4. PISOLITE or Pea-stone.

Oviform Limestone, var. Kirw. i. 91. La Pierre de Pois, Broch. i. 555. Chaux Carbonatée Globuliforme, Hauy, ii. 171.

Exter. Char.-This mineral is found massive, and in the eavities in which it is formed, the surface is kidneyshaped; internally dull; fracture difficult to determine, but appears even; fragments rather sharp-edged.

Colour white, snow white, grayish, reddish or yellowish white; opaque; rarely translucent at the edges; soft, and brittle.

Localities, & e .- Pisolite is found at Carlsbad in Bohemia, where it has been long known, and where an entire bed was discovered in digging the foundations for a church. Each of the grains of pisolite contains for a nucleus a particle of sand. These have been incrusted with the earbonate of lime held in solution by water.

tion.

ssifica- water, and particularly by the warm springs of Carlshad. New concentric layers being deposited, they at last fall to the bottom, and are there united into larger masses by new depositions of the same calcareous matter. Pisolites are also found in Hungary and in Silesia.

4. Species. CALCAREOUS TUFA.

Exter. Char .- This mineral has usually the form of the substance on which the calcarcous matter has been deposited, as that of moss which is most common, grass or leaves ; internally dull, or weakly glimmering; fracture uneven or earthy; fragments bluntedged.

Colour yellowish gray of various shades; opaque, or translucent at the edges; soft, sectile, and easily frangible; light; almost swims on water.

Localities, &c .- This substance is found in all limestone countries, through the strata of which water passes, thus forming springs impregnated with carbonate of lime, which is afterwards deposited on plants or other substances. This mineral, therefore, is found in alluvial land, and the process of its formation is constantly going on.

5. Species. FOAM EARTH.

Silvery Chalk, Kirw. i. 78. L'Ecume de Terre, Broch. 1. 557.

Exter. Char .- This mineral is found massive, disseminated, or in scaly particles, which are somewhat friable; internal lustre shining or semimetallic; the solid varieties have a curved foliated fracture; fragments blunt-edged.

Colour yellowish or greenish white, sometimes silvery white; opaque; stains; very soft or friable; feels a little greasy or silky.

Chem. Char .- Effervesces and dissolves in acids.

Constituent Parts.

Lime,	51.5
Carbonic acid	39.
Silica,	5.7
Oxide of iron,	3.2
Water,	1.
	TOO F

Localities, &c .- This mineral has been found in mountains of stratified limestone at Jena in Misnia, and at Eisleben in Thuringia.

This is considered by some as belonging to the following species, and by others as merely a variety of agaric mineral.

6. Species. SLATY SPAR.

Argentine, Kirw. i. 105. Le Spathe Schisteux, Broch. i. 558. Schiefer Spath of the Germans. Id. Phillips, Phil. Mag. xiv. 289. and 293.

Exter. Char .- Found massive or disseminated ; internal lustre shining, pearly; fracture curved foliated; fragments wedge-shaped, or blunt-edged.

Colour grayish, reddish, or yellowish white; transluvent; soft; brittle; feels greasy. Spec. grav. 2.723. Vol. XIV. Part I.

Chem. Char .- Effervesces briskly with acids.

Constituent Parts.

Carbonate of lime,	98.11
Silica,	.05
Oxide of iron,	.8
Loss,	1.04
	100.00

Localities, &c .- This mineral is found in Saxony, in a bed of limestone, where it is accompanied with galena; in Norway; and in Cornwall in England.

7. Species. ARRAGONITE.

Arragon Spar, Kirw. i. 87. L'Arragonite, Broch. i. 576. Id. Haüy, iv. 337.

Exter. Char .- This mineral is always found crystallized in six-sided equiangular prisms, or with two opposite faces broader, to which correspond the two faces of an acute bevelment, which terminates the prism. The edges of the bevelment are also truncated. The crystals are variously grouped, and commonly in the form of a cross; crystals streaked longitudinally; lustre shining or resplendent, vitreous ; fracture foliated.

Colour grayish or greenish white; translucent and semitransparent; refraction double; hard, scratches calcareous spar; brittle, and easily frangible. Specific gravity 2.946.

Chem. Char .- Effervesces with acids, and is entirely dissolved. The constituent parts, according to numerous and accurate analysis, are the same as those of calcareous spar; but its superior hardness, diversity of form, and other external characters, have long puzzled chemical philosophers; and it still remains undetermined to what that diversity is owing in this mineral.

Localities, &c .- Arragonite was first found imbedded in foliated and fibrous, gypsum, in the province of Arragon in Spain, from which it derives its name. It has been also found in France, the Pyrcnees, in Saltzburg, sometimes in an argillaceous schistus, and sometimes in quartz, accompanied by calcareous spar and pyrites.

8. Species. BROWN SPAR.

Sidero-Calcite, Kirw. i. 105. Le Spath Brunissant, Broch. i. 563. Chaux Carbonatée Ferrifére Perlée, Hauy, ii. 179.

Exter. Char .- Found massive or disseminated, or in kidney-shaped, globular, or carious pieces; very often crystallized. The forms are lenses or rhomboids, which latter have either convex or concave faces; double pyramids composed of two pyramids with three obtuse faces : simple three-sided pyramids, and oblique sixsided pyramids. The surface of the crystals drusy, rarely smooth; lustre weakly shining or shining; internal lustre shining, pearly, or vitreous; fracture foliated; fragments rhomboidal.

Colour milk-white, grayish, yellowish, or reddish white; bright or brownish red; translucent at the Cc edges ; 201

Calcareous

art I.

tion.

Calcareous edges; semihard; brittle, easily frangible; streak grayish genus. white. Spec. grav. 2.83.

Chem. Char.—Becomes black and hard before the blow-pipe, and unless reduced to powder, effervesces slowly with acids.

Constituent Parts.	Bergman.
Carbonate of lime, Oxide of iron, Oxide of manganese,	50 22 28
	100

Localities, &c.-Brown spar is found in Bohemia, Saxony, France, Sweden, and Britain. It is usually found in metallic veins.

9. Species. DOLOMITE.

Id. Kirw. i. 111. Dolomie, Brochant, i. 334. Chaux Carbonatée Aluminifere, Hauy, ii. 173.

Exter. Char.-Found massive ; fracture appears to be foliated ; fragments blunt-edged.

Colour grayish or yellowish white; translucent on the edges; semihard; rather difficultly frangible; feels mcagre. Spec. grav. 2.85.

Constituent Parts.	Saussure.

100.00

Chem. Char .- Effervesces slowly in nitric acid.

Phys. Char.—Phosphoresces in the dark by the percussion of a hard body.

10. Species. RHOME or BITTER-SPAR.

Crystallized Muricalcite, Kirw. i. 92. Le Spath Magnesien, Brochant, i. 560. Chaux Carbonatée Magnesifere, Hauy, ii. 187.

Exter. Char.—Found massive or disseminated in rhomboidal pieces, which have a crystallized appearance; lustre shining or resplendent, and vitreous or pearly; fracture foliated; cleavage threefold; fragments rhomboidal.

Colour grayish white, yellowish or reddish brown; translucent at the edges; semibard; brittle; streak snow-white. Spec. grav. 2.48.

Chem. Char .- Becomes gray or brown before the

blow-pipe without splitting or fusion. Effervesces a Class little with acids.

Constituent Parts.	Klapro	oth.
Carbonate of lime,	52	73
Dxide of iron and mangane	45 ese, 3	25 2
I any elies of vict hay pear	IOO	100

Localities, &c.—Found in the Tyrol and Saltzburg, and in Sweden. It is always accompanied with asbestus, talc, and tremolite, and imbedded in chlorite schistus, serpentine, and indurated talc.

11. Species. SWINE STONE.

Id. Kirw. i. 89. La Pierre Puante, Brochant, i. 567-Chaux Carbonatée Factide, Hauy, ii. 288.

Exter. Char.—Found massive ; internal lustre glimmering or dull ; fracture splintery, sometimes earthy or foliated ; fragments splintery.

Colour grayish black, or blackish brown; opaque, rarely translucent at the edges; streak grayish white; semihard, sometimes soft; easily frangible. Spec. grav. 2.71.

Phys. Char.-When rubbed with a hard body, it gives out a very foetid odour of rotten eggs.

Chem. Char.—Soluble with effervescence in nitric acid; before the blow-pipc is deprived of its odour, which is supposed to be owing to sulphurated hydrogen.

Localities, &c.-Forms entire heds in stratiform limestone rocks, as in France, Saxony, and Sweden.

12. Species. MARL.

This is divided into two subspecies ; I earthy ; and, 2 indurated.

Subspecies 1. EARTHY MARL.

Id. Kirw. i. 74. La Marne Terreuse, Brochant, i. 569. Argile Calcariferc, Hauy, iv. 455.

Exter. Char.—This variety is composed of loose or slightly coherent particles; stains a little; feels meagre and rough; is light; almost swims on water.

Colour yellowish gray, or grayish white.

Localities, &c. — Found in many places of France and Germany, as well as in different places of England and Scotland, forming beds in limestone countries, and often immediately under the soil.

Uses.-It is sometimes employed in the manufacture of pottery, but its principal use is for the purposes of agriculture.

Subspecies 2. INDURATED MARL.

Id. Kirw. i. 95. La Marne Endurcic, Brochant, i. 571.

Exter. Char.—Found massive, dull, or slightly glimmering; fracture earthy, splintery, or slaty; fragments blunt-edged.

Colour yellowish, or smoke gray; opaque; streak grayish white; soft; not very brittle; easily frangible. Spec. grav. 1.6 to 2.8.

202

silica. Chem. Char.-Melts before the blow-pipe into a on. grayish black slag; effervesces briskly with acids.

Marl is considered as a mixture of carbonate of lime and alumina; and according to the different proportions of these ingredients, it is denominated calcareous marl or clay marl, and sometimes it is known in agriculture by the names of soft and hard marl.

Localities, &c.—Found in Bohemia, Saxony, Sweden, Italy, France, and Britain, in stratiform mountains, sometimes in extensive beds, frequently accompanying limestone, coal, and basalt.

Uses.—It is employed in agriculture for improving the soil, sometimes for building, and sometimes as a limestone. It serves also as a flux for some ores of iron.

13. Species. BITUMINOUS MARL SLATE.

Marno-bitumineux, Brochant, i. 574. Chaux Carbonatée Bituminifere, Hauy, ii. 189.

Exter. Char.—Found massive; surface rough, dull, rarely glimmering; or when divided into curved plates, smooth and shining; fracture slaty; straight or waved; fragments tabular.

Colour grayish or brownish black; opaque; streak shining; soft; easily frangible; feels rather meagre.

Chem. Char. — Effervesces with acids; inflames before the blow-pipe; gives out a bituminous odour, and then melts into a black slag.

Localities, &c.—Found in different places of Thuringia, in mountains of stratiform limestone, forming particular beds, which repose frequently on a species of sandstone. It is frequently mixed with different ores of copper, so that it is sometimes wrought as a copper ore. In this bituminous schistus, petrified fishes and marine plants are frequently found, disposed in regular order, from which some have conjectured that they must have died a violent dcath; or, according to others, that they have been poisoned by the copper with which it abounds.

14. Species. APATITE.

Phospholite, Kirw. i. 128. L'Apatite Commune, Brochant, i. 580. Chaux Phosphatée, Hauy, ii. 234.

Exter. Char.—Foundalmost always crystallized, rarely disseminated. The forms of its crystals are, 1. A regular six-sided prism; 2. The same prism truncated on its lateral edges; 3. Also on its angles and terminal edges; 4. Bevelled on each of the lateral edges; 5. With an obtuse and regular six-sided pyramid, and one or both extremities, the summit being slightly truncated; 6. A three-sided prism with the lateral edges bevelled, and the terminal edges truncated; 7. A six-sided table, having its terminal edges strongly, and the lateral edges slightly truncated. Lateral faces of the prisms longitudinally streaked; faces of the pyramid smooth; lustre shining and resplendent; internal lustre shining, bctween resinous and vitreous. Cross fracture foliated; in other directions fine grained, uneven, or conchoidal. Fragments rather sharp-edged.

Colour green of various shades, blue, sometimes pearl gray, and greenish gray; semitransparent, sometimes transparent, or only translucent; semihard; is scratched by fluor spar; brittle, and easily frangible. Spec. grav. 2.8 to 3.2. Chem. Char.—Thrown on hot coals it gives out a Calcareous greenish phosphorescent light; infusible before the blowpipe, but loses its colour. It is almost entirely soluble in nitric acid.

Phys. Char.-Becomes electric by friction, but not by heat.

Localities, &c.—Apatite is found in different places of Germany, chiefly in tin mines, where it is accompanied by fluor spar, quartz, and metallic ores. It is also found in Cornwall in similar circumstances.

15. Species. ASPARAGUS STONE.

La Pierre d'Asperge, Broch. i. 586. Chaux Phosphatée, Hauy, ii. 234.

Exter. Char.—This mineral has been only found crystallized in equiangular six-sided prisms, terminated by a slightly obtuse six-sided pyramid; lateral edges sometimes truncated; lateral faces longitudinally streaked, the others smooth; external lustre shining or resplendent; internal, resplendent and resinous; fracture foliated, cross fracture imperfectly conchoidal; fragments not very sharp-edged.

Colour asparagus green, greenish white; commonly transparent, often only semitransparent, or even translucent; semihard. Spec. grav. 3.09.

Chem. Char.—Infusible before the blow-pipe; soluble with effervescence in nitric acid, but thrown on hot coals does not phosphoresce.

Constituent Parts.	Vauquelin.
Lime, Phosphonia agid	53.32
Loss,	43.72
	100.00

Localitics, &c.—This stone has been found at Caprera, near Cape de Gates in Spain, and also, it is said, near Arendal in Norway.

16. Species. PHOSPHORITE.

L'Apatite Terreuse, Broch. i. 584. Chaux Phosphatée Terreuse, Hauy, ii. 239.

Exter. Char.—Found massive, and having little coherence; dull; fracture earthy, or fine grained uneven; fragments blunt-edged, sometimes wedge shaped.

Colour yellowish or grayish white; opaque; semihard; often friable; easily frangible; feels mcagre. Spec. grav. 2.82.

Chem. Char.—Before the blow-pipe it phosphoresces, and according to some, melts into a white glass, but according to others, infusible. Soluble in acids, and with sulphuric acid gives out white vapours.

Lime, Silica, Phosphoric Fluoric aci Carbonic a Muriatic a Oxide of in	e acid, id, icid, cid, ron,	59. 2. 34. 2.5 I. .5 I.	
		100.0	

Localities, &c....This mineral is found in the north of Scotland, and in the province of Estremadura in Spain, where it forms an entire mountain. It is mixed with quartz; has been long known by the inhabitants of the country for its property of phosphorescing when thrown on hot coals.

17. Species. FLUOR.

This has been divided into three subspecies : 1. earthy ; 2. compact ; and, 3. fluor spar.

Subspecies I. EARTHY FLUOR.

Sandy or Earthy Fluor, Kirw. i. 126. Le Fluor Terreux, Broch. i. 593. Chaux Fluatcé Amorphe, Hauy, ii. 260.

Exter. Char.—Is composed of particles which are slightly cohering; dull, or scarcely glimmering.

Colour greenish white, sometimes bluish green ; stains a little ; feels rough.

Chem. Char.-Thrown on hot coals, it gives out a bluish green light.

Localities, &c .- Has been found in Hungary, in a vein accompanied with quartz.

Subspecies 2. COMPACT FLUOR.

Id. Kirw. 127. Id. Broch. i. 594.

Exter Char.—Is found massive; dull, lustre sometimes glimmering, vitreous; fracture even, conchoidal, and rarely splintery; fragments sharp-edged.

Colour greenish gray, or greenish white; sometimes different colours are disposed in spots; translucent; streak shining; hard, and brittle.

Chem. Char .- Phosphoresces on hot coals.

Localities, &c.—This mineral is found in the Hartz, in Sweden, and Siberia, always accompanying fluor spar.

Subspecies 3. FLUOR SPAR.

Foliated or Sparry Fluor, Kirw. i. 127. Le Spath Fluor, Broch. i. 595. Chaux Fluatée, Hauy, ii. 247.

Essen. Char.—Insoluble in water, and divisible into a regular octahedron.

Exter. Char.—Fluor spar is found massive or disseminated, but most frequently crystallized. Primitive form a regular octahedron, which is easily obtained by mechanical division; integrant molecule a regular tetrahedron. The usual forms are, 1. The cube, which is either perfect, or with truncated edges or truncated angles, or with the edges bevelled, having on each of

its angles a three-sided pyramid, corresponding to the faces of the cube. 2. The octahedron, which is either perfect, or has its angles or its edges, or both, truncated. Surface of the crystals smooth, shining or resplendent, sometimes drusy; internal lustre shining, resplendent, and vitreons or pearly; fracture foliated, straight or curved; cleavage fourfold, in the direction of the faces of the regular octahedron; fragments tetrahedral, or rhomboidal.

Colours of fluor spar extremely various and beautiful. The principal are, greenish white, grayish, or yellowish; blue, green, brown, and red, of various shades; and different colours are sometimes arranged in stripes and spots. Most commonly translucent, sometimes transparent, or only translucent at the cdges. Semihard; brittle; casily frangible. Spec. grav. 3.09 to 3.19.

Chem. Char.—Fusible before the blow-pipe into a transparent glass; decrepitates when heated. The powder thrown on hot coals gives out a bluish or greenish phosphorescent light; and two pieces rubbed against each other, shine in the dark.

Constituent Parts.	Scheele.
Lime,	57
Fluoric acid,	16
Water,	27

Localities, &c.—Fluor spar is sometimes found in beds, but most frequently in mineral veins. It is very common in many places of the world, particularly in Cornwall and Derbyshire, and also in the counties of Durham and Cumberland in England; at Chamouni in Savoy, the octahedral variety of a rose red colour is found. Fluor spar is found also in the interior part of Aberdeenshire in Scotland.

Uses.—This mineral is successfully employed as a flux for different metallic ores. As it is susceptible of a fine polish, it is cut and formed into a great variety of ornamental objects, as pyramids, vases, &c. which, on account of the beauty of the colours, are greatly estecmed.

18. Species. GYPSUM.

This species is divided into four subspecies: 1. earthy; 2. compact; 3. foliated; and, 4. fibrous.

Subspecies I, EARTHY GYPSUM.

Farinaccous Gypsum, Kirw. i. 120. Le Gypse Terreux, Broch. i. 601. Chaux Sulphatée Terreuse, Hauy, ii. 278.

Exter. Char.—This is composed of particles which are more or less cohering; dull, in some places weakly glimmering; feels meagre and rough.

Colour white, gray, or yellowish.

Localities, &c.—This substance is rare; it is only found in the fissures and cavities of gypsum rocks, and is supposed to be a deposition of loose particles of gypsum, carried along by water. Found in Saxony, and Monte Martre near Paris.

Part

204 Calcareous genus.

Subspecies 2. COMPACT GYPSUM.

Id. Kirw. i. 121. Id. Broch. i. 602. Id. Hauy, ii. 278.

Exter. Char .- Found massive ; lustre weakly glimmering, almost dull ; fracture compact, even, or splintery; fragments blunt-edged.

Colour yellowish and grayish white, sometimes reddish; and different colours exhibit stripes; translucent at the edges; soft, and easily frangible. Spec. grav. about 2.3.

Localities, &c .- Found in Italy, Germany, France, Spain, and England.

Subspecies 3. FOLIATED GYPSUM.

Granularly Foliated Gypsum, Kirw. i. 123. Id. Broch. ì. 606.

Exter. Char .- Found massive or disseminated, and sometimes, it is said, crystallized in six-sided prisms, obtusely bevelled at each extremity; lustre glimmering or shining, between vitreous and pearly; fracture foliated, sometimes radiated ; fragments blunt-edged.

Colour usually snow white, grayish, yellowish, or reddish white ; and several colours are arranged in spots, stripes, and veins. Translucent, rarely semitransparent; refraction double ; very soft ; easily frangible. Spec. grav. 2.27 to 2.31.

Foliated gypsum has some resemblance to granular limestone, but may be readily distinguished from it by its softness.

Subspecies 4. FIBROUS GYPSUM.

Id. Kirw. i. 122. Id. Broch. i. 604. Id. Hauy, ii. 278.

Exter. Char .- This is found massive, but in thin layers ; lustre shining, or weakly shining, pearly ; fracture fibrous; in some varieties the longitudinal fracture is foliated; cross fracture fibrous; fragments long, splintery.

Colour snow white, grayish, yellowish, or reddish white; translucent; very soft; easily frangible.

Chem. Char.- The different varieties of gypsum pos-sess nearly the same chemical characters. When pure, there is no effervescence with acids. Before the blowpipe gypsum immediately becomes white, is converted into a white enamel, which, at the end of 24 hours, falls into powder.

Localities, &c .- Gypsum, in general, constitutes mountains or beds, which are subordinate to sandstone, or limestone. It is found in all kinds of rocks. Gypsum is found in great abundance in the neighbourhood of Paris, in several parts of England, but sparingly in Scotland.

Uses .- Gypsum is employed along with lime as a cement. It is also very extensively employed under the name of plaster of Paris, for making casts and models. With this view it is exposed to a strong heat, to drive off the water of crystallization. It is then in the state of powder, which being again mixed with water, is put into the mould in the form of paste; and, from its strong affinity for water, it soon becomes solid.

19. Species. SELENITE.

Calcareous genus.

205

Broad Foliated Gypsum, Kirw. i. 123. La Sclenite, Broch. i. 609. Chaux Sulfatée, Hauy, ii. 266.

Essen. Char .- Divisible into smooth plates, which

break under angles of 113° and 67°. Exter.Char.—Selenite is found massive; and frequent-ly also crystallized. The primitive form of its crystals is a four-sided prism, whose bases are obliquely parallelograms; the integrant molecule is the same. The usual forms are, a six-sided prism, having two broad and two narrow faces, and terminated by an oblique bevelment, whose sides correspond to the broad sides of the prism; a similar prism terminated by a feur-sided pyramid; double crystals composed of two of the former united by their smaller lateral faces, so that the summits united form on one side a salient angle, and on the other a reentering angle; another form is a spheroidal or conic lens. These crystals are often grouped, divergent, fascicular, or stellated ; and of the six sides of the prism, the two opposite are smooth, and the four others longitudinally streaked; lustre resplendent or shining, between vitreous and pearly; fracture foliated, straight or curved ; cleavage threefold ; fragments rhomboidal, with two faces smooth and shining, and two others streaked.

Colour usually white, grayish, yellowish, or snow white, sometimes iridescent ; transparent, sometimes only translucent; very soft; in thin plates, flexible, but not elastic ; easily frangible. Spec. grav. 2.32.

Chem. Char .- Before the blow-pipe more easily fusible than gypsum, and splits into thin plates.

Constituent Parts.	Bergman.
Lime, Sulphuric acid, Water	32 46
water,	22

Localities, &c Selenite is found among beds of gypsum, and particularly among those which alternate with clay and sand-stone. It is also found in nests in clay. It is not uncommon in many places, as among the gypsum rocks near Paris, in different parts of England, and at Lord Glasgow's coal works in Scotland, where it is found among clay, and in the cavities or on the surface of the limestone which reposes on the strata of coal.

Uses .- Selenite also, after calcination, is employed in modelling; but it is said that it possesses less solidity than what is obtained from gypsum.

20. Species. ANHYDRITE.

Chaux Sulfatée Anhydre, Hauy, iv. 348.

Exter. Char .- This mineral is found massive ; lustre shining or weakly shining, and pearly; fracture curved foliated, sometimes radiated, and fine splintery : fragments sharp-edged; translucent; semihard; not very brittle, rather easily frangible. Spec. grav. 2.964.

Chem. Char.-Before the blow-pipe it neither exfoliates nor becomes white, like selenite.

Localities, &c.-This mineral has been found in Switzerland, in the salt pits in the canton of Berne.

21. Species. CUBE SPAR.

Chaux Sulfatée Anhydre, Hauy, iv. 348. Saude Muriatcé Gypsifere, Id. ii. 365. Muriacite, Klaproth.

Exter. Char.—This mineral is found massive, and also crystallized, in four-sided prisms, which are nearly cubical; two of the opposite lateral faces are broader than the other two. The lateral edges are sometimes truncated, and hence arises an cight-sided prism: sometimes also the truncations are so great as to destroy the narrow lateral faces, and form again a six-sided prism. External lustre of the broad faces resplendent and pearly; of the narrow, shining. Internal lustre shining and pearly; fracture foliated; cleavage threefold; fragments cubical.

Colour milk-white, grayish, yellowish, and reddish white; sometimes pearl gray; translucent; semihard. Spec. grav. 2.92 to 2.96.

Constituent Parts.	Klaproth.

Localities, &c.-Found in the salt pits at Halle in the Tyrol, where it is called splintery gypsum.

22. Species. DATHOLITE.

Chaux Datholite, Brochant, ii. 397. Chaux Boratéc Siliceuse, Hauy.

Exter. Char.—This mineral has only been found crystallized; the primitive form is a rectangular prism, with rhomboidal bases, whose angles are 109° 18' and 70° 42'; lustre shining, vitreous; fragments conchoidal.

Colour grayish or greenish white; translucent; scratches fluor spar. Spec. grav. 2.98.

Chem. Char.—In the flame of a candle it becomes dull white, and is easily reduced to powder. Before the blow-pipe it melts into a glass of a palc rose-red colour.

Localities, &c.-Found near Arendal in Norway, Classifica, and some specimens are accompanied by greenish-coloured, foliated talc.

VII. BARYTIC GENUS.

1. Species. WITHERITE, or Carbonate of Barytes.

Barolite, or Aerated Barytes, Kirw. i. 134, La Witherite, Brochant, i. 613. Baryte Carbonatée, Haüy, ii. 308.

Essen. Char.-Forming a white precipitate in weak nitric acid before solution.

Exter. Char.—Found massive, or disseminated, rarely crystallized; forms of its crystals are, a six-sided prism, with a six-sided pyramid set on the lateral faces; the same prism having all the angles truncated; a double six-sided pyramid. The crystals, which are small, are usually imbedded in the mineral itself; sometimes grouped in bundles, or crossing each other. Surface smooth; lustre of the principal fracture shining, or weakly shining, resinous; fracture between radiated and foliated; cross fracture fine grained uneven; fragments wedge-shaped.

Colour yellowish gray, grayish, or yellowish white; translucent, or semitransparent; semihard, or soft; brittle; easily frangible. Spec. grav. 4.3 to 4.33.

Chem. Char.-Infusible according to Hauy before the blow-pipe; but according to Brochant, melts before the blow-pipe to a white enamel.

Carbonate of copper,	.008

100.000

Localities, &c.—This mineral was discovered by Dr Withering at Anglesark in Lancashire, in lead veins, which traverse the coal strata, and it is accompanied with heavy spar and blende.

Uses.—Barytes acts as a strong poison on the animal economy. It has been long employed at Anglesark for the purpose of destroying rats. It has also been tried as a medicine in scrofula, but seemingly with little effect; and it ought to be had recourse to with extreme caution.

2. Species. HEAVY SPAR, or Sulphate of Barytes.

This species has been divided into eight subspecies; earthy, compact, granulær, foliated, common, columnar, prismatic, and bolognian.

Subspecies 1. EARTHY HEAVY SPAR. Earthy Baroselenite, Kirwan, i. 138. Le Spath Pesant Terreux, Brochant, i. 617.

4

Exter.

Exter. Char .- Found massive; lustre scarcely glimissificamering, or dull; consists of earthy particles, which are slightly cohering; stains a little; feels meagre.

> Colour snow white, grayish, ycllowish, or reddish white.

> Localities, &c.-This a rare mineral. It has been found in Saxony, covering masses of heavy spar, and also in Derbyshire and Staffordshire in England.

Subspecies 2. COMPACT HEAVY SPAR.

Compacte Baroselenite, Kirw. i. 138. Baryte Sulfate Compacte, Hauy, ii. 303. Id. Broch. i. 618.

Exter. Char .- Found massive, sometimes in kidneyform or globular pieces, with cubical impressions; lustre glimmering, sometimes dull, and sometimes weakly shining; fracture coarse earthy, sometimes uneven; fragments not very sharp-edged.

Colour yellowish, grayish white, sometimes palc flcsh red; opaque, or translucent at the edges; soft; not very brittle; easily frangible; feels meagre.

Localities, &c.-Found in mineral veins in Saxony, and in England; in clay slate, in Savoy; and we have found it in sand stone in Northumberland.

Subspecies 3. GRANULAR HEAVY SPAR.

Exter. Char.-This also is found massive; lustre glimmering, nearly shining, and pearly; fracture foliated, or splintery; fragments blunt-edged.

Colour snow-white, milk-white, yellowish, or reddish; translucent; soft; not very brittle; easily frangible. Spec. grav. 3.8.

Constituent Parts.	Klaproth.
Barytes, Sulphuric acid,	60 30
Silica,	16

100

Localities, & c .- Found in mineral veins in Saxony, along with galcna, and in-Siberia, accompanied by copper and silver ores.

Subspecies 4. FOLIATED HEAVY SPAR.

Exter. Char .- Found massive, and in kidney-shaped, globular, and cellular pieces, composed of four-sided tables, or lenses, with a drusy surface; lustre glimmering or shining, between pearly and vitreous; fracture curved foliated, sometimes splintery; fragments not very sharp-edged, sometimes wedge-shaped.

Colour yellowish, reddish, or grayish white, sometimes flesh or brownish red; translucent; soft; not very brittle; easily frangible.

Localities, &c .- Is not uncommon in mineral veins ; sometimes also in beds, in many countries. It is also found in Britain.

Subspecies 5. COMMON HEAVY SPAR.

Foliated Barosclenite, Kirw. i. 140. Broch. i. 624.

Exter. Char.-This mineral is found in masses, or disseminated, and very often crystallized. Its principal forms are, I. A double four-sided pyramid; 2. A

four-sided prism, rectangular or oblique ; 3. A four- Barytic sided table, rectangular or oblique; 4. A six-sided prism; 5. A six-sided table; and, 6. A long eightsided table. These forms are variously modified by truncations and bevelments, and they are differently grouped together; the prisms cross one another; the tables are attached by their lateral faces, and form globular or kidney-shaped groups; surfaces smooth, sometimes rough and drusy. Lustre resplendent, shining, glimmering, or only dull : internal lustre shining or resplendent, between pearly and resinous : fracture straight foliated ; cleavage threefold ; fragments somewhat rhomboidal.

Colour commonly white, snow-white, milk-white, grayish, yellowish, or reddish; in masses translucent; in crystals transparent or semitransparent; refraction double; soft; brittle. Spec. grav. 4.29 to 4.47, and

Chem. Char .- Fusible before the blow-pipe into a solid white enamel, which being moistened, gives out the odour of sulphurated hydrogen. Does not effervesce with acids.

Constituent Parts.

Barytes, Sulphuric acid, Water,	Withering. 67.2 32.8	Bergman. 84 13 3
	100.0	100

Localities, &c .- This is a very common mineral, and particularly in metallic veins that traverse primitive mountains. It accompanies ores of silver, copper, lead, and cobalt, as well as fluor spar, calcareous spar, and quartz.

Subspecies 6. COLUMNAR HEAVY SPAR.

Le Spath Pesant en Barres, Broch. i. 631. Baryte Sulphatée Bacillaire, Hany, ii. 302.

Exter. Char .- Found always crystallized : 1. In oblique four-sided prisms; 2. The same prism terminated by an acute bevelment; 3. The same prism terminated by a four-sided pyramid placed on the lateral edges; and, 4. A six-sided prism bevelled at the extremity. The crystals are acicular, and are grouped together in bundles; surface shining, or weakly shining; internal lustre shining; longitudinal fracture radiated; cross fracture even. Fragments rhomboidal.

Colour silvery, gravish or greenish white; translucent; soft, and brittle.

Localities, &c .- Found in Saxony, and Derbyshire in England, accompanied by other varieties of heavy spar, quartz, and fluor spar.

Subspecies 7. PRISMATIC HEAVY SPAR.

Exter. Char .- Found massive, and frequently crystallized. The usual forms are, I. An oblique four-sided prism, bevelled at the extremities; 2. An oblique four-sided prism, terminated by a four-sided pyramid placed on the lateral edges; 3. An elongated octahe-dron; and, 4. A six-sided prism. Lustre shining or resplendent, between resinous and pearly; fracture foliated; cleavage threefold.

genus.

tion.

208

Strontian genus.

pale blue, and rarely flesh red; translucent; when crystallized, transparent; soft, and not very brittle; very easily frangible.

Colour yellowish, greenish, or pearl gray, sometimes

Localities, &c .- Sometimes found in mineral veins, as in Saxony.

Subspecies 8. BOLOGNIAN HEAVY SPAR.

Le Spath de Bologne, Brochant, i. 633. Striated or fibrous heavy spar, Kirwan, i. 141. Baryte sulfatée radiée, Hauy, ii. 302.

Exter. Char .- This is found in rounded pieces; external surface uneven, dull, or glimmering; internal lustre shining, or weakly shining, between adamantine and pearly; fracture radiated, parallel, diverging, or fibrous, sometimes foliated; fragments splintery, sometimes rhomboidal.

Colour, smoke or yellowish gray ; translucent, soft, very brittle, and easily frangible.

Chem. Char .- This mineral has been long known by its property of shining in the dark, after being heated. Other heavy spars, indeed, have a similar property.

Constituent Parts.	Arvidson.
Sulphate of barytes,	62.
Siliea,	15.
Alumina,	14.75
Gypsum,	6.
Oxide of iron,	.25
Water,	2.

100.00

Localities, &c .- This mineral is found at Monte Paterno near Bologna in Italy, in rounded masses, which have an uneven surface : they are imbedded in an argillaceous or marly rock, which is a kind of amygdaloid, and from which they are detached by the action of the waters.

VIII. STRONTIAN GENUS.

I. Species. STRONTITES, Carbonate.

La Strontianite, Brochant, i. 637. Id. Kirw. i. 332. Strontiane Carbonatée, Hauy, ii. 327.

Essen. Char .- Soluble in nitric acid with effervescence; paper dipped in the solution, and dried, burns with a purple flame.

Exter. Char.-Found massive, and sometimes crystallized in needles, which are grouped together; form of the erystals a regular six-sided prism ; lustre weakly shining, or only glimmering; internal lustre shining, and weakly shining, between resinous and pearly; fracture radiated, straight, diverging, or fibrous; cross fracture fine grained, uneven, or splintery; fragments wedge-shaped, or sharp-edged.

Colour asparagus green, greenish, whitish, or yellowish gray; translucent; semihard, brittle and easily frangible; feels a little greasy. Spec. grav. 3.4 to 3.67

Chem. Char .- Before the blow-pipe whitens without fusion, and afterwards exposed to the air, falls to powder.

Constituent Parts.			Class

Strontites,	69.5	- 62	-	
Carbonic acid,	30.	30		
Water,	.5	8		
	100.0	100		

Localities. &c .- This mineral has been hitherto found only at Strontian in Scotland, in a lead vein which traverses a gneiss rock. It is said also to have been found at Leadhills. .

2. Species. CELESTINE, Sulphate of Strontites.

La Celestine, Brochant, i. 640. Strontiane sulfatée, Hauy, ii. 313.

Essen. Char .- Divisible into a rhomboidal prism, with angles of about 105° and 75°; gives a light red colour to the blue part of the flame produced by the blow-pipe.

Exter. Char .- Primitive form of its crystals a rectangular prism, whose bases are rhombs ; integrant molecule a triangular prism with square bases. The forms under which it generally appears are four or six-sided prisms, which are terminated by a two-sided bevelment, a four-sided, or an eight-sided pyramid.

This species has been divided into two subspecies : 1. fibrous; and, 2. foliated.

Subspecies 1. FIBROUS CELESTINE.

Exter. Char.-Found massive or crystallized; lustre of the longitudinal fracture shining; that of the cross fracture, weakly shining between pearly and resinous. Longitudinal fracture foliated ; eross fracture fibrous, eurved; fragments splintery; rather blunt-edged.

Colour indigo blue, bluish gray, and sometimes with whitish bands, or with yellowish brown spots; translucent; soft, and easily frangible. Spec. grav. 3.83.

Constituent Parts. Klaproth.

Strontites, Sulphuric acid	and oxide	of iron,	58 42

Localities, &c .- Has been found in Pennsylvania in America, and near Toul in France.

Subspecies 2. FOLIATED CELESTINE.

Exter. Char.-This is also found massive and crystallized; lustre weakly shining, or shining; that of the crystals resplendent; fracture foliated, straight, or radiated; cleavage threefold.

Colour milk-white, grayish, and bluish-white : semitransparent, or translucent; semi-hard; very easily frangible.

The following are the constituent parts of a variety of sulphate of strontites, which is found at Mont Martre near Paris.

Sulphate of strontites,	91.42	
Carbonate of lime,	8.33	* Vaugu
Oxide of iron,	.25	lin, Jour
	Concernant and	de Mine
	100.00*	Nº 53.
	Tocal	ties p. 355

3

Localities, &c.—This variety is found in great abundance near Bristol in England, where the sulphate of strontites was first discovered by Mr Clayfield. It has been since found in Sicily, where it is accompanied with fibrous gypsum and native sulphur.

+ T

fica-

SECOND CLASS. SALTS.

I. GENUS. SULPHATES.

I. Species. NATIVE VITRIOL.

Mixed vitriol, or sulphate of iron, copper and zinc. Kirwan, ii. 24. Vitriol Natif, Brochant, ii. 2.

Exter. Char.—This mineral is found massive or disseminated, and also in a stalactitical, cylindrical, and capillary form; internal lustre shining, or weakly shining, between silky and vitreous; external surface rough and uneven; fracture usually fibrous, sometimes foliated.

Colour grayish, or yellowish white, sometimes different shades of sky blue; the colour varies by exposure to the air. Soft; semi-transparent or translucent; taste sour and astringent.

Chem. Char.—These arc different, according to the proportions of the constituent parts. Before the blowpipe, sulphurated hydrogen gas is given out; the iron is detected by giving a black colour to the solution of nut galls; the copper, by immersing a plate of iron; and the zinc, by a white efflorescence, which appears when the native salt is exposed to the air.

This substance is a mixed salt, composed of the sulphates of iron, zinc and copper, in variable proportions, so that its appearance and characters must also be variable.

Localitics, &c.—Native vitriol is not uncommon in mountains of clay slate which contain metallic ores, and particularly those of copper and iron pyrites, and hlende; by the decomposition of which it is formed. It is found in Bohemia, Saxony, and Hungary, as well as in the mines of Britain, where such metallic ores abound.

The native sulphate of iron is common in coal mines which contain iron pyrites, as in many of the coal mines of Britain. The substance is very abundant in the earl of Glasgow's coal mines near Paisley, where the manufacture of copperas, by purifying and crystallizing the native salt, has been long carried on.

Uses.—The mixed substance, native vitriol, can only be employed to any useful purpose, by obtaining the different salts in a separate form. The uses of these salts are well known in various arts, but particularly in dyeing, and some of them in medicinc.

2. Species. NATIVE ALUM.

Alum, Kirwan, ii. 13. L'Alun Natif, Brochant, ii. 6. Alumine Sulfatée alkaline, Hauy, ii. 387, 388.

Exter. Char.—Native alum is usually found in small capillary crystals, sometimes adhering to other minerals, and very rarely in stalactitical masses. The form of the crystal of alum is the regular octahedron, which is usually obtained artificially. Externally it is dull, or slightly glimmering, but internally shining, with a Vol. XIV. Part I. silky or vitreous lustre, fracture fibrous; vcry soft; Salts. taste astringent.

Alum is a triple salt, a sulphate of alumina and potash. It rarely happens that all the three ingredients exist together in nature. The potash is usually added during the preparation of artificial alum.

According to the examination of native alum by Klaproth, from the alum cavern at Cape Miscno near Naples, it appears that from 1000 lbs. of the material furnished by nature, 470 lbs. may be obtained, having the requisite quantity of potash; and by an addition of potash to promote the crystallization, 290 lbs. more may be obtained. *Analyt. Ess.* i. 268. The following is the analysis of the aluminous schistus from Freyenwalde by the same chemist.

Alumina,	15.25
Oxide of iron,	7.50
Potash,	.25
Sulphynia and and maken of a dill' d'	

Sulphuric acid and water of crystallization, 77.

100.00* * Analyt. Ess. ii. 78.

Localities, &c.—Native alum is found in those places where the aluminous stones, already described, abound, as in the neighbourhood of voleanoes, and in coal mines. An extensive alum manufactory has been carried on for several years with great skill and success, at Lord Glasgow's coal work near Paisley, mentioned above. The materials are obtained from the rubbish in the old wastes, which consists of the aluminous schistus from the roof and pavement of the coal. These mines also abound with iron pyrites ; and from the decomposition of all these substances the native vitriol and native alum are obtained.

Uses.—The uses of alum in various arts are too well known to require any enumeration.

3. Species. MOUNTAIN BUTTER.

La Beurre de Montagne, Broch. ii. 10.

Exter. Char.—Found massive; internal lustre strongly glimmering, waxy; fracture foliated; fragments blunt-edged.

Colour grayish white, sulphur yellow, or yellowish brown; translucent at the edges; feels greasy; taste astringent.

Localities, &c.— This species is found in similar situations with the former. In its native repository it is nearly as soft as butter, and has something of the appearance, from which it has its name. Perhaps it ought to be considered merely as a variety of the former. The same remark may be applied to another variety called *plumose alum*.

4. Species. CAPILLARY SALT. Sulphate of Magnesia.

Le Sel Capillaire, Broch. ii. 8. Haar Salz, or Hair Salt, of the Germans.

Exter. Char.—This salt is always found in fine capillary crystals, so closely united together as to form a compact mass; lustre shining, or weakly shining, silky; fracture fibrous. 2IO Salts

Colour white, sometimes greenish, grayish, or yellowish; translucent, friable; taste astringent.

Constituent Parts.—This salt was supposed to be a plumose or native alum; but it appears from the analysis of Klaproth, to be a sulphate of magnesia, with a small proportion of iron. We have examined a similar capillary salt from the coal mines near Paisley, which also appeared to be a sulphate of magnesia, but with a greater proportion of sulphate of iron.

Localities, &c.-This native salt is found in similar situations with the former species.

5. Species. NATIVE EPSOM SALT, or Sulphate of Magnesia.

Le Sel amer Natif, Broch. ii. 11. Epsom Salt, Kir. ii. 12.

Exter. Char.—The characters already given of the former species are equally applicable to this, excepting that it is said to exist sometimes in an earthy form, when it has a dull appearance.

Localities, &c.—Found in a state of efflorescence on limestone, porphyry, sandstones; and it exists in solution in many mineral waters, as in that of Epsom in England, from which it has its name. This salt also constitutes part of the efflorescence which is observed on walls built with lime.

6. Species. NATIVE GLAUBER SALT, or Sulphate of Soda.

Glauber Salt, Kirw. ii. 9. Le Sel de Glauber Natif, Broch. ii. 14.

Exter. Char.—This salt is sometimes found massive or earthy, rarclystalactitical or crystallized. The crystals are often acicular, or in irregular, six-sided prisms, terminated by a three-sided pyramid, placed on the lateral edges or sides. Lustre shining, vitreous; but exposed to the air becomes dull. Fracture uneven; that of the crystals conchoidal. Fragments blunt-edged.

Colour yellowish or grayish white; opaque or transparent; brittle; taste cooling or bitter.

Localities, &c.—This salt is usually found in the neighbourhood of mineral springs which hold common salt in solution, from the decomposition of which, and the combination of its base with sulphuric acid, it is obtained. It is not unfrequent on the banks of salt lakes, and in a state of efflorescence on sandstone, marl, sometimes on the surface of the ground, and sometimes on walls built with stone and mortar. It is found in most countries in the world.

II. GENUS. NITRATES.

1. Species. NATIVE NITRE, or Nitrate of Potash.

Nitre, Kirw. ii. 25. Le Nitre Natif, Broch. ii. 17. Potasse Nitratée, Hauy, ii. 346. Saltpetre.

Essen. Char.—Does not deliquesce, and detonates with a combustible body.

Exter. Char.—Thissalt is commonly found superficial, in accentar crystals, rarely massive, and more rarely crystallized in six-sided prisms; lustre shining, vitreous; fracture conchoidal; fragments sharp-edged.

Colour snow white, grayish or yellowish white ; trans-

£ -

lucent; soft; easily frangible or friable; taste saline, Classific cooling.

Constituent Parts.	Klaproth.
Nitrate of potash,	42.55
Muriate of potash,	.20
Sulphate of lime,	25.45
Carbonate of lime,	30.40
Loss,	1.40
	100.00*

Exter. Char. &c.—Native nitre is found in Italy near Molfetta, in Naples, from which that analyzed by Klaproth was obtained, and which is disposed in small beds, or more rarely in veins, on limestone. Native nitre is also not uncommon in Hungary, Spain, France, and Peru, in which latter country, and in the East Indies, where it is very abundant, it is found efflorescent on the surface of the ground at certain seasons of the year.

Uses.—The uses of nitre for some coononical purposes, in various arts, in medicine, but particularly in the manufacture of gunpowder, are well known.

III. GENUS. MURIATES.

I. Species. ROCK SALT.

Common Salt, Sal Gem, Kirw. ii. 31. Le Sel de Cuisine, Broch. ii. 20. Soude Muriatée, Hauy, ii. 356.

Essen. Char.-Soluble in water, and divisible into cubes.

This species is divided into two subspecies : 1. foliated, and 2. fibrous rock salt.

Subspecies 1. FOLIATED ROCK SALT.

Le Sel Gemme Lamelleux, Broch. ii. 21. Lamellar Sal Gem, Kirw. ii. 32. Soude Muriatée, Amorphe, Hauy, ii. 359.

Exter. Char.—Usually found massive in considerable beds, sometimes disseminated in large masses, or kidneyform, stalactitical, or crystallized in perfect cubes; surface of the crystals smooth; lustre shining, vitreous; fracture foliated; cleavage threefold and rectangular; fragments cubic.

Colour grayish, yellowish, or reddish white, flesh or brownish red; transparent or translucent; soft; streak grayish white; taste saline.

Chem. Char.-This salt decrepitates violently when thrown on burning coals.

Constituent Parts.

Soda, Muriatic acid, Water.	Kirwan. 35 40 25	Bergman. 42. 52 6
Water,	100	100

The above are the analyses of pure salt; for as it is found in nature, it contains several other ingredients.

Localities, &c.-Foliated rock salt constitutes a peculiar kind of stratiform mountain, in which it usually

* Analy

ally alternates with beds of clay, which are more or sificaless penetrated with salt. It is also accompanied with gypsum, sandstone, limestone. It is sometimes also found in veius.

Rock salt is found in most countries of the world; the most celebrated mines are those of Wiliczka, which have been wrought for 500 years. There are mines of this mineral in Poland, Silesia, and in Bavaria and Siheria; at Cordova in Spain it constitutes an entire mountain, four or five hundred feet high. Rock salt is also found in abundance in Cheshire in England. It is found also in Africa, Asia, as well as in North and South America.

Subspecies 2. FIBROUS ROCK SALT.

Fibrous Sal Gem, Kirw. ii. 32. Le Sel Gemme Fibreux, Broch. ii. 25. Soude Muriatée Fibreuse, Hauy, ii. 379.

Exter. Char .- This variety is found massive, in small wedge-shaped veins ; lustre glimmering, rarely weakly shining; fracture fibrous, curved parallel or divergent; fragments wedge-shaped, with sharp cdges.

Colour grayish white, yellowish or pearl gray, lavender blue, violet blue, or flesh red ; varies between translucent and semitransparent. The other characters of fibrous rock salt correspond with those of the preceding subspecies, and it is found in similar situations accompanying it.

2. Species. SEA SALT.

This salt can perhaps scarcely be considered as a separate species. It is found on the shores of the occan, or of salt lakes during the dry seasons of the year, in consequence of the evaporation and diminution of the water which holds it in solution.

Uses .- The various uses of salt in domestic economy and many of the arts are well known.

3. Species. NATIVE SAL AMMONIAC.

Sal Ammoniac, Kirw. ii. 33. Le Sel Ammoniac Natif, Broch. ii. 27. Ammoniaque Muriatée, Hauy, ii. 380.

Essen. Char.-Entirely volatile by the application of heat.

Exter. Char.-Most commonly found in superficial layers, or efflorescent; sometimes also massive or stalactitical, and rarely crystallized. Primitive form of its crystals a regular octahedron ; integrant molecule a regular tetrahedron. The crystals are described to be in the form of cubes, six-sided pyramids, and dodecahedral; lustre shining, often only glimmering or dull and vitre-Fracture even ; fragments sharp-edged. ous.

Colour white, grayish, or yellowish; soft, and often friable ; taste saline, pungent, and bitter.

Chem. Char .- Very soluble in water, producing a considerable degree of cold ; rubbed with lime, gives out a pungent odour of ammonia.

Constituent Parts. Klaproth.

Sulphate	of ammonia, of ammonia,	77.5
		· Bert warmen werde

Localities, &c .- This salt is a volcanic production, and found deposited in the cavities of lava, as on Vesuvius and Ætna, and in the Lipari islands. It is also met with in Iceland, in Persia, and different places of Asia. The substance analyzed by Klaproth was from Tartary. This salt has also been discovered in the neighbourhood of coal mines in Britain, which have been accidentally on firc. Sal ammoniac from Egypt may be considered rather as an artificial production.

IV. GENUS. CARBONATES.

1. Species. NATIVE SODA, or Carbonate of Soda.

Natron, Kirw. ii. 6. L'Alkali Mineral, Broch. ii. 30. Soude Carbonatée, Hauy, ii. 373.

Essen. Char .- Soluble in water, and effervesces with nitric acid.

Exter. Char .- Found in small particles, which are usually in the state of powder; is dull and meagre to the touch.

Colour grayish white, or yellowish gray; taste sharp alkaline.

Chem. Char .- Very fusible before the blow-pipe; the solution renders vegetable blues green.

The following are the constituent parts of Egyptian natron or soda, analysed by Klaproth.

Carbonate of soda,	32.6
Sulphate of soda,	20.8
Muriate of soda,	15.
Water,	31.6

100.0

Localities, &c .- Native soda is found on the surface of the soil, or on the borders of lakes which evaporate during the summer, in Egypt, where it has been long collected, and known under the name of natron. In the neighbourhood of Debreczin in Hungary, it is found efflorescent on a heathy soil; in Bohemia, in decomposed gueiss rock, where it is annually collected in considerable quantity in the spring of the year. Natron is also found near Naples, in Persia, Bengal, and China. It exists also in solution in many mineral waters.

Uses .- This salt is very extensively employed in many arts.

Another variety of native soda has been described. This is in the form of radiated masses, which are composed of acicular crystals. It seems to be a purer carbonate of soda. The following are the constituent parts according to the analysis of Klaproth.

Soda,	37.
Carbonic acid,	38.
Water,	22.5
Sulphate of soda,	2.5

100.0

2. Species. NATIVE MAGNESIA, or Carbonate of Magnesia.

A pretty pure carbonate of magnesia, discovered by Dr Mitchell; and another which contains an admixture Dd2 of

Salts.

rt I.

on.

100.0

Salts. of silica discovered by Giobert, has been already deseribed under the magnesian genus, species 1. which see.

V. GENUS. BORATES.

1. Species. BORAX.

Id. Kirw. ii. 37. Borax Natif, Broch. ii. 33. Soude Boratée, Hauy, ii. 366.

Essen. Char.-Taste sweetish; fusible with considerable intumescence into a vitreous globule.

Exter. Char.—This salt is found massive and disseminated, but most frequently crystallized; the forms are a six-sided prism with the two opposite faces broader; the same prism having its lateral edges truncated, or having its too narrow terminal edges truncated; the crystals are usually imbedded in an earthy mass; surface a little rough, sometimes smooth, and usually covered with a white earthy crust; lustre shining, waxy; fracture foliated.

Colour grayish white, yellowish or greenish; semitransparent, or only translucent; refraction double; soft; brittle; greasy to the feel. Spec. grav. 1.740.

Constituent Parts.—When borax is purified, it is a compound of soda and boracic acid; but in its native state it is always contaminated with earthy matters.

Localities, &c.-Borax is brought from Persia and Thibet. According to some travellers, it is got from the waters of a lake by evaporation in the open air; but according to others it is ready formed on the borders of the lake, where common salt is also collected.

Uses.—Borax is still farther purified after it is brought to Europe, for the purposes of employing it in the arts, particularly as a flux in metallurgical operations.

2. Species. BORACITE, or Borate of Magnesia.

Boracite, Kirw. i. 172. Id. Brochant, i. 589.

Exter. Char.—Always found crystallized: 1. In cubes, having the edges and four of the angles truncated; 2. The cube, having all the edges and angles truncated. When these truncations are increased on the edges, a dodecahedron is nearly formed, or when they increase on the angles, the resulting form is an octahedron. Surface of the crystals smooth, sometimes rough; lustre shining or resplendent; internal lustre shining, resinous; fracture conchoidal; fragments sharpedged.

Colour ash or yellowish gray, grayish or greenish white; semitransparent or translucent, oftener opaque; semihard; rather easily frangible. Spec. grav. 2.56.

Chem Char.—Melts before the blow-pipe, froths up, and yields a yellowish enamel, on which small rough points appear, and are thrown off like sparks by continuing the heat.

Constituent Parts.	Westrumb.
Magnesia,	13.5
Lime,	II.
Silica,	2
Alumina,	I.
Oxide of iron,	.7
Boracic acid,	68.
Loss,	3.8

100.0

Phys. Char.—Boracite has the property of becoming electric by heat, and exhibiting both kinds of electricity by opposite points. These electric poles are the extremities of the axes of the cubc, each axis giving out at one extremity positive, and at the other negative electricity.

Localities, &c.—This mincral has been only found at Lunebourg in Lower Saxony, in a mountain composed almost entirely of foliated gypsum, in which the detached crystals are imbedded.

VI. GENUS. FLUATES.

1. Species. CRYOLITE, or Fluate of Soda and Alumina.

Id. Brochant, ii. 505. Alumine Fluatée Alkaline, Hauy, ii. 398.

Exter. Char-Found massive; lustre shining, vitreous; fracture foliated; fragments cubical.

Colour grayish white ; translucent ; immersed in water, transparent ; semihard ; streak snow-white. Spec. grav. 2.94.

Chem. Char.—Mclts in the flame of a candle, and from its easy fusibility it derives its name. It then becomes hard, and is changed into a slag, which is somewhat elastic. Soluble with effervescence in sulphuric acid, and gives out white vapours that corrode glass.

	Constituent Parts.	
	Klaproth.	Vauquelin.
Soda,	36.	32
Alumina,	23.5	21
Fluoric acid an	d water, 40.5	47
	(inclusion of the second secon	
	100.0	100

Localities, &c.-Cryolite was brought to Copenhagen from Greenland, but nothing is known of its repository (B).

THIRD CLASS. COMBUSTIBLES.

I. GENUS. SULPHUR.

1. Species. NATIVE SULPHUR.

Id. Kirwan, ii. 69. Le Soufre Natif, Brochant, ii. 37.

This species is divided into two subspecies; 1. Common; 2. Volcanic native sulphur.

Subspecies

(B) Boracite and cryolite do not certainly possess all the characters that entitle them to a place among the salts; but as magnesia is the predominant base of the one and soda of the other, it was thought better to introduce them here than to multiply divisions.

Subspecies I. COMMON NATIVE SULPHUR.

t I.

sifica-

011.

Essen. Char.—The sulphurous odour when heated; colour yellow.

Exter. Char .- Sulphur is found massive, disseminated in superficial layers, or crystallized. Primitive form of its crystals is an octahedron, whose sides are scalene triangles; the integrant molecule is an irregular tetrahedron. The usual forms of the crystals are, 1. That of the primitive form, in which two four-sided obliqueangled pyramids are joined base to base, of which the common base is a rhomb, whose two diagonals are as 5 to 4; 2. The same form having its summits truncated; 3. The first form having its summit surmounted by an obtuse four-sided acumination, set on the lateral faces; 4. Or, having the common case truncated; or, 5. Having its obtuse lateral edges truncated; or, 6. Having the obtuse angles of the common base truncated. The erystals are of various sizes, most frequently grouped : surface smooth ; lustre resplendent ; internal lustre shining, or weakly shining, between resinous and adamantine; fracture fine grained, uneven, sometimes conchoidal or splintery ; fragments sharp-edged.

Colour yellow, greenish, or grayish yellow; translucent or semitransparent; refraction double; soft; brittle, and very easily frangible; gives out by rubbing a sulphureous smell. Spee. grav. 19 9 to 2.03.

Chem. Char.-Burns with a peculiar hlue flame, and gives out a pungent odour, which is well known.

Native sulphur is not always pure ; it is often contaminated with carthy matters.

Phys. Char.—Sulphur becomes electric by friction, and its electricity is negative.

Localitics, &c.—Native sulphur is most commonly found in stratiform mountains, chiefly in those of gypsum, marl, and compact limestone, and there it exists in the form of nodules. Found also, but rarely, and in small quantity, in the veins of primitive mountains. Sulphur is found in many countries of the world, as in Poland, Hungary, Switzerland, Spain, and Sicily, where the finest crystals yet known are found.

Subspecies 2. NATIVE VOLCANIC SULPHUR.

Exter. Char.—Found massive, in rounded pieces, stalactitical, cellular, or in thin sublimed layers, sometimes also erystallized in confused groups; internal lastre weakly shining or shining; fracture uneven; fragments blunt-edged.

Colour the same as the former, but inclining sometimes a little towards gray; translucent; in other characters it resembles the preceding.

Localities, &c.—As its name imports, this variety is found near volcanoes, where it is sublimed among the lava. The sulphur of Ætna and Vesuvius chiefly, and also that of Iceland, and of some of the islands in the West Indies, is collected, and forms a very important article in commerce.

Uses.—Sulphur is one of the most valuable substances in various arts. It is employed in the bleaching of woollen stuffs and silks; it forms an essential ingredient in gunpowder, and it is the base of sulphureous and sulphurie acid, which are so extensively employed in tanning, hat-making, dycing, and other arts and manufactures. 1. Species. PETROLEUM, or Mineral Oil.

Exter. Char .- Found fluid and somewhat viscid.

Colour blackish or reddish brown; almost opaque; feels very greasy; exhales a strong bituminous odour; taste pungent, acid. Spec. grav. 0.708 to 0.854.

Chem. Char.—Burns easily with a dense smoke, and leaves some earthy residue. When exposed to the air it becomes thicker and less fluid.

Its constituent parts are carbone, hydrogen, and a small portion of oxygen.

Localities, &c.—Petroleum is generally found in the vicinity of coal, rising to the surface of the water which flows from coal strata. It is not uncommon in different parts of the world. It is found in Lancashire in England, and at St Catharine's well near Libberton, in the vicinity of Edinburgh.

Naptha, which is considered merely as a purer kind of mineral oil, is found in considerable abundance in different parts of Persia, on the shores of the Caspian sea, in Calabria, Sieily, and America. In 1802, a spring of naphtha of a topaz yellow colour, burning easily, and leaving little residue, with a specific gravity of 0.83, was discovered in the state of Parma in Italy, and allorded such a quantity as to be sufficient to illuminate the streets of Genoa.

Uses.—Naphtha has been sometimes employed in the composition of varnish, in that of fire-works, for the purpose of heating rooms, when it is mixed with a small quantity of earth; and in Persia and other countries it is burnt in lamps as a substitute for oil. Formerly it was employed in medicine as a vernifuge.

2. Species. MINERAL PITCH.

This is divided into three subspecies; I. elastie; 2. earthy; and, 3. slaggy.

Subspecies 1. ELASTIC MINERAL PITCH.

Mineral Caoutchone, Kirw. ii. 48. La Poir Minerale Elastique, Broeh. ii. 64. Bitume Elastique, Hauy, iii. 313.

Exter. Char.—Found in masses of different sizes, disseminated, sometimes superficial, or stalactitical; lustre dull, rarely glimmering; internal lustre shining, resinous.

Colour brownish black, hair-brown, often veined yellow; translueent at the edges; soft consistence like elastic gum, and also elastic. It gives out the smell of leather. Spec. grav. 0.902 to 1.23.

Localities, &c.—This mineral was diseovered in 1785 in the mine of Odin in Derbyshire in England, where it is accompanied with galena, calcareous spar, heavy spar, fluor spar, and blende.

This substance effaces the marks of black lead on paper, like elastie gum; but stains the paper.

Subspecies

3

213 Combustibles. 214 Combus-

tibles

Subspecies 2. EARTHY MINERAL PITCH.

Semicompact Mineral Pitch, or Maltha, Kirw. ii. 46. La Poix Minerale Terreuse, Br ch. ii. 65.

Exter. Char.-Found massive ; internally dull ; fracture earthy, sometimes uneven ; fragments blunt-edged.

Colour blackish brown, sometimes clove brown; streak shining, and darker coloured; very soft; feels greasy; smell bituminous.

Chem. Char.—Burns with much flame and smoke; exhales a strong odour, and leaves carbonaceous and earthy matter.

Localities, &c.-Found in the principality of Neufchatel in Switzerland.

Subspecies 3 SLAGGY MINERAL PITCH.

Compact Mineral Pitch, Kirw. ii. 46. La Poix Minerale Scoriacée, Broch. ii. 66. Bitume Solide, Hauy iii. 313. Asphaltum, or Jews Pitch, of others.

Exter. Char.—Found massive and disseminated, superficial or stalactitical; lustre resplendent, resinous; fracture conchoidal; fragments sharp-edged.

Colour perfectly black, sometimes brownish black; opaque, rarely translucent at the edges; lustre remains in the streak; soft; feels greasy; by rubbing gives out a bituminous odour. Spec. grav. 1.07 to 1.6.

Localities, &c .- This variety frequently accompanies the preceding. It is found at Morsfeld in the Palatinate, at Neufchatel in Switzerland It is found floating on the surface of the lake Asphaltum in Judea, from which it derives its name of Jews pitch. It is there collected by the inhabitants of the country as an object of commerce, and at the same time, it is said to diminish the quantity of noxious vapours which it exhales-so noxious that birds flying over it drop down dead, whence it has the name of Dead sea. This variety of mineral pitch is found in other places, sometimes connected with coal and limestone strata, and sometimes with mineral veins. But the island of Trinidad furnishes the greatest quantity of this substance. In that island there is a pitch lake of about four miles in circumference; but it appears from the information of Mr Spon, in a letter to Mr Tobin of Bristol, by whom this information was communicated, along with a number of specimens to Mr Hatchett, that the substance formerly supposed to be mineral pitch, is nothing more than a porous stone impregnated with that substance; so that what was supposed to be an immense lake of mineral pitch or asphaltum, is only the stone of the country impregnated with bitumen. Mr Hatchett thinks this stone may be arranged in the argillaceous genus *.

* Lin. Trans. viii. 251.

3. Species. AMBER.

Id. Kirw. ii. 65. Le Succin, Broch. ii. 69. Id. Havy, ii. 327.

This is divided into two subspecies.

Subspecies I. WHITE AMBER.

Exter. Char.—Found massive, and in rounded pieces; lustre shining or weakly shining; fracture conchoidal; fragments sharp-edged.

Colour yellowish white, or straw-yellow; slightly classifier translucent; soft; easily frangible; by friction, or reducing to powder, it gives out an agreeable odour.

Chem. Char.—Burns with a yellow flame, without melting, giving out at the same time a peculiar odour; Icaves very little residue.

Subspecies 2. YELLOW AMBER.

Exter. Char.—Also found in rounded pieces of various sizes; surface rough and uneven; dull, sometimes glimmering; internal lustre resplendent, resinous; sometimes transparent. In its other external and chemical characters, it resembles the preceding.

Phys. Char.—Amber becomes strongly electric by friction, a property known to the ancients. From the Greek and Latin word *electrum*, the term electricity is derived.

Constituent Parts.—Amber is composed of a large proportion of oil, and of a peculiar acid, the succinie, which is obtained by distillation.

Localities, &c.—Amber is found in the vicinity of bituminous wood, but most commonly in the sand on the shores of the ocean, and chiefly on the shores of the Baltic. It is found also in Sweden, France, Italy, and on the east coast of England. Amber frequently contains small parts of vegetables, and entire insects. Of the origin of this substance nothing certain is yet known.

Uses.—The uses of amber for ornamental purposes, are well known. In this country it was formerly in higher estimation than at present. It still forms an important article of commerce in eastern countries.

4. Species. MELLITE, or HONEY STONE.

Id. Hauy, iii. 335. La Pierre de Miel, Broch. ii. 73. Mellilite, Kirw. ii. 68.

Exter. Char.—Found usually crystallized, in double four-sided pyramids; the surface smooth and shining; internal lustre resplendent, between resinous and vitreous; fracture conchoidal; fragments rather sharpedgcd.

Colour honey yellow, sometimes hyacinth red; transparent or translucent; refraction double; soft; brittle. Spec grav. 1.58 to 1.66.

Chem. Char .- Becomes white before the blow-pipe, and is reduced to ashes, without flame.

Constituent Parts.	Kaprom.
Alumina,	16
Mellitic acid,	46
Water,	38
	1. 100

Phys. Char .- Becomes slightly electric by friction.

Localities, &c.—This mineral is hitherto rare. It has been found only in Switzerland, accompanied with mineral pitch, and at Arten in Thuringia, attached to bituminous wood.

5. Species. BROWN COAL.

This is divided into five subspecies; 1. common; 2. bituminous wood; 3. earthy coal; 4. alum earth; 5. moor coal.

Subspecies
tion.

ins.

MINERALOGY.

Subspecies 1. COMMON BROWN COAL.

La Houille Brune, Broch. ii. 47.

Exter. Char .- Found massive; lustre shining, resinous; fracture conchoidal; longitudinal fracture slaty; fragments rather sharp-edged.

Colour brownish black, or blackish brown; streak shining : soft ; not very brittle.

Chem. Char .- Burns with a blue-coloured flame, and gives out an odour like that of bituminous wood.

Constituent Parts. Hatchett *.

			Carains
Water which	soon came	over acid. and	lafterwarde
1 1 1 1 1		Cl.	anter mar do
turbid by th	e mixture	of bitumen,	60

Thick brown, oily bitumen, 21 90

Charcoal,

Hydrogen, carbonated hydrogen, and carbonic acid gases, 29

200

The above is the analysis of 200 grains of Bovey. coal by distillation.

Localities, &c .- This variety is not uncommon in many places of Germany. It is found also at Bovey near Exeter in England, from which it is called Bovey coal.

Subspecies 2. BITUMINOUS WOOD.

Carbonated Wood, Kirw. ii. 60. Le Bois Bitumineux, Broch. ii. 44.

Exter. Char .- Has a ligneous form, and even sometimes the appearance of branches and roots of trees; glimmering in the principal fracture, in the cross fracture, conchoidal; fragments splintery, wedge-shaped, or tabular.

Colour commonly light blackish brown, sometimes wood brown; opaque; streak shining; soft, and easily frangible.

Chem. Char .- Burns with a bright flame, and gives out a sweetish, bituminous smell.

Localities, &c .- This variety is found in the same places with the other varieties of coal, and also in places where the more common kinds of coal are rare, or in small quantity, as in the island of Iceland, where it is known by the name of surturbrand; and in the island of Skye in Scotland. It is found also in the coal fields round Edinburgh, and also at Bovey near Exeter, and in various places on the continent.

Subspecies 3. EARTHY COAL.

Bois Bitumineux Terreux, Brochant, ii. 45.

Exter. Char.__The consistence of this variety is intermediate between solid and friable; dull, rarely glimmering ; fracture carthy.

Colour blackish brown, or liver brown; streak shin-

ing; stains; very soft. Localitics, &c.-This is found in Saxony, Bohemia, France, and particularly in the vicinity of Cologne, where it is known by the name of umber or Cologne earth, which is employed in the fabrication of colours;

and from certain varieties which contain pyrites, alum Combusis extracted. tibles.

Subspecies 4. ALUM EARTH.

This has been already described under the name of aluminous schistus, in the argillaceous genus.

Subspecies 5. MOOR COAL.

La Houille Limoneuse, Brochant, ii. 48.

Exter. Char .- This variety is found massive, and in extensive beds; internally glimmering; cross fracture even, sometimes flat conchoidal; longitudinal fracture slaty; fragments trapezoidal or rhomboidal.

Colour blackish brown, and brownish black; streak shining ; soft, very easily frangible. Localities, &c.-Moor coal is abundant in Bohemia ;

it is found also in Transylvania, and chiefly among sandstone, limestone, and trap rocks. It seems to approach nearly to carth coal.

6. Species. BLACK COAL.

This species is divided into six subspecies; pitch, columnar, slaty, cannel, foliated, and coarse coal.

Subspecies I. PITCH COAL.

La Houville Piciforme, Brochant, ii. 49.

Exter. Char .- Found massive or disseminated; and sometimes parts of vegetables, such as the branches of trees, are observed. Lustre shining, resplendent, resinous; fracture conchoidal; fragments sharp-edged.

Colour perfect black, and the longitudinal fracture sometimes brownish; soft; easily frangible. Specific gravity 1.3.

Localities, &c .- This is one of the most common varieties of coal, and therefore is found in all coal countries.

Uses .- As it is susceptible of a fine polish, it is employed for various ornamental purposes. The substance known by the name of jet, belongs to this variety.

Subspecies 2. COLUMNAR COAL.

La Houille Scapiforme, Brochant, ii. 15.

Exter. Char .- Found massive ; in its fracture shining or weakly shining, resinous ; fracture more or less perfectly conchoidal; fragments indeterminate.

Colour perfect black, or brownish black. It is composed of distinct concretions, which are columnar, parallel, slightly curved, whose surfaces are smooth and shining; is soft, and easily frangible.

Localities, &c.-This is a very rare variety of coal. It is found in the Meisner, near Almerode, in Hessia, in a basaltic mountain.

Subspecies 3. SLATY COAL.

La Houille Schisteuse, Brochant, ii. 52.

Exter. Char .- Found massive in entire beds; lustre shining, sometimes only weakly shining or glimmering, resinous; principal fracture slaty; cross fracture imperfect conchoidal; fragments in the form of tables; not very sharp-edged.

tibles.

216

Colour perfect black, often also grayish, rarely brownish black ; streak shining ; soft, or semi-hard ; easily frangible. Specific gravity 1.25 to 1.37.

Localitics, &c .- This is the prevailing coal in Britain, as at Newcastle and Whitehaven in England, and in the eoal country both in the cast and west of Seotland.

Subspecies 4. CANNEL COAL.

La Houille de Kilkenny, Brochant, ii. 55. Id. Kirwan, ii. 52.

Exter. Char .- Found massive; lustre weakly shining, resinous; fracture commonly conchoidal, sometimes even and foliated ; fragments sometimes rhomboidal or cubical.

Colour grayish black ; streak shining ; soft ; easily frangible. Spec. grav. 1.23 to 1.27.

Localities, &c .- This coal accompanies the former in many places of England and Scotland, as at Whitehaven and Wigan in Lancashire in England; in the neighbourhood of Edinburgh; and at Muirkirk, and other places in Ayrshire in Scotland. The coal at Kilkenny in Ireland belongs also to this variety; and from the places where it is found, is called Wigan or Kilkenny coal.

Uses .- Beside being employed as fuel with other kinds of coal, this variety, being susceptible of a fine polish, is cut and formed into various useful and ornamental purposes. It is said that the choir of the cathedral church of Litchfield is covered with plates of this coal alternating with black marble.

Subspecies 5. FOLIATED COAL.

Le Charbon Lamelleux, Brochant, ii. 54.

Exter. Char .- Found massive; principal fracture resplendent; cross fracture shining; principal fracture more or less foliated ; cross fracture somewhat uneven ; fragments rhomboidal.

Colour perfect black, and on the sides of the fissures superficial colours appear, like the colours of tempered steel, or those of the peacock's tail; easily frangible.

Localitics, &e .- This coal is found at Liege, in Saxony, near Dresden, and in some parts of France.

Subspecies 6. COARSE COAL.

La Houille Grossiere, Brochant, ii. 55.

Exter. Char .- Found massive ; is weakly shining, resinous; fracture uneven, or more or less slaty; fragments blunt-cdged.

Colour grayish black, sometimes brownish black; streak shining; soft; casily frangible.

Localities, &c.-Accompanies the other kinds of coal, whose localities have been already mentioned.

7. Species. COAL BLENDE.

This is divided into two subspecies, conchoidal and slaty.

Subspecies 1. CONCHOIDAL COAL BLENDE.

La Houille Eclatante, Brochant, ii. 50. Glauz-kohle of the Germans.

Exter. Char .- Found massive, rarely disseminated ; Classifi lustre shining or resplendent, approaching to metallic; tion fracture.perfectly concludid; fragments not very sharpedged.

Colour iron black, inclining to brown, or exhibiting the superficial colours like tempered steel; soft; easily frangible.

Chem. Char.-Burns without any flame, leaving a white ash.

Localities, &c .- This variety of eoal is very rare. It is found at Newcastle, and at Meissiner in Hessia, along with the other varieties of coal.

Subspecies 2. SLATY COAL BLENDE.

Native Mineral Carbone, Kirw. ii. 49. La Blende Charbonneuse, Brochant, ii. 57. Anthracite, Hauy, 11. 307.

Exter. Char .- Found massive and disseminated; internal lustre shining, or resplendent, and between metallic and vitreous; fracture more or less perfectly slaty; cross fracture flat conchoidal; fragments sometimes cubic, and sometimes in tables.

Colour perfect black, approaching more or less to iron black, or grayish or bluish black ; opaque ; stains, but does not write ; soft ; rather brittle ; very easily frangible. Spec. grav. 1.3 to 1.8.

Chem. Char .- Reduced to powder, and heated in a crucible, this coal gives neither a sulphureous nor bitu. minous smell, and neither sulphur nor bitumen can be obtained from it. After being long exposed to heat, it consumes slowly without flame, and loses during the process about two-thirds of its weight. The residue is of a blackish gray colour, which shows that the combustion has not been complete.

Constituent Parts.

	Panzenberg.	Dolomicu.
Pure carbone,	90	72.05
Silica,	2	13.19
Alumina,	5	3.29
Oxide of iron,	3	3.47
Loss,		8.
	TOO	100.00

Localities, &c .- This variety has been found in a vein at Schemnitz in Hungary, in Pais de Vaud, in a transported rock, which seems to be intermediate between granite and breecia; at Konigsberg in Norway, where it is accompanied with native silver ; in Saxony it forms an entire bed in a mountain of clay slate; also found in the island of Arran, and near Kilmarnock in Seotland.

III. GRAPHITE GENUS.

I. Species. GRAPHITE, or BLACK LEAD.

Plumbago, Kirw. ii. 58. Le Graphite, Broch. ii. 76. Fer Carburé, Hauy, iv. 98.

This species is divided into two subspecies, scaly and compact.

Subspecies 1. SCALY GRAPHITE.

Exter. Char .- Found massive and disseminated ; lustre glimmering or shining, metallic; fracture foliated, conchoidal, stifica. choidal, sometimes uneven or slaty; fragments bluntion.
 edged, sometimes trapezoidal; commonly appears in distinct granular concretions, which are small or fine grained, with a splintery aspect.

Colour intermediate between bluish black and light iron black; sometimes steel gray, or brownish black; opaque; streak shining; stains and writes; soft; easily frangible; feels greasy.

Subspecies 2. COMPACT GRAPHITE.

Exter. Char.—This subspecies approaches so near to the former in its characters, that it seems difficult to distinguish it. The following characters and circumstances connected with the natural history of graphite, refer to both. Specific gravity 1.987 to 2.456.

Chem. Char.—When exposed to heat in a furnace, it gives out, during combustion, a great proportion of carbonic acid, leaving a residuum of red oxide of iron.

Constituent Parts.

Carbone	Berthollet.	Scheele.	Vauquelin.
no Iron.	0.1	10	23
16. Silica,	-	-	38
Alumina,	-	-	37
		Sugarant Subscription	
	100.0	100	100

Of the above analysis it must be observed, that the two first by Berthollet and Scheele must have been very pure specimens of graphite; and, on the contrary, the specimens analyzed by Vauquelin must have been very impure, containing so large a proportion of earthy matters, and so small a proportion of the proper ingredients of that mineral.

Localities, &c.—This mineral, which is not very common, is found chiefly in primitive mountains. It is met with in Spain, France, Bavaria, and Hungary. In England at Borrowdale near Keswick in Cumberland; and at Craigman, near New Cumnock, in Ayrshire in Scotland, where it is found in detached masses among rocks nearly similar to those which accompany coal.

Uses.—Graphite or black lead is employed for making pencils. The coarser parts are employed in making crucibles. It is also employed for covering cast iron, such as grates, to defend them from rust; and on account of its unctuous property, it is applied to those parts of machines which are subject to friction, for the purpose of diminishing it.

2. Species. MINERAL CHARCOAL.

This substance, which accompanies the other varieties of coal already described, is of a woody texture, and has therefore a fibrous fracture, with somewhat of a shining and silky lustre. It is usually found in thin layers with the other varieties of coal, and perhaps it might be considered as coal less perfectly formed; but in its characters it agrees so much with the varieties of coal blende, that it seems quite unnecessary to make it a separate species.

Vol. XIV. Part I.

FOURTH CLASS. METALLIC ORES.

I. PLATINA GENUS.

Species. NATIVE PLATINA.

Id. Kirw. ii. 103. Le Platine Natif, Broch. ii. 86. Platine Natif Ferrifere, Hauy, iii. 368.

Essen. Char.—Of a silver white colour, and infusible. Exter. Char.—Platina is found in the form of small flat or rounded grains; surface smooth, with shining metallic lustre; streak resplendent.

Colour light steel gray, or silver white; semi-hard; ductile; flexible in thin plates. Spec. grav. 15.601 to 17.7; but when purified, and hammered, 23, and according to some, 24.

Chem. Char.—Is almost infusible without addition, in the focus of a burning glass, or exposed to the action of oxygen gas. It does not amalgamate with mercury, and is only soluble in nitro-muriatic acid.

Localities, &c.—Platina was first brought to Europe by Don Ulloa in 1748. The repository of this metal is not known, and it has been found only in South America, till lately that it was discovered in gray silver ore from the mine of Guadalcanal in Spain. In the analysis of this ore, Vauquelin found the platina to be in the proportion of $\frac{r}{16}$.

Uses.—Platina is one of the most valuable mineral substances, as, on account of its hardness and infusibility, it may be applied to many of the purposes of gold and iron; and from its properties of being less liable to change when exposed to the air, or to the action of other chemical agents, it answers those purposes in a superior degree.

Platina in its crude state is alloyed with other metallic substances. It has been long known that it is accompanied with particles of iron, gold, and some other substances. It contains also an ore of one of the new metals. This is iridium, which is alloyed with osmium, another new metal, both which were discovered by Mr Tennant. This ore is composed of plates; it is not malleable; its specific gravity is 19.5, and it is not acted on by nitro-muriatic acid, which dissolves platina. Rhodium and palladium, two other new metals, are alloyed with platina.

II. GOLD GENUS.

Species. NATIVE GOLD.

This species is divided into three subspecies; 1. golden yellow; 2. brass yellow; and, 3. grayish yellow.

Subspecies 1. GOLDEN-YELLOW GOLD.

L'Or Natif, Jaune d'Or, Broch. ii. 89. Native Gold, Kirw. i. 93.

Exter. Char.—Gold is found most frequently disseminated, superficial, or in grains; reticulated, dendritical, capillary, or cellular, often in small plates, more rarely crystallized. The forms of its crystals which have been observed, are small perfect enbes, regular octahedrons, dodecahedrons, double eight-sided pyramids, terminated by four-sided summits, placed on the E e

art I.

Ores.

Metallic four lateral edges of the pyramids alternately; but the crystals are small and ill defined; the surface is smooth and resplendent; that of the small plates drusy and shining; that of the grains only strongly glimmering; internal lustre weakly shining, metallic; fracture hackly.

This variety presents the perfect colour of gold. It is soft; perfectly ductile, flexible, but not elastic; streak resplendent. Spcc. grav. of pure gold 19.25 to 19.64.

Subspecies 2. BRASS-YELLOW GOLD.

L'Or Natif d'un jaune de laiton, Broch. ii. 91.

Exter. Char .- This variety is almost always found disseminated in small particles, or superficial; sometimes also capillary, in small plates, or crystallized in thin six-sided tables.

The colour is that of brass of various shades, according to the proportion of alloy. In other characters it resembles the former, excepting in the specific gravity, which is inferior, owing to the greater proportion of other metals with which it is alloyed.

Subspecies 3. GRAYISH-YELLOW GOLD.

L'Or Natif d'un jaun grisatre, Broch. ii. 92.

Exter. Char.-This variety is also found disseminated in small flattened grains; surface is not very smooth; almost uneven, and weakly shining.

Colour steel gray, approaching to that of brass : spec. grav. of this variety is greater than the last, but inferior to the first. In other external characters they are the same.

Chem. Char .- Native gold is only soluble in nitromuriatic acid, platina is also soluble in the same acid, but it is not, like gold, precipitated from its solution by sulphate of iron.

Constituent Parts .- Native gold is not always found pure. It is frequently alloyed with silver or copper, or with both, and sometimes also, it is said, with platina. To these alloys the difference of colour, which is the foundation of the division into three varieties, is owing. The first variety is the purest, containing only a small proportion of silver or copper; the second has a greater proportion of these metals; and the third, it is supposed, is alloyed with a small portion of platina.

Uses .- Gold (on account of its indestructible nature, and its remarkable malleability and ductility), is one of the most important and valuable of the metals for many purposes; but its uses, whether as money, or articles of luxury, are too well known to require enumeration. As pure gold has no great degree of hardness, it is necessary to alloy it with a portion of copper. This is not less than $\frac{\tau}{24}$ and never more than $\frac{\tau}{4}$.

Localities, &c .- Gold is chiefly found in primitive mountains, and there it is usually in veins, sometimes disseminated in the rock itself. The accompanying substances are quartz, feldspar, limestone, heavy spar, pyrites, red silver, vitreous silver, and galena. Gold is also mixed with manganese, gray cobalt, nickel, and malachite. Gold has also been found, it is said, in fossil substances, as in petrified wood, penetrated with siliceous earth, a mass of which was dug out at the depth of 50 fathoms, in an argillaceous breccia, or, as

is supposed by some, a porphyry with an argillaccous Classifier basis, in Transylvania. This is considered as a proof of the more recent formation of gold, as well as the discovery of Patrin, who found native gold surrounded hy muriate of silver, in the mine of Zmeof in Siberia. Muriate of silver is supposed to be comparatively a late production.

But gold is perhaps more common to alluvial soil; there it is disseminated in grains, along with siliceons, argillaceous, and ferruginous sand, of which certain soils are composed ; and also in the sand of many rivers: and it is observed that the gold is most abundant when the waters are at the lowest, and especially soon after floods, which shews that the gold is carried down along with the earthy matters which are swept away by the violence of the current. It has been supposed too, that the gold found in the bed of rivers, has been detached, by the force of the waters, from the veins and primitive rocks traversed by these currents; and according to this opinion, attempts have been made to trace the source of these auriferous sands, in the hope of discovering the native repository of this precious metal ; but these attempts have usually failed, for it has been found that the gold is peculiar to the alluvial soil through which the stream is carried, and in which the gold is collected. This point seems to be established by the observations of naturalists. I. The soil of those plains frequently contains, to a certain depth, and in particular places, particles of gold, which may be separated by washing. 2. The hed of the rivers and auriferous streams yields a greater proportion of gold, after the plains which are traversed by those rivers have been flooded, than in any other circumstances. 3. It has always been observed, that gold is found in the sand of rivers in a very limited space. By examining the sand of these rivers higher up, and nearer to their source, no gold is found ; so that if this metal were derived from the rocks, which are swept by the currents, the quantity would be greatest nearcst to their sources ; but observation has proved the contrary. Thus the river Orco contains no gold, but from Pont to the place where it joins the Po. The Tesin affords no gold till it has traversed Lake Major, where its course must have been retarded, and where all the heavy particles of matter which it carried along with it from the primitive mountains, must have been deposited. The quantity of the gold collected on the Rhine near Strasburg, is greater than what is found near Basle, which is more in the vicinity of the mountains. No gold has been discovered in the sands of the Danube during the first part of its course. Those sands become only auriferous below Efferding. The same remark may be applied to the Ems. The sands of the upper part of this river, which traverses the mountains of Stiria, contain no gold; but from the place where it enters the plain at Steyer, till it joins the Danube, its sands are auriferous, and sufficiently rich to be washcd with advantage.

The most of the auriferons sands in all parts of the world, are of a black or reddish colour, and consequently ferruginous. From this circumstance, connected with the gold of alluvial land, some naturalists have inferred, that it is owing to the decomposition of auriferous pyrites. It was observed by Reaumur, that the sand which accompanies gold in most of the rivers, and particularly in the Rhone and the Rhine, is like that of Ceylon

4

art I.

pain.

29

Pied-

ary.

France.

assifica- Ceylon and Expailly, composed of iron and small grains of rubies, corundum, hyacinth. Titanium also has been discovered. It has been observed besides, that the gold of alluvial soil is purer than that which is immediately obtained from rocks, from which it is supposed that it has a different origin. It does not appear to he certainly ascertained, that gold is found in volcanic soil.

Such are the general facts relative to the repositories of gold. We shall now briefly mention the more remarkable places where gold has been found and colleced, beginning with those of Europe.

Spain formerly had mines of gold; the richest was d mines in the province of Asturias, where it was dug out from regular veins. These mines, according to ancient historians, were wrought by the Phœnicians, and afterwards by the Romans; but they have been totally abandoned since the discovery of America, and the mineral riches of that country. The rivers of Spain, as well as the Tagus in Portugal, contain auriferous sand.

The only mine of gold which in modern times has been wrought in France, was discovered in 1781, at Gardette, in the valley of Oysans, department of Isere. This was a regular vein of quartz, traversing a mountain of gneiss, and containing auriferous sulphurct of iron, and some fine specimens of native gold; but it was not sufficiently rich to defray the expence of the operations. Many of the rivers of that country contain auriferous sand, as the Rhone, the Rhine, the Garonne, and others of smaller note; and it is said that gold is also found among the black sand, and particles of morassy iron ore, in the neighbourhood of Paris.

In Piedmont there are some mines of gold. At the foot of Mount Rosa, veins of auriferous sulphuret of iron have been discovered, traversing gneiss; and although these pyrites do not yield more than 10 or 11 grains of gold in the quintal, it has been found worth while to continue the operations. On the south side of the Apennine mountains, there are several auriferous rivers and soils.

Some of the rivers of Switzerland also contain auriferous sands. Such are those of the Reuss and the Aar.

In Germany the only gold mine which is wrought is in Saltsburg, in the chain of mountains which traverses that country from east to west, and which separates it from the Tyrol and Carinthia.

But Schemnitz and Cremnitz are the most remarkable places in Europe for mines of gold and auriferous sands. The gold of Schemnitz is accompanied by silver, lead, and iron pyrites, and the matrix is quartz. Auriferous sand is found not only in the bed of the river Neva, but this sand is still richer in the plain through which the river flows. According to De Born, this is a ferruginous sand, lying below a bed of chalk.

In Transylvania the celebrated gold mine of Nagyag is remarkable for having the gold combined with native tellurium. There is also another mine at Felsobanya, the ore of which is an auriferous sulphuret of silver, in a vein of a kind of jasper. The rivers of this country also contain gold. The plain on the banks of the river Moros contains an auriferous sand, which is deposited between two beds, neither of which yields a particle of gold. The upper stratum is vcgetable soil, and the lower is composed of schistus.

The mines of Hungary are the only gold mines in Metallic Europe which are of any importance.

In Sweden gold is obtained from the mine of Edelfors in the province of Smoland. This mine yields na- Sweden. tive gold, and auriferous iron pyrites. The veins are composed of brown quartz, traversing a mountain of schistose hornstone. The gold is sometimes disseminated in the rock itself.

In Greece, the island of Thasos in the Archipelago Greece. was celebrated in antiquity for its rich mines of gold. The ancients also, it is said, found abundance of gold in Thrace and Macedonia.

The alluvial soil in several places of the British Ireland. islands, have also furnished gold. Not many years ago, a considerable quantity of gold was collected in a sandy soil, on the mountains of Wicklow in Ireland. Several masses of native gold, exceeding an ounce in weight, were found in that soil; one weighing 22 ounces was found, which is said to be the largest specimen of native gold found in Europe.

It would appear that gold was collected at a very Scotland early period in Scotland, and particularly in the mine field of Leadhills; but the most extensive operations were carried on by Bulmer an Englishman, in the time of Queen Elizabeth. The trenches, heaps of soil that had been turned up, and other marks of these operations, yet visible between Leadhills and Elvanfoot, still retain the name of Bulmer's Workings, and the place where the gold was washed, is still called the gold scour. At that time, it is said, an immense quantity of gold was collected. Not many years ago, similar operations were resumed by the advice of a German; but so far as we understand, the quantity of gold collected was scarcely equal to the expence. The operations during the last attempt were carried on under the superintendance of the late Mr John Taylor, manager of the mines at Wanlockhead; a man of no common sagacity, by which he was enabled to collect many curious facts with regard to the natural history of gold. The gold was found in that country immediately under the vegetable soil; and the method of conducting the operation was, to direct a small stream of water so as to carry this soil along with it, to basons or hollow places, where the water might deposit the matters which had been carried along by its current. The matter deposited was repeatedly washed, till the whole of the earthy substances were carried off. The gold being heaviest, sunk to the bottom, and remained behind. Among other facts which Mr Taylor communicated to us, and which he observed during the progress of these operations he found, that the gold was always most abundant near the top of the lead veins which traverse that country. He was so satisfied of this fact, that he could tell. merely by the quantity of gold increasing, when they approached to a vein; and on the other hand the quantity diminishing as they receded from the vein. This fact shows that there is some connection between metallic veins and the formation or deposition of gold.

Gold is still found in the soil of that country; but whether the quantity be less than formerly, or the expence of collecting it, from the difference in the price of labour, greater, the produce is by no means equal to the expences, and therefore searching for gold is now only the employment of the leisure hours of some of the miners.

·Ec2

The

The whole extent of the continent of Asia furnishes gold, in greater or smaller quantity. Gold is found in several of the mines of Siberia, and particularly in that of Beresof, which yields antiferons pyrites partially decomposed, and disseminated in a vein of quartz. In the southern parts of Asia, many mines, and particularly the sands of the rivers, contain gold. The Pactolus, a small river of Lydia, was celebrated in antiquity for the quantity of gold which it yielded, and it was supposed to be the source of the riches of Crœsus. Japan, Formoso, Ceylon, Java, Sumatra, Borneo, the Philippines, and other islands of the Indian Archipelago, are supposed to be rich in gold at this day.

The greatest quantity of gold which the ancients possessed, beside what was obtained from Spain, was brought from Africa. The gold of Africa, which still forms an important article of commerce, is always in the state of gold dust; a circumstance which shews that it is chiefly extracted from alluvial soil by washing. Little gold is found in the northern parts of Africa; three or four places are remarkable for the quantity of gold which they yield. The first is that part of the country between Darfour and Abyssinia. The gold collected there is brought by the Negroes for sale in quills of the ostrich and of the vulture. It would appear that this country was known to the ancients, who regarded Ethiopia as a country rich in gold; and Herodotus mentions that the king of that country exhibited to the ambassadors of Cambyses, all the prisoners bound with chains of gold.

The second great source of gold dust in Africa is to the south of the great desert Zara, in the western part of that country. The gold is collected in that extensive flat which stretches along the foot of the lofty mountains, among which the rivers Senegal, Gambia, and Niger, have their origin. Gold is found in the sands of all these rivers. Bambouk, which lies to the north-west of these mountains, supplies the greatest part of the gold which is sold on the western coast of Africa; at Morocco, Fcz, and Algiers, as well as that which is brought to Cairo and Alexandria in Egypt.

A third region of Africa where gold is abundant, is on the south-east coast, opposite to Madagascar; and it is said that the gold brought from Ophir, in the time of Solomon, was from that part of Africa.

38 America.

America is the richest country of the world, in modern times, in this precious metal. There it is collected in the alluvial soil, and in the beds of rivers, and sometimes, but more rarely, in veins. In Mexico, gold is chiefly found in the numerous silver veins of that country. All the rivers in the province of the Caraccas, about 10° north of the equator, furnish gold. In the Spanish part of America, Chili furnishes gold from the alluvial soil, as well as the province of Choco, where it is more abundant; while that of Peru is obtained from veins of quartz, marked with ferruginous spots.

But the greatest quantity of gold of commerce comesfrom Brazil, where it is collected in the alluvial soil, and in the sand of rivers, and extracted by washing. Gold is found almost everywhere in that country, at the foot of the immense chain of mountains which is nearly parallel with the coast, and which stretches from the 5° to the 30° of S. Lat.

III. MERCURY GENUS.

I. Species. NATIVE MERCURY.

Mercury, Kirw. ii. 223. Meroure Natif, Broch. ii. 241. Id. Hauy, iii. 423.

Essen. Char.—Remains liquid till the temperature be reduced to 40° below o Fahrenheit.

Exter. Char.—Native mercury exists disseminated, in globules of different sizes, in small cavities of other ores of mercury; lustre resplendent, metallic.

Colour shining white, or tin white ; opaque ; perfectly fluid ; does not wet the finger ; feels very cold. Sp. gr. 13.568 to 13.581.

Chem. Char.-Volatile before the blow-pipe, without diffusing any perceptible odour.

Native mercury is understood to be pure, and having all the properties of that metal; but it is sometimes amalgamated with a little silver, which destroys its fluidity in a slight degree, and renders it somewhat viscous.

Localities, &c.—Native mercury is usually found along with the other ores of that metal, as at Idria, in Friouli, and at Almaden in Spain; but the great proportion of the mercury of commerce is obtained by distillation from native cinnabar. There is also it is said, a rich mine of native mercury near Guança Velica in Peru.

Uses.—For many purposes mercury is one of the most important of metallic substances. It is extensively employed in metallurgy, in extracting gold and silver from their ores, by the process to be afterwards described, called *amalgamation*. The uses of mercury in gilding, in silvering the backs of mirrors, and in medicine, are well known.

2. Species. NATIVE AMALGAM.

Natural Amalgam, Kirw. ii. 223. L'Amalgam Natif, Broch. ii. 99. Mercure Argental, Hauy, iii. 432.

Essen. Char.—Communicating to copper a silvery colour by friction.

Exter. Char.—This species is rarely found massive, but usually disseminated, or superficial, sometimes imperfectly erystallized. The form of its crystals is the octahedron, dodecahedron, but it is usually found in thin plates or leaves; lustre resplendent, or shining; fracture conchoidal.

Colour between shining or tin white, and silvery white, according to the predominance of the mercury or silver; soft, and partially fluid; brittle, and easily frangible.

Chem. Char.-Exposed to heat the mercury is driven off, and the silver remains behind.

ssifica- whose veins are crossed by veins of silver ores. It is found chiefly at Rosenau in Hungary, in Moersfeld, and Mosehellansberg, in the duchy of Deux Ponts, and at Sahlberg in Sweden. It is usually found in a yellowish or reddish ferruginous clay, and accompanied by other ores of mercury.

3. Species. CORNEOUS ORE OF MERCURY.

Mercury mineralized by the vitriolic and marine acids, Kirw. ii. 229. Le Mine de Mercure cornée, Broch. ii. 101. Mercure muriaté, Hauy, iii. 447.

Essen. Char.-Colour pearl gray, volatilized by the blow-pipe.

Exter. Char.-Rarely found massive or disseminated, but usually in thin crusts, or in small globules, composed of an assemblage of small crystals, which are either perfect cubes, or six-sided prisms, terminated by a four-sided pyramid; a six-sided prism bevelled at the extremity; or an eight-sided prism with four broad and four narrow alternating faces. Crystals shining, sometimes resplendent; internal lustre shining and adamantine; fracture foliated.

Colour smoke gray, ash gray, or grayish white; translucent; tender, and easily frangible.

Chem. Char .- Entirely volatilized before the blowpipe, without leaving any residuum, and without decomposition.

The constituent parts are about 70 of mercury, 29 of muriatic acid, and a small portion of sulphuric acid.

Localities, &c .- This mineral has only been known about 13 years, and it is hitherto but rare. It was discovered in the mercury mines of the duchy of Deux Ponts by Woulfe, and has been since found at Almaden in Spain, and at Horsowitz in Bohemia. The repository is in the cavities of a ferruginous clay, which is mixed with malaehite and gray copper ore.

4. Species. LIVER OF HEPATIC ORE OF MERCURY.

Mine de Mercure hepatique, Broch. ii. 104. Hepatic mercurial ore, Kirw. ii. 224. Mercure sulfuré bituminifere, Hauy, iii. 446.

This is divided into two subspecies, 1. compact, and 2. slaty.

Subspecies 1. COMPACT LIVER ORE OF MERCURY.

Exter. Char .- Found massive or disseminated ; lustre glimmering, metallic; fracture even, sometimes fine-grained uneven; fragments blunt-edged.

Colour between lead gray, and cochineal red ; colour of the streak deep cochineal red, and shining ; tender, and easily frangible. Sp. gr. 7.18 to 7.93.

Subspecies 2. SLATY LIVER ORE OF MERCURY.

Exter. Char .- Found massive; lustre shining, and resplendent; in the cross fracture glimmering; lustre in general metallic, but sometimes vitreous; principal fracture slaty, in curved thick leaves; cross fracture compact and even ; fragments in plates.

Colour of the preceding, but somewhat darker, and approaching to that of iron; opaque; streak shining; powder between cochineal and searlet red; tender, and very easily frangible.

Localities, &c.-This is the most common ore of

mercury in Idria, where it forms considerable beds, Metallic and yields about 60 per cent of mercury. It is found also, along with other ores of mercury, in Spain and Siberia.

Liver ore of mercury consists of cinnabar, or the sulphuret of mercury, mixed with a portion of indurated bituminous elay. At Idria it is called branderz, or coaly earth, on account of the predominance of the bitumen.

5. Species. CINNABAR.

This species is also divided into two subspecies, conmon and fibrous.

Subspecies 1. COMMON CINNABAR.

Le Cinnabre Commun, Broch. ii. 107. Dark Red Cinnabar, Kirw. ii. 223. Mercure Sulfuré compacte, Hauy, iii. 440.

Exter. Char .- Found massive or disseminated, or in superficial layers, or cellular and kidney-form, and also crystallized. Forms of the crystals are, a double foursided pyramid with truncated summits; a cube having its opposite diagonal angles truncated; a rhomboidal prism; a three-sided prism terminated by a three-sided pyramid, which also is truncated. The crystals, which are usually small, are confusedly grouped together : surface of the rhomboidal prism transversely streaked, of the others smooth ; external lustre shining or resplendent ; internal the same, or only glimmering, vitreous, or adamantine; fracture foliated, uneven, or rarely splintery; fragments sharp-edged.

Colour cochineal red, carmine red, and in some varieties lead-gray; opaque, rarely translucent at the edges ; crystals translucent, or semitransparent ; streak shining, scarlet red ; tender, and easily frangible. Spec. grav. 6.902 to 7.86.

Chem. Char .- Before the blow-pipe common cinnabar is entirely volatilized with a blue flame, and a sulphureous odour.

Constituent	Parts.	Lampadius	5.
Mercury,		81	
Sulphur,		15	
Iron,		4	
		descention resident	
		IOO	

Localities, &c .- This is the most common ore of mercury, and may be considered as the gaugue or matrix of the other ores. Found not only in primitive mountains, where it forms beds in clay and chlorite slate, but also in stratiform mountains, and even in alluvial rocks. The mines of Almaden in Spain, of Idria in Friouli, and those of the duchy of Deux Ponts, have furnished the greatest quantity of common cinnabar. It is also found in Bohemia, Saxony, and Hungary, and in small quantity in France.

Subspecies 2. FIBROUS CINNABAR.

Le Cinnabre d'un Rouge vif, Brochant, ii. 111. Bright red Cinnabar, Kirwan, ii. 229. Mercure sulfuré fibreux, Hauy, in. 440.

Exter. Char .- Found massive, disseminated, or superficial; Ores.

222

Metallic

Ores.

ficial; lustre glinnaering, silky, often also entirely dull: fracture fine grained earthy, or fibrous; fragments bluntedged.

Colour bright scarlet red, sometimes crimson or aurora red; opaque; streak shining scarlet red; stains; very tender or friable, and very easily frangible.

Localities, &c.—This variety is very rare in a state of purity. According to Hauy, most of the specimens owe their texture to an admixture of radiated sulphuret of iron. It has been found chiefly at Wolfstein in the Palatinate, where it is accompanied by brown iron ore and hematites.

Uses.—Cinnabar is dug out chiefly for the purpose of extracting the metallic mercury. It is employed also as a colouring matter in painting; but the cinnabar used for this purpose is chiefly artificial.

Some other varieties of cinnabar, or sulphuret of mercury, have been noticed by mineralogists, as a native ethiops mineral. This is of a black colour, a loose consistence, and it stains the fingers. It appears to be some bituminous substance penetrated with cinnabar. It is found at Idria.

Alkaline cinnabar of De Born is found at the same place; is of a bright red colour, foliated fracture, with rhomboidal fragments; and supposed to be cinnabar penctrated with an alkaline sulphuret, the odour of which it gives out by friction. Another variety of cinnabar, usually called native vermilion, is in the form of powder. This substance is very rare, but is also sometimes found at Idria.

IV. SILVER GENUS.

I. Species. NATIVE SILVER.

Id. Kirwan, ii. 108. Id. Brochant, ii. 114. Id. Hauy, iii. 384.

This is divided into two subspecies, common and auriferous.

Subspecies 1. COMMON NATIVE SILVER.

Exter. Char.—Common native silver is usually found disseminated or superficial, under different imitative forms, as dentiform, filiform, capillary, dendritic, reticulated, veined, or in thin plates; and sometimes crystallized, in cubes, octahedrons, rectangular four-sided prisms, double six-sided pyramids with truncated extremities, double three-sided pyramids with truncated angles, and hollow four-sided pyramids. The crystals are small and grouped together in rows, or dendritical, or reticulated; surface smooth; that of the plates drusy, that of dentiform, filiform, and capillary silver; longitudinally streaked; external lustre glimmering or resplendent; internal always glimmering, metallic; fracturc hackly; fragments rather sharp-edged.

Colour silvery white, but sometimes on the surface yellowish brown, or grayish black; opaque; soft; perfectly ductile; flexible, but not elastic; streak shining, metallic. Spec. grav. 10 to 10.47.

Chem.Char.—Native silver is soluble in nitric acid, and may be precipitated by muriatic acid, the muriate of silver being insoluble; or by immersing a plate of cop-

per in the solution of nitrate of silver, the silver is re- Classi duced, and appears in the metallic state.

Localities, &c.—Native silver is not uncommon in most of the mines which furnish the other ores of that metal. The accompanying substances are usually heavy spar, quartz, calcareous spar, fluor spar, pyrites, blende, cobalt, and galena. Native silver is very abundant in Mexico and Peru, and it is also not uncommon in Siberia, in Germany, France, and was lately discovered in the Herland mine in Cornwall.

Subspecies 2. AURIFEROUS SILVER.

Exter. Char.—This variety is rarely found-massive, but is usually disseminated in small particles, or superficial, or reticulated, or in thin plates; lustre shining or resplendent; fracture hackly.

Colour between silver white and brass yellow, sometimes approaching to gold yellow; it is soft, perfectly ductile; flexible without being elastic, and its specific gravity is greater than common native silver in proportion to the quantity of gold with which it is alloyed.

Constituent Parts.—Auriferous silver is a compound of silver alloyed with gold, the latter sometimes in very considerable proportion.

Localities, &c.—This mineral is very rare. It is found at Konigsberg in Norway, disseminated in massive calcareous spar, fluor spar, and rock crystal, accompanied by blende, galena, and pyrites, in a vein which traverses a rock of slaty hornblende. It is also found in Siberia, in granular heavy spar accompanied by vitreous silver ore, vitreous copper ore, and pyrites.

2. Species. ANTIMONIAL SILVER ORE.

Argent Antimonial, Brochant, ii. 119. Id. Hauy, iii. 391. Antimoniated Native Silver, Kirwan, ii. 110.

Essen. Char.-Colour silvery white ; brittle.

Exter. Char.--Found massive or disseminated, kidneyform; or crystallized in four-sided oblique prisms, in six-sided prisms, sometimes with the lateral edges truncated, in six-sided tables, and in cubes, having some of the angles truncated. Surface of the crystals longitudinally streaked; lustre weakly shining, or only glimmering; internal lustre shining or resplendent; fracture foliated.

Colour silvery white, sometimes a superficial colour between yellow, black, and gray, or the colour of tempered steel; streak shining; semihard. Spcc. grav. 9.44.

Chem. Char.— Before the blow-pipe it is easily reduced; the antimony is driven off and gives out its peculiar odour, while the pure silver remains behind incrusted with a brown slag, which communicates to borax a green colour.

When antimonial silver is dissolved in nitric acid, a whitish crust, which is the oxide of antimony, soon appears on the surface.

This mineral, as its name imports, is an alloy of silver and antimony, in which sometimes a small portion of iron is observed. The proportions of the two metals seem to be very variable.

Localities, &c .- This ore of silver is accompanied by calcareous spar, heavy spar, native silver, galena, and quartz, in a vein near the duchy of Furstenburg in Swabia. It has also been found in carbonatc of lime and heavy spar near Guadalcanal in Spain.

3. Species. ARSENICAL SILVER ORE.

Id. Kirw. ii. 111. Argent Antimonial Arsenifere, et ferrifere, Hauy, iii. 398.

Exter. Char .- Found massive or disseminated, kidney-form or globular, and also crystallized in perfect six-sided prisms; in similar prisms a little flattened, and having the lateral edges rounded; and in acute six-sided pyramids with truncated summits. Lustre weakly shining, sometimes shining ; internal lustre shining or resplendent; fracture foliated; fragments sharp-edged.

Colour tin-white, or lead gray, but exposed to the air yellowish, or steel gray; streak shining; soft;

Chem. Char .- Before the blow-pipe the arsenic is driven off in fumes, diffusing the smell of garlic; there remains behind an impure globule of silver.

100.00

Localities, &c .- Muriate of silver is always found at the upper part of the vein, and it is said that it sometimes accompanies organized substances. Leaves of native silver have been found attached to petrifactions, at Frankenburg in Hessia; it is supposed that this metallic silver is the result of the decomposition of the muriate of silver. Corneous silver ore is almost always accompanied by vitreous silver, sooty silver, brown iron ore; more rarely by native silver, red silver, galena, quartz, and heavy spar. It is found in Peru and Mexico, in the mines of Freyberg in Saxony, at Allemont in France, and in Siberia.

Another variety of muriate of silver has been described by some mineralogists under the name of earthy corneous silver ore; or, according to the fanciful German name, butter-milk earth. This variety has an earthy fracture, owing to a portion of alumina which is combined with it. It is almost friable ; the lustre of the streak is resinous, and it feels somewhat greasy.

Chem. Char .- Before the blow-pipe it is slightly agglutinated without melting, and small globules of silver exude from the mass.

100

This variety is found at Andreasberg in the Hartz. Another variety has been described under the name of alkaline silver ore, which is nothing more than the muriate of silver combined with earbonate of lime.

5. Species. SOOTY SILVER ORE.

Id. Kirw. ii. 117. L'Argent Noir, Broch. ii. 132.

Exter. Char .- Found massive or disseminated, perforated or corroded; in superficial layers upon other minerals, or in rounded pieces, covered by muriate of silver; consistence intermediate between solid and friable; dull; fracture fine grained earthy; fragments bluntedged.

Colour bluish black, or blackish gray; streak shining, metallic; stains a little; easily frangible.

Chem. Char.-Melts easily before the blow-pipe into a slaggy mass, which, by continuing the heat, is partially volatilized, and the globule of silver remains.

Metallic

Ores.

Its constituent parts are still unknown; as it is usually accompanied by vitreous, corneous, and some other silver ores, it is supposed to be a mixture of those orcs in different proportions.

Localities, &c .- Found in Saxony, in France, and in Hungary.

6. Species. VITREOUS SILVER ORE.

Sulphurated Silver Ore, Kirw. ii. 115. L'Argent Vitreux, Brochant, ii. 134. Argent Sulphuré, Hauy, iii. 398.

Exter. Char .- Commonly found massive, disseminated, or superficial; sometimes dentiform, filiform, capillary, dendritic, or reticulated, with other forms and impressions. It is also crystallized in cubes, which are either perfect or truncated on the angles or edges; in octahedrons, which are either perfect, or truncated on the angles; in flat, double, three-sided pyramids, the edges of the one corresponding to the faces of the other; in rectangular four-sided prisms, terminated by a four-sided pyramid; in equiangular six-sided prisms, terminated at the two extremitics by a three-sided pyramid; corresponding alternately to three of the lateral edges, forming the garnet dodecahedron, of which all the lateral edges are sometimes slightly truncated; in broad and flat six-sided prisms bevelled at the extremity, and having the angles at the acute lateral edges truncated. The crystals are commonly small, and grouped together in rows, or in knots, like the steps of a stair ; the cube and the octahedron are the most common, and the cube is sometimes hollow. The surface of the crystal is usually smooth, sometimes rough or drusy; lustre between shining and weakly glimmering; internal lustre shining, metallic; fracture conchoidal, sometimes foliated; fragments blunt-edged.

Colour dark lead-gray, steel-gray, or blackish gray, varying by exposure to the air; streak shining; soft; ductile ; may be cut with a knife ; flexible without being elastic. Spec. grav. 6.909 to 7.215.

Chem. Char .- Before the blow-pipe vitreous silver is reduced to the metallic state, and the sulphur is driven By gradually heating it in a furnace, the sulphur off. may be dissipated without fusion, and the silver is reduced to the metallic state in a dendritical or capillary form, exactly resembling native silver.

Constituent Parts.

Silver Sulphur,	Bergman. 75 25	Sage. 84 16	Klaproth. 85 15
	100	100	100

Localities, &c .- Vitreous silver is one of the most common silver ores. It is usually accompanied by heavy spar, calcareous spar, and fluor spar; along with the other ores of silver and lead, cobalt and blende. It is found in Bohemia, Saxony, Norway, Siberia, and South America.

7. Species. BRITTLE VITREOUS SILVER ORE. L'Argent Vitreux Aigre, Brochant, ii. 138.

Exter. Char .- Found massive, disseminated, superfi-

cial, or crystallized in equiangular six-sided prisms, he Classifi terminal faces being sometimes plane, and sometimes convex or concave; the same prism truncated on its terminal edges, or terminated by a six-sided pyramid set on the lateral faces, and having its summit truncated; in equiangular six-sided tables, or in very flat rhomboids. Crystals small, and grouped together; surface smooth, sometimes drusy; prisms longitudinally streaked ; lustre shining or resplendent ; internal lustre shining, or weakly shining; fracture conchoidal, sometimes uneven; fragments rather sharp-edged.

Colour iron-black, or steel or lead gray ; soft ; brittle.

. Spec. grav. 7.208. Chem. Char.—Before the blow-pipe it melts with difficulty; sulphur, antimony, and arsenic, are partially driven off, and there remains a button of metallic silver, which is not very ductile, accompanied by a brown slag.

Constituent Parts.]	Klaproth.
Silver,	66.5
Sulphur,	12.
Antimony,	IO.
Iron,	5.
Copper and arsenic,	.5
Earthy matters,	I.
Loss,	5.
	100.0

Localities, &c.-This is one of the richest silver ores ; and it is usually accompanied by red silver ore, vitreous silver ore, some other metallic ores, and various carthy spars. It is pretty common in Saxony and Hungary, but less abundant than vitrcous silver ore. It is also occasionally met with in most other silver mines.

8. Species. RED SILVER ORE.

Id. Kirw. ii. 122. Id. Broch. ii. 143. Argent Antimonié Sulphuré, Hauy, iii. 402.

This is divided into two subspecies ; dark red, and bright red silver ore.

Subspecies 1. DARK RED SILVER ORE.

Exter. Char .-- Found massive or disseminated, superficial, dendritical, or crystallized in equiangular six-sided prisms, which is either terminated by a three-sided pyramid set on the lateral edges, or has its terminal edges truncated, or is terminated by an obtuse six-sided pyramid set on the lateral faces, and having the summit and lateral edges of the pyramid truncated; sometimes the summit of the pyramid is terminated by a second threesided pyramid, and sometimes the lateral edges of the prism are bevelled. The crystals are small, and variously grouped together, commonly smooth and resplendent, rarely streaked ; intern al lustre weakly shining, or only glimmering, adamantine, often semimetallic; fracture usually uneven, sometimes conchoidal; fragments rather blunt-edged.

Colour between cochineal red and lead-gray, and sometimes iron black ; crystals translucent ; in masses opaque; streak but weakly shining, between cochi neal red

tion

sifica. red and crimson red; soft; brittle, and easily frangible. Spec. grav. 5.56 to 5.58.

rt I.

Chem. Char .- Before the blow-pipe it decrepitates and flies off before becoming red, and then melts with frothing up; part is volatilized and sublimes in the form of a yellowish white powder, and leaves a button of metallic silver.

Its constituent parts arc supposed to be nearly the same as the following.

Localities, &c .- Found in almost all silver mines, and is usually accompanied by other silver ores, as well as different metallic ores.

Subspecies 2. BRIGHT RED SILVER ORE.

Exter. Char .- Found massive, disseminated, or superficial, and very often crystallized. The forms of its crystals resemble some of those of the former, or are simple six-sided pyramids, or acute six-sided pyramids, having the lateral angles alternately acute and obtuse, with the summit surmounted by a three-sided pyramid placed on the obtuse edges of the first; or surmounted by a six-sided pyramid set on the lateral faces. The crystals are sometimes acicular, and are combined together in a fascicular or reticulated form. Surface of the crystals sometimes smooth, sometimes drusy; streaked longitudinally, but the pyramids are streaked transversely or obliquely; lustre resplendent or shining; internal lustre shining or weakly shining and adamantine; fracture conchoidal, or fine grained uneven ; fragments rather blunt-edged.

Colour blood red, or light cochineal red, sometimes bluish on the surface; crystals semitransparent; in masses translucent, often opaque; streak aurora red; soft, easily frangible. Spec. grav. 5.44 to 5.59.

Chem. Char .- Melts before the blow-pipe ; blackens, and burns with a bluish flame, giving out white fumes with the odour of garlic. A button of nearly purc silver remains behind.

Constituent Parts.

Silver,	Klaproth.	Vauquelin.

The garlic smell, which was formerly supposed to be owing to arsenic, arises from the antimony, which is volatilized by the action of the blow-pipe; although, according to Proust, there are ores of red silver which contain sometimes arsenic and sometimes antimony separately, and sometimes the two metals combined. The red colour of this ore is by Thenard ascribed to the antimony in the state of purple oxide.

Localities, &c .- Red silver ore is usually accompanied by native arsenic, other ores of silver, as well as other metallic ores; and it is found in Bohemia, Saxony, France, Spain, and Hungary.

9. Species. WHITE SILVER ORE.

- Id. Broch. ii. 150. Light Gray Silver Ore, Kirw. ii. 119. +
 - Vol. XIV. Part I.

Exter. Char .- Found massive and disseminated ; Metallic lustre strongly glimmering ; fracture even ; fragments Ores. blunt-edged.

Colour bright lead-gray, or steel-gray; soft; streak sliining. Spec. grav. 5.322.

Constituent Parts .- According to some, this mineral is composed of silver, antimony, and sulphur; but according to others, minerals which have been reckoned white silver ores, contain a very considerable proportion of lead, and therefore ought to be arranged among the ores of that metal. Such are the following analyses by Klaproth.

	Light coloured.	Dark coloured
Silver,	20.40	0.25

T		

Localities, & c.- The real white silver ore has been chiefly found in the mine of Himmelfurst, near Freyberg in Saxony, in a gangue of quartz, and accompanied by galena, red silver, and blende.

10. Species. BLACK SILVER ORE.

Exter. Char .- This ore of silver is of a cellular texture; the streak is shining and metallic; it is brittle, and of a black colour; but it can only be known to be a silver ore by obtaining globules of silver under the blow-pipe. It is usually accompanied by vitreous red silver ores. It is supposed that it is some of the other species of silver ores that may have undergone some change from chemical agents. The silver it contains is in very variable proportions.

Localities, &c .- Found in some of the silver mines at Freyberg in Saxony, and Allemont in France. It is common in Peru and Mexico, and it is called by the Spaniards, negrillo.

Beside the silver ores already described, other species have been mentioned by mineralogists, the existence of which has not been distinctly ascertained; as the carbonate of silver of Widenmann and Kirwan, composed of 72.5 parts of silver, 12 of carbonic acid, and 15.5 of carbonate of antimony and oxide of copper *: the * II. 112. reddish and greenish black silver ore, also described by Kirwan, which is supposed to be a mixture of native and sulphurated silver t. Light lamellar silver ore 1, + Ibid. 125. composed of alumina, sulphuret of silver, oxide of iron ‡ 1bid. 116. and manganese.

V. COPPER GENUS,

1. Species. NATIVE COPPER.

Id. Kirw. ii. 128. Id. Broch. ii. 158. Id. Hauy, iii. 518.

Essen. Char .- Colour reddish yellow, and malleable. Exter. Char .- Native copper is found massive, disseminated, superficial, or in rounded pieces ; also dendritical and capillary, and very often crystallized in per-Ff fect

Ores.

226

Metallic fect cubes, or with truncated edges or angles ; double four-sided pyramids; simple and acute three-sided pyramids. Crystals small, and grouped in a dendritical or botryoidal form ; lustre shining or weakly shining ; internal lustre glimmering or weakly shining; fracture

hackly; fragments blunt-edged. Colour light copper-red, but exposed to the air, yellowish, blackish, or greenish : streak shining ; soft, or semihard ; ductile, and flexible, but not elastic. Spec. grav. 7.72 to 8.58.

Chem. Char .-- Copper immersed for some time in a solution of ammonia, or volatile alkali, changes it to a beautiful blue colour.

Localities, &c .- Native copper is not a very rare mineral; it is found in many copper mines accompanied by the other ores of copper, as in the copper mines of Siberia, Saxony, Hungary, Sweden, and Cornwall in England.

2. Species. VITREOUS COPPER ORE.

Id. Kirw. ii. 144. Id. Broch. ii. 162. Cuivre Sulfuré, Hany, iii. 551.

This is divided into two subspecies ; compact and foliated.

Subspecies 1. COMPACT VITREOUS COPPER ORE.

Exter. Char .- Found massive or disseminated, sometimes superficial, and rarely crystallized in perfect cubes with convex faces ; in perfect octahedrons, or in six sided prisms, terminated by a three-sided pyramid, set on three of the lateral edges. Crystals small; surface smooth and shining; internal lustre strongly glimmering or shining; fracture rhomboidal or even, fragments rather sharp-edged.

Colour lead-gray, iron gray, or yellowish, but sometimes the colour of tempered steel when tarnished ; streak shining or resplendent ; soft, and easily frangible. Spec. grav. 4.81 to 5.338.

Constituent Parts.	Klaproth.

4. Species. COPPER PYRITES.

Id. Kirwan, ii. 140. Id. Brochant. ii. 169. Id. Hauy, iu. 529.

Exter. Char-Found massive, disseminated, sometimes superficial, more rarely in imitative forms, as dendritical, &c. bnt often crystallized. Forms are, the tetrahedron, which is either perfect, or with its four angles truncated, giving it the appearance of a six-sided table; the perfect octahedron, the summit terminated by a line; a double crystal formed of two tetrahedrons base to base, the angles of the bases being slightly truncated, produce three re-entering angles, and the lateral faces three salient angles. Crystals are small ; surface smooth, shining; internal lustre shining or resplendent; fracture often uneven, sometimes conchoidal, fragments rather sharp-edged.

Colour in the fresh fracture, brass yellow, sometimes gold yellow, and steel gray; sometimes with variegated colours; soft or semi-hard; brittle. Spec. grav. 4.08 to 4.3.

Chem. Char .- Before the blow-pipe it decrepitates; gives out a sulphureous odour; fuses into a black globule, and the heat being continued, metallic copper ap-Borax heated with it acquires a green copears. lour.

This ore of copper is composed of sulphur, copper, (asificaand iron in variable proportions, and sometimes also a small admixture of gold or silver.

Irt I.

ion.

Localitics, &c .- This is a very common copper ore. It is equally found in primitive and stratiform mountains, either in veins or in beds, and sometimes in great abundance; in Saxony, Hungary, Sweden, France, and England.

5. Species. WHITE COPPER ORE.

Id. Kirwan, ii. 152. Id. Brochant, ii. 173.

Exter. Char .- Found massive or disseminated ; internal lustre weakly shining; fracture fine grained, uneven; fragments rather sharp-edged.

Colour between silver white and brass yellow ; semihard; brittle. Spec. grav. 4.5.

Chem. Char .- Before the blow-pipe it gives out a white fume, with the smell of arsenic, and melts into a grayish black slag.

This ore is said to be composed of copper, iron, arsenic, and sulphur.

6. Species. GRAY COPPER ORE.

Id. Kirwan, ii. 146. Id. Brochant, ii. 175. Id. Hauy, 111. 537.

Exter. Char .- Found massive or disseminated, superficial, and often crystallized in regular tetrahedrons, which are rare; or having all the edges truncated, or bevelled, sometimes slightly, and sometimes strongly; or having each of its angles surmounted by a three-sided pyramid, set on the lateral faces, with some other Crystals of various sizes; surface modifications. smooth, shining; internal lustre between glimmering and resplendent; fracture uneven, or conchoidal; fragments rather sharp-edged.

Colour steel gray of various shades, lead gray, and the tarnished colours are often variegated; streak black or brown; semi-hard; brittle. Specific gravity 4.44 to 4.86.

Chem. Char.-Before the blow-pipe it decrepitates, and melts into a brittle metallic globule of a gravish colour, giving out a white fume, and communicating to borax a yellowish red colour.

Constituent Parts. Klaproth.

Copper,	16.25	31.36

Loss,	4.75	4.68
	100.00	100.00

Localitics, &c .- This mineral is most frequently found in vcins in primitive mountains, accompanied by other ores of copper, as in Germany, France, Sweden, Siberia, and in England.

7. Species. BLACK COPPER ORE.

Id. Kirwan, ii. 143. Id. Brochant, ii. 180.

Exter. Char.-Found in the state of powder, with a dull appearance, and little coherence, sometimes incrusting other ores of copper; usually friable; stains; feels meagre.

Colour brownish black, sometimes deep brown.

Chem. Char .- Gives out before the blow pipe a sulphureous smell, and melts with borax into a greenish slag.

It is supposed to arise from the decomposition of vitreous copper ore and copper pyrites, and contains sometimes from 40 to 50 per cent. of copper.

8. Species. RED COPPER ORE.

Id. Kirwan, ii. 135. Id. Brochant, ii. 181.

This is divided into three subspecies ; compact, foliated and capillary.

Subspecies 1. COMPACT RED COPPER ORE.

Exter. Char .- Found massive, disseminated, or superficial; lustre glimmering, semi-metallic; fracture even, or slightly conchoidal; fragments rather sharpedged.

Colour cochineal red, or lead gray; opaque; streak shining, of a brick red colour; semi-hard, and brittle.

Subspecies 2. FOLIATED RED COPPER ORE.

Exter. Char .- Found massive, disseminated, or superficial, often crystallized in octahedrons, which are cither truncated on the angles or edges; in perfect cubes, which are sometimes truncated on the angles, and sometimes on the edges. Crystals small, usually aggregated ; surface smooth, shining ; internally shining, or weakly shining, between metallic and adamantine; fracture imperfectly foliated; fragments rather sharp-edged.

Colour similar to the former; opaque, translucent at the edges; crystals semi-transparent.

Subspecies 3. CAPILLARY RED COPPER ORE.

Fibrous Red Copper Ore, Kirwan, ii. 137. Le Cuiere Oxidé Rouge Capillaire, Brochant, ii. 184.

Exter. Char .- Found in small capillary crystals, which are disseminated in small bundles, or sometimes form a superficial incrustation; lustre shining and adamantine.

Colour carmine red, cochineal or scarlet red; crystals translucent.

Chem. Char .- Red copper ore is easily reduced before the blow-pipe without any odour; entirely soluble in muriatic acid without effervescence, but effervesces in nitric acid; by which means it may be distinguished from cinnabar, which is insoluble, and from red silver ore, which dissolves with effervescence.

The constituent parts of red copper ore are supposed to be copper and oxygen, and not a carbonate of copper, as was formerly conjectured.

Localities, &c .- Red copper ore is found in various places accompanying the other ores of the same metal, Ff2 and

Metallie

Ores.

Metallic and particularly native copper. The crystallized varie-Ores. ties are rare.

9. Species. BRICK-RED COPPER ORE.

Id. Kirwan, ii. 127. Id. Brochant, ii. 187.

Of this also there are two subspecies, earthy and indurated.

Subspecies 1. EARTHY BRICK-RED COPPER ORE.

Exter. Char .- Found massive or disseminated, or superficial, in the fissures of other copper ores, composed of fine earthy particles slightly cohering; dull, friable, and staining.

Colour hyacinth red, reddish brown, brownish red, or yellow.

Subspecies 2. INDURATED BRICK-RED COPPER ORE.

Exter. Char .- Found massive, disseminated, or superficial; lustre glimmering, or weakly shining; fracture imperfectly conchoidal, even or earthy; fragments rather sharp-edged.

Colour deep hyacinth red, brownish red, or deep brown; streak shining; soft, or semihard; brittle.

Chem. Char .- Before the blow-pipe it is infusible and blackens.

The constituent parts of this ore arc supposed to be a mixture of red copper ore, or oxide of copper, and brown oxide of iron, in variable proportions.

Localities, &c .- This ore is usually found accompanying red copper ore.

10. Species. EMERALD COPPER ORE.

Dioptase, Hauy, iii. 136. Id. Brochant, ii. 511.

Essen. Char .- Divisible into an obtuse rhomboid, whose plain angles are 111° and 69°.

Exter. Char .- Found crystallized in six sided prisms, terminated by a three-sided summit, placed on the three alternate lateral edges; lustre shining, vitreous; fracture foliated; cleavage threefold, parallel to the lateral edges of the summit.

Colour emerala green ; translucent, or semi-transpa-

rent; semi-hard. Spec. grav. 3.3. Chem. Char.-Infusible before the blow-pipe, but becomes brown, and tinges the flame of a candle yellowish green.

Constituent Parts.	Vauquelin.

Silica,	28.57
Carbonate of lime,	42.85
Loss,	.0I
	Barrow Carlow Contraction
	100.00

Localities, & c .- This mineral is found in Siberia, in a matrix covered with malachite.

11. Species. AZURE COPPER ORE, or Carbonate of Copper.

Bhue Calciform Copper Ore, Kirwan, ii. 129. L'Azur de Cuivre, Brochant, ii. 190. Cuivre Carbonaté Bleu, Hauy, iii. 562.

This species is divided into two subspecies, earthy Classification tion and indurated.

Subspecies I. EARTHY AZURE COPPER ORE.

Exter. Char .- Rarely found massive, usually disseminated or superficial; composed of fine particles which are dull and somewhat coherent ; fracture earthy.

Colour smalt blue, sometimes sky blue; opaque; stains a little; soft or friable.

Subspecies 2. INDURATED OF RADIATED AZURE COP-PER ORE.

Exter. Char .--- Rarely found massive, sometimes disseminated, often superficial, or in imitative forms, as stalactitical, botryoidal, &c. and also crystallized in rectangular four-sided prisms, terminated by four-sided acute pyramids set on the lateral edges; in oblique four-sided prisms, with two broad and two narrow faces, with a four-sided pyramid sct on the lateral faces; sometimes the lateral edges are truncated, and the termination is by a six-sided pyramid. Crystals usually small, and variously aggregated; broad faces of the prisms transversely streaked; narrow faces longitudinally; lustre shining or resplendent, vitreous ; fracture radiated; fragments blunt-edged, or wedge-shaped.

Colour light azure blue, Prussian or indigo blue; translucent or semi-transparent; streak sky blue; soft; brittle. Spec. grav. 3.4 to 3.608.

Chem. Char .- Soluble with effervescence in nitric acid; nearly infusible before the blow-pipe, but is easily reduced with borax, which assumes a fine green eolour.

Constituent Parts.	Pelletier.
Copper.	66
Carbonic acid,	18
Oxygen,	8
Water,	2
Loss,	6
	Augo-radoug/12/2000/00
	100

Localities, &c .- This variety of copper ore is not very abundant; but it accompanies the other ores of copper, and other metallic ores, as those of lead, zinc, and iron. It is found in Bohemia, Norway, Siberia, and in the different mines of lead and copper in Britain.

The earthy variety is found in superficial layers on a slaty marl in Hessia, and it is also found superficial on sandstone in Thuringia. Sometimes the whole of the sandstone is impregnated with this earthy carbonate of copper, there called copper sand earth, or copper sandstone. A similar sandstone, at Gourock near Greenock in Scotland, was a few years ago dug out for the purpose of extracting copper.

12. Species. MALACHITE.

Id. Kirwan, ii. 131. Id. Brochant, ii. 197.

This species is divided into two subspecies, fibrous and compact.

Subspecies I. FIBROUS MALACHITE.

Cuivre Carbonaté Vert Soyeux. Hauy, iii. 573.

rt I.

ssification.

> Exter. Char.-Rarelymassive, sometimes disseminated, but often superficial, and in the form of small capillary or acicular crystals grouped together in different forms; lustre shining, or when massive glimmering; internal lustre weakly shining, silky; fracture fibrous, straight, or radiated ; fragments blunt-edged.

> Colour, emerald or apple green ; opaque ; streak of a lighter colour ; soft ; brittle,

Subspecies 2. COMPACT MALACHITE.

Exter. Char .- Sometimes found massive, disseminated or superficial," but most frequently globular, botryoidal, stalactitical, &c.; surface rough or drusy, sometimes smooth, almost always dull, and rarely shining; internal lustre dull or weakly shining; fracture conchoidal; fragments rather sharp-edged or wedgeshaped.

Colour emerald green, apple green, and blackish green; opaque; soft; brittle. Spec. grav. 3.57 to 3.64.

Chem. Char .- Decrepitates before the blow-pipe, and blackens without fusion; effervesces with acids; colours borax green, and communicates a blue colour to the solution of ammonia.

Constituent Parts. Klaproth.

Comp	act Malachite.
Copper,	58
Carbonic acid,	18
Oxygen,	12.5
Water,	11.5
	100.0

Localities, &c .- Both the fibrous and compact malachites are usually found in the same repository, and accompanied with other ores of copper. They are found in Germany, but the finest specimens are brought from Siberia. Scotland affords fibrous malachite in small quantity, as at Leadhills and in Shetland. Malachite is also met with in Cornwall and Derbyshire in England.

Uses .- Malachite, when pure, is sometimes employed as a pigment. The compact variety is susceptible of a fine polish; which, with its beautiful and delicate colours, has brought it into much estimation for various ornamental purposes.

The largest and finest specimen of compact malachite known, is in the cabinet of Dr Guthrie at Petersburgh. It is 32 inches long, 17 broad, and two inches thick. It is estimated, according to the account of Patrin, who describes it, at 20,000 francs, above 800l. sterling. If we are rightly informed, this splendid mass of malachite was once offered to sale in Britain, but, having found no purchaser, was carried back to Russia.

13. Species. GREEN COPPER ORE.

Mountain Green, Kirw. ii. 134. Id. Broch. ii. 203.

Exter. Char .- Found massive or disseminated, but

usually superficial on other ores; dull; fracture con- Metallic choidal or uneven; fragments blunt-edged.

ores.

Colour verdigris green, cmerald green, sometimes sky blue, opaque, or translucent at the edges ; soft, or friable; brittle.

Chem. Char .- Becomes black before the blow-pipe without fusion. Colours borax green.

Constituent Parts .- Supposed to be a mixture of oxide of copper, or according to others, a carbonate, with alumina and lime.

Localities, &c-It is usually accompanied by gray copper ore, and some other copper ores, particularly with malachite, and sometimes with iron ochre, alumina, and quartz. Found in Saxony, Hungary, aud Siberia.

14. Species. FERRUGINOUS GREEN COPPER ORE.

This is divided into two subspecies; 1. earthy; and, 2. slaggy.

Subspecies 1. EARTHY FERRUGINOUS GREEN COPPER ORE.

Iron-shot Mountain Green, Kirw. ii. 155. Id. Broch. 11. 205.

Exter. Char.- Found massive, but most frequently disseminated ; dull, with an earthy fracture ; fragments blunt-edged.

Colour light olive green ; soft, friable ; brittle ; meagrc to the feel.

Subspecies 2. SLAGGY FERRUGINOUS GREEN COPPER ORE.

Glassy Iron-shot Mountain Green, Kirw. ii. 152.

Exter. Char .- Massive, or disseminated; lustre shining, vitreous; fracture conchoidal; fragments sharpedged.

Colour deep olive green, sometimes black ; soft ; brittle.

Constituent Parts .- Seems to be a mixture of oxide of copper with iron ochre, in variable proportions.

Localities, &c .- Found along with other copper ores, and is accompanied by iron ochrc, heavy spar and quartz. It is a rare mineral. Has been found in Saxony, and it is said in the Hartz.

15. Species. MICACEOUS COPPER ORE, or Arseniate of Copper.

Olive Copper Ore, Kirw. ii. 151. Le Cuivre Arsenical, Broch. ii. 208. Cuivre Arseniate, Hauy, iii. 575. Arseniate of Copper, Bournon, Phil. Trans. 1801. p. 193.

This species is divided into two subspecies, foliated and lenticular.

Subspecies 1. FOLIATED MICACEOUS COPPER ORE.

Exter. Char .- Found massive, disseminated, or crystallized in oblique four-sided prisms, in six-sided prisms, in acute rhomboids, or in very small cubes. These crystals are also variously modified ; lateral faces streaked longitudinally; lustre resplendent, pearly, or adamantine; fracture foliated, sometimes conchoidal.

Colour olive green, sometimes emerald green, or verdigris Metallic digris green; translucent; crystals semitransparent; Ores. soft. Spec. grav. 2.54.

Subspecies 2. LENTICULAR MICACEOUS COPPER ORE.

Exter. Char.—This variety is found crystallized in octahedrons, composed of two four-sided pyramids, with isosceles triangular faces; crystals small; external lustre shining; fracture foliated.

Colour sky blue, or verdigris green; scratches calcareous spar; brittle; easily frangible. Spec. grav. 2.88.

Chem. Char.—The crystals of these varieties decrepitate before the blow-pipe, and give out the odour of arsenic. They melt into a grayish globule, which being treated with borax, yields a button of copper.

Constituent Parts.	Vauquelin.
Oxide of copper,	39
Arsenic acid,	43
Water,	17
Loss,	I

100

100

Localities, &c.—These varieties of copper ores are very rare; and have been hitherto discovered only in the Carrarach mine, Cornwall, accompanied by brown iron ore and other copper ores.

Other arseniates of copper have been described by Bournon. In many respects they resemble the preceding varieties. The spec. grav. which is 4.28, is considerably greater, and yet the proportions of the constituent parts approach very near.

Constituent Parts. Chenevix.

16. Species. MURIATE of COPPER, or Green Sand of Peru.

Id. Broch. ii. 149. Id. Broch. ii. 545.

Char. Exter.—Found massive, or crystallized in very small six-sided prisms, bevelled at the extremities, or in small oblique four-sided prisms, also bevelled at the extremities, but the sides corresponding to the obtuse

lateral edges; surface of the crystals smooth and rc- Classific splendent; lustre adamantine; fracture foliated; fragments rather sharp-edged.

Colour between emerald and leek green; opaque; crystals a little transparent; soft; streak pale apple green. Spec. grav. 3.57 to 4.43.

Chem. Char. Thrown on burning coals, it communicates a green colour to the flame; soluble in nitric acid without effervescence.

Constituent Parts.				
	Pro	oust.	Klaproth	
Oxide of copper, Muriatic acid, Water,	76.6 10.6 12.8	70.6 11.4 18.1	73. 10.1 16.9

Localities, &c.—This mineral has been found in the sand of rivers, accompanied by quartz, schorl, copper and iron ores, near Remolinos in Chili. It has also been found in a similar situation in Peru.

PHOSPHATE OF COPPER.—This mineral has been found massive, or crystallized in oblique six-sided prisms, with convex faces, lining cavities; lustre resplendent, between vitreous and adamantine; internal lustre silky; fracture fibrous.

··· Colour grayish black, but internally emerald green; opaque; streak apple green; soft, or semihard.

Constituent Parts. Klaproth.

Oxide of copper,	68.13
Phosphoric acid,	30.95
Loss,	.92
	100.00

Localitics, &c.-This mineral has been found near Bologne, along with malachite, in a white drusy quartz.

COPPER MINES.—In addition to the history of copper ores now given, we shall just name some of the more celebrated copper mines in the world. The copper mines of Spain are situated on the frontiers of Portugal, and yield from veins of considerable thickness, yellow pyrites. France possesses copper mines in the Pyrenees, near Lyons, in Vosges, and in the neighbourhood of Savoy, in the department of Mont Blanc. There are extensive copper mines in Picdmont, which have been wrought to a very considerable depth.

The copper mines of Cornwall in England, which are in primitive rocks, have been long celebrated. The most abundant ores are copper pyrites, accompanied by native copper, which latter, it is observed, is most usually found near the surface. The same mines yield all the varieties of arseniate of copper. The Acton copper mines on the borders of the counties of Derby and Stafford are situated in limestone, in very declining or nearly perpendicular beds; but the richest copper mines in England are those of the island of Anglesea, where is a mass of pyritous copper ore of immense thickness, yielding from 16 to 40 per cent. of copper. Native copper is also found near the surface, and immediately under the turf.

230

The mines of Cronebane, in the county of Wicklow in Ireland, are very considerable. They are situated in a primitive mountain, composed of flinty slate and argillaccous schistus, which alternate with beds of steatites.

In Germany, Hungary, Sweden, Norway, and Siberia, there are many extensive and valuable copper mines. In the eastern parts of the Asiatic continent, in the island of Japan, in China, and in some of the islands of the Indian ocean, rich copper ores are abundant.

Africa, in various places of that extensive region, abounds with ores of copper, as in the mountains to the north of the Cape of Good Hope. On the western coast of Africa, the natives dig out copper ore, and are acquainted with the mode of extracting it.

In North America masses of native copper have been found, near Hudson's Bay; but the richest copper mines in the world are those of South America, and particularly in Chili, from which masses of native copper of immense magnitude have been obtained. The copper mines of Peru and Mexico are also wrought to great advantage.

VI. IRON GENUS.

1. Species. NATIVE IRON.

Id. Kirw. ii. 156. Id. Brochant, ii. 215. Id. Hauy, IV. I.

Exter. Char .- Found massive or branched; surface smooth, shining; internal lustre shining, metallic; fracture hackly; fragments rather sharp-edged.

Clour light steel gray, or silvery white; semihard; streak shining; perfectly ductile; flexible; but not elastic.

Localities, &c .- The existence of native iron as a terrestrial production still remains doubtful. It is said that it has been found along with other ores of iron, in Saxony and in France. The only instances fully established of the discovery of native iron, are those of the immense mass found by Pallas in Siberia, which amounted to no less than 1680lb. or 15 cwt. and another of 3 cwt. which was discovered by Rubin de Celis in South America; but these masses correspond so nearly with the substances which are certainly known to have fallen from the atmosphere, in their constituent parts, that it seems extremely probable they have had a similar origin. But for a full account of this curious subject, see METEOROLITE.

2. Species. IRON PYRITES.

Martial Pyrites, Kirwan ii. 76. Id. Brochant, ii. 221. Fer sulfuré, Hauy, iv. 65.

Subspecies 1. COMMON IRON PYRITES.

Exter. Char .- Found massive or disseminated, superficial, or in imitative forms, and frequently crystallized. . The forms are, a perfect cube with plane or convex faces; or with truncated angles, or edges; or having a three-sided pyramid on each angle; the perfect octahedron, or truncated on all its angles; the dodecahedron with pentagonal faces, or with six opposite and parallel edges truncated, or truncated on eight of its angles; or the perfect icosahedron, which is rare.

Crystals small, excepting the cube, and grouped to- Metallic gether; surface smooth or streaked; lustre shining, resplendent; internal lustre shining, metallic; fracture uneven; sometimes conchoidal; fragments rather sharpedged.

Chem. Char .- Before the blow-pipe it gives out a strong sulphurcous smell, and burns with a bluish flame; a brownish globule is then obtained, which is attracted: by the magnet.

Constituent Parts. Hatchett.

Sulphur, Iron,	52.15 47.85	52.5 47.5
	100.00	100.0

Some varieties of common iron pyrites contain a mixture of gold, which is supposed to be accidental, as the external characters are not affected by it, and it is only recognized by chemical analysis. These varieties are called auriferous pyrites.

Subspecies 2. RADIATED IRON PYRITES.

Exter. Char .- Found massive, or in different imitative forms, and also crystallized in small cubes or octahedrons; surface smooth or drusy; lustre shining or resplendent; fracture radiated; fragments wedgeshaped.

Colour bronze yellow, lighter than the former ; sometimes steel gray, and sometimes tarnished ; hard ; brittle, and easily frangible.

Subspecies 3. CAPILLARY IRON PYRITES.

Exter. Char .- Found in small, capillary, or acicular crystals, having the appearance of flocks of wool ; sometimes the crystals are acicular or in a stellated form; lustre shining or weakly shining, metallic.

Colour bronze yellow, approaching to steel gray.

Subspecies 4. HEPATIC IRON PYRITES.

Exter. Char .- Massive or disseminated, or in different imitative forms, as stalactitical, cellular, &c.; sometimes crystallized in perfect six-sided prisms or in sixsided tables, which are either perfect or bevelled on the terminal faces. Crystals small; sometimes smooth ; sometimes drusy; internal lustre glimmering, or weakly shining; fracture even, or imperfectly conchoidal; fragments sharp-edged.

Colour bronze yellow, steel-gray, sometimes brownish or tarnished; streak shining; hard; brittle.

Physical Char .- By rubbing gives out a sulphureous odour, and, according to some, the smell of arsenic.

Constituent Parts .- According to some mineralogists this variety is composed of sulphur and iron, with a portion of arsenic.

Localities, &c .- The first variety is universally diffused; it is found in every kind of rock, and often in great abundance.

The second is rarer; but is not uncommon in veins of lead and silver, and sometimes in nests in indurated marl. It is found in Saxony and Bohemia, in Derbyshire Ores.

Metallic shire in England, and at Leadhills and the island of Ores. Islay in Scotland.

This variety is more subject than the first to decomposition.

Capillary pyrites is only found in small quantity, as in Saxony, and Andreasberg in the Hartz.

Hepatic pyrites is only found in veins, particularly those of silver and lead, accompanied with quartz, calcareous spar, and heavy spar, as in Germany and Siberia, and at Wanlockhead in Scotland.

Exposed to the air, this variety is extremely liable to decomposition.

3. Species. MAGNETIC PYRITES.

Id. Kirwan, ii. 79. Id. Brochant, ii. 232.

Exter. Char.—Massive or disseminated; internal lustre shining or weakly shining; fracture uneven, rarely conchoidal; fragments rather sharp-edged.

Colour between copper red and bronze ycllow; when exposed to the air it becomes brownish or tarnished; hard, or semihard; brittle. Spec. grav. 4.51.

Phys. Char.—This variety of pyrites acts on the magnetic needle, but not very powerfully.

Chem. Char.—Before the blow-pipe it gives out a slight odour of sulphur, and melts easily into a grayish black globule, which is attracted by the magnet.

Constituent Parts. Hatchett. Iron, 63.5 Sulphur, 36.5

100,0

Localities, &c.-Magnetic pyrites has been only found in primitive rocks, as in micaceous schistus; and is usually disposed in beds, along with other ores of iron, and accompanied by quartz, hornblende, and garnets. It is found in Saxony, Bavaria, Bohemia, and in Caernarvonshire in Wales.

Uses.—This, as well as the former species, is employed for the purpose of extracting sulphur, or of manufacturing copperas, or sulphate of iron.

4. Species. MAGNETIC IRON ORE.

Magnetic Ironstone, Kirwan, ii. 158. Id. Brochant, ii. 235. Fer Oxidulé, Haüy, iv. 10.

This is divided into two subspecies, common and arenaceous.

Subspecies 1. COMMON MAGNETIC IRON ORE.

Exter. Char.—Massive or disseminated, and often also crystallized in six-sided prisms, having a three-sided pyramid at each extremity, set on three alternate lateral edges; an oblique four-sided prism; a double foursided pyramid, or perfect octahedron, which is sometimes truncated on all its edges. Crystals of various sizes; faces sometimes smooth; those of the four-sided prism streaked transversely; lustre shining; internal lustre resplendent, or weakly glimmering; fracture uneven, sometimes conchoidal or foliated; fragments rather blunt-edged.

Colour iron-black, perfect black, or steel-gray; streak Classifica brownish black; semihard, or hard; brittle; more or less easily frangible. Spec. grav. 4.2 to 4.93.

Subspecies 2. ARENACEOUS MAGNETIC IRON ORE.

Exter. Char.—Found in rounded grains, from the size of millet to that of a nut, and sometimes in small octahedral crystals; external surface rough or weakly glimmering; internal shining or resplendent; fracture conchoidal; fragments sharp-edged.

Colour deep iron black, sometimes ash-gray.

Phys. Char.—Magnetic iron ore, as the name imports, strongly attracts the magnetic needle, and iron filings; to the compact varietics of this ore, in which this property was first discovered, the name of natural magnet is given.

Chem. Char.—Magnetic iron ore becomes brown before the blow-pipe, and colours borax dark green.

Constituent Parts.—This is supposed to be an oxide of iron in considerable purity, as it yields from 80 to 90 per cent. of metallic iron.

Localities, &c.—Common magnetic iron ore is very common in primitive mountains, particularly in those of gneiss and micaceous schistus, where it forms very powerful beds, and even entire mountains. It is disseminated in crystals in chlorite schistus, as in Corsica, and in basalt and greenstone, at Taberg in Sweden. Found in Saxony, Bohemia, and Italy, and particularly in the island of Elba in the Mediterranean; and indecd is very universally distributed over every part of the globe.

The second variety, or magnetic sand, is found in the beds of rivers, in a loose state, and sometimes imbedded in basalt and wacken. It is found in those countries where the other ores of iron abound; and also in the saud of many of the rivers within the torrid zone, as in Jamaica, St Domingo, &c.

Uses.—Magnetic iron is wrought for the purpose of obtaining metallic iron. Most of the Swedish iron ores belong to this variety, and furnish the iron which is so celebrated on account of its superior qualities, throughout Europe.

Magnetic sand, where it is abundant, is also smelted as an iron ore.

5. Species. SPECULAR IRON ORE.

Id. Broch. ii. 242. Id. Kirw. ii. 162. Micaceous Iron Ore, ibid. 284. Fer Oligiste, Hauy, iv. 38.

This species is divided into two subspecies, common and micaceous.

Subspecies 1. COMMON SPECULAR IRON ORE.

Exter. Char.—Massive or disseminated, but most frequently crystallized in double three-sided pyramids, flattened, and the lateral faces of the one set on the lateral edges of the other; the same pyramid with the angles at the common base truncated; in perfect cubes, having the angles truncated; or the cube considered as a double three-sided pyramid; or as a rhomboid, in which the summits are surmounted by an obtuse threesided pyramid, set on the lateral faces; the same cube bevelled at each of the angles of the common base; in six-sided tables variously modified, or in perfect lenses. Surface

232

art I.

tion.

233 Metallic

Ores.

Surface of the crystals smooth, resplendent; interlassificanal lustre weakly shining or resplendent; fracture uneven, sometimes conchoidal or foliated ; fragments sharpedged.

Colour steel-gray, bluish or reddish ; sometimes with tarnished colours; which are iridescent; streak dark cherry-red; hard; opaque; brittle. Spec. grav. 4.79 to 5.21.

Chem. Char .- Before the blow-pipe it is infusible; but heated on charcoal becomes white, and melts with borax into a dirty yellow slag.

Phys. Char .- Affects the magnetic needle, but does not attract iron filings.

Constituent Parts .- This variety is supposed to be a pretty pure oxide of iron, yielding from 60 to 80 per cent. of iron.

Of this subspecies two varieties have been formed, compact and foliated, depending probably on the appearance of the fracture.

Subspecies 2. MICACEOUS IRON ORE.

Exter. Char .- Massive or disseminated, or in thin six-sided tables, so grouped together as to appear cellular; surface smooth, resplendent; internal lustre resplendent; fracture foliated; fragments in tables.

Colour iron-black, steel-gray, or dark red; in thin plates slightly translucent; streak dark cherry-red; semihard; brittle. Spec. grav. 4.5 to 5. Localities, &c.—These varieties are found in primi-

tive mountains, in beds or veins, accompanied by other ores of iron, and in such quantity in many places as to be dug out for the purpose of manufacture, as in Germany, France, Russia, Sweden, Siberia, and particularly in the islands of Corsica and Elba, which furnish the finest specimens of specular iron ore for the cabinet.

The latter variety is found in England, and some parts of Scotland.

6. Species. RED IRON ORE.

This is divided into four subspecies; I. red iron froth; 2. compact; 3. red hæmatites; and, 4. rcd ochre.

Subspecies 1. RED IRON FROTH.

Id. Broch. ii. 249. Red Scaly Iron Ore, Kirw. ii. 172.

Exter. Char .- Sometimes massive, and frequently superficial; lustre glimmering or shining, usually composed of scaly friable particles which stain strongly; feels greasy.

Colour dark cherry-red, blood-red, brownish-red, or steel-gray.

Chem. Char .- Blackens before the blow-pipe.

Constituent	Parts.	Hauy

Oxygen,	28.5
Silica,	4.25
Alumina,	1.25
~	100.00*

Localities, &c .- A rare mineral, usually incrusting other orcs of iron. Found in Germany, and in Cornwall and at Ulverstone in Lancashire in England. Vol. XIV. Part I.

ou ito.

Subspecies 2. COMPACT RED IRON ORE.

Id. Broch. ii. 251. Id. Kirw. ii. 170.

Exter. Char .- Massive or disseminated, in imitative forms, as cellular, &c. or crystallized in perfect cubes, or four-sided pyramids with truncated summits. Surfaces of the cube smooth; that of the pyramids rough and dull; internal lustre glimmering; fracture even, sometimes uneven or conchoidal; fragments rather blunt-edged.

Colour brownish-red, dark steel-gray, sometimes blood-red ; semihard ; brittle, streak blood-red ; stains. Spec. grav. 3.4 to 3.8.

Chem. Char .- Infusible before the blow-pipe.

Constituent Parts. Lampadius.

	100.0

Localities, &c .- Found along with other iron ores, abundant in Cumberland and Lancashire, and various places of the world.

Subspecies 3. RED HÆMATITES.

Id. Kirw. ii. 168. Id. Broch. ii. 254.

Exter. Char .- Massive, and in various imitative forms ; surface smooth or drusy ; internal lustre shining, or only glimmering ; fracture fibrous ; fragments wedgeshaped.

Colour brownish-red, steel-gray, or blood-red; streak light blood-red; hard or semihard; brittle; stains. Spec. grav. 4.7 to 5.

Constituent Parts .- It yields from 60 to 70 per cent. of iron, and contains, it is supposed, a portion of alumina, silica, and manganese.

Localities, &c.-This ore of iron is not very common, although in some places it is very abundant, as in the west of England. It is disposed in veins and beds, accompanied by the former variety.

Subspecies 4. RED OCHRE.

Id. Kirw. ii. 171. Id. Broch. ii. 256.

Exter. Char .- Found massive, disseminated, or superficial; dull; fracture earthy.

Colour between blood-rcd and brownish-red; stains much ; soft ; often friable.

Localities, &c .- This variety usually accompanies the former, and is a very fusible iron ore.

7. Species. BROWN IRON ORE.

This is divided into four subspecies ; 1. brown iron froth ; 2. compact ; 3. brown hæmatites ; and, 4. brown ochrc.

Subspecies 1. BROWN IRON FROTH.

Brown Scaly Iron Ore, Kirw. ii. 166. Le Eisenrahm brun, Broch. ii. 258. Gg

Exter.

Metallic Ores.

234

Exter. Char .- Massive or disseminated, often superficial, or spumiform; strongly glimmering or shining; fracture foliated or compact.

Colour between brown and dull gray; very soft; almost friable; stains; feels greasy; nearly swims on water.

Chem. Char .- Blackens before the blow-pipe without fusion.

Localities, &c .- Accompanies other iron ores, as in Saxony, but is rare.

Subspecies 2. COMPACT BROWN IRON ORE.

Exter. Char .- Massive or disseminated, sometimes in different imitative forms ; dull, or rarely glimmering ; fracture smooth, carthy, or conchoidal.

Colour clove brown, or brownish yellow ; streak yellowish brown; semihard; brittle. Spec. grav. 3.07 to

3.75. Localities, &c.-In veins or beds, accompanied by other iron ores, in various parts of the world.

Subspecies 3. BROWN HÆMATITES.

Id. Kirw. ii. 163. Id. Broch. ii. 261.

Exter. Char .- Massive, but most frequently in different imitative forms; surface smooth, granulated, rough or drusy; lustre shining; internal lustre glimmering or weakly shining ; fracture fibrous ; fragments splintery or wedge-shaped.

Colour clove brown ; blackish brown, sometimes ycllow, and sometimes with tarnished colours; opaque; streak yellowish brown ; semihard ; brittle. Spcc. grav. 3.78 to 4.02.

Localities, &c .- Always accompanies the preceding variety, but in smaller quantity.

Subspecies 4. BROWN OCHRE.

Id. Kirw. ii. 167. Id. Broch. ii. 263.

Exter. Char .- Massive or disseminated ; dull ; fracturc earthy; fragments blunt-cdged.

Colour yellowish brown, or ochre yellow; soft; sometimes friable; stains more or less.

Localities, &c.-Always accompanies compact brown iron ore, and is therefore found in similar places.

8. Species. SPARRY IRON ORE.

Id. Broehant, ii. 264. Id. Kirw. ii. 190.

Exter. Char .- Massive, disseminated, sometimes with impressions, and often crystallized. Its forms are, the rhomboid with plane or convex faces, or having two opposite angles strongly truncated; and the lens, the equiangular six-sided prism, or the simple or double four-sided pyramid. Crystals small; surface smooth, sometimes drusy, sometimes a little rough ; lustre shining and somewhat metallic; internal lustrc shining, rarely resplendent, between pearly and vitreous; fracture foliated; fragments rhomboidal.

Colour yellowish gray, grayish white, and exposed to the air, blackish brown, or with tarnished colours; sometimes translucent at the edges ; those of a dark colour, opaque ; semihard, or soft ; brittle. Spec. grav. 3.6 to 4.

Chem. Char .- Before the blow-pipe it blackens with- Classific tion out fusion.

Constituent Parts .- According to Bergman, this mineral contains equal parts of carbonate of lime and of iron, with about one-fourth of manganese.

Localities, &c .- Found equally in primitive and stratiform rocks, and always accompanied by calcareous spar, and other orcs of iron, as in Saxony, France, Britain and Ireland.

9. Species. BLACK IRON ORE.

Id. Kirw. ii. 167. Id. Broch. ii. 268.

This species is divided into two subspecies : 1. compaet; and 2. black hæmatites.

Subspecies 1. COMPACT BLACK IRON ORE.

Exter. Char .- Massive, or in various imitative forms; surface rough or dull; internal lustre glimmering; fracture flat conchoidal; fragments sharp-edged.

Colour between steel gray and bluish-black; semihard; brittle.

Subspecies 2. BLACK HEMATITES.

Exter. Char .- Massive or kidney-form ; internal lustre glimmering and shining ; fracture fibrous, sometimes even ; fragments wedge-shaped.

Colour steel gray.

Constituent Parts .- This ore is supposed to contain a larger proportion of manganese, with alumina and lime, than other ores of iron.

Localities, &c .- Found in veins in primitive mountains, and sometimes also in stratiform mountains, accompanied by brown and sparry iron orc.

10. Species. ARGILLACEOUS IRON STONE.

This is divided into six subspecies : 1. red chalk ; 2. columnar argillaceous iron stone; 3. granular; 4. common; 5. reniform; and, 6. pisiform.

Subspecies 1. RED CHALK.

Id. Broch. ii. 271.

Exter. Char .- Massive ; fracture slaty ; lustre glimmering ; cross fracture carthy, dull; fragments in plates, or splintery.

Colour brownish red, black or blood red; streak blood red; writes and stains; soft; adheres to the tongue; feels meagre. Spec. grav. 3.13 to 3.93.

Chem. Char .- Decrepitates, and becomes black when exposed to a red heat.

Localities, &c .- Usually accompanies clay slate, cither in thin beds, or in masses, as at Thalitter in Hessia, where it is dug out in considerable quantity. It is also found in Bohemia and Saxony.

Uses .- Employed as crayons in drawing, and for this purpose it is dug out, rather than as an ore of iron.

Red chalk, on account of the quantity of alumina and other earths which it contains, was formerly arranged in the argillaceous genus.

Subspecies

Subspecies 2. COLUMNAR IRON STONE.

Id. Kirw. ii. 176. Id. Broch. ii. 273.

Irt I.

ion.

ssifica-

Exter. Char.-Found in angular or rounded picces; surface rough and dull ; fracture dull and earthy ; composed of columnar distinct concretions, which are often a little curved, sometimes straight and articulated, and very easily separated ; surface of the concretions rough and dull.

Colour cherry red, blood or brownish red; streak blood red, sometimes yellowish brown; soft; adheres to the tongue; feels meagre, and is a little rough.

Localities, &c .- Usually met with in beds of clay, in stratiform mountains, and particularly in the neighbourhood of subterranean fires, by the effects of which, as it is supposed, it may have been produced. It is found in Bohemia and some other places, where it is wrought as an ore of iron.

Subspecies 3. GRANULAR IRON STONE.

Id. Broch. ii. 274. Acinose Iron Ore, Kirw. ii. 177.

Exter. Char .- Massive, or constituting the base of petrifactions ; strongly glimmering or weakly shining ; fracture uneven, sometimes slaty; fragments blunt-edged.

Colour reddish and yellowish brown, or grayish black; streak blood red, or varying according to the colour of the ore, usually soft or semilard. Specific gravity 2.673.

> Constituent Parts. Lampadius. Oxide of iron, 64. Alumina, 23. Silica, 7.5 Water, 5. Loss, .5 100.0

Localities, &c .- Is found only in stratiform mountains, as in Bohemia, Bavaria, and Switzerland.

Subspecies 4. COMMON IRON STONE.

Id. Kirw. ii. 173. Id. Broch. ii. 276.

Exter. Char .- Massive or disseminated, sometimes cellular or botryoidal; dull; fracture earthy; fragments rather sharp-edged.

Colour yellowish or bluish gray ; yellowish brown, or brownish red; streak varies with the colour; soft; brittle; adheres to the tongue; feels meagre.

Localities, &c.-A common ore of iron in many places of Saxony and Bohemia, in Norway, and in England. It is connected with stratiform mountains, alternating with beds of clay slate.

Subspecies 5. RENIFORM IRON STONE.

Id. Broch. ii. 278. Nodular Iron Ore, Kirw. ii. 178.

Exter. Char .- Found in rounded or tuberculated pieces, of a kidney-form figure ; surface rough, covered with earthy particles ; internal lustre glimmening ; frac-·ture smooth or earthy ; fragments rather sharp-edged ; composed of lamellar and concentric distinct conerctions, including a nodule which is usually moveable.

Colour yellowish brown; streak the same; soft;

brittle; adheres to the tongue; feels meagre. Specific Metallic gravity 2.57.

Ores.

235

Localities, &c.-Found in Bohemia, Saxony, Silesia, and Poland, and in the coal countries of England and Seotland, and almost always in clay beds, sometimes accompanied with bituminous wood, in stratiform mountains.

This variety was formerly called ætites or eagle-stone, as it was supposed that the eagle carried it to its nest.

Subspecies 6. PISIFORM IRON STONE.

Id. Kirw. ii. 178. Id. Broch. ii. 280.

Exter. Char .- In spherical or flattened particles, which are generally small; surface rough, dull; internal lustre glimmering or weakly shining ; fracture smooth.

Colour between brown and red; streak yellowishbrown; semihard; brittle. Spec. grav. 5.2.

Constituent Parts.	Vauquelin.
Iron,	30
Oxygen,	18
Alumina,	31
Silica,	15
Water,	6
	- Million and and

Localities, &c .- This variety is found in considerable beds in stratiform mountains. It is abundant in France, Switzerland, and some parts of Germany.

11. Species. BOG IRON ORE.

This is divided into three subspecies : I. morassy ; 2. swampy; and 3. meadow.

Subspecies 1. MORASSY BOG IRON ORE.

Id. Kirw. ii. 183. Id. Broch. ii. 283.

Exter Char.-Sometimes earthy, sometimes in amore phous, tuberculated, or corroded masses; fracture earthy. Colour yellowish-brown; stains; soft; friable; feels

meagre.

Subspecies 2. SWAMPY IRON ORE.

Id. Kirw. ii. 138.

Exter. Char.-In amorphous masses, which are tuberose or corroded ; dull or slightly glimmering ; fracture earthy; fragments blunt-edged.

Colour dark yellowish-brown, blackish brown, or steel-gray; streak light yellowish brown; very soft; brittle; heavier than the former.

Subspecies 3. MEADOW IRON ORE.

Id. Kirw. ii. 182. Id. Broch. ii. 284.

Exter. Char .- In kidney-form, tuberose, often corroded masses ; externally dull or rough ; internal lustre shining, resinous; fracture conchoidal, or earthy when it is dull; fragments rather blunt-edged.

Colour dark blackish-brown, or yellowish-brown; streak yellowish-brown; soft and brittle.

Constituent Parts .- Bog iron ore is an oxide of iron, combined with the phosphate of iron, with some earthy matters, as alumina and silica.

Localities.

236

Metallic Ores.

Localitics, &c .- Bog iron ore is more abundant in the northern than in the southern parts of Europe. It is not uncommon in Poland, Prussia, Sweden, and in the Western islands of Scotland, as Jura and Islay. It is sometimes found in extensive beds, alternating with sandstone and clay.

12. Species. BLUE EARTHY ORE.

Id. Broch. ii. 288. Blue Martial Earth, Kirw. ii. 185. Native Prussiate of Iron, of others.

Exter. Char.-Usually found slightly cohering, or loose, or friable; particles dull; stains, and feels meagre.

Colour gravish-white, indigo blue, rarely smalt-blue.

Chem. Char.-Becomes reddish-brown before the blow-pipe; melts into a black globule; easily soluble in acids.

Constituent Parts.-It was suspected by Bergman, that this was a native Prusian blue; but according to Klaproth, it is composed of iron and phosphoric acid, with a mixture of alumina.

Localities, &c .- Found in small nests in beds of clay, or bog iron ore, as in Saxony, Russia, and Siberia.

13. Species. GREEN EARTHY IRON ORE.

Green Martial Earth, Kirw. ii. 188.

Exter. Char.-Found friable and superficial, rarely massive; internally dull; fracture carthy.

Colour yellowish or olive-green; stains; soft; feels meagre.

Chem. Char.-Becomes red before the blow-pipe, and then dark-brown, but without fusion.

Constituent Parts .--- It is conjectured to be a compound similar to the former, but in different proportions.

Localities, &c.-Found in Saxony, in veins, and accompanied with quartz and pyrites.

14. Species. PHOSPHATE OF IRON.

Id. Jour. de Physique, lviii. 259. Ann. de Chim. 1. 200.

Exter. Char.-Found in rounded pieces, composed of capillary crystals, which seem to be four-sided prisms; fracture radiated and divergent.

Colour blue, from a blue powder coating the crystals, which are otherwise colourless ; semitransparent. Spec. grav. 2.5 to 2.6.

Localities, &c .- This mineral is found imbedded in clay in the isle of France, and in Brazil.

15. Species. PITCHY IRON ORE, or Phosphate of Iron and Manganese.

Id. Broch. ii. 533. Jour. de Mines, Nº 64. p. 295. 3

Exter. Char.-Massive ; surface earthy and dull ; in- Class ternal lustre weakly shining, resinous; fracture compact tic or foliated.

Par

Colour dark reddish-brown, or black; opaque; semihard; brittle; streak dark red. Spec. grav. 3.956.

Chem. Char.-Mclts before the blow-pipe into a black enamel.

Constituent Parts. Vauqu	clin.
Oxide of iron,	31
Oxide of manganese,	42
Phosphoric acid,	27
	100

Localities, &c.-Found near Limoges.

16. Species. CUBE ORE, or Arseniate of Iron.

Id. Phil. Trans. 1801. p. 190.

Exter. Char.-Found crystallized in small cubes. grouped together in a drusy form; crystals sometimes truncated on their angles; surface smooth, shining; lustre between resinous and adamantine; fracture conchoidal.

Colour olive-green, yellow, or brown ; translucent ; semihard; powder yellow. Spec grav. 3.

Chem. Char .- Before the blow-pipe froths up with the smell of arsenic, and melts into a yellowish-gray metallic globule.

Constituent Parts.

Oxide of iron, Oxide of copper, Arsenic acid, Silica, Lime, Water,	Vauquelin, 48 18 2 32	Chenevix. 45.5 9. 31. 4. -
	100	100.0

Localities, &c.-Found in the copper mines in Cornwall.

17. Species. ARSENIATE OF IRON AND COPPER.

Id. Phil. Trans. 1801. p. 219.

Exter. Char.-Crystallized in four-sided rhomboidal prisms, with two edges very obtuse, and two very acute, terminated by an acute four-sided pyramid; edges of the prism are sometimes truncated.

Colour bluish-white; crystals semitransparent; semihard. Spcc. grav. 3.4.

Constituent Parts.

Oxide of iron,	27:5
Oxide of copper,.	22.5
Arsenic acid,	33.5
Silica,	3.
Water,	12.
Loss,	1.5

rt I. ssification

Localities, &c .- Found in Cornwall, in Siberia, and Spain.

18. Species. CHROMATE OF IRON.

Id. Broch. ii. 534. Id. Hauy, iv. 129.

Exter. Char .- Massive ; glimmering or weakly shining; fracture compact and uneven, or imperfectly foliated.

Colour grayish or blackish brown; opaque; streak ash-gray; smell earthy when breathed on; hard. Spec. grav. 4.032.

Chem. Char .- Infusible before the blow-pipe; melts with borax, and colours it of a beautiful green.

Constituent Parts.

Oxide of iron, Chromic acid, Alumina,	35 43 20
Silica,	2
	-
	100

Localities, &c.-Discovered by Pontier in France, in the department of Var, and found in considerable abundance in veins and nodules, in beds of serpentine; found also in Siberia.

VII. LEAD GENUS.

1. Species. GALENA.

This is divided into two subspecies; common and compact galena.

Subspecies 1. COMMON GALENA.

Id. Kirw. ii. 216. Id. Broch. ii. 294. Plomb Sulfuré, Hauy, iii. 456.

Exter. Char .- Massive, disseminated, superficial, in imitative forms, or crystallized in cubes, octahedrons, six-sided prisms, and six-sided tables; all which are variously modified by truncations and bevelments on the edges and angles. Crystals grouped or imbedded ; surface smooth, or drusy; lustre from glimmering to resplendent; internal the same; fracture foliated; fragments cubic, excepting the fine-grained galena.

Colour lead-gray, sometimes tarnished, or iridescent; soft ; easily frangible ; stains a little. Spec. grav. 7.22 to 7.58.

Chem. Char.-Decrepitates before the blow-pipe, and fuses, giving out a sulphureous odour.

Constituent Parts .-- Composed of sulphur and lead in variable proportions, and generally a little silver, sometimes antimony. The proportion of lead is from 50 to 80 per cent.

Localities, &c.-This is the most common ore of lead, and exists in all kinds of rocks, either in beds or veins. In many countries this lead ore is dug out to a great extent, as in Germany, France, and Britain.

Subspecies 2. COMPACT GALENA.

Id. Kirw. ii. 218. Id. Broch. ii. 301.

Exter. Char .- Massive, disseminated, kidney-form, or specular; lustre of the specular variety resplendent;

the others only glimmering; internal lustre glimmer- Metallic ing; fracture even or concluoidal; fragments rather Ores. sharp-edged.

Colour lead or steel gray; streak shining; stains; soft. Spec. grav. 7.44.

Localities, &c .- This is a rare mineral. It is found along with common galena, in Saxony, and other parts of Germany; in Derbyshire, where it is known by the name of slickenside, and in the county of Durham, where it is known by the name of looking-glass ore.

2. Species. BLUE LEAD ORE.

Id. Kirw. ii. 220. Id. Broch. ii. 203.

Exter. Char .- Rarely massive, most commonly crystallized in regular six-sided prisms, which are often a little curved, and sometimes fascicularly grouped; surface rough; longitudinally streaked; lustre glimmering; fracture even.

Colour between lead-gray and indigo blue; opaque; streak shining; soft, easily frangible. Specific gravity 5.46.

Chem. Char .- Melts casily before the blow-pipe ; burns with a bluish flame, and a sulphureous odour, leaving a globule of lead.

Its constituent parts have not been exactly ascertained. Supposed to be a green lead ore, which has undergone some change, but retaining its original form.

Localities, &c .- This ore has only been found in Saxony, and also, it is said, in France and Hungary.

3. Species. BROWN LEAD ORE.

Id. Kirw. ii. 222. Id. Broch. ii. 305.

Exter. Char.-Rarely massive, commonly crystallized in equal six-sided prisms, or the crystals are acicular or capillary; lustre glimmering; internal shining; fracture_uneven.

Colour reddish or clove-brown; translucent at the edges; streak white; soft; brittle. Spec. grav. 6.6 to 6.97.

Chem. Char .- No effervescence with acids; fuses readily before the blow-pipe, but is not reduced; crystallizes in small needles on cooling.

Constituent Parts.	Klaproth.
Oxide of lead,	78.58
Phosphoric acid,	19.73
Muriatre acid,	1.65
11038	•04
	100.00

Localities, &c .- Found along with white lead ore, quartz, and heavy spar, in France and Germany.

4. Species. BLACK LEAD ORE.

Id. Kirw. ii. 221. Id. Broch. ii. 307.

Exter. Char.__Massive, disseminated, cellular, but most frequently crystallized in six-sided prisms, with equal or unequal sides, or bevelled at the extremity. Crystals small, irregularly grouped; smooth, and sometimes longitudinally streaked ; lustre shining ; fracture uneven.

Part

238 Metallic

Ores.

Colour grayish black; opaque; streak grayish black; soft; brittle. Spec. grav. 5.7. *Chem. Char.*—Decrepitates before the blow-pipe; and

Chem. Char.—Decrepitates before the blow-pipe; and is then reduced to the metallic state.

Constituent Parts.	Lampadius.
Oxide of lead,	78.5
Carbonic acid,	18.
Carbone,	1.5
Water,	2.
	(particular second
	100.0

Localities, & c-Found in Saxony, England, and Scotland, frequently accompanying white lead ore.

5. Species. WHITE LEAD ORE, or Carbonate of Lead.

Id. Kirw. ii. 203. Id. Broch. ii. 309. Plomb Carbonaté, Hauy, iii. 475.

Exter. Char.—Rarely massive, commonly disseminated, superficial, or crystallized in six-sided prisms; in four-sided prisms; in double crystals, composed of two four-sided prisms; in oblique four-sided prisms, and in double six-sided praymids. These are variously modified by truncations and acuminations on the edges and angles. They are also of various sizes, and variously grouped together : surface usually smooth, resplendent, sometimes rough or streaked; lustre shining, adamantine; fragments conchoidal, splintery, or fibrous.

Colour white, yellowish, or grayish white; transparent or translucent; refraction double. Specific gravity 6.48 to 7.23.

Chem. Char.—Decrepitates before the blow-pipe, becomes yellowish or reddish, and melts into a metallic globule; effervesces strongly with acids.

Constituent Parts.

	Klaproth.	Macquart
Oxide of lead,	82	. 73
Carbonic acid,	16	24
Water,	2	3
	i the second	- Episonete
	IOO	100

Some carbonates of lead, are also combined with a small portion of iron and earthy matters.

Localities, &c.—Found in veins, accompanied by galena and other lead ores, in Germany, France, and Britain.

6. Species. GREEN LEAD ORE, or Phosphate of Lead.

Plomb Phosphaté, Hauy, iii. 490. Id. Broch. ii. 314. Phosphorated Lead Ore, Kirw. ii. 207.

Exter. Char.—Massive or disseminated, botryoidal or reniform, and often crystallized in six-sided prisms, truncated on all the edges, or on the terminal edges, or terminated by a six-sided pyramid; in six-sided prisms with the lateral faces converging towards one of the extremities; and in six-sided pyramids; but this last is rare. Surface smooth, shining; internal lustre weakly shining and resinous; fracture uneven.

Colour olive green, emerald green, yellow or brown; grayish, greenish, or yellowish white; translu-

cent, or only at the edges; streak greenish white; Classifica brittle. Spec. grav. 6.909 to 6.941. tion.

Chem. Char.—Melts easily before the blow-pipe, into a grayish polyhedral globule, but without being reduced; soluble in acids, without effervescence, but sometimes with difficulty.

Gonstituent Par	ts. K	laproth.
Oxide of lead,	77.10	80.

Muriatic acid,	1.54	1.62
Oxide of iron,	.10	
Loss,	2.26	,38
	100.00	100.00

Localities, &c.-Found in veins along with other lead ores, and generally near the top of the vein, in Germany, France, and Leadhills in Scotland.

7. Species. RED LEAD ORE, or Chromate of Lead.

Id. Broch. ii. 318. Red Lead Spar, Kirw. ii. 214.

Exter. Char.—Rarely massive, sometimes disseminated or superficial, but most frequently crystallized in oblique four-sided prisms with the extremity bevelled, or the lateral edges truncated; and in six-sided prisms, with two broad and two narrow faces; lateral faces longitudinally streaked; external surface smooth, shining; fracture even.

Colour aurora red, or hyacinth red; translucent or semitransparent; streak orange yellow; soft; brittle. Spec. grav. 5.75 to 6.02.

Chem. Char.-No effervescence with acids; decrepitates a little before the blow-pipe, and melts into a black slag.

Vauquelin.
64
.36

Localities, &c.—Found in veins at Beresof in Siberia, accompanied by other ores of lead, some ores of iron, and native gold.

A similar ore of lead, but of a brown colour, was brought from Mexico by Humboldt.

8. Species. YELLOW LEAD ORE, or Molybdate of Lead.

Id: Broch. ii. 322. Yellow Lead Spar, Kirw. ii. 212. Hauy, iii. 498.

Exter. Char.—Rarely massive, usually crystallized in rectangular four-sided tables; in perfect cubes, with plane or convex faces, or truncated on the terminal faces, in obtuse octahedrons, truncated on the summit, the lateral angles, or lateral edges. Crystals small; surface smooth and shining; internally shining; lustre waxy; fracture conchoidal.

Colour wax yellow, or honey yellow; translucent, or only at the edges; soft; brittle. Spec. grav. 5.48 to 5.7 *Chem.*

Chem. Char .- Before the blow-pipe it decrepitates lassificastrongly, and then melts into a blackish-gray globule, in which are seen particles of lcad. Soluble in nitric acid, and in fixed alkalies.

Constituent Parts.

Oxide of lcad, Molybdic acid, Oxide of iron, Silica, Carbonate of lime, Loss,	Macquart. 63.5 28. - 4. 4.5	Hatchett. 58.4 38. 2.1 .28	
1.10SS,	100.0	1.22	

Localities, &c .- This ore of lead was first discovered at Bleyberg in Carinthia; it has been since found in Saxony and France.

9. Species. NATIVE SULPHATE of LEAD.

Id. Kirw. ii. 211. Broch. ii. 325. Hauy, iii. 503.

Exter. Char.-Crystallized in irregular octahedrons, which are variously truncated and bevelled. Crystals smooth and shining ; lustre shining and vitreous ; fracture compact.

Colour snow white, grayish or yellowish white; translucent; semihard. Spec. grav. 6.3.

Chem. Char .- Reduced even in the flame of a candle ; insoluble in nitric acid.

> Constituent Parts. Klaproth. Oxide of lead, 70.5 Sulphuric acid, 25.75 Water, 2.25 Loss, 1.5

100.00

Localities, &c .- Found on brown iron ore in the island of Anglesea, and on galcna in the veins at Leadhills and Wanlockhead in Scotland.

10. Species. EARTHY LEAD ORE.

Id. Broch. ii. 327. Id. Kirwan, ii. 105.

This is divided into two subspecies: 1. friable; and, 2. indurated.

Subspecies I. FRIABLE LEAD ORE.

Exter. Char .- This is composed of fine earthy particles, which are dull, and have little coherence.

Colour sulphur or ochre yellow, yellowish or smoke gray; stains; fcels meagre.

Subspecies 2. INDURATED LEAD ORE.

Exter. Char .- Massive or disseminated ; dull ; fracture uneven or earthy.

Colour of the former; opaque; streak lighter colour; very soft and friable.

Chem. Char .- Easily reduced before the blow-pipe, into a black slag; effervesces a little with acids.

Constituent Parts .- Earthy lead ore is supposed to

be a mixture of oxide of lead, with a little oxide of Metallic iron, and some earthy matters. Ores.

Localities, &c .- Found on the surface, or in the cavities of other lead ores, in Saxony, France, Siberia, and at Leadhills and Wanlockhead in Scotland.

II. Species. MURIATE of LEAD.

Exter. Char.-Massive, or crystallized in cubes, or flat six-sided prisms ; external surface shining ; internal lustre resplendent, adamantine ; fracture foliated.

Colour between asparagus green and winc ycllow; semitransparent; soft; not brittle; streak dull, white.

M

Constituent Parts.	Klaproth.
Oxide of lead, Muriatic acid,	55 45
	IOO

Localities, &c .- Found in Derbyshire, and also, it is said, in the mountains of Bavaria, but not crystallized.

12. Species. MURIO-CARBONATE of LEAD.

Id. Bournon and Chenevix, Nich. Jour. 4to. p. 219.

Exter. Char .- Crystallized in cubes, which are variously modified; Instre shining, adamantine; fracture foliated ; cross fracture conchoidal.

Colour straw yellow, or clear white; semitransparent; streak dull, snow white; easily scratched by . carbonate of lead. Spec. grav. 6.065.

Constituent Parts. Chenevix.

Oxide of lead, Muriatic acid,	51 8 } M	Iuriate of lead,	59
Oxide of lead, Carbonic acid,	³⁴ ₆ }c	arbonate of lead,	40
LIOSS,	I	1	I
	100		DOI

Localities, &c .- Found in Derbyshire.

13. Species. ARSENIATE of LEAD.

Id. Broch. ii. 546.

Exter. Char.-Disseminated sometimes in an earthy state, sometimes in silky filaments, and crystallized in small, double, six-sided pyramids. Dull, or weakly glimmering; lustre silky.

Colour citron or greenish yellow; very soft; friable: Chem. Char .- Before the blow-pipe is melts easily into a globule of lead, and gives out the smell of gar-

Const. Parts .- Composed of oxide of lead and of arsenic, with some oxide of iron and earthy matters.

VIII. TIN GENUS.

I. Species. TIN PYRITES.

Id. Kirw. ii. 200. Id. Broch. ii. 332.

Exter. Char .- Found-massive or disseminated; lustre shining

tion.

Metallio shining or weakly shining; fracture uneven; fragments Ores rather blunt-edged.

Colour steel gray, sometimes brass or bronze yellow; semihard; brittle. Spec. grav. 4.3 to 4.7.

Chem. Char.-Before the blow-pipe it melts easily into a black slag, but without being reduced, and gives out a sulphureous smell.

Constituent Parts.Klaproth.Tin,34Copper,36Iron,3Sulphur,25Earthy substances,2

100

Localities, &c.-This is a rare mineral, found only in Cornwall, in a vein along with copper pyrites.

2. Species. COMMON TINSTONE, or Oxide of Tin.

Id. Kirw. ii. 197. Id. Broch. ii. 334. Hauy, iv. 137.

Exter. Char.—Massive, disseminated, in rounded pieces or grains, and often crystallized in rectangular four-sided prisms, which are variously modified by truncations and bevelments; in octahedrons, which are rare; in eight-sided prisms, or in double octahedrons, which are so united by one of their summits as to form a re-entering angle. Crystals of various sizes, always grouped together; surface smooth; lustre shining or resplendent; internal lustre shining, between vitreous and resinous; fracture uneven.

Colour brownish black, blackish brown, yellowish gray, or grayish white; opaque, or semitransparent; streak light gray; hard; brittle. Specific gravity 6.3 to 6.9.

Chem. Char.—Before the blow-pipe it decrepitates, loses its colour, and is partially reduced to the metallic state.

> Constituent Parts. Klaproth. Tin, 77.5 Iron, .25 Oxygen, 21.5

119	
ygen,	21.5
ica,	.75

Localities, &c.—Found in Germany, in the East Indies, and particularly in Cornwall in England. It is not very universally distributed; but where it exists, it is deposited in granite, gneiss, micaceous schistus, and porphyry; and either in masses, veins, or disseminated in the rocks.

3. Species. GRAINED TIN ORE, or Wood Tin.

Id. Broch. ii. 340. Id. Kirw. ii. 298.

Exter. Char.—Found only in small pieces, rounded or angular; surface rough; weakly shining; internal lustre glimmering; a little silky; fracture fibrous; fragments wedge-shaped.

Colour hair brown of various shades ; streak yellowish gray; hard and brittle. Spec. grav. 5.8 to 6.4.

Chem. Char.-Becomes brownish red before the Classific, blow-pipe, then decrepitates strongly, but is infusible.

Const. Parts.—According to Klaproth, it is composed of 63 of tin in the 100, with a little iron and arsenic.

Localities, &c.-Found in Cornwall, in alluvial land, where it seems to have been deposited in a stalactitical form, accompanied by common tin.

IX. BISMUTH GENUS.

I. Species. NATIVE BISMUTH.

Id. Kirw. ii. 264. Id. Broch. ii. 343. Id. Hauy, iv. 184.

 $E \propto ter$. Char.—Rarely massive, but usually disseminated in a plumose or reticulated form, and rarely crystallized, in small four sided tables or cubes; lustre shining or resplendent; frac ure foliated.

Colour silvery white, inclining to red; colours commonly tarnished; soft; almost ductile. Specific gravity 9.02 to 9.82.

Chem. Char.—Fusible almost in the flame of a candle; by increasing the heat it is volatilized; soluble with effervescence in nitric acid, and precipitated by water in the form of a white powder.

Localities, &c.—Bismuth is a rare metal, found in veins in primitive mountains, accompanied by calcareous spar, heavy spar, and quartz, and commonly with gray cobalt, sometimes also with black blende and native silver. Found in Saxony, Bohemia, France, and Sweden.

2. Species. VITREOUS BISMUTH ORE.

Sulphurated Bismuth, Kirwan, ii. 266. Id. Brochant, ii. 346.

Exter. Char.—Massive or disseminated, rarely crystallized in small imbedded capillary prisms; lustre shining or resplendent; fracture radiated or foliated.

Colour between lead gray and tin white; stains a little; soft; easily frangible. Specific gravity 6.13 to 6.46.

Chem. Char.—Easily fusible before the blow-pipe, with a sulphureous odour.

Const. Parts.-Composed of bismuth about 60 per cent. and sulphur with a little iron.

Localities, &c.-Found in Bohemia, Saxony, and Sweden, and is usually accompanied by native bismuth.

3. Species. OCHRE OF BISMUTH.

Id. Kirwan, ii. 265. Id. Brochant, ii. 348.

Exter. Char.—Rarely massive, commonly disseminated on the surface of other minerals; internally glimmering; fracture uneven or earthy.

Colour yellowish gray, ash gray, or straw yellow, opaque; soft; sometimes even friable. Spec. grav. 4.37.

Chem Char.--Very easily reduced before the blowpipe to the metallic state; effervesces with acids.

Localities, &c.—This mineral is very rare, and chiefly found near Schneeberg in Saxony, along with native bismuth; and also in Bohemia and Suabia.

X. ZINC GENUS.

I. Species. BLENDE.

Id. Brochant, ii. 350. Id. Kirwan, ii. 237. Zinc Sulfuré, Hauy, iv. 167.

This species is divided into three subspecies ; yellow, brown, and black.

Subspecies 1. YELLOW BLENDE.

Exter. Char.—Massive or disseminated, or sometimes crystallized in cubes or octahedrons, but they are so confused as to prevent the form being easily discovered. Surface smooth, resplendent; internal lustre resplendent, between adamantine and vitreous; fracture foliated; cleavage six-fold; fragments rather sharp-edged, or assume sometimes a dodecahedral form, which is the result of the complete cleavage.

Colour dark sulphur yellow, olive green, or brownish red; translucent, sometimes semitransparent; streak yellowish gray; semi-hard; brittle. Spec. grav. 4.04 to 4.16.

Chem. Char.-Decrepitates before the blow-pipe, and bccomes gray, but is infusible.

100

de.

Physical Char.-Most of the varieties of yellow blende become phosphorescent by friction in the dark. Localities, &c.-Found in Saxony, Bohemia, Hungary and Norway, accompanied by lead, copper, and iron ores. It is rather a rare mineral.

Subspecies 2. BROWN BLENDE.

Exter. Char.—Massive, disseminated, and sometimes crystallized in simple three-sided pyramids, octahedrons, and four-sided prisms, which are variously modified. External lustre shining or resplendent; surface sometimes drusy; internal lustre shining, between vitreous and resinous; fracture foliated; cleavage sixfold.

Colour reddish, or yellowish brown; colour sometimes tarnished; translucent, or opaque; crystals trans-Vol. XIV. Part I. parent; streak yellowish gray; semi-hard; brittle. Metallic Spec. grav. 4. Ores.

Constituent Parts.	Bergman.
Zinc,	44
Sulphur,	17
Iron,	5
Silica,	24
Alumina,	5
Water,	5
	100

Localities, &c.-Very common in veins of lead ore, in most parts of the world.

Subspecies 3. BLACK BLENDE.

Exter. Char.—Massive, or disseminated, or crystallized like the former, which it resembles in most of its characters.

Colour perfect black, brownish black, or blood red; often iridescent.

Constituent Parts.	Bergman.
Zinc, Sulphur	45
Iron,	29 9
Lead, Silica,	6
Water, Arsenic	6
Tarbonne,	

Localities, &c.-Found in the same places with the former.

2. Species. CALAMINE.

This is divided into two subspecies, compact and foliated.

Subspecies 1. COMPACT CALAMINE.

Id. Kirwan, ii. 234. Id. Brochant, ii. 361.

Exter. Char. - Massive or disseminated, cellular, or stalactitical; dnll; fracture compact or earthy.

Colour grayish white, yellowish, or reddish, or milk white; opaque; semi-hard or friable; brittle; stains sometimes. Spec. grav. 3.52, to 4.1.

Chem. Char.—Decrepitates before the blow-pipe when suddenly heated; is infusible. Forms a jelly with acids, and sometimes effervesces.

Constituent Parts.

Oxide of zinc, Silica, Iron, Alumina, Water, Loss,	Bergman. 84 12 3 1	Tennant. 68.3 25 - 4.4. 2.3

Another variety examined by the same chemist contained,

Oxide of zinc,	71.4
Carbonic acid,	13.5
Water,	15.1
	100.0

From these analyses it appears, that calamines are very different in their composition, consisting sometimes of oxide of zinc, silica, and water, and this variety forms a jelly with acids; others are composed of carbonic acid and oxide of zinc, which effervesce in sulpluric acid, but do not form a jelly; a third variety is composed of oxide of zinc, carbonic acid, and water, constituting a hydro-carbonate of zinc, which is soluble with effervescence in sulphuric acid.

Localities, &c.-Usually accompanied with iron ochre, and very often with galena, white lead, and other metallic ores. Found in Bohemia, Bavaria, France, and Britain, in some places in considerable abundance.

Subspecies 2. FOLIATED CALAMINE.

Id. Brochant, ii. 364. Kirwan, ii. 236. Hauy, iv. 161.

Exter. Char.—Found massive or disseminated, stalactitical, incrusted, or crystallized, in small four-sided tables, or in very small cubes with plane or convex faces, shining, or glimmering; lustre between pearly and vitreous; fracture radiated.

Colour yellowish, or smoke gray; grayish, or yellowish white; translucent or semitransparent; semihard; brittle. Specific gravity 3.52.

Chem. Char.-Becomes white before the blow-pipe, but is infusible, and does not effervesce with acids.

Phys. Char.-Becomes electric by heat.

Localities, &c.—This variety accompanies the former, lining its cavities, but is less common. It is found in the same places.

XI. ANTIMONY GENUS.

1. Species. NATIVE ANTIMONY.

Id. Brochant, ii. 369. Id. Kirwan, ii. 245. Id. Hauy, iv. 252.

Exter. Char.-Found massive, disseminated, or reniform; resplendent; fracture foliated.

Colour tin white; but exposed to the air, grayish or yellowish; soft; easily frangible. Spec. grav. 6.7.

Chem. Char.—Before the blow-pipe it is very easily fusible into a metallic globule, which gives out fumes with the odour of garlic.

Const. Parts.—Native antimony sometimes contains a small proportion of arsenic.

Localities, &c.-Has only been found in two places: at Sahlberg in Sweden, where it was discovered in

1748, in limestone; and at Allemont in France, where Classific it is accompanied by other ores of antimony and cobalt.

2. Species. GRAY ORE OF ANTIMONY.

Id. Brochant, ii. 371. Kirwan, ii. 246. Hany, iv. 64.

This is divided into four subspecies; compact, foliated, radiated, and plumosc.

Subspecies 1. COMPACT GRAY ORE OF ANTIMONY.

Exter. Char.-Massive or disseminated; shining; fracture uneven.

Colour lead gray, or steel gray; soft; not very brittle; stains a little; streak shining. Spec. grav. 4.36.

Localities, &c.-This variety is rarer than the others, but is met with in Saxony, Hungary, and France.

Subspecies 2. FOLIATED ORE OF ANTIMONY.

Exter. Char.—Massive or disseminated; fracture foliated. In other characters it resembles the other varieties, and is usually accompanied by the following.

Subspecies 3. RADIATED ORE OF ANTIMONY.

 $E \propto ter.$ Char.—Massive, disseminated, and very often crystallized in acicular, often in capillary crystals, and in six and four-sided prisms variously modified; surface streaked longitudinally; internal lustre resplendent; fracture radiated, straight, parallel, or divergent.

Colour similar to the preceding; soft; not very brittle. Spec. grav. 4.1 to 4.5.

Constituent Parts.	Bergman.
Antimony, Sulphur,	74 26
	100

Localities, &c.—This is the most common ore of antimony, and is found in Germany, France, and Sweden. There is only one mine of antimony in Britain, which is in the south of Scotland, near Westerhall, in the neighbourhood of Langholm.

Subspecies 4. PLUMOSE ORE OF ANTIMONY.

Exter. Char.—Usually found in capillary crystals, so interwoven, that they form a superficial covering to other minerals: these groups are externally weakly shining; internal lustre glimmering; fracture fibrous.

Colour similar to the former, and sometimes tarnished brown or like tempered steel; opaque; soft; sometimes almost friable; brittle.

Const. Parts.—Plumose antimony is composed of suphuret of antimony combined with arsenic, iron, and accidentally a little silver.

Chem. Char.—Before the blow-pipe this and the other varieties of gray antimony give out white fumes, with a sulphureous smell, and are almost entirely volatilized, or changed into a black slag.

Localities, &c.-Plumose antimony is found at Freyberg in Saxony, in the Hartz, and in Hungary.

3. Species.

Part

3. Species. BLACK ORE OF ANTIMONY.

Exter. Char.—Found crystallized in rectangular four-sided tables, truncated on the edges or angles; crystals smooth; lustre sluning; fracture conchoidal.

Colour iron black ; soft.

Localitics, &c.—This species, which is also a sulphuret of antimony, combined probably with some other ingredients, is found in Cornwall.

4. Species. RED ORE OF ANTIMONY.

Id. Kirwan, ii. 250. Id. Brochant, ii. 379. Antimoine Hydrosulfure, iv. 276.

Exter. Char.—Massive or disseminated, but most commonly in capillary crystals; lustre weakly shining, vitreous; fracture fibrous.

Colour cherry red, brown, reddish, or bluish; soft, almost friable; brittle. Specific gravity 3.7 to 4.

Chem. Char.-Before the blow-pipe it melts easily, and in nitric acid a white powder is deposited.

Constituent Parts. Klaproth.

Oxide of antimony,	78.3
Sulphur,	19.7
Loss,	2.
	-

100.0

Localities, &c.-Found in Saxony and France, usually accompanying gray or native antimony.

5. Species. WHITE ORE OF ANTIMONY.

Muriated Antimony, Kirwan, ii. 151. Antimoine Oxidé, Hauy, iv. 273.

Exter. Char.—Rarely massive, usually superficial, in divergent fibres, or crystallized in rectangular foursided tables, cubes, or four-sided prisms. Crystals aggregated; smooth; streaked longitudinally; resplendent; internal lustre shining, between adamantine and pearly; fracture foliated.

Colour snow white, yellowish white, or grayish; translucent; soft; brittle.

Chem. Char.-Crystals decrepitate before the blowpipe, but in powder is easily fusible.

Const. Parts.—Was formerly supposed to be a muriate of antimony, but according to Klaproth, it is a pure oxide. The white ore of France, according to Vauquelin, contains,

Oxide of antimony,	86
Silica	30
Loss,	3
	100

6. Species. OCHRE OF ANTIMONY.

Id. Brochant, ii. 383. Id. Kirwan, ii. 252.

Exter. Char.-Massive, disseminated, or in superficial crusts, on gray antimony; dull; fracture earthy.

Colour straw yellow, or yellowish gray; soft; friable. Chem. Char.—Infusible before the blow-pipe; becomes white, and cmits white fumes. Its constituents are unknown.

Localities, &c.—In Saxony and Hungary, accompanying gray and red antimony, and in the antimony mine near Westerhall, in the south of Scotland.

XII. COBALT GENUS.

I. Species. WHITE COBALT ORE.

Id. Kirw. ii. 382. Id. Broch. ii. 386.

Exter. Char.—Massive, disseminated, reniform, and rarely crystallized in small four-sided tables, or in small cubes or octahedrons. Lustre weakly shining, or shining; fracture uneven.

Colour tin white, but on the surface variable, and tarnished; streak shining; hard; brittle.

Chem. Char.—Easily fusible before the blow-pipe, emitting a dense vapour, with a smell of arsenic, and leaves a white metallic globule; colours borax-blue. Localities, &c.—Found in Norway, Sweden, and

Localities, &c.—Found in Norway, Sweden, and Saxony, in bcds of micaceous schistus, along with red cobalt ore, quartz, and hornblende. Its composition is not known, but supposed to be alloyed with some other metals.

2. Species. GRAY COBALT ORE.

Id. Kirw. ii. 271. Id. Broch. ii. 388.

Exter. Char.-Massive, disseminated, reniform, and botryoidal ; lustre shining ; fracture even.

Colour light steel gray, or tin white; surface steel tarnished; streak shining; semi-hard; brittle.

Chem. Char.—Infusible before the blow-pipe; emitting fumes and the smell of arsenic.

onstituent Parts.	Klaproth.	
Cobalt,	20	
Arsenic,	33	
Iron,	24`	
Loss,	23	
	-	

100

It contains also sometimes nickel and silver. Localities, &c.-Found in Saxony, France, Norway, and Cornwall in England, with other ores of cobalt.

3. Species. SHINING COBALT ORE.

Id. Broch. ii. 390. Kirw. ii. 273.

Exter. Char.—Massive, disseminated, superficial, in various imitative forms, and crystallized in cubes and octahedrons, which are variously modified; crystals small, smooth, and resplendent, rarely drusy; lustre shining; fracture uneven, radiated, or fibrous.

Colour tin white, commonly grayish, or yellowish tarnished; hard; brittle. Spec. grav. 6.3 to 6.4. *Chem. Char.*—Before the blow-pipe it burns with a

Chem. Char.—Before the blow-pipe it burns with a small white flame, and a white vapour, smelling strongly of garlic; then blackens, and is almost infusible; soluble in nitric acid.

243 Metallic Ores. 244 Metallic

Ores.

Localities, &c.—This is the most common orc of cobalt; and it is usually accompanied by the other ores, and sometimes also by vitreous, red, and native silver. It is found in Bohemia, Saxony, Sweden, and Cornwall in England, and usually in beds in primitive

mountains.

Uses.—This ore of cobalt is commonly wrought for the purpose of employing it in the preparation of the fine blue colour known by the name of *smalt*, which is used in the manufacture of porcelain, glass, and as a pigment.

4. Species. BLACK COBALT OCHRE.

Id. Broch. ii. 396. Kirw. ii. 275. Hauy, iv. 214.

This is divided into two subspecies, friable and indurated.

Subspecies 1. FRIABLE COBALT OCHRE.

Exter. Char.-Composed of particles which are more or less cohering; stains a little.

Colour brownish, bluish, or grayish black; streak shining; feels meagre. In other characters it agrees with the following.

Subspecies 2. INDURATED COBALT OCHRE.

Exter. Char.—Massive, disseminated, in imitative forms, or marked with impressions; dull, or weakly glimmering; fracture earthy.

Colour bluish black; streak shining, resinous; soft; semihard; rather brittle. Spec. grav. 2.01 to 2.42.

Chem. Char.-Before the blow-pipe it gives out an arsenical odour, but is infusible.

Its constituent parts are supposed to be oxide of cobalt, with some iron and arsenic.

Localities, &c.- Both varieties are found together, and accompanied by ores of silver, copper, iron, in Saxony, Suabia, and the Tyrol, as well as in France and Spain.

5. Species. BROWN COBALT OCHRE.

Id. Broch. ii. 400.

Exter. Char.—Massive, or disseminated; always dull; fracture carthy; streak shining, resinous.

Colour light or dark liver brown; soft, almost friable; very casily frangible.

Constituent Parts.-Supposed to be composed of oxide of cobalt and iron.

Localities, &c.-Found at Saalfeld in Thuringia, in stratiform mountains, and in Wirtemberg, in primitive mountains, accompanied by other varieties of cobalt ochre.

6. Species. YELLOW COBALT OCHRE.

Id. Kirw. ii. 277. Broch. ii. 401.

Exter. Char.—Massive, or disseminated, or adhering to the surfaces of other minerals; dull; fracture earthy; streak shining, resinous.

Colour dirty straw yellow, or yellowish gray; very soft or friable.

Chem. Char.—Before the blow-pipe it gives out an odour of arsenic, and is infusible.

Its constituents are supposed to be oxide of cobalt, Classific and a little arsenic.

Localities, &c.-Found in the same places with the former, but is rare.

7. Species. RED COBALT OCHRE, or Arseniate of Cobalt.

Id. Kirw. ii. 278. Broch. ii. Cobalt Arseniaté, Hauy, iv. 216.

This is divided into two subspecies; earthy and radiated.

Subspecies I. EARTHY RED COBALT OCHRE.

Exter. Char.—In thin superficial layers, or crusts; dull, or weakly glimmering; fracture earthy.

Colour peach-blossom red, rose rcd, or rcddish white; streak a little shining; very soft, friable.

Localities, &c.-Found in Bohemia, Saxony, France, and Norway.

Subspecies 2. RADIATED RED COBALT OCHRE, or Cobalt Bloom, or Flowers of Cobalt.

Exter. Char.—Massive, or disseminated, rarely botryoidal or reniform; often superficial, and in small drusy crystals, whose forms are rectangular four-sided tables, four-sided prisms, double six-sided pyramids, with different modifications. Crystals small and variously aggregated, smooth and shining, sometimes resplendent; fracture radiated; fragments wedge-shaped, or splintery.

Colour peach blossom red, crimson red, or, exposed to the air, brownish, grayish, or whitish; traaslucent; crystals semitransparent; soft; brittle.

Chem. Char.—Before the blow-pipe becomes blackish gray, giving out a feeble odour of arsenic, without any fumes, but is infusible. Colours borax a fine blue.

This species has not been particularly analysed, but is considered as a compound of cobalt and arsenic acid.

Localities, &c.—The same as the former, and also in Cornwall in England, and along with copper ores at Alva in Scotland.

8. Species. SULPHATE OF COBALT.

A saline substance in a stalactitical form, of a pale rose red colour and translucent, is found at Herrengrund near Newsohl in Hungary, which was at first supposed to be a sulphate of manganese, and alterwards a sulphate of cobalt.

This substance has been examined by Klaproth, who dissolved it in water, added an alkali, and obtained a bluish precipitate, which coloured borax of a beautiful sapphire blue; and with muriatic acid he obtained from it a sympathetic ink.

XIII. NICKEL GENUS.

I. Species. COPPER COLOURED NICKEL.

Id. Brochant, ii. 408. Sulphurated Nickel, Kirw. ii. 286. Nickel Arsenical, Hauy, iii. 518. Kupfernickel of the Germans.

Exter. Char.-Massive or disseminated, rarely reticulated; art I.

tion.

ssifica- lated; shining, or weakly shining; fracture uneven, sometimes eonehoidal; fragments rather sharp-edged. Colour pale copper red, whitish, or grayish ; semihard; brittle. Spee. grav. 6.64 to 7.56.

Chem. Char .- Before the blow-pipe it gives out the fumes and odour of arsenic ; melts with difficulty into a slag, mixed with metallic particles. Solution in acids, green.

Constituent Parts.	Sage.	
Nickel,	75	
Arsenic,	22	
Sulphur,	2	
Loss,	I	
	-	
	100	

Localities, &c.-Found in veins, in primitive and stratiform mountains, almost always accompanied with ores of cohalt, and often with rich silver orcs. It is found in Bohemia, Saxony, France, Spain, and Cornwall in England.

2. Speeies. NICKEL OCHRE, or Oxide of Nickel.

Id. Kirw. ii. 283. Broeh. ii. 411. Hauy, iii. 516.

Exter. Char .--- Usually disseminated and efflorescent on other minerals ; composed of friable, loose, and slightly agglutinated particles.

Colour apple-green of different shades ; stains ; feels meagre.

Chem. Char .-- Remains unchanged before the blowpipe; colours borax yellowish red, and is insoluble in. nitric aeid.

Constituent Parts.	Lampadius.
Oxide of nickel,	67.
iron,	23.2

Localities, & e .- Found in similar situations with the preceding species.

XIV. MANGANESE GENUS.

- 1. Species. GRAY ORE OF MANGANESE, or Oxide of Manganese.
- Id. Brochant, ii. 414. Id. Kirwan, ii. 291. Id. Hauy, iv. 243.

This species is divided into four subspecies : 1. radiated; 2. foliated; 3. compact; and, 4. earthy.

Subspecies 1. RADIATED GRAY ORE OF MANGANESE.

Essen. Char .- Colours borax violet.

Exter. Char .- Massive or disseminated, or erystallized in oblique four-sided prisms, or in acicular prisms fascicularly grouped together; the crystals are variously modified. Faces streaked longitudinally; shining or resplendent; fracture radiated; fragments wedge-shaped.

Colour steel gray, or iron black ; streak black, with- Metallic out lustre; stains; soft; brittle. Specific gravity 3.7 Ores. to 4.7.

Loss,	.5	.25
· By	100.0	100.00

Subspecies 2. FOLIATED GRAY ORE OF MANGANESE.

Exter. Char .- Found massive, disseminated, or erystallized in small, rectangular, four-sided tables, faseicularly grouped; lustre shining; fracture foliated.

Colour similar to the former ; streak black and dull ; stains; soft, and brittle. Spec. grav. 3.74.

Subspecies 3. COMPACT GRAY ORE OF MANGANESE.

Exter. Char .- Massive or disseminated, in angular, or botryoidal, or dendritical forms ; lustre glimmering; fracture uneven, sometimes even or conchoidal.

Colour steel gray, or bluish black ; stains ; semihard, or soft; brittle.

Const. Parts-approach pretty nearly to those of the radiated variety.

Subspecies 4. EARTHY GRAY ORE OF MANGANESE.

Exter. Char.-Found massive, disseminated, sometimes superficial and dendritical; dull; sometimes a little glimmering ; fracture earthy.

Colour between steel gray and bluish black ; stains very much; very soft, often even friable; feels meagre.

Constituent Parts-supposed to be the same as the former, but with a larger proportion of oxide of iron.

Chem. Char.-Gray ore of manganese is infusible before the blow-pipe, but becomes of a blackish brown colour; gives a blue colour to borax.

Localities, &c .- All the varieties of this species are usually found together, and chiefly in primitive mountains. The earthy ore of manganese almost always accompanies sparry iron ore, and other ores of iron. Manganese is found in considerable abundance in Saxony, Bohemia, France, near Exeter in England, and in Aberdeenshire in Scotland.

2. Species. BLACK ORE OF MANGANESE.

Exter. Char .- Found massive, disseminated, or crystallized in small four-sided double pyramids, arranged in Metallic in rows; surface shining; internal lustre weakly glim-Ores mering; fracture imperfectly foliated.

Colour grayish black, and brownish black; streak dull, brownish red; soft; brittle.

Localities, &c.—This species is of rare occurrence. It has been found in Thuringia, forming a crust on gray ore of manganese, and also, it is said, in Piedmont.

3. Species. RED ORE OF MANGANESE, or Carbonate of Manganese.

Exter. Char.—Massive, disseminated, botryoidal, &c. or crystallized in flat rhomboids, or in very small pyramids or lenses. Surface of the crystals smooth; dull, or weakly glimmering; fracture uneven or splintery.

Colour rose red, or brownish white; translucent at the edges; semihard; brittle. Spec. grav. 3.23.

Chem. Char.-Infusible before the blow-pipe; becomes grayish black, and colours borax violet blue, or crimson red.

Constituent Parts.	Lampadius.
Oxide of manganese,	48
iron,	2.1
Carbonic acid,	49
-Silica,	.9
	100.0

Localities, &c.—This species of manganese, which is rare, is found in Transylvania at Offenbanya, and particularly at Nagyag, where it constitutes part of the masses of an auriferous vein, from which the gold ore of Nagyag is obtained.

XV. MOLYBDENA GENUS.

1. Species. SULPHURET OF MOLYBDENA.

Id. Brochant, ii. 432. Id. Kirwan, ii. 322. Id. Hauy, iv. 289.

Exter. Char.—Massive or disseminated, sometimes in plates, and rarely crystallized in equal six-sided tables; crystals small, imbedded, the lateral faces shining; internal lustre shining; fracture foliated; fragments rather blunt-edged, sometimes in plates.

Colour lead gray; opaque; stains, and writes; very soft, and easily frangible; flexible in thin plates, but not elastic; feels greasy. Spec. grav. 4.56 to 4.73.

Chem. Char.—Infusible before the blow-pipe; gives out a sulphureous smell; nitric acid converts it to a white oxide, which is the molybdic acid.

Constituent Parts.

Molybdic acid, Sulphur,	Pelletier. 45 55	Klaproth. 60 40
	100	100

Localities, &c.—Always found in primitive mountains, in nests or nodules, and very commonly in the neighbourhood of tin ores. It is also accompanied by wolfram, quartz, native arsenic, and fluor spar. It is

found in Bohemia, Saxony, Sweden, France, and Eng- Classifiand.

XVI. ARSENIC GENUS.

I. Species. NATIVE ARSENIC.

Id. Broch. ii. 435. Id. Kirw. ii. 255. Id. Hauy, iv. 220.

Exter. Char.—Massive, disseminated, in imitative forms, or with impressions; surface rough or granulated; dull, or weakly glimmering; internal lustre weakly shining; fracture uneven, sometimes imperfectly foliated; fragments rather blunt-edged in plates.

Colour light lead gray, tin-white or grayish black when tarnished; streak shining; semihard; very easily frangible. Spec. grav. 5.72 to 5.76.

frangible. Spec. grav. 5.72 to 5.76. Chem. Char.—Melts readily before the blow-pipe, giving out white vapour, with the smell of garlic; then burns with a bluish flame, and is dissipated, leaving only a whitish powder, which is the oxide of arsenic.

Constituent Parts.—Native arsenic is usually alloyed with a small portion of iron, and sometimes also with a little gold or silver.

Localities, &c.—Found in veins in primitive mountains, accompanied by ores of silver, lead, copper, quartz, and earthy spars, in Bohemia, Saxony, and France.

2. Species. ARSENICAL PYRITES.

Id. Broch. ii. 438. Id. Kirw. ii. 256. Fer Arsenical, Hauy, iv. 56.

This is divided into two subspecies, common and argentiferous.

Subspecies 1. COMMON ARSENICAL PYRITES.

Exter. Char.—Massive, disseminated, often crystallized in oblique four-sided prisms, acute octabedrons, and lenses; the prisms being variously modified on their angles, faces, and extremities. Crystals small; lateral faces smooth, shining; bevelled faces streaked transversely; lustre shining; fracture uneven.

Colour silvery white, but usually tarnished yellow, or bluish, and iridescent; hard; brittle. Specific gravity 5.75 to 6.52.

ty 5.75 to 6.52. Phys. Char.—By friction gives out the odour of garlic.

Chem. Char.—Before the blow-pipe gives out a white vapour with the odour of arsenic, the fumes depositing a white powder on cold bodies; a reddish brown matter, which is infusible, remains.

Constituent Parts.-Composed of arsenic, iron, and sulphur.

Subspecies 2. ARGENTIFEROUS ARSENICAL PYRITES.

Exter. Char.—Rarely massive, often disseminated, and crystallized in small, acicular, four-sided prisms; lustre shining, or weakly shining; fracture uneven.

Colour tin-white, or silvery-white, usually tarnished.

Localities, &c.—Arsenical pyrites is found in Bohemia, Saxony, and Silesia, in veins of primitive mountains, or disseminated in the rocks.

The second variety is found in similar places, and differs only from the first, in being combined with a small quantity of silver, which varies from 1 to 10 per cent. 3. Species.

246

Part

3. Species. ORPIMENT.

Id. Kir. ii. 260. Id. Broch. ii. 444. Hauy, iv. 234.

This species is divided into two subspecies, yellow and red.

Subspecies I. YELLOW ORPIMENT.

Exter. Char.-Massive, disseminated, superficial, and crystallized in oblique four-sided prisms, bevelled at the extremity, or terminated by a four-sided pyramid, or in acute octahedrons. Crystals small, and confusedly aggregated; surface smooth; that of the bevelment and pyramids finely streaked; internal lustre resplendent, between resinous and adamantine ; fracture foliated; fragments in plates.

Colour citron-yellow, golden-yellow, or aurora-red; translucent; in thin plates, semitransparent; soft; flexible in thin plates. Spec. grav. 3.31 to 3.45.

Chem. Char.-Gives out a blue flame before the blow-pipe, with white vapour, and the smell of arsenic and sulphur.

Constituent	Parts.

	Kirwan.	Westrumb.
Arsenic,	84	80
Sulphur,	16	20
	and-resultment	
	100	100

Localities, &c .- Usually found in stratiform mountains, accompanied by clay, quartz, and sometimes by red orpiment, in Transylvania, Hungary, and other places.

Subspecies 2. RED ORPIMENT.

Exter. Char .- Rarely massive, usually disseminated, or superficial, and often crystallized in oblique foursided prisms, with obtuse lateral edges, truncated, or bevelled : crystals small, streaked longitudinally ; shining or resplendent; internal lustre shining between vitreous and resinous; fracture uneven, or conchoidal.

Colour light aurora-red, scarlet-red, orange yellow; translucent or semitransparent, often opaque; streak orange, or citron-yellow ; very soft : somewhat brittle. Spec. grav. 3.2.

Chem. Char .- Similar to the former.

Constituent Parts .- According to some, the same as the preceding, but with the addition of iron and silica, with a smaller proportion of sulphur.

Localities, &c .- Chiefly found in primitive mountains, as in Saxony, Hungary, France, and in the neighbourhood of Ætna and Vesuvius.

4. Species. NATIVE OXIDE OF ARSENIC.

Id. Kirw. ii. 258. Id. Broch. ii. 450. Id. Hauy, iv. 225.

Exter. Char.-Found superficial in an earthy form, and friable, on other minerals; rarely indurated, sometimes botryoidal, or crystallized in capillary crystals, very small octahedrons, or four-sided tables; lustre glimmering or dull; fracture earthy or fibrous.

Colour snow-white, yellowish white, reddish or

greenish white ; opaque ; crystals translucent ; soft, or Metallic friable. Spec. grav. 3.706.

Ores.

Chem. Char .- Before the blow-pipe it gives out a white fume and a garlic odour; burns with a bluish flame, and is entirely dissipated ; soluble in water and acids.

Constituent Parts .- This is a pure oxide of arsenic, with an accidental mixture of earth.

Localities, &c .- A rare mineral, but is found in small quantity, along with native arsenic, and ores of cobalt, in Bohemia and Hungary.

5. Species. PHARMACOLITE, or Arseniate of Lime.

Id. Broch. ii. 523. Chaux Arseniaté, Hauy, ii. 293.

Exter. Char .- Found in small capillary crystals; lustre glimmering, silky ; fracture fibrous or radiated.

Colour snow-white ; translucent ; very soft. Specific gravity 2.53 to 2.64.

Chem. Char .- Soluble in nitric acid with effervescence, and gives out the odour of arsenic before the blow-pipe.

Constituent Parts.	Klaproth.
Arsenic acid, Lime, Water,	50.54 25. 24.46
	100.00*

* Analyt. Ess. ii. 23.

Localities, &c .- Found in a vein in primitive rocks, accompanied by heavy spar and gypsum, near Wittichen in Suabia. It has also been found in France.

XVII. TUNGSTEN GENUS.

I. Species. WOLFRAM.

Id. Kirw. ii. 316. Id. Broch. ii. 456. Scheelin Ferruginé, Hauy, iv. 314. "

Exter. Char.-Found massive, disseminated, or crystallized in six-sided prisms, and in rectangular foursided tables, which are variously modified. Crystals not very small, usually grouped; internal lustre shining or resplendent ; longitudinal fracture foliated ; cross fracture uneven.

Colour brownish black, or perfect black, sometimes tarnished; opaque; streak dark reddish brown; soft; brittle. Spcc. grav. 7.11 to 7.33.

Chem. Char.-Before the blow-pipe it decrepitates. but is infusible.

2. Species. TUNGSTATE OF LIME.

Tungsten, Kirw. ii. 314. Id. Broch. ii. 453. Scheelin Calcaire, Hauy, iv. 320.

Exter. Char .- Massive, disseminated, sometimes crystallized in regular octahedrons, which are sometimes slightly bevelled on the edges of the common base. Crystals usually small; surface smooth, resplendent; bevelled surface streaked transversely; internal lustre shining or resplendent, resinous or adamantine ; fracture foliated.

Colour grayish or yellowish white; translucent; semihard; brittle. Spec. grav. 6.06.

Chem. Char .- Before the blow-pipe dccrepitates, and loses its transparency, but is infusible. Reduced to powder, and digested with nitric or muriatic acid, it leaves a citron yellow residuum, which is tungstic acid.

		100.00	100.00

Localities, &c .- This is a rare mineral, usually found in primitive mountains, accompanied by ores of tin, some iron ores, quartz, fluor spar, &c. in Sweden, Saxony, and Cornwall in England.

XVIII. TITANIUM GENUS.

I. Species. MENACHANITE.

Id. Brochant, ii. 468. Id. Kirwan, ii. 326. Hauy, iv. 305.

Exter. Char .- Found in small, detached, rounded grains; surface rough, or weakly glimmering; lustre shining, semi-metallic; fracture imperfectly foliated.

Colour grayish or iron black; soft or semi-hard; brittle. Spec. grav. 4.4. Chem. Char.—Infusible before the blow-pipe; co-

lours borax greenish brown.

Constituent Parts.

	Chenevix.	Klaproth.
Oxide of titanium,	45.25	40
- iron,	51.	49
Silica,	3.5	II
Oxide of manganese,	2.5	
	times and a second second	
	100.00	TOO

Localities, &c .- This mineral was first discovered by Mr Gregor, among sand, in the bed of a rivulet, in the valley of Menachan in Cornwall; hence its name. It has since been found in the island of Providence, one of the Bahamas, and at Botany Bay in New Holland.

2. Species. OCTAHEDRITE.

Anatase, Hauy, iii. 129. Id. Brochant, ii. 548. Octahedrite, Saussure, Voyages, § 1901.

Exter. Char .- Found only crystallized, in elongated octahedrons with square bases, and truncated or acuminated; crystals small and imbedded; lateral faces streaked transversely; lustre resplendent, vitreous; fracture foliated.

Colour steel gray, sometimes light indigo blue ; translucent; semi-hard; brittle. Spec. grav. 3.85.

Chem. Char .- Infusible before the blow-pipe, but melts with borax, which it colours green, and in cooling, crystallizes in needles.

Const. Parts .- It is chiefly composed of oxide of titanium.

Localities, &c .- Has been found lining the cavities of a vein, accompanied by quartz and feldspar, in a primitive rock, in Dauphiné in France.

3. Species. TITANITE.

Id. Kirwan, ii. 329. Le Ruthile, Brochant, ii. 470. Titane Oxidé, Hauy, 1v. 296. Red Schorl of many.

Exter. Char.-Found crystallized in oblique foursided prisms, the lateral edges truncated; sometimes these crystals are double, being united obliquely; also in acicular and capillary crystals, imbedded and grouped together; surface longitudinally streaked, shining; internal lastre shining, adamantine ; fracture foliated.

Colour blood-red or reddish brown ; opaque, or translucent; hard; brittle. Spec. grav. 4.1 to 4.24.

Chem. Char .--- Infusible before the blow-pipe, but loses its transparency, and becomes gray.

Const. Parts .- Composed chiefly of oxide of titanium.

Localities, &c .- Found in Hungary, in gneiss, and imbedded in quartz. It has been found also in Switzerland, Spain, and France.

4. Species. NIGRINE.

Kirwan, ii. 331. Brochant, ii. 474. Hauy, iv. 307.

Exter. Char .- Disseminated, sometimes amorphous, often crystallized in oblique four-sided prisms, variously modified by truncations and bevelments. Surface smooth; lustre shining, or resplendent, between resinous and vitreous; fracture foliated.

Colour dark brownish black, yellowish white or violet brown; opaque, or translucent; semi-hard. Spec. grav. 3.51 to 4.6.

Chem. Char .- Infusible before the blow-pipe.

XIX. URANIUM GENUS.

I. Species. PITCHY ORE OF URANIUM.

Id. Brochant, ii. 460. Kirw. ii. 305. Hauy, iv. 280.

Exter. Char.—Massive, disseminated, sometimes cellular; shining or glimmering; fracture imperfectly conchoidal; fragments rather sharp-edged.

Colour velvet black, iron black, or bluish, sometimes steel-tarnished; streak black; opaque; semihard; brittle. Spec. grav. 6.5 to 7.5.

Chem. Char.-Infusible before the blow-pipe; soluable in nitric acid.

Constituent Parts. Klaproth.

Uranium a little oxidated,	86.5
Sulphuret of lead,	6.
Oxide of iron,	2.5
Silica,	5.
	100.0

Localities, &c.—Found in Bohemia and Saxony, accompanying galena, copper pyrites, iron ochre, and some ores of silver and cobalt.

2. Species. MICACEOUS URANITE.

Id. Brochant, ii. 463. Kirwan, ii. 304.

Exter. Char.—Sometimes in thin layers, but often crystallized in rectangular four-sided tables; in cubes, and six-sided prisms variously modified. Crystals small, and grouped together; lustre shining, pearly; fracture foliated.

+

VOL. XIV. Part I.

Colour emerald or grass green of various shades, Metallic rarely wax yellow; translucent; streak greenish white; Ores. soft; not very brittle. Spec. grav. 3.12.

Chem. Char.-Soluble, without effervescence, in nitric acid, which it colours citron yellow.

Const. Parts.-This species is an oxide of uranium, with a small portion of copper.

Localities, &c.-Found in Saxony, France, and Cornwall in England, accompanied by some ores of iron, sometimes by cobalt.

3. Species. URANITE OCHRE.

Id. Broch. ii. 466. Id. Kirw. ii. 303.

Exter. Char.—Found massive, but usually disseminated, or superficial; is dull, or rarely shining; fracture earthy, or foliated; fragments blunt-edged.

Colour citron yellow, aurora red, or sulphur yellow; opaque; soft and friable; brittle; stains a little; feels meagre. Spec. grav. 3.15 to 3.24.

Constituent Parts.—Composed of oxide of uranium, with a portion of iron.

Localities, &c.-Found in similar places with the former.

XX. TELLURIUM GENUS.

1. Species. NATIVE TELLURIUM.

Id. Broch. ii. 480. Sylvanite, Kirw. ii. 324. Hauy, iv. 325.

Exter. Char.-Massive or disseminated ; shining ; fracture foliated.

Colour between tin and silvery white; soft; not very brittle. Spec. grav. 5.7 to 5.1.

Chem. Char .- Melts easily before the blow-pipe.

onsti	tuent	Pa	arts.	K	laj	proth.

Tellurium, Iron, Gold,	92.6 7.2 .2
	100.0

Localities, &c.--Has been only found at Fatzebay in Transylvania, where it exists in veins, in mountains of gray wacken and transition limestone. The ore is dug out for the purpose of extracting the gold.

It was called *aurum paradoxum*, and *aurum proble maticum*, because its external appearance did not indicate that it contained gold.

2. Species. GRAPHIC ORE OF TELLURIUM.

Id. Broch. ii. 482. Hauy. iv. 327.

Exter. Char.—Massive and crystallized in flat four or six-sided prisms, which are arranged in rows, exhibiting something of the appearance of written characters, and hence the name graphic ore. Surface smooth, shining; longitudinal fracture foliated and resplendent; cross fracture uneven.

Colour tin white, yellowish, or lead gray; soft and brittle. Spec. grav. 5.72.

Chem. Char,-Burns with a greenish flame before the blow-pipe.

Localities, &c.-Found only at Nagyag in Transylvania.

4. Species. BLACK or FOLIATED ORE OF TELLURIUM.

Id. Broch. ii. 486. Hauy, iv. 327.

Exter. Char.—Found in plates, which are united into masses, or disseminated, rarely crystallized in sixsided tables; surface smooth, shining; external lustre resplendent; fracture foliated.

Colour between lead gray and iron black; stains; soft; flexible in thin plates. Spec. grav. 8.91.

Chem. Char.—Before the blow-pipe the sulphur and tellurium are dissipated in white fumes, and a metallic globule remains, surrounded by a black slag.

Constituent Parts.	Klaproth.
Tellurium,	33.
Lead,	50.
Gold,	8.5
Siver and copper,	1.
Sulphur,	7.5
	100.0

Localities, &c.-Found only in the same place with the preceding.

XXI. CHROMIUM GENUS.

1. Species. NEEDLE ORE OF CHROMIUM.

Exter. Char.—Found in small crystals, which are imbedded; lustre shining; fracture uneven or conchoidal.

Colour steel gray, and usually covered with a greenish classifi, efflorescence; soft, or semihard; not very brittle.

Constituent Parts.—This is supposed to be an alloy of chromium.

Exter. Char. &c.—Found in the gold mine of Rudnick near Schlangenberg in Suabia, in a matrix of white quartz, containing gold and galena.

2. Species. OCHRE OF CHROMIUM.

Exter. Char.-Massive, disseminated, and in thin plates; dull; fracture uneven or earthy.

Colour verdigris green, or yellowish ; soft.

Localities, &c.-Found only in the same place, accompanying the former.

The chromates of lead and iron have been already described among the ores of those metals.

XXII. COLUMBIUM GENUS.

Exter. Char.-Massive; fracture uneven, or foliated; lustre shining.

Colour dark gray; opaque; not very hard; brittle. Spec. grav. 5.918.

Constituent Parts.

Oxide	of	columbium,	78
Loss,			I
		-	100

Localities, & c.—This mineral, of which the only specimen known is in the British Museum, was brought from Massachussets in America; it was analyzed by Mr Hatchett, and found to contain a new metal, which he denominated columbium.

XXIII. TANTALIUM GENUS.

Two species of this mineral have been discovered; tantalite, and yttrio-tantalite.

1. Species. TANTALITE.

Exter. Char.—Crystallized in octahedrons; surface smooth; fracture compact.

Colour bluish gray, or black. Spec. grav. 7.95.

Constituent Parts.—Composed of tantalium, iron, and manganese.

Localities, &c.-Found in Finland, in globular pieces, in a vein of red feldspar, traversing a gneiss rock.

2. Species. YTTRIO-TANTALITE.

Exter. Char.-Disseminated, in pieces of the size of a nut; fracture even; lustre metallic.

Colour dark gray; may be scratched with a knife; powder gray. Spec. grav. 5.13.

Constituent Parts.-Composed of iron, manganese, tantalium, and the new earth yttria.

Localities, &c.-Found at Ytterby in Sweden, in the same place with gadolinite.

These minerals were analyzed by Eckeberg, who discovered in them the new metal tantalium, which isnow supposed to be the same with columbium.

Localities, &c .- This mineral was examined by Professor Gadolin of Sweden, whose name it bears, and found to contain a peculiar earth. It was found near Ytterby in Sweden, and hence the new carth was called Yttria.

The unavoidable length to which the first part of this treatise has extended, and some other circumstances, render it necessary for us to introduce in a different part of the work, what we propose to lay before our readers in the second part relative to the analysis of stones and metallurgical operations. See ORES, Reduction of, and STONES, Analysis of.

EXPLANATION OF THE PLATES.

PLATE CCCLI.

Fig. 1. Represents the goniometer or graphometer, an instrument invented by Carangeau for measuring the angles of crystals. MTN is a graduated semicircle of brass or silver, furnished with two arms or rulers AB, FG, one of which, FG, has a slit from a to R, excepting the cross bar at K, which strengthens the instrument. This arm is fixed to a brass ruler at R and c placed behind, and which makes part of the semicircle. The arm FG is connected with the ruler behind by nails which enter the slit and arc furnished with nuts. The other arm has also a slit or opening from x to c, where it is fixed to the first by the screw nail which passes through both. By slackening the screws, the two parts c G and c B may be shortened at pleasure. The arm AB being only fixed at c, which is the centre of the circle, moves round this centre, while the arm GF remains constantly fixed in the direction of the diameter which passes through the points 0 and 180°. The upper part of the arm AB should be brought to a thin edge from z to s, and the line of this edge should pass through the centre c; because it is by this edge that the

measure of the angle on the graduated circumference is indicated.

To discover the measure of any angle of a crystal, the two arms c B, c G arc brought into contact with the sides containing the angle, and the degree indicated by the line z s on the circumference denotes the measure of that angle. The instrument is so contrived that the arms may be shortened for the convenience of applying it in different cases. But it might happen that it could not be applied in cases where the crystals are aggregated or attached to the matrix. This difficulty is obviated by another contrivance. The semicircle is furnished with a hinge at 90°, by which means it may be diminished at pleasure to a quadrant, by folding back one half. There is a small bar of steel, one end of which is fixed behind the immoveable arm FG, and the other is attached by a notch and screw nail at O. When this nail is unscrewed, the bar c O falls behind the ruler which supports FG, and thus one half of the semicircle folds back, and any angle not exceeding 90° may be measured; but when the angle is greater, it must be replaced.

Fig. 2. is an apparatus by which small degrees of Ii 2 electricity

Part

Explana. Cleetricity may be observed in minerals. A is a small fitted with a small brass plug kept down by a thin slip Expla of iron 1, the other end of which slips over the top of tion of tion of the brass needle with knobs a b, and moveable on the pivot the upright pillar d, and is confined between two flat screw-plates m n. The use of this is as a safety value Plates. , at the middle. The mineral whose electricity is to be tried, is rubbed on silk or woollen, and then presented to take away all danger of the boiler bursting by the

to one of the knobs; and by the distance at which the knob begins to be attracted, the strength of the electricity may be, in some degree, estimated. In the same way substances which become electric by heat, such as the tourmaline, are to be tried ; the same apparatus may he employed. To ascertain in what part of the mineral the different electricities exist, take a stick of sealing wax, at the extremity of which a silk thread has been attached, and having rubbed the wax, bring alternately the opposite extremities of the substance, for example, each of the summits of a tourmaline, within a small distance of the silk thread. If the extremity which is brought near the thread possess negative electricity, the thread will be repelled; on the contrary, it will be attracted. Or the experiment may be made in another way, particularly when the electrical body is small, or its electricity feeble. At B, fig. 2. the tourmaline t t'is held by a pair of pincers in such a way that the pole t is at a small distance from the knob a of the needle. C c is the stick of wax, one of whose extremities is placed on a tube of glass Uu, and which acts by its extremity C, on the knob a, to excite in it positive electricity. In this case the wax, after the extremity which has been rubbed is placed in the position described, communicates to the knob of the needle to which it is presented, an electricity contrary to its own; so that the extremity of the tourmaline acted on by positive electricity, repels the needle to which it is presented, and the other extremity, possessing negative electricity, attracts the needle.

Fig. 3. is a spirit of wine blow-pipe, nearly on the plan of that invented by Mr Paul. It is made of brass, and consists of the following parts.

a Is a hollow oval frame about five inches in its longest dimension, which supports the pillar d and the two lamps bc, which may burn either oil or alcohol, but the latter is the best. The rim ee slips upon the pillar d as low as the shoulder of the latter will permit, but the rim may be raised at pleasure and kept fast by the screw peg f. The rim supports the boiler g, which is a single hollow piece of thick brass containing about an ounce of alcohol, and has four openings, viz. three at top h, i, k, and one at bottom to receive the tube o. This latter is long enough to reach the level of the outside of the top of the boiler, and consequently the alcohol within the boiler cannot readily boil over into the tube, and the opening k which corresponds with it, is closely shut by a screw stopper, holfowed out a little beneath, to allow the free passage of the vapour down the tube. Here the vaporized alcohol is prevented from condensing at the point o by the contiguity of the flame of the lamp b, and as it passes on through the hollow pq into the jet tube r, it is immediately kindled by the flame of the lamp c, and the united flames arc compelled sideways with such violence as to form a long pencil of blue flame, attended with a considerable roaring noise. This continues as long as any alcohol is left in the boiler, which allows ample time for most blow-pipe operations. The boiler is filled at the opening λ . The centre hole i is nicely

confined vapour not being able to escape fast enough through the jet-pipe r, for when the internal pressure is great, the elasticity of the iron spring l allows the valve i to rise sufficiently to let out part of the enclosed vapour. The screw stoppers h and k are made still tighter by collars of leather, as is the part where the tube o joins the boiler. The jet-pipe r has a complete rotatory motion, so that the flame may be impelled in any direction. This is effected by turning in the form of a ball that part of the pipe which is inclosed in the hollow pq. But this blow-pipe, although an elegant philosophical apparatus, will not be found to answer where a great

degree of heat is required to be kept up for a considerable time. Other contrivances, therefore, of a simpler nature, have been proposed; and perhaps the best of these is the blow-pipe which is used by the mouth. The following is a description of a blow-pipc of this kind.

Fig. 4. represents this blow-pipe. a Is a brass tube, having a circular enlargement c, for the purpose of condensing the moisture which is blown from the lungs; the smaller end d is moveable round the centre c, so that any degree of obliquity may be given to the flame. Fig. c. is a separate jet-pipe with a small opening, which is screwed on the blow-pipe at d; and it may be convenient to have two or three jet-pipes of different sizes, according as a larger and more mederate, or a smaller and more intense flame is wanted. b Is a piece of ivory which slips on the larger end, for the purpose of being applied to the mouth, as being more agreeable.

The best kind of flame for blowing through with the common blow-pipe is a wax or tallow candle with a very large wick, which should be kept snuffed moderately low, and the wick turned a little aside from the pipe. A spirit lamp is sometimes used, which makes a perfectly clear flame without smoke, but weak when used in this way. There is a kind of knack in blowing with the mouth, which is not easily described, and requires a little practice to be performed with ease. As the flame must often be kept for several minutes, the act of respiration must be carried on through the nostrils without interruption, and the stress of blowing must be performed merely by compression of the cheeks upon the air in the mouth.

The substance to be heated is placed either on a piece of charcoal or a metallic support. When the former is used, a large close well-burnt piece of charcoal must be chosen, a small shallow hole scooped out with a knife, and the substance laid upon it. The charcoal itself kindles all round the hole, and the hole is thus gradually enlarged ; and the heat too is kept up round the substance much more uniformly than when a metal support is used. At the same time however the chemical effect produced by heated charcoal should not be forgotten, particularly the reduction of metallic oxides, and the dcoxygenation of the fixed acids; so that, for example, a small heap of minium or litharge heated red-hot on charcoal

5.

plana- charcoal by the blow-pipe, is speedily reduced to a gloof the bule of metallic lead; the phosphates are partially relates. duced to phosphurets, &c.

For a metallic support, platina is in general by fir the best material. A small spoon of this metal, the shank of which may be stuck in a cork when held, and a small silver cup, the shank of which is fixed into a wooden handle, may be used in fusions with borax or alkaline fluxes. A small forceps lately brought into use, and made entirely of two thin pieces of platina joined by rivets, and bent, will be useful in holding any small hard substance in the blow-pipe flame for any length of time, without danger of the points of the forceps melting; and it is also found that this metal is so much worse a conductor of heat than any other, that the forceps never gets too hot for the naked fungers to touch at the bend *.

Fig. 6. represents a portable pocket blow-pipe, invented by Dr Wollaston, and of its actual size. The interior tube is longer than the exterior, that it may be readily withdrawn; and the upper edge of the large end is turned outward, to diminish the effort of the lips requisite for retaining it in the mouth.

Fig. 7. represents the whole apparatus, one half of its real dimensions, and connected for use. The small extremity a is placed obliquely at an angle of about 120°, that the flame impelled by it may be carried to a more convenient distance from the eye, and thus answering the purpose of a longer blow-pipe. This oblique piece a is composed of three parts, the largest of which is made stronger, that it may not be injured by use. One end is closed, and into the other is inserted a small pcg of wood, perforated so as to receive the tip which is intended to be occasionally separated, for the purpose of passing a fine needle into it, to remove obstructions +.

MIN

Minerva MINERVA, or PALLAS, in Pagan worship, the goddess of seicnces and of wisdom, sprung completely Mingrelia. armed from Jupiter's brain : and on the day of her na-

tivity it rained gold at Rhodes. She disputed with Neptune the honour of giving a name to the city of Athens; when they agreed that whosoever of them should produce what was most useful to mankind, should have that advantage. Neptune, with a stroke of his trident, formed a horse; and Minerva caused an olive to spring from the ground, which was judged to be most useful, from its being the symbol of peace. Minerva changed Arachne into a spider, for pretending to excel her in making tapestry. She fought the giants; favoured Cadmus, Ulysses, and other heroes; and refused to marry Vulcan, choosing rather to live in a state of celibacy. She also deprived Tiresias of sight, turned Medusa's locks into snakes, and performed several other exploits.

Minerva is usually represented by the poets, painters and seulptors, completely armed, with a composed but agreeable countenance, bearing a golden breastplate, a spear in her right hand, and her ægis or shield in the left, on which is represented Medusa's head encircled with snakes, and her helmet was usually entwined with olives.

Minerva had several temples both in Greece and Italy. The usual victim offered her was a white heifer, never yoked. The animals sacred to her were the cock, the owl, and the basilisk.

MINERVÆ Castrum, Aræ Minervæ, Minervium, or Templum Minervæ, in Ancient Geography, a citadel, temple, and town on the Ionian sea, beyond Hydrus; seen a great way out at sea. Now Castro, a town of Otranto in Naples. E. Long. 19. 25. N. Lat. 46. 8.

MINERVÆ Promontorium, in Ancient Geography, the seat of the Sirens, a promontory in the Sinus Paestanus, the south boundary of Campania on the Tuscan coast; so called from a temple of Minerva on it; situated to the south of Surrentum, and therefore called Surrentium. Now Capo della Minerva, on the west coast of Naples, over against the island Capri.

MINERVALIA, in Roman antiquity, festivals celebrated in honour of Minerva, in the month of March; at which time the scholars had a vacation, and usually made a present to their masters, called from this festival *Minerval*.

MINGRELIA, aneiently COLCHIS, a part of Western Georgia, in Asia; bounded on the east by Iberia, or *Georgia* properly so called; on the west, by

MIN

the Euxine sca; on the south, by Armenia, and part Mingre of Pontus; and on the north, by Mount Caucasus.

Colchis, or Mingrelia, is watered by a great many rivers; as the Corax, the Hippus, the Cyaneus, the Charistus, the Phasis, where the Argonauts landed, the Absarus, the Cissa, and the Ophis, all cmptying themselves into the Euxine sea. The Phasis does not spring from the mountains in Armenia, near the sources of the Euphrates, the Araxes, and the Tigris, as Strabo, Pliny, Ptolemy, Dionysius, and after them Arrian, Reland, Calmet, and Sanson, have falsely asserted; but rises in Mount Caucasus; and flows not from south to north, but from north to south, as appears from the map of Colchis or Mingrelia in Thevenot's collection, and the account which Sir John Chardin gives of that country. This river forms in its course a small island called also Phasis : whence the pheasants, if Isidorus is to be credited, were first brought to Europe, and thence ealled by the Greeks Phasiani. The other rivers of Colchis are considerable.

The whole kingdom of Colchis was in ancient times very pleasant and fruitful, as it is still where duly cultivated; abounded in all necessaries of life; and was enriched with many mines of gold, which gave occasion to the fable of the Golden Fleece and the Argonautic expedition, so much eelebrated by the ancients.

Sir John Chardin tells us, that this eountry extends above 100 miles in length and 60 in breadth; being not near so extensive as the ancient Colchis, which reached from the frontiers of Iberia or Georgia Proper, westward to the Palus Mæotis : that it is beautifully diversified with hills, mountains, valleys, woods, and plains, but badly eultivated : that there are all the kinds of fruits which are found in England, growing wild, but tasteless and insipid for want of eulture: that, if the natives understood the art of making wines, those of this country would be the finest in the world : that there are many rivers which have their source in Mount Caucasus, particularly the Phasis, now called the Rione: that the country abounds in beeves, hogs, wild boars, stags, and other venison; and in partridges, pheasants, and quails : that falcons, eagles, pelieans, lions, leopards, tygers, wolves, and jackals, breed on Mount Caucasus, and sometimes greatly annoy the country : that the people are generally handsome, the men strong and well made, and the women very beautiful; but both sexes very vieious and debauched : that they marry their nieces, aunts, or other relations, indifferently; and take two or three WIVES

MIN

their bishops are rich, have a great number of vassals, Mingrelia. and arc clothed in scarlet and velvet; and that their service is according to the rites of the Greek church, Miniature. with a mixture of Judaism and Paganism.

will: that they not only make a common practice of selling their children, but even murder them, or bury them alive, when they find it difficult to bring them up: that the common people use a sort of paste, made of a plant called gom, instead of bread ; but that of the better sort consists of wheat, barley, or rice : that the gentry have an absolute power over their vassals, which extends to life, liberty, and estate : that their arms are the bow and arrow, the lance, the sabre or broadsword, and the buckler : that they are very nasty, and eat sitting cross-legged upon a carpet, like the Persians; but the poorer sort upon a mat or bench, in the same posture : that the country is very thin of inhabitants, no less than 12,000 being supposed to be sold yearly to the Turks and Persians : that the principal commodities exported from it are, honey, wax, hides, castor, martens skins, flax seed, thread, silk, and linen cloth; but that there are no gold or silver mines now, and very little money: that the revenue of the prince or viceroy amounts to about 20,000 crowns per annum : that the inhabitants calls themselves Christians; but that both they and their priests are altogether illiterate, and ignorant of the doctrines and precepts of Christianity : that

The citics of most note in this country in ancient times were Pityus; Dioscurias, or Dioscorias, which was so called from Castor and Pollux, two of the Argonauts, by whom it is supposed to have been founded, and who in Greek are styled Dioscuroi, at present known by the name of Savatapoli; Aea on the Phasis, supposed to be the same as Hupolis ; Phasis, so called from the river on which it stood ; Cyta, at the mouth of the river Cyaneus, the birth place of the famous Medea, called from thence, by the poets, Cytais; Saracæ, Zadris, Surium, Madia, and Zolissa. As for modern cities, it does not appear that there are any here considerable enough to merit a description; or, if there are, they seem to be little, if at all, known to Europeans.

MINHO, a great river in Spain, which taking its rise in Galicia, divides that province from Portugal, and falls into the Atlantic at Caminha.

MINIATURE, in a general sense, signifies representation in a small compass, or less than the reality.

MINIATURE PAINTING.

DELICATE kind of painting, consisting of A little points or dots; usually done on vellum, ivory, or paper, with very thin, simple, water colours .---The word comes from the Latin minium, " red lead ;" that being a colour much used in this kind of painting. The French frequently call it mignature, from mignon, " fine, pretty," on account of its smallness and delicacy: and it may be ultimately derived from ungos, " small."

Miniature is distinguished from other kinds of painting by the smallness and delicacy of its figures and faintness of the colouring; on which account it requires to be viewed very near.

SECT. I. Of Drawing and Designing.

To succeed in this art, a man should be perfectly skilled in the art of designing or drawing : but as most people who affect the one, know little or nothing of the other, and would have the pleasure of painting without giving themselves the trouble of learning to design (which is indeed an art that is not acquired without a great deal of time, and continual application), inventions have been found out to supply the place of it; by means of which a man designs or draws without knowing how to design.

The first is chalking : that is, if you have a mind to do a print or design in miniature, the backside of it, on another paper, must be blackened with small coal, and then rubbed very hard with the finger wrapped in a linen cloth : afterwards the cloth must be lightly drawn over the side so blackened that no black grains may remain upon it to soil the vellum you would paint upon; and the print or draught must be fastened upon the vellum with four pins, to keep it from shifting. Vol. XIV. Part I.

And if it be another paper that is blackened, it must be put between the vellum and the print, or draught, with the blackened side upon the vellum. Then, with a blunted pin or needle, you must pass over the principal lines or strokes of the print, or draught, the contours, the plaits of the drapery, and over every thing else that must be distinguished ; pressing so hard, that the strokes may be fairly marked upon the vellum underneath.

Copying by squares is another convenient method for such as are but little skilled in the art of designing, and would copy pictures, or other things, that cannot be chalked. The method is this : The piece must be divided into many equal parts by little squares, marked out with charcoal, if the picce be clear and whitish, and the black can be fairly seen upon it; or with white chalk, if it be too brown and dusky. After which, as many squares of equal dimensions must be made on white paper, upon which the piece must be designed; because, if this be done immediately upon vellum, (as one is apt to miscarry in the first attempt), the vellum may be soiled with false touches. But when it is neatly done upon paper, it must be chalked upon the vellum in the manner before described. When the original and the paper are thus ordered, observe what is in each square of the piece to be designed ; as a head, an arm, a hand, and so forth ; and place it in the corresponding part of the paper. And thus finding where to place all the parts of the piece, you have nothing to do but to form them well, and to join them together. By this method you may reduce or enlarge a piece to what compass you please, making the squares of your paper greater or less than those of the original; but they must always be of an equal number.

To copy a picture, or other thing, in the same size Kk and

Drawing and proportion, another method is, to make use of varnished paper, or of the skin of a hog's bladder, very Designing transparent, such as is to be had at the gold-beaters.

Talc or isinglass will likewise do as well. Lay any one of those things upon your piece; through it you will see all the strokes and touches, which are to be drawn upon it with a crayon or pencil. Then take it off; and fastening it under paper or vellum, set up both against the light in the manner of a window; and with a crayon, or a silver needle, mark out upon the paper or vellum you have put uppermost, all the lines and touches you shall see drawn upon the varnished paper, bladder, tale, or isinglass, you have made use of, and which will plainly appear through this window.

After this manner, making use of the window, or of glass exposed to the light, you may copy all sorts of prints, designs, and other pieces on paper or vellum : laying and fastening them under the paper or vellum upon which you would draw them. And it is a very good and a very easy contrivance for doing picces of the same size and proportion.

If you have a mind to make pieces look another way, there is nothing to be done but to turn them; laying the printed or drawn side upon the glass, and fastening the paper or vellum upon the back of it; remembering to let your lights fall on the left side.

A good method likewise to take a true copy of a picture in oil, is to give a touch of the pencil upon all the principal strokes, with lake tempered with oil; and to clap upon the whole a paper of the same size : then passing the hand over it, the touches of the lake will stick and leave the design of your piece expressed upon the paper, which may be chalked like other things. But you must remember to take off with the crumb of bread what remains of the lake upon the picture before it be dry.

You must likewise make use of pounce, made of powdered chareoal put in a linen rag; with which the piece you would copy must be rubbed, after you have pricked all the principal strokes or touches, and fastened white paper or vellum underneath.

When the piece is marked out upon the vellum, you must pass with a peneil of very clear earmine over all the traces, that they may not be effaced as you work : then clean your vellum with the crumb of bread, that no black may remain upon it.

The vellum must be pasted upon a plate of brass or wood, of the size you would make your piece, to keep it firm and tight. But this pasting must be on the edges of your vellum only, and behind the plate, for which purpose your vellum must exceed your plate above an inch on every side ; for the part you paint upon must never be pasted; because it would not only give it an ill look, but you could not take it off if you would. Cut off the little shags and locks of the vellum ; and wetting the fair side with a linen cloth dipped in water, clap the other upon the plate with a clean paper between them : so much as hangs over must be pasted upon the back of the plate, drawing it equally on all sides, and hard enough to stretch it well.

SECT. II. Of Materials.

THE chief colours made use of for painting in miniature are,

Carmine. Venice and Florence lake. Rose pink. Vermilion. Red lead. Brown red. Red orpiment. Ultramarine. Verditer. Indigo. Gall stone. Yellow ochre. Dutch pink. Gamboge. Naples yellow. Pale masticot. Deep yellow masticot. Ivory black. Lamp black. True Indian ink. Bistre, or wood soot. Raw umber. Burnt umber. Sap green. Verdigris. Flake white. Crayons of all colours. Gold and silver shells. Leaf gold and leaf silver.

The seven transparent colours, which are used where writing is seen through the colour.

> Lake. Blue. Yellow. Liquid { Grass-green. Dark-green. Purple colour. Brown.

Most of these colours necessary for miniature painting may easily be prepared by attending to the directions given under the article COLOUR-Making.

As colours taken from earth and other heavy matter are always too coarse be they never so well ground, especially for delieate work, because of a certain sand remaining in them; the finest parts may be drawn out by diluting them with the finger in a cup of water. When they are well steeped, let them settle a while : then pour out the clearest, which will be at top, into another vessel. This will be the finest, and must be let dry; and when it is used, must be diluted with gum water.

If you mix a little of the gall of an ox, a carp, or an eel, particularly of the last, in green, black, gray, yellow, and brown, colours, it will not only take away their greasy nature, but also give them a lustre and brightness they have not of themselves. The gall of eels must be taken out when they are skinned, and hung upon a nail to dry; and when you would use it, it must be diluted with brandy; add a little of it mixed with the colour you have diluted already. This likewise makes. the colour stick better to the vellum, which it hardly does when it is greasy: moreover, this gall hinders it from scaling.

Some

and

Sect.]

Some colours are made clearer by fire; as yellow, oehre, brown red, ultramarine, and umber: all others are darkened by it. But if you heat the said colours with a sharp fire, they change; for the brown red becomes yellow; yellow ochre becomes red; umber reddens also. Ceruss by fire takes the colour of citron, and is often called *masticot*. Observe, that yellow ochre heated, becomes more tender than it was, and softer than brown red. Likewise brown red heated becomes softer than fine yellow ochre. Both are very proper. The finest and truest ultramarine, heated upon a redhot iron, becomes more glittering; but it wastes, and is coarser and harder to work with in miniature.

ect. II.

blours,

SEC.

All these colours are diluted in little cups of ivory, made on purpose, or in sea shells, with water in which gum arabic and sugar candy are put. For instance, in a glass of water put a piece of gum as big as a walnut, and half that quantity of sugarcandy. This last hinders the colours from scaling when they are laid on, which they generally do when they want it, or the vellum is greasy.

This gum water must be kept in a neat bottle corked; and you never must take any out of it with a pencil that has colour upon it, but with a quill or some such thing.

Some of this water is put in the shell with the colour you would temper, and diluted with the finger till it be very fine. If it be too hard, you must let it soften in the shell with the said water before you dilute it. Afterwards let it dry; and do thus with every colour, except lily-green, sap-green, and gamboge, which must be tempered with fair water only. But ultramarine, lake, and bistre, are to be more gummed than other colours.

If you make use of sea shells, you must let them steep two or three days beforehand in water: then cleanse them in boiling hot water, mixed with vinegar, in order to carry off a certain salt, which otherwise sticks to them, and spoils the colours that are put to them.

To know whether colours are sufficiently gummed, you have nothing to do but to give a stroke of the pencil upon your hand when they are diluted, which dries immediately : if they chap and scale, there is too much gum; if they rub out by passing the finger over them, there is too little. It may be seen likewise when the colours are laid on the vellum, by passing the finger over them. If they stick to it like a powder, it is a sign there is not gum enough, and more must be put to the water with which you temper them : but take care you do not put too much; for that makes the colour extremely hard and dry. It may be known likewise by their glueiness and brightness: so the more they are gummed, the darker they paint; and when you have a mind to give a greater strength to a colour than it has of itself, you have nothing to do but to give it a great deal of gum.

Provide yourself with an ivory pallet, very smooth, as big as your hand; on one side of which the colours for the carnation, or naked parts of a picture, are to be ranged in the following manner. In the middle put a great deal of white, pretty largely spread; because it is the colour most made use of: and upon the edge, from the left to the right, place the following colours at a little distance from the white. Masticot. Dutch pink. Orpiment. Yellow ochre. Green ; composed of verditer, Dutch pink, and white, in equal quantities. Blue; made of ultramarine, indigo, and white, to a great degree of paleness. Vermilion. Carmine. Bistre, and Black.

On the other side of the pallet, spread some white in the same manner as for the carnation. And when you have a mind to paint draperies, or other things, place near the white the colour you would make them of, in order to work, as shall be shown hereafter.

The use of good pencils is a great matter. In order to make a good choice, wet them a little; and if the hairs keep close together as you turn them upon the finger, and make but one point, they are good: but if they close not together, but make several points, and some are longer than others, they are good for nothing. When they are too sharp pointed, with only four or five hairs longer than the rest, yet closing all together, they are, notwithstanding, good; but they must be blunted with a pair of seissars, taking care at the same time you do not clip away too much. It is proper to have two or three sorts of them; the largest for laying the grounds and dead colouring, and the smallest for finishing.

To bring the hairs of your pencil to join close together and make a good point, you must often put the pencil just between your lips when you are at work ; moistening and pressing it close with the tongue, even when there is colour upon it; for if there be too much. some of it is taken off by this means, and enough left for giving fine and equal touches. You need not apprehend this will do you any harm. None of the colours for mimature, except orpiment, when they are prepared, have either ill taste or ill quality. This expedient must especially be used for dotting, and for finishing, particularly the naked parts of a picture, that the touches may be neat and fair, and not too much charged with colour. As for draperies and other things, as well in dead colouring as in finishing, it is sufficient, in order to make the hairs of your pencil join well, and to unload it when it has too much colour, to draw it upon the edge of the shell, or upon the paper you must put upon your work to rest your hand on, giving some strokes upon it before you work upon your piecc.

To work well in miniature, you must do it in a room that has but one window, and fix yourself very near it, with a table and desk almost as high as the window; placing yourself in such a manner, that the light may always come in on the left side, and never forward or on the right.

When you would lay a colour on all parts equally strong, as for a ground, you must make your mixtures in shells, and put in enough for the thing you design to paint; for if there be not enough, it is a great chance but the colour you mix afterwards is too dark or too light. 259 Colours, &c.

SECT.

MINIATURE PAINTING.

260 Of Working. V

SECT. III. Of Working.

AFTER having spoke of vellum, pencils, and colours, let us now show how they are to be employed. In the first place, then, when you would paint a piece, be it carnation, drapery, or any thing else, you must begin by dead-colouring; that is to say, by laving your colours on with liberal strokes of the pencil, in the smoothest manner you can, as the painters do in oil ; not giving it all the force it is to have for a finishing ; that is, make the lights a little brighter, and the shades less dark, than they ought to be; because in dotting upon them, as you must do after dead-colouring, the colour is always fortified, and would at last be too dark.

There are several ways of dotting; and every painter has his own. Some make their dots perfectly round ; others make them a little longish; others hatch by little strokes that cross each other every way, till the work appears as if it had been wrought with dots. This last method is the best, the holdest, and the soonest done : wherefore such as would paint in miniature ought to use it, and to inure themselves from the first to dot in the plump and the soft way; that is to say, where the dots are lost, in a manner, in the ground upon which you work, and only so much appears as is sufficient to make the work seem dotted. The hard and the dry way is quite the reverse, and always to be avoided. This is done by dotting with a colour much darker than your ground, and when the peneil is not moistened enough with the colour, which makes the work seem rough and uneven.

Study likewise carefully to lose and drown your colours one in another, so that it may not appear where they disjoin; and to this end, soften or allay your touches with colours that partake of both, in such sort that it may not appear to be your touches which cut and disjoin them. By the word cut, we are to understand what manifestly separates and divides, and does not run in and blend itself with the neighbouring colours ; which is rarely practised but upon the borders of drapery.

When your pieces are finished, to heighten them a little, give them a fine air; that is to say, give, upon the extremity of the lights, small touches with a colour yet lighter, which must be lost and drowned with the rest.

When the colours are dry upon your pallet or in your shells, in order to use them they must be diluted with water. And when you perceive they want gum, which is seen when they easily rub off the hand or the vellum if you give a touch with them upon either, they must be tempered with gum water instead of pure water, till they are in condition.

There are several sorts of grounds for pictures and portraitures. Some are wholly dark, composed of bistre, umbre, and Cologn earth, with a little black and white; others more yellow, in which is mixed a. great deal of ochre; others grayer, which partake of indigo. In order to paint a ground, make a wash of the colour or mixture you would have it, or according to that of the picture or portraiture you would copy; that is to say, a very light lay, in which there is hardly any thing but water, in order to soak the vellum.

Then pass another lay over that, somewhat thicker, and strike it on very smoothly with large strokes as quick Work as you can, not touching twice in the same place before it be dry; because the second stroke carries off what has been laid on at the first, especially when you lean a little too light upon the pencil.

Other dark grounds are likewise made of a colour a little greenish ; and those are most in use, and the properest to lay under all sorts of figures and portraitures; because they make the carnation, or naked parts of a picture, appear very fine; arc laid on very easily, and there is no occasion to dot them, as one is often obliged to do the others, which are rarely made smooth and even at the first; whereas in these one seldom fails of success at the first bout. 'To make them, you must mix black, Dutch pink, and white, all together : more or less of each colour, according as you would have them darker or lighter. You are to make one lay very light, and then a thicker, as of the first grounds. You may also make them of other colours, if you please ; but these are the most common.

When you paint a holy person upon one of these grounds, and would paint a small glory round the head of your figure, you must not lay the colour too thick in that part, or you may even lay none at all, especially where this glory is to be very bright; but lay for the first time with white and a little ochre mixed together, of a sufficient thickness; and in proportion as you go from the place of the head, put a little more ochre; and to make it lose itself, and die away with the colour of the ground, hatch with a free stroke of the pencil, following the round of the glory sometimes with the colour of which it is made, and sometimes with that of the ground, mixing a little white or ochre with the last when it paints too dark to work with : and do this till one be insensibly lost in another, and nothing can be seen to disjoin them.

To fill an entire ground with a glory, the brightest part is laid on with a little ochre and white, adding more of the first in proportion as you come nearer the edges of the picture : and when the ochre is not strong enough (for you must always paint darker and darker), add gall stone, afterwards a little carmine, and lastly bistre. This first laying, or dead colouring, is to be made as soft as possible; that is to say, let these shadowings lose themselves in one another without gap or Then the way is to dot upon them with intersection. the same eolours, in order to drown the whole together; which is pretty tedious, and a little difficult, especially when there are clouds of glory on the ground. Their lights must be fortified in proportion as you remove from the figure, and finished as the rest, by dotting and rounding the clouds; the bright and obseure parts of which must run insensibly into one another.

For a day sky, take ultramarine and a good deal of white, and mix them together. With this make a lay, as smooth as you can, with a large pencil and liberal strokes, as for grounds; applying it paler and paler as you deseend towards the horizon; which must be done with vermilion or red lead, and with white of the same strength with that where the sky ends, or something less; making this blue lose itself in the red, which you bring down to the skirts of the earth, or tops of houses; mixing towards the end gall stone and. a

Of

a good deal of white, in such a manner that the mixorking ture he still paler than the former, without any visible intersection or parting between all these colours of the

sky. When there are clouds in the sky, you may spare the places where they are to be; that is to say, you need not lay on any blue there, but form them, if they are reddish, with vermilion gall stone and white, with a little indigo; and if they are more upon the black, put in a good deal of the last; painting the lights of one and the other with masticot, vermilion, and white, more or less of any of these colours, according to the strength you would give them, or according to that of the original you copy; rounding the whole as you dot; for it is a difficult matter to lay them very smooth at the first painting: and if the sky is not even enough, you must dot it also.

It is at your pleasure to exempt the places of the clouds, for you may lay them upon the ground of the sky; heightening the bright parts by putting a good deal of white, and fortifying the shadows by using less. This is the shortest way.

A night or stormy sky, is done with indigo, black, and white, mixed together; which is laid as for a day sky. To this mixture must be added ochre, vermilion, or brown rcd, for the clouds ; the lights of which are to be of masticot or red lead, and a little white, now redder, now yellower, at discretion. And when it is a tempestuous sky, and lightning appears in some places, bc it blue or red, it is to be done as in a day sky, drowning and losing the whole together at the first forming or dead colouring, and at the finishing.

SECT. IV. Of Draperies.

To paint a blue drapery, put ultramarine near the white upon your pallet; and mix a part of the one with the other, till it makes a fine pale, and has a body. With this mixture you must form the brightest parts; and then adding more ultramarine, form such as are darker; and go on after this manner till you come to the deepest plaits and the thickest shades, where you must lay pure ultramarine : and all this must be done as for a first forming or dead colouring; that is to say, laying the colour on with free strokes of the pencil, yet as smooth as you can; losing the lights in the shadows with a colour neither so pale as the light nor so dark as the shades. Then dot with the same colour as in the first forming, but a small matter deeper; that the dots may be fairly seen. All the parts must be drowned one in another, and the plaits appear without intersection. When the ultramarine is not dark enough to make the deeper shadows, how well soever it be gummed, mix a little indigo with it to finish them. And when the extremities of the lights are not bright enough, heighten them with white and a very little ultramarine.

A drapery of carmine is done in the same manner as the blue; except that in the darkest places there is to be a lay of pure vermilion, before you dead colour with carmine, which must be applied at top; and in the strongest shades, it must be gummed very much. To deepen it the more, mix a little bistre with it.

There is likewise made another red drapery, which is first drawn with vermilion, mixing white with it Draperies. to dead colour the bright places, laying it pure and unmixed for those that are darker, and adding carmine for the grand shades. It is finished afterwards, like other draperies, with the same colours. And when the carmine with the vermilion do not darken enough, work with the first alone, but only in the deepest of the shades.

A drapery of lake is made in the same manner with that of carmine; mixing a good deal of white with it for the bright places, and very little for those that are dark. It is finished likewise with dotting; but you have nothing to do with vermilion in it.

Violet draperies are likewise done after this manner; after making a mixture of carmine and ultramarine, putting always white for the bright parts. If youwould have your violet be columbine or dove colour, there must be more carmine than ultramarine : but if you would have it bluer and dceper, put more ultramarine than carmine.

A drapery is made of a flesh colour, beginning with a lay made of white, vermilion, and very pale. lake; and making the shades with the same colours, using less white in them. This drapery must be very pale and tender, because the stuff of this colour is thin and light; and even the shades of it ought not to be deep.

To make a yellow drapery, put a lay of masticot over all; then one of gamboge upon that, excepting the brightest places, where the masticot must be left entire; the dead colour with ochre, mixed with a little gamboge and masticot, putting more or less of the last according to the strength of the shades. And when these colours do not darken enough, add gall stone. And gall stone pure and unmixed is used for. the thickest shades; mixing a little bistre with it, if. there be occasion to make them still darker. You finish by dotting with the same colours you dead-colourcd with, and losing the lights and the shades in one another.

If you put Naples yellow, or Dutch pink, in lieu of masticot and gamboge, you will make another sort of yellow.

The green drapery is made by a general lay of verditer; with which, if you find it too blue, mix masticot for the lights, and gamboge for the shades. Afterwards add to this mixture lily-green or sap-green, to shadow with; and as the shades are thicker, put more of these last greens, and even work with them pure and unmixed where they are to be extremely dark. You finish with the same colours, a little darker.

By putting more yellow, or more blue, in these colours, you may make different sorts of green as you please.

To make a black drapery, you dead colour with black and white, and finish with the same colour, putting more black as the shades are thicker; and for the darkest, mix indigo with it, especially when you would have the drapery appear like velvet. You may always give some touches with a brighter colour, to heighten the lights of any drapery whatsoever.

A white woollen drapery is made by a lay of white, in which there must be a very small matter of ochre, orpiment, or gall stone, that it may look a little yellowish.

Of

lowish. Then dead-colour, and finish the shades with Of Draperies blue, a little black, white, and bistre; putting a great deal of the last in the darkest.

The light gray is begun with black and white, and finished with the same eolour deeper.

For a brown drapery, make a lay of bistre, white, and a little brown red ; and shadow with this mixture, made a little darker.

There are other draperies called variable, because the lights are of a different colour from the shades. These are mostly used for the vestments of angels, for young and gay people, for searfs and other airy attire, admitting of a great many folds, and flowing at the pleasure of the wind. The most common are the violets : of which they make two sorts ; one, where the lights are blue; and the other, where they are yellow.

For the first, put a lay of ultramarine and very pale white upon the lights; and shadow with carmine, ultramarine, and white, as for a drapery wholly violet; so that only the grand lights appear blue. Yet they must be dotted with violet, in which there is a great deal of white, and lost insensibly in the shades.

The other is done by putting upon the lights only, instead of blue, a lay of masticot; working the rest as in the drapery all violet, excepting that it must be dotted, and the light parts blended with the shadowy, that is, the yellow with the violet, with a little gamboge.

The carmine red is done like the last; that is, let the lights be done with mastieot, and the shades with carmine; and to lose the one in the other, make use of gamboge.

The lake red is done like that of earmine.

The green is done as the lake: always mixing verditer with lily or sap green, to make the shades; which are not very dark.

Several other sorts of draperies may be made at discretion, always taking eare to preserve the union of the colours, not only in one sort of cloth or so, but also in a group of several figures; avoiding, as much as the subject will allow, the putting of blue near the colour of fire, of green against black ; and so of other colours which cut and disjoin, and whose union is not kind enough.

Several other draperies are made of foul colours, as brown red, bistre, indigo, &e. and all in the same manner. Likewise of other colours, simple and compound; the agreement between which is always to be minded, that the mixture may produce nothing harsh and disagreeable to the eye. No certain rule can be laid down for this. The force and effect of your colours are only to be known from use and experience, and you must work according to that knowledge.

Linen cloths are done thus : After drawing the plaits or folds, as is done in a drapery, put a lay of white over all; then dead colour, and finish the shades with a mixture of ultramarine, black, and white, using more or less of the last, according to their strength or tenderness; and in the greatest deepenings put bistre, mixed with a little white; giving only some touches of this mixture, and even of pure bistre, upon the extremities of the greatest shadows, where the folds must be drawn, and lost with the rest.

They may be done in another manner, by making a general lay of this mixture of ultramarine, black, Draper and very pale white; and dead colour (as has been said before) with the same colour, but a little deeper. And when the shades are dotted and finished, heighten the lights with pure white, and lose them with the deepenings of the linen. But of whatever sort you make them, when they are finished, you must give a vellowish teint of orpiment and white to certain places; laying it lightly on, and as it were in water; so that what is underneath may, notwithstanding, plainly appear, as well the shadows as the dotting.

Yellow linen eloth is done by putting a lay of white, mixed with a little ochre. Then form and finish the shades with bistre, mixed with white and ochre; and in the thickest shades use pure bistre ; and before you finish, give some teints here and there of ochre and white, and others of white and ultramarine, as well upon the shades as the lights; but let them be very bright: and drown the whole together in dotting, and it will look finely. As you finish, heighten the extremities of the lights with masticot and white. You may add to this sort of linen, as well as to the white, eertain bars from space to space, as in Turkey mantuas; that is, small stripes blue and red with ultramarine and carmine; one of red between two of blue, very bright and elear upon the lights, and deeper upon the shades. Virgins are pretty often dressed with veils of this sort (by Popish painters), and searfs of this kind are put about necks that are bare; because they become the teint mighty well.

If you would have both these sorts of linen transparent, and the stuff or other thing that is beneath appear through them, make the first lay for them very light and elear, and mix in the eolour to shadow with, a little of that which is underneath, especially towards the end of the shades; and only do the extremities of the lights, for the yellow, with masticot and white; and for the white, with pure white.

They may be done in another manner, especially when you would have them altogether as clear as muslin, lawn, or gauze. To this end form and finish what is to be beneath, as if nothing was to be put over it. Then mark out the light and clear folds with white or masticot; and a shadowy with bistre and white, or with black, blue, and white, according to the colour you would make them off; making the rest somewhat fainter: yet this is not necessary but for the parts that are not to be so elear.

Crape is done the same way; excepting that the folds of the shades and the lights, and the borders too, are to be marked out with little filaments of black upon what is underneath; which is likewise to be finished beforehand.

When you would make a stuff like a watered tabby, make the waves upon it with a colour a little lighter, or a little darker, in the lights and the shades.

There is a manner of touching draperies which distinguishes the silken from the woollen. The last are more terrestrial and sensible; the others more light and fading. But it must be observed, that this is an effect which depends partly upon the stuff and partly upon the colour; and for the employing these in a manner suitable to the subjects and the deepenings of painting,

262

0

ect. IV.

Or painting, we shall here touch upon their different quali-

We have no colour which partakes more of light, nor which comes nearer the air, than white; which shows it to be fiekle and fleeting. It may, nevertheless, be held and brought to by some neighbouring colour, more heavy and sensible, or by mixing them together.

Blue is a most flecting colour: and so we see, that the sky and the remotest views of a picture are of this colour; but it will become lighter and fickler in proportion as it is mixed with white.

Pure black is the heaviest and most terrestrial of all colours; and the more of it you mix with others, the nearer you bring them to the eye.

Nevertheless, the different dispositions of black and white make also their effects different: for white often makes black disappear, and black brings white more into vicw; as in the reflection of globes, or other figures to be made round, where there are always parts that fly as it were from the eye, and deceive it by the craft of art: and under the white are here comprehended all the light colours; as under the black, all the heavy colours.

Ultramarine is then soft and light.

Ochre is not so much so.

Mastieot is very light; and so is verditer.

Vermilion and earmine come near this quality.

Orpiment and gamboge not so near.

Lake holds a certain mean, rather soft than rough.

Dutch pink is an indifferent colour, easily taking the quality of others. So it is made terrestrial by mixing it with colours that are so; and, on the contrary, the most light and fleeting by joining it with white or blue.

Brown red, umber, dark greens, and bistre, are the heaviest and most terrestrial, next to black.

Skilful painters, who understand perspective, and the harmony of colours, always observe to place the dark and sensible colours on the fore parts of their pictures; and the most light and fleeting they use for the distances and remote views. And as for the union of colours, the different mixtures that may be made of them will learn you the friendship or antipathy they have to one another. And upon this you must take your measures for placing them with such agreement as shall please the eye.

For the doing of laee, French points, or other things of that nature, put over all a lay of blue, black, and white, as for linen; then heighten the flowerwork with pure white : afterwards make the shades above with the first colour, and finish them with the same. When they are upon the carnation or naked parts of a pieture, or upon any thing else that you would show through another, finish what is beneath, as if nothing was to be put over it : and at top, make the points or laee with pure white, shadowing and finishing them with the other mixture.

If you would paint a fur, you must begin with a kind of drapery, done, if it be dark, with bistre and white, making the shadowings of the same colour, with less white. If the fur be white, do it with blue, white, and a little bistre. And when this beginning, or first forming, is done, instead of dotting, draw small strokes, turning, now in one manner, now in another, according to the course and flatting of the hair. Heighten Of the lights of dark furs with ochrc and white, and of the Carnations. other with white and a little blue.

For doing a building, if it be of stone, take indigo, bistre and white, with which make the beginning or first form of it; and for shadowing it, put less of this last; and more bistre than indigo, according to the colour of the stone you would paint. To these you may likewise add a little ochre, both for the forming and the finishing. But to make it finer, you must give, here and there, especially for old fabrics, blue and yellow teints, some with ochre, others with ultramarine, mixing always white with them, whether before the first forming, provided they appear through the draught, or whether upon it, losing or drowning them with the rest when you finish.

When the building is of wood, as there are many sorts, it is done at discretion; but the most ordinary way is to begin or first form with ochre, bistre, and white, and finish without white, or with very little; and if the shades are deep, with pure bistre. In the other they add sometimes vermilion, sometimes green or black; in a word, just according to the colour they would give it; and they finish with dotting, as in draperies and every thing else.

SECT. V. Of Carnations, or the naked parts of a-Painting.

THERE are in carnation so many different colourings, that it would be a difficult thing to give general rules upon so variable a subject. Nor are they minded, when one has got, by eustom and practice, some habit of working easily: and such as arc arrived to this degree, employ themselves in copying their originals, or else they work upon their ideas, without knowing how: insomuch that the most skilful, who do it with less reflection and pains than others, would likewise be more put to it to give an account of their maxims and knowledge in the matter of painting, if they were to be asked what colours they made use of for such and such a colouring, a teint here, and another there.

Nevertheless, as beginners want some instruction at the first, we will show in general after what manner several earnations are to be done.

In the first place, After having drawn your figure with carmine, and ordered your piece, apply for women and children, and generally for all tender colourings, a lay of white, mixed with a very little of the blue made for faces, of which we have told the composition; but let it hardly be seen.

And for men, instead of blue, they put in this first lay a little vermilion; and when they arc old, a little ochre is mixed with it.

Afterwards follow all the traces with vermilion, carmine, and white, inixed together; and begin all the shades with this mixture, adding white in proportion as they are weaker; and putting but little in the darkest, and none, in a manner, in certain places where strong touches are to be given : for instance, in the corner of the eye; under the nose; at the ears; under the ehiu; in the separations of the fingers; in all joints; at the corners of the nails; and generally in every part where you would mark out separations in

in shades that are obscure. Neither need you fear to Carnations give to those places all the force and strength they ought to have as soon as you begin or first form them, because in working at top with green, the rcd you have

put there is always weakened. After having begun, or first formed, or dead-coloured, with red, make blue teints with ultramarine and a great deal of white, upon the parts which fly from the eye; that is to say, upon the temples; under and in the corners of the eyes ; on both sides the mouth, above and below; a little upon the middle of the forehead; between the nose and the eyes; on the side of the checks; on the neck and other places where the flesh assumes a bluish cast. Yellowish teints are likewise made with ochre or orpiment, and a little vermilion mixed with white, under the eyebrows, on the sides of the nose towards the bottom, a little underneath the checks, and upon the other parts which rise and come nearer the cye. It is especially from these teints that the natural complexion is to be observed, in order to eatch it; for painting being an imitation of nature, the perfection of the art consists in the justness and simplicity of the representation, especially in face paint-

When, therefore, you have done your first lay, your When, therefore, you have done your first lay, your dead-colouring, and your teints, you must work upon the shades, dotting with green for the carnations or naked parts, mixing, according to the rule we have given for the teints, a little blue for the parts which fly from the eye; and, on the other hand, making it a little yellower for those that are more sensible; that is to say, which rise, and come nearer the eye: and at the end of the shades, on the side of the light, you must blend and lose your colour insensibly in the ground of the carnation with blue, and then with red, according to the places where you paint. If this mixture of green does not work dark enough at first, pass over the shades several times, now with red, and now with green; always dotting: and this do till they are as they should be.

And if you cannot with these colours give the shades all the force they ought to have, finish, in the darkest, with bistrc mixed with orpiment, ochre, or vermilion, and sometimes with pure bistre, according to the colouring you would make, but lightly, laying on your colour very clear.

You must dot upon the clear and bright places with a little vermilion or carmine, mixed with much white, and a very small matter of ochre, in order to lose them with the shadowy, and to make the teints die away insensibly into one another; taking care, as you dot, or hatch, to make your strokes follow the turnings and windings of the fleshy parts. For though the rule be to cross always, this dotting or hatching ought to appear a little more here, because it rounds the parts. And as this mixture might make a colouring too red, if it was always to be used, they work likewise in every part, to blend the teints and the shades with blue and a little green, and much white, so mixed as to be very pale; excepting, nevertheless, that this colour must not be put upon the cheeks, nor upon the extremities of the clear parts, no more than the other mixture upon these last, which must be left with all their light; as certain places of the chin, of the nose, and of the forehead, and upon the cheeks; which, and

3

the cheeks, ought nevertheless to be redder than the Of rest, as well as the feet, the hollows of the hands, and Carnation the fingers of both.

Observe, that these two last mixtures ought to be so pale, that the work shall hardly be visible; for they serve only to soften it; to unite the teints with one another, and the shades with the lights, and to drown the traces. Care must likewise be taken that you work not too much with the rcd mixture upon the blue teints, nor with the blue upon the others; but change the colour from time to time, when you perceive it works too blue or too red, till the work be finished.

The white of the eyes must be shadowed with this same blue, and a little flesh colour ; and the corners, on the side of the nose, with vermilion and white; giving them a little touch of carmine. The whole is softened with this mixture of vermilion, carmine, white, and a very small matter of ochre.

The apples or balls of the eyes are done with the mixture of ultramarine and white ; the last prevailing a little ; adding a little bistre, if they are yellowish ; or a little black, if they are gray. Make the little black circle in the middle, called the crystal of the eye; and shadow the balls with indigo, bistre, or black, according to the colour they are of; giving to each a small touch of pure vermilion round the crystal; which must be lost with the rest at the finishing. This gives vivacity to the eye.

The round or circumference of the eye is done with bistre and carmine ; that is to say, the slits or partings, and the eyelids, when they are large and bold ; especially the upper ones; which must afterwards be softened with the red or blue mixtures we have mentioncd before, to the end they may be lost in one another, and nothing seem intersected. When this is done, give a little touch of pure white upon the crystal, on the side of the lights. This makes the eye shine, and gives life to it.

The month is dead coloured with vermilion, mixed with white; and finished with carmine, which is softened as the rest. And when the carmine does not work. dark enough, mix a little bistre with it. This is to be understood of the corners in the separation of the lips and particularly, of certain mouths half open.

The hands, and all the other parts of carnation, are done in the same manner as the faces ; observing, that the ends of the fingers be a little redder than the rest. When your whole work is formed and dotted, mark the separations of all the parts with little touches of carmine and orpiment mixed together, as well in the shadowy as the light places; but a little deeper and stronger in the first, and lose them in the rest of the carnation.

The eyebrows and the beard are dead-coloured, as are the shades of carnations; and finished with bistre, ochre, or black, according to the colour they are of. drawing them by little strokes the way they ought to go; that is to say, give them all the nature of hair. The lights of them must be heightened with ochre and bistre, a little vermilion, and much white.

For the hair of the head, make a lay of bistre, ochre, and white, and a little vermilion. When it is very dark coloured, use black instead of ochre. Afterwards form the shadowy parts with the same colours, putting less

264

less white in them; and finish with pure bistre, or mixations. ed with ochre or black, by small strokes very fine, and close to each other, waving and buckling them accord-ing to the curling of the hair. The light parts must also be heightened by little strokes with ochre or orpiment, white, and a little vermilion. After which, lose the lights and the shades in each other, by working sometimes with a dark and sometimes with a light colour.

And for the hair about the forehead, through which the skin is seen, it must be first formed with the colour thereof, and that of the carnation, working and shadowing with one and the other, as if you designed to paint none. Then form it, and finish with bistre. The lights are to be heightened as the other. Gray bair is dead-coloured with white, black, and bistre, and finished with the same colour, but deeper ; heightening the bright and clear parts of the hair, as well as those of the eyebrows and the beard, with white and very pale blue, after having formed them as the others, with the colour of the flesh or skin; and finish with bistre.

But the most important thing is to soften one's work ; to blend the teints in one another, as well as the beard and the hair about the forehead, with the other hair and the carnation; taking especial care not to work rough and dry; and that the traces, turnings, and windings of the carnation or naked parts, be not intersected. You must likewise accustom yourself to put white in your colours only in proportion as you work lighter or darker; for the colour you use the second time must be always a little stronger and deeper than the first, unless it be for softening.

Different colourings are easily made, by putting more or less of red, or blue, or yellow, or bistre, whether for the dead-colouring, or for the finishing .--That for women ought to be bluish; that for children a little red; and both fresh and florid. That for men ought to be yellower; especially when they are old.

To make a colouring of death, there must be a first lay of white and orpiment, or a very pale ochre : deadcolour with vermilion, and lake, instead of carmine, and a good deal of white; and afterwards work over it with a green mixture, in which there is more blue than any other colour, to the end the flesh may be livid and of a purple colour. The tints are done the same way as in another colouring; but there must be a great many more blue than yellow ones, especially upon the parts which fly from the sight, and about the eyes; and the last are only to be upon the parts which rise and come nearer the eye. They are made to die away in one another, according to the ordinary manner; sometimes with very pale blue, and sometimes with ochre and white, and a little vermilion; softening the whole together. The parts and contours must be rounded with the same colours. The mouth is to be, in a manuer, of a quite violet. It is deadcoloured, however, with a little vermilion, ochre, and white; but finished with lake and blue; and to give it the deep strokes, they take bistre and lake, with which they likewise do the same to the eyes, the nose, and the ears. If it be a crucifix, or some martyr, upon whom blood is to be seen, after the finishing the

Vol. XIV. Part I.

carnation, form it with vermilion, and finish it with Of Land carmine, making in the drops of blood a little bright scapes. reflecting spark, to round them. For the crown of thorns, make a lay of sea-green and masticot; shadow it with bistre and green; and heighten the clear and light parts with masticot.

Iron is formed, or first laid, with indigo, a little black and white; and finished with pure indigo, heightening it with white.

For painting fire and flames, the lights are done with masticot and orpiment; and for the shades, they mix vermilion and carmine.

A smoke is done with black, indigo, and white, and sometimes with bistre; one may likewise add vermilion or ochre, according to the colour it is to be of.

Pearls are painted by putting a lay of white, and a little blue: they are shadowed and rounded with the same colour, deeper; a small white dot is made almost in the middle on the side of the light; and on the other side, between the shadow and the edge of the pearl, they give a touch with masticot, to make the reflection; and under the pearls is made a little shadow of the colour of the ground they are upon.

Diamonds are made with pure black; then they heighten them with little touches of white on the side of the light. It is the same thing for any other jewels you have a mind to paint : there is nothing to be done but to change the colour.

For making a figure of gold, put a lay of shell-gold, and shadow it with gallstone. Silver is done the same way; excepting that it must be shadowed with indigo.

One great means of acquiring a perfection in the art, is to copy excellent originals. We enjoy with pleasure and tranquillity the labour and pains of others. But a man must copy a great number before he is able to produce as fine effects ; and it is better to be a good copier than a bad author.

SECT. VI. Of Landscapes.

In the first place, After having ordered the economy of your landscape as of your other pieces, you must form the nearest grounds or lands, when they are to appear dark, with sap or lily-green, bistre, and a little-verditer, to give a body to your colour; then dot with this mixture, but a little darker, adding sometimes a little black to it.

For such pieces of ground as the light falls upon, and which are therefore clear and bright, make a lay of ochre and white, then shadow and finish with bistre. In some they mix a little green, particularly for shadowing and finishing.

There are sometimes upon the fore part certain reddish lands; which are dead-coloured with brown-red, white, and a little green; and finished with the same, putting a little more green in them.

For the making of grass and leaves upon the foreground, you must, when that is finished, form with seagreen, or verditer, and a little white : and for those that are yellowish, mix masticot. Afterwards shadow them with lily-green, or bistre and gallstone, if you would have them appear withered.

The grounds or lands at a little distance are formed LI with

Sect. VI.

Of

Of Land- with verditer, and shadowed and finished with sapscapes. green, adding bistre for some of the touches here and there.

Such as are at a greater distance, are done with sea-green and a little blue; and shadowed with verditer.

In a word, the farther they go, the more bluish they are to be made; and the farthest distance ought to be of ultramarine and white; mixing in some places small touches of vermilion.

Water is painted with indigo and white, and shadowed with the same colour, but deeper; and to finish it, instead of dotting, they do nothing but make strokes and traces without crossing; giving them the same turn with the waves, when there are any. Sometimes a little green must be mixed in certain places, and the light and clear parts heightened with pure white, particularly where the water foams.

Rocks are dead-coloured like buildings of stone; excepting that a little green is mixed for forming and shadowing them. Blue and yellow teints are made upon them, and lost with the rest in finishing. And when there are small branches, with leaves, moss, or grass, when all is finished, they are to be raised at top with green and masticot. They may be made yellow, green, and reddish, for appearing dry in the same manner as on the ground. Rocks are dotted as the rest; and the farther they are off the more grayish they are made.

Castles, old houses, and other buildings of stone and wood, are done in the manner above mentioned; speaking of those things, when they are upon the first lines. But when you would have them appear at a distance, you must mix brown-red and vermilion, with much white; and shadow very tenderly with this mixture; and the farther they are off, the weaker are the strokes to be for the separations. If they are covered with slate, it is to be made bluer than the rest.

Trees are not done till the sky be finished ; one may, nevertheless, spare the places of them when they contain a good number; and however it be, such as come near the eye, are to be dead-coloured with verditer, mixing sometimes ochre; and shadowed with the same colours, adding lily-green. Afterwards you must work leaves upon them by dotting without crossing: for this must be done with small longish dots, of a darker colour, and pretty full of it, which must be conducted on the side the branches go, by little tufts of a little darker colour. Then heighten the lights with verditer or sea-green, and masticot, making leaves in the same manner; and when there are dry branches or leaves, they are dead-coloured with brown-red or gallstone, with white ; and finished with gallstone, without white, or with bistre.

The trunks of trees are to be dead-coloured with ochre, white, and a little green, for the light and clear parts; and for the dark they mix black, adding bistre and green for shadowing one and the other.— Blue and yellow tints are likewise made upon them, and little touches given here and there with white and masticot; such as you ordinarily see upon the bark of trees.

The branches which appear among the leaves are done with ochre, verditer, and white; or with bistre

and white; according to the light they are placed in. They must be shadowed with bistre and lily-green.

Trees, which are at a little distance, are dead-eoloured with verditer and sea-green; and are shadowed and finished with the same colours, mixed with lilygreen. When there are some which appear yellowish, lay with oehre and white, and finish with gallstone.

For such as are in the distances and remote views, you must dead-colour with sea-green; with which, for finishing, you must mix ultramarine. Heighten the lights of one and the other with masticot, by small disjoined leaves.

It is the most difficult part of landscape, in manner of miniature, to leaf a tree well. To learn, and break one's hand to it a little, the way is to copy good ones; for the manner of touching them is singular, and cannot be acquired but by working upon trees themselves; about which you must observe to make little boughs, which must be leafed, especially such as are below and toward the sky.

And generally, let your landscapes be coloured in a handsome manner, and full of nature and truth; for it is that which gives them all their beauty.

SECT. VII. Of Flowers.

IT is an agreeable thing to paint flowers, not only on account of the splendour of their different colours, but also by reason of the little time and pains that are bestowed in trimming them. There is nothing but delight in it; and, in a manner, no application. Yea maim and bungle a face, if you make one eye higher than another; a small nose with a large mouth; and so of other parts. But the fears of these disproportions constrain not the mind at all in flower painting; for unless they be very remarkable, they spoil nothing. For this reason, most persons of quality, who divert themselves with painting, keep to flowers. Nevertheless, you must apply yourself to copy justly; and for this part of miniature, as for the rest, we refer you to nature, for she is your best model. Work, then, after natural flowers; and look for the tints and different colours of them upon your pallet : a little use will make you find them easily; and to facilitate this to you at the first, we shall, in the continuance of our design, show the manner of painting some ; for natural flowers are not always to be had; and one is often obliged to work after prints, where nothing is seen but graving.

It is a general rule, that flowers are designed and laid like other figures; but the manner of forming and finishing them is different: for they are first formed only by large strokes and traces, which you must turn at the first the way the small ones are to go, with which you finish: this turning aiding much thereto. And for finishing them, instead of hatching or dotting, you draw small strokes very fine, and very close to one another, without crossing; repassing several times, till your dark and your clear parts have all the force you would give them.

Of ROSES.—After making your first sketch, draw with carmine the red rosc, and apply a very pale lay of carmine and white. Then form the shades with the same colour, putting less white in it: and lastly, with pure DE-

pure carmine, but very bright and clear at the first; wers. fortifying it more and more as you proceed in your work, and according to the darkness of the shades. This is done by large strokes. Then finish; working upon it with the same colour by little strokes, which you must make go the same way with those of the graving, if it be a print you copy; or the way the leaves of the rose turn, if you copy after a painting, or after nature; losing the dark in the clear parts, and heightening the greatest lights, and the brightest or most lightsome leaves, with white and a little carmine. You must always make the hearts of roses, and the side of the shadow darker than the rest; and mix a little indigo for shadowing the first leaves, particularly when the roses are blown, to make them seem faded. The seed is dead-coloured with gamboge; with which a little sap-green is mixed for shadowing. Roses streaked with several colours, ought to be paler than others, that the mixture of colours may be better seen; which are done with carmine; a little darker in the shades, and very clear in the lights; always hatching by strokes. For white roses you must put a lay of white, and form and finish them as the red; but with black, white, and a little bistre; and make the seed a little yellower. Yellow roses are done by putting in every part a lay of masticot, and shadowing them with gamboge, gallstone, and bistre; heightening the clear and light places with masticot and white.

The stiles, the leaves, and the buds of all sorts of roses are formed with verditer, with which is mixed a little musticot and gamboge; and for shadowing them, they add sap green, putting less of the other colours when the shades are deep. The outside of the leaves ought to be bluer than the inside; wherefore it must be dead-coloured with sea green, and sap green mixed with that for shadowing, making the veins or fibres on this side clearer than the ground, and those on the other side darker. The prickles which are upon the stiles and buds of roses, are done with little touches of carmine, which are made to go every way; and for those that are upon the stalks, they are formed with verditer and carmine, and shadowed with carmine and bistre: making the bottom of the stalks more reddish than the top, i. e. you must mix with the green carmine and pure bistre.

Of TULIPS .- As there is an infinity of tulips, different from one another, one cannot pretend to mention the colours with which they are all done. We will only touch upon the handsomest, called streaked; and these streaks are dead-coloured with very clear carmine in some places, and with darker in others; finishing with the same colour by little strokes, which must be carried the same way with the streaks. And in others is put first a lay of vermilion. Then they form them by mixing carmine, and finish them with pure carmine. In some they put Florence lake over the vermilion instead of carmine. Some are done with lake and carmine mixed together, and with lake alone, or with white and lake for the first forming; whether it be roscpink or Florence lake. There are some of a purple colour, which are formed with ultramarine, carmine, or lake, sometimes bluer and some-times redder. The manner of doing both one and the other is the same; there is no difference but in the colours. You must, in certain places, as between

the streaks of vermilion, carmine, or lake, sometimes put blue made of ultramarine and white, and some-Flowers times a very bright purple, which is finished by strokes as the rest, and lost with the streaks. There are some likewise that have sallow tints, that are made with lake, bistre, and ochre, according as they are: but this is only in fine and rare tulips, and not in the common ones. For shadowing the bottom of them, they ordinarily take indigo and white for such whose streaks are of carmine. For such as are of lake, they take black and white ; with which, in some, bistre is mixed, and in others green. Some are likewise to be shadowed with gamboge and umber, and always by strokes and traces, that turn as the leaves turn. Other tulips are likewise done, called bordered; that is to say, the tulip is not streaked but on the edges of the leaves, where there is a border. It is white in the purple; red in the yellow; yellow in the red; and red in the white. The purple is laid with ultramarine, carmine, and white ; shadowing and finishing it with this mixture. The border is spared ; that is to say, let only a light lay of white be put there, and let it be shadowed with very bright indigo. The yellow is formed with gamboge, and shadowed with the same colour, mixing ochre and umber or bistre with it. The border is laid with vermilion, and finished with a very small matter of carmine. The red is formed with vermilion, and finished with the same colour, mixing carmine or lake with it. The bottom and the border arc done with gamboge; and for finishing, they add gallstone and umber, or bistre. The white is shadowed with black, blue, and white. Indian ink is very proper for this. The shadowings of it are very tender. It produces alone the effect of blue and white, mixed with the other black. The border of this white tulip is done with carmine. In all these sorts of tulips, they leave a nerve or sinew in the middle of the leaves that are brighter than the rest; and the borders are drowned at the bottom by small traces, turning crosswise; for they must not appear cut and separated, as the streaked or party-coloured. They make them likewise of several other colours. When they happen to be such whose bottoms on the inside are black, as it were, they form and finish them with indigo, as also the seed about the nozzle or stalk. And if the bottom is yellow, it is formed with gamboge, and finished by adding umber or bistre. The leaves and the stalks of tulips are ordinarily formed with sea green, and shadowed and finished with lily green, by large traces all along the leaves. Some may likewise be done with verditer, mixing masticot with it, and shadowed with sap green, that the green of the shades may be yellower.

The ANEMONY, or Wind-flower .- There are several sorts of them, as well double as single. The last are ordinarily without streaks. Some are made of a purple colour, with purple and white, shadowing them with the same colour; some redder, others bluer; sometimes very pale, and sometimes very dark. Others are formed with lake and white, and finished with the same, putting less white ; some without any white at all. Others are formed with vermilion, and shadowed with the same colour ; adding carmine. We see likewise white ones, and some of a citron colour. The last are laid with masticot; and one and the other shadowed

10

L12

Sect. VI

Of

Of Flowers.

268

shadowed and finished sometimes with vermilion, and sometimes with very brown lake, especially near the seed, at the bottom; which is often likewise of a blackish colour, that is done with indigo, or black and blue, mixing for some a little bistre; and always working by very fine strokes and traces, and losing the lights in the shades. There are others that are brighter and clearer at the bottom than anywhere else; and sometimes they are perfectly white there, though the rest of the flower be dark. The seed of all these anemonies is done with indigo and black, with a very little white, and shadowed with indigo; and in some it is raised with masticot. The double anemonies are of several colours. The handsomest have their large leaves streaked. Some are done, that is, the streaked or party coloured, with vermilion, to which carmine is added for the finishing; shadowing the rest of the leaves with indigo; and for the small leaves within, a lay is put of vermilion and white, and they are shadowed with vermilion mixed with carmine, mixing here and there some stronger touches, especially in the heart of the flower, next the great leaves on the side of the shadow. They finish with carmine, by little strokes and traces, turning the same way with the mixed or party colours, and the leaves. They form and finish the streaks or party colours of some others, as well as the small leaves, with pure carmine; leaving, nevertheless, in the middle of the last, a little circle, in which is laid dark purple, which is lost with the rest. And when all is finished, they give some touches with this same colour round about the small leaves, especially on the side of the shadow, drowning them with the large ones, the remainder of which is shadowed either with indigo or black. In some, the small leaves are done with lake or purple, though the party colours of the large ones be done with carmine. There are others, whose mixed colours are done with carmine, in the middle of most of the large leaves; putting in some places vermilion underneath, and losing these colours with the shadows of the bottom; which are done with indigo and white. The small leaves are laid with masticot, and shadowed with very dark carmine on the side of the shade, and with very clear on the side of the light, leaving there in a manner pure masticot, and giving only some little touches with orpiment and carmine, to separate the leaves, which may be shadowed sometimes with a very little pale green. There are double anemonies painted all red, and all purple. The first are formed with vermilion and carmine, in a manner without white, and shadowed with pure carmine, well gummed, that they may be very dark. Purple anemonies are laid with purple, and white, and finished with white. In a word, there are double anemonies as there are single ones, of all colours; and they are done in the same manner. The green of one and the other is verditer; with which masticot is mixed for forming. It is shadowed and finished with sap green. The stiles of them are a little reddish; wherefore they are shadowed with carmine mixed with bistre, and sometimes with green, after having laid them with masticot.

The CARNATION and the PINK .- It is with pinks and carnations as with anemonies and tulips; that is, there are some mixt-coloured, and others of one single colour. The first are streaked and diversified some-

times with vermilion and carnine; sometimes with pure lake, or with white ; some streaks very dark, and Flower others very pale; sometimes by little streaks and diversifications, and sometimes by large ones. Their bottoms are ordinarily shadowed with indigo and white. There are pinks of a very pale flesh colour, and streaked and diversified with another, a little deeper, made with vermilion and lake. Others, which are of lake and white, are shadowed and streaked without white. Others all red, which are done with vermilion and carmine as dark as possible. Others all of lake. And, lastly, there are others, wherein nature or fancy is the rule. The green of one and the other is sea green, shadowed with lily green or sap green.

The RED LILY .- It is laid with red lead, formed with vermilion, and in the deepest of the shades with carmine; and finished with the same colour by strokes and traces, turning as the leaves turn. The clear and light parts are heightened with red lead and white. The seed is done with vermilion and carmine. The green parts are done with verditer, shadowed with lily or sap green.

The DAY LILY .- There are three sorts of them :

I. The gridelin, a little red;

2. The gridelin, very pale ; and,

3. The white.

For the first they put a lay of lake and white, and shadow and finish with the same colour deeper; mixing a little black to deaden it, especially in the darkest places.

The second are laid with white, mixed with a very little lake and vermilion, in such a manner that these two last colours are hardly seen. Afterwards they shadow with black and a little lake, working redder in the middle of the leaves, next the stalks; which ought to be, as also the seed, of the same colour, particularly towards the top; and at the bottom a little greener.

The stile of the seed is laid with masticot, and shadowed with sap green.

The other day lilies are done by putting a lay of pure white, and shadowing and finishing with black and white.

The stalks of these last, and the greens of them all, are done with sea green, and shadowed with sap green.

The HYACINTH, or Purple-flower .- There are four sorts of them :

The blue, a little dark; Others paler; The gridelin;

And the white.

The first are laid with ultramarine and white; and shadowed and finished with less white. Others are laid and shadowed with pale blue. The gridelines are formed with lake and white, and a very small matter of ultramarine; and finished with the same colour a little deeper. For the last they put a lay of white; then they shadow them with black, with a little white; and finish them all by strokes and traces, following the turnings and windings of the leaves. The green and the stalks of such as are bluc, are done with sea and lily green very dark : and in the stalks of the first may be mixed a little carmine, to make them reddish. The stalks of the two others, as also the green, are

are formed with verditer and masticot, and shadowed Of wers. with sap green.

The PIONY .- A lay of Veniee lake and white must be put on all parts, pretty strong : then shadow with less white, and with none at all in the darkest places : after which finish with the same colour by traces, turning them as for the rose; gumming it very much in the deepest of the shades; and raising the lights and the edges of the most lightsome leaves with white and a little lake. Little veins are likewise made, which go like the strokes in hatching, but are more visible. The green of this flower is done with sea green, and shadowed with sap green.

CowsLIPS .- They are of four or five colours. There are some of a very pale purple.

The gridelin. The white and the yellow.

The purple is done with ultramarine, carmine, and white; putting less white for shadowing. The gridelin is laid with Venice lake, and a very small matter of ultramarine, with much white ; and shadowed with the same colour deeper. For the white a lay of white must be put; and they must be shadowed with black and white ; and finished, as the others, by traces or strokes. The heart of these cowslips is done with masticot in the shape of a star, which is shadowed with gamboge, making a little circle in the middle with sap green. The yellow are laid with masticot, and shadowed with gamboge and umber. The stiles, the leaves, and the buds, are formed with verditer, mixed with a little mastieot, and finished with sap green; making the fibres or veins, which appear upon the leaves, with this same colour; and heightening the lights of the largest with masticot.

The RANUNCULUS, or Crow-foot .- There are several sorts of them: the finest are the orange-coloured. For the first, they put a lay of vermilion, with a very small matter of gamboge; and add earmine for shadowing; finishing it with this last colour, and a little gallstone. In the others may be put Veniee lake instead of carmine, especially in the heart of the flower. The orange-coloured are laid with gamboge, and finished with gallstone, vermilion, and a little earmine ; leaving some little yellow streaks. The green of the stalks is done with verditer and very pale masticot; mixing lily green to shadow them. That of the leaves is a little darker.

The CROCUS .- These are of two colours :

Yellow and purple. The yellow are formed with mastieot and gallstone, and shadowed with gamboge and gallstone: after which, upon each leaf, on the outside, are made three streaks, separate from one another, with bistre and pure lake; which are lost, by little traces, in the bottom. The outside of the leaves is left all yellow .- The purple is laid with carmine, mixed with a little ultramarine, and very pale white. They are formed and finished with less white ; making likewise, in some, purple stripes or streaks, very dark, as in the yellow; and in others only small veins. The seed of both is yellow, and is done with orpiment and gallstone. For the stiles, they put a lay of white, and shadow with black, mixed with a little green. The green of this flower is formed with very pale verditer, and shadowed with sap-green.

The IRIS .- The Persian iris is done by putting, for the inside leaves, a lay of white, and shadowing them with indigo and green together, leaving a little white separation in the middle of cach leaf; and for Flowers. those on the outside, they put in the same place a lay of masticot, which is shadowed with gallstone and orpiment; making little dark and longish dots over all the leaf, at a small distance from one another. And at the end of each are made large stains, with bistre and lake in some, and in others with pure indige, but very black. The rest, and the outside of the leaves, are shadowed with black. The green is formed with sea green, and very pale masticot, and shadowed with sap green. The Susian iris is laid with purple and white, putting a little more earmine than ultramarine ; and for the shades, especially in the middle leaves, they put less white; and, on the contrary, more ultramarine than earmine; making the veins of this very colour, and leaving in the middle of the inside leaves a little yellow sinew. There are others which have this very sinew in the first leaves; the end of which only is bluer than the rest. Others are shadowed and finished with the same purple, redder: They have also the middle sinew on the outside leaves; but white and shadowed with indigo. There are likewise yellow ones; which are done by putting a lay of masticot and orpiment; shadowing them with gallstone, and making the veins upon the leaves with bistre. The green of one and the other is done with sea green, mixing a little masticot for the stiles. They are shadowed with sap green.

The JASMINE.-It is done with a lay of white, and shadowed with black and white; and for the outside of the leaves, they mix a little bistre; making the half of each, on this side, a little reddish with carmine.

The TUBEROSE .- For the doing of this, they make a lay of white, and shadow with black, with a little bistre in some places; and for the outside of the leaves they mix a little earmine, to give them a reddish teint, particularly upon the extremities. The seed is done with masticot, and shadowed with sap green. The green of it is laid with verditer, and shadowed with sap green.

The HELLEBORE .- The flower of hellebore is done almost in the same manner; that is, let it be laid with white, and shadowed with black and bistre, making the outside of the leaves a little reddish here and there. The seed is laid with dark green, and raised with masticot. The green of it is foul and rusty, and is formed with verditer, masticot, and bistre ; and finished with sap green and bistre.

The WHITE LILY .- It is laid with white, and shadowed with black and white. The seed is done with orpiment and gallstone. And the green is done as in the tuberose.

The SNOW-DROP .- It is formed and finished as the white lily. The seed is laid with masticot, and shadowed with gallstone. And the green is done with sea and sap green.

The JONQUIL.-It is laid with masticot and gallstone, and finished with gamboge and gallstone. The green is formed with sea green, and shadowed with sap green.

The DAFFODIL .- All daffodils, the yellow, the double, and the single, are done by putting a lay of masticot : they are formed with gamboge, and finished by adding umber and bistre; excepting the bell in the middle, which is done with orpiment and gallstone, bordered

270

bordered or edged with vermilion and carmine. The Flowers. white are laid with white, and shadowed with black and white; excepting the cup or bell, which is done with masticot and gamboge. The green is sea green, shadowed with sap green.

The MARIGOLD .- It is done by putting a lay of masticot, and then one of gamboge; shadowing it with this very colour, after vermilion is mixed with it : and for finishing, they add gallstone and a little carmine. The green is done with verditer, shadowed with sap green.

The AUSTRIAN ROSE .- For making the Austrian rose, they put a lay of masticot, and another of gamboge. Then they form it, mixing gallstone; and finish it with the last colour, adding bistre and a very small matter of carmine in the deepest shades.

The INDIAN PINK, or French Marigold .--- It is done by putting a lay of gamboge; shadowing it with this colour, after you have mixed a good deal of carmine and gallstone with it; and leaving about the leaves a little yellow border of gamboge, very clear in the lights, and darker in the shades. The seed is shadowed with bistre. The green, as well of the rose as the pink, is formed with verditer, and finished with sapgreen.

The SUN-FLOWER .- It is formed with masticot and gamboge, and finished with gallstone and bistre. The green is laid with verditer and masticot, and shadowed with sap green.

The PASSION FLOWER .- It is donc as the rose, and the green of the leaves likewise; but the veins are done with a darker green.

POETICAL PINKS and SWEET WILLIAM .- They are done by putting a lay of lake and white; shadowing them with pure lake, with a little carmine for the last; which are afterwards dotted on all parts with little round dots, separate from one another; and the threads in the middle are raised with white. The green of them is sea green, which is finished with sap green.

The SCABIOUS .- There are two sorts of scabious, the red and the purple. The leaves of the first are laid with Florentine lake in which there is a little white; and shadowed without white; and for the middle, which is a great boss or husk in which the seed lies, it is formed and finished with pure lake, with a little ultramarine or indigo to make it darker. Then they make little white longish dots over it, at a pretty distance from one another, clearer in the light than in the shade, making them go every way. The other is done by putting a lay of very pale purple, as well upon the leaves as the boss in the middle ; shadowing both with the same colour, a little deeper: and instead of little white touches for the seed, they make them purple; and about each grain they make out a little circle, and this over the whole boss or husk in the middle. The green is formed with verditer and masticot, and shadowed with sap green.

The SWORD or Day Lily .-- It is laid with Florence lake and very pale white; formed and finished with pure lake, very clear and bright in some places, and very dark in others; mixing even bistre in the thickest of the shades. The green is verditer, shadowed with sap green.

HEPATICA, or Liverwort .- There is red and blue. The last is done by putting on all parts a lay of ultra-

marine, white, and a little carmine or lake : shadow-Of ing the inside of the leaves with the mixture, but Flower deeper; excepting those of the first rank; for which, and for the outside of every one of them, they add indigo and white, that the colour may be paler, and not so fine. The red is laid with lake columbine and very pale white ; and finished with less white. The green is done with verditer, masticot, and a little bistre; and shadowed with sap green, and a little bistre, especially on the outside of the leaves.

The POMEGRANATE .- The flower of the pomegranate is laid with red lead; shadowed with vermilion and carmine; and finished with this last colour. The green is laid with verditer and masticot, and shadowed with sap green.

The flower of the Indian BEAN .- It is done with a lay of Levant lake and white; shadowing the middle leaves with pure lake ; and adding a little ultramarine for the others. The green is verditer, shadowed with sap green.

The COLUMBINE .- There are columbines of several colours: the most common are the purple, the gridelin, and the red. For the purple, they lay with ultramarine, carmine, and white; and shadow with this mixture deeper. The gridelin are done the same way, putting a great deal less ultramarine than carmine. The red are done with lake and white, finishing with less white. There are some mixed flowers of this kind, of several colours ; which must be formed and finished as the others, but paler, making the mixtures of a little darker colour.

The LARK'S HEEL .- These are of different colours, and of mixed colours: the most common are the purple, the gridelin, and the rcd; which are done as the columbines.

VIOLETS and PANSIES .- Violets and pansies are done the same way; excepting that in the last the two middle leaves are bluer than the others; that is, the borders or edges; for the inside of them is yellow: and there little back veins are made, which take their beginning from the heart of the flower, and die away towards the middle.

The MUSCIPULA, or Catch-fly .- There are two sorts of it, the white and the red ; the last is laid with lake and white, with a little vermilion, and finished with pure lake. As for the knot or nozzle of the leaves, it is formed with white and a very small matter of vermilion, mixing bistre or gallstone to finish it. The leaves of the white are laid with white; adding bistre and masticot upon the knots which are shadowed with pure bistre, and the leaves with black and white. The green of all these flowers is done with verditer and masticot, and shadowed with sap green.

The CROWN IMPERIAL, -- which is of two colours, the yellow and the red. The first is done by putting a lay of orpiment, and shadowing it with gallstone and orpiment with a little vermilion. The other is laid with orpiment and vermilion, and shadowed with gallstone and vermilion; making the beginning of the leaves next the stile, with lake and bistre, very dark; and veins with this mixture both in one and the other, all along the leaves. The green is done with verditer and masticot, shadowed with sap green and gamboge.

The CYCLAMEN, or Sowbread.-The red is laid with

nister.

with carmine, a little ultramarine, and much white; owers. and finished with the same colour, deeper; putting, in a manner, only carmine in the middle of the leaves, next the heart, and in the rest add a little more ultramarine. The other is laid with white, and shadowed with black. The stalks of one and the other ought to be a little reddish; and the green, verditer and sap green.

The GILLIFLOWER .- There are several sorts of gilliflowers; the white, the yellow, the purple, the red, and the mixed of various colours. The white arc laid with white, and shadowed with black, and with a little indigo in the heart of the leaves. The yellow, with masticot, gamboge, and gallstone. The purple are formed with purple and white; and finished with less white; making the colour brighter in the heart, and even a little ycllowish. The red with lake and white; finishing them with white. The mixed coloured are laid with white, and the mixtures are sometimes made with purple, in which there is much ultramarine; others again, in which there is more carmine. Sometimes they are of lake, and sometimes of carmine. Some are done with white, and others without white; shadowing the rest of the leaves with indigo. The seed of all is formed with verditer and masticot, and finished with sap green. The leaves and stiles are laid with the same green, mixing sap green to finish them.

FRUITS, fishes, serpents, and all sorts of reptiles, are to be touched in the same manner as the figures of men are; that is, hatched or dotted.

Birds and all other animals are done like flowers, by strokes or traces.

Never make use, for any of these things, of white lead. It is only proper in oil. It blackens like ink when only tempered with gum; especially if you set your work in a moist place, or where perfumes are. Ceruss of Venice is as fine, and of as pure a white. Be not sparing in the use of this, especially in forming or dead-colouring; and let it enter into all your mixtures, in order to give them a certain body, which will

render your work gluish, and make it appear soft, plump, and strong.

The taste of painters is, nevertheless, different in this point. Some use a little of it, and others none at all. But the manner of the last is meagre and dry. Others use a great deal; and doubtless it is the best method, and most followed among skilful persons; for besides that it is speedy, one may by the use of it copy all sorts of pictures; which would be almost impossible otherwise; notwithstanding the contrary opinion of some, who say, that in miniature we cannot give the force and all the different teints we see in pieces in oil. But this is not true, at least of good painters; and effects prove it pretty plainly: for we see figures, landscapes, pictures, and every thing else in miniature, touched in as grand, as true, and as noble a manner (though more tender and delicate), as they are in oil.

However, painting in oil has its advantages; were they only these, that it exhibits more work, and takes up less time. It is better defended likewise against the injuries of time; and the right of birth must be granted it, and the glory of antiquity.

But miniature likewise has its advantages; and without repeating such as have been mentioned already, it is neater and more commodious. You may easily carry all your implements in your pockets, and work when and wherever you please, without such a number of preparations. You may quit and resume it when and as often as you will; which is not done in the other; in which one is rarely to work dry.

To conclude: In the art of painting, excellence does not depend upnn the greatness of the subject, but upon the manner in which it is handled. Some catch the airs of a face well; others succeed better in landscapes : some work in little, who cannot do it in large : some are skilled in colours, who know little of design : others, lastly, have only a genius for flowers : and even. the Bassans got themselves a fame for animals; which they touched in a very fine manner, and better than any. thing else.

#### M Ι N

MINIM, in Music, a note equal to two crotchets, or half a semibrevc. See Music.

MINIMS, a religious order in the church of Rome, founded by St Francis de Paula, towards the end of the 15th century. Their habit is a coarse black woollen stuff, with a woollen girdle, of the same colour, tied in five knots. They are not permitted to quit their habit and girdle night nor day. Formerly they went barefooted, but are now allowed the use of shoes

MINIMUM, in the higher geometry, the least quantity attainable in a given case.

MINISTER, a person who preaches, performs religious worship in public, administers the sacraments, &c.

MINISTER of State, a person to whom the prince intrusts the administration of government. See COUN-CIL.

#### Ι N M

Foreign MINISTER, is a person sent into a foreign Minister country, to manage the affairs of his province or of the state to which he belongs. Of these there are two kinds : those of the first rank are ambassadors and envoys extraordinary, who represent the persons of their sovereigns; the ministers of the second rank are the ordinary residents.

MÍNIUM, or RED-LEAD. See CHEMISTRY Index.

MINNIN, a stringed instrument of music among the ancient Hebrews, having three or four chords to it, although there is reason to question the antiquity of this instrument; both because it requires a hair bow, which was a kind of plectrum not known to the ancients, and because it so much resembles the modern viol. Kircher took the figures of this, the machul, chinnor, and psaltery, from an old book in the Vatican library.

Flowers.

Minnin.

MINOR.

Minor.

MINOR, a Latin term, literally denoting less ; Minorca. used in opposition to major, greater.

MINOR, in Law, denotes a person under age; or who, by the laws of the country, is not yet arrived at the power of administering his own affairs, or the posession of his estate. Among us, a person is a minor till the age of twenty-one, before which time his acts are invalid. See AGE, and INFANT.

It is a maxim in the common law, that in the king there is no minority, and therefore he hath no legal guardian; and his royal grants and assents to acts of parliament are good, though he has not in his natural capacity attained the legal age of twenty-one. It is also provided by the custom and law of parliament, that no one shall sit or vote in either house unless he be twenty-one years of age. This is likewise expressly declared by stat. 7 and 8 Will. III. cap. 25. with regard to the house of commons.

MINOR in Logic, is the second proposition of a formal or regular syllogism, called also the assumption.

MINOR, in Music, is applied to certain concords, which differ from or are lower than others of the same denomination by a lesser semitone or four commas .---Thus we say, a third minor, or lesser third, or a sixth major and minor. Concords that admit of major and minor, i. e. greater and less, are said to be imperfect concords.

MINORCA, an island of the Mediterranean, situated between 39 and 40 degrees of north latitude, and near four degrees of east longitude. It is about 33 miles in length from north-west to south-east, in breadth from eight to twelve, but in general about ten miles ; so that in size it may nearly equal the county of Huntingdon or Bedfordshire. The form is very irregular; and the coasts are much indented by the sea, which forms a great number of little creeks and inlets, some of which might be very advantageous.

This island is one of those called by the ancient Romans Baleares, which arose from the dexterity of the inhabitants in using the sling. It fell under the power of the Romans, and afterwards of the northern barbarians. From them it was taken by the Arabs; who were subdued by the king of Majorea, and he by the king of Spain. The English subdued it in 1708; it was afterwards retaken by the French in 1756, but restored to Britain by the treaty of Paris in 1763. The Spaniards took it in 1782; the British regained it in 1798; but it was given up in 1802, and continues in the possession of Spain.

The air of this island is much more clear and pure than in Britain ; being seldom darkened with thick fogs ; yet the low valleys are not free from mists and unwholesome vapours; and in windy weather the spray of the sea is driven over the whole island. Hence it happens that utensils of brass or iron are extremely susceptible of rust, in spite of all endeavours to preserve them ; and household furniture becomes mouldy. The summers are dry, clear, calm, and excessively hot ; the autumns moist, warm, and unequal; at one time perfectly serene, at another cloudy and tempestuous. During the winter there are sometimes violent storms, though neither frequent nor of long continuance; and whenever they cease, the weather returns to its usual serenity. The spring is always variable, but resembles the winter more than the summer. The changes of heat and cold

Ι

are neither so great nor so sudden in this climate as in Minorea many others. In the compass of a year, the thermometer seldom rises much above the 80th, or falls below the 48th degree. In summer there is scarcely ever a difference of four or five degrees between the heat of the air at noon and at night; and in winter the variation is still less considerable. But this must be understood of a thermometer shaded from the influence of the solar beams: for if exposed to them it will often rise 12, 14, or 16 degrees higher than what we have mentioned; and in other seasons the difference between the heat of the air in the sun and the shade is much greater. Yet even in the dog-days, the heat of the atmosphere, at least in open places, seldom surpasses that of human blood. The winds are very boistcrous about the equinoxes, and sometimes during the winter. At other times they are generally moderate, and, according to the observations of seamen, they rarely blow in the same direction near the islands adjacent to the gulf of Lyons as in the open sea. During the summer there is commonly a perfect calm in the mornings and evenings; but the middle of the day is cooled by refreshing breezes which come from the east, and following the course of the sun, increase gradually till two or three in the afternoon, after which they insensibly die away as night approaches. This renders the heat of the sun less dangerous and inconvenient; and if these breezes intermit for a day or two, the natives grow languid and inactive from the heat. The northerly winds in general are clear and healthy, dispel the mists, and make a clear blue sky; whilst those which blow from the opposite quarter, render the air warm, moist, and unhealthy. The north wind is superior in power to all the rest; which appears from hence, that the tops of all the trees incline to the south, and the branches on the north side are bare and blasted. The next to it in force is the north-west. Both are frequent towards the close of winter and in the spring; and, being dry and cold, they shrivel up the leaves of the vegetables, destroy their tender shoots, and are often excessively detrimental to the vineyards and rising corn. The piercing blasts at that season from the north-east, as they are more moist, and more frequently attended with rain, are less prejudicial. The south and south-east winds are by much the most unhealthy. In whatever seasons they blow, the air is foggy, and affects the breathing; but in the summer season they are sultry and suffocating. An excessive dejection of spirits is then a universal complaint; and on exposing the thermometer to the rays of the sun, the mercury has frequently riscn above the 100th degree. The west wind is usually drier than the south : the east is cold and blustering in the spring, and sultry in the summer.

The weather in Minorca is generally fair and dry; but when it rains, the showers are heavy, though of short continuance, and they fall most commonly in the night. The sky in summer is clear, and of a beautiful azure, without clouds or rain ; but moderate dews descend regularly after sunset. In autumn the weather becomes less serene; whirlwinds and thunder become frequent; and in the night time lightning, and those meteors called falling stars, are very common. Water spouts also are often seen at that season, and frequently break upon the shore. A sudden alteration in the weather takes place about the autumnal equinox; the skies are

inorea. are darkened with clouds, and the rains fall in such quantities, that the torrents thereby occasioned, pouring down from the hills, tear up trees by the root, carry away cattle, break down fences, and do considerable mischief to the gardens and vineyards. But these anniversary rains are much more violent than lasting; always falling in sudden and heavy showers, with intervals of fair weather. They are accompanied with thunder, lightning, and squalls of wind, most commonly from the north. Hail and snow are often intermixed with the rains which fall in winter and in spring ; but the snow, for the most part, dissolves immediately; and ice is here an uncommon appearance.

The whole coast of Minorea lies low; and there are only a few hills near the centre, of which the most considerable, named Toro by the inhabitants, may be seen at the distance of 12 or 14 leagues from the land. The surface of the island is rough and unequal; and in many places divided by long narrow vales of a considerable depth, called *barancoes* by the natives. They begin towards the middle of the island, and after several windings terminate at the sea. The south west side is more plain and regular than towards the north-east; where the hills are higher, with low marshy valleys betwixt them, the soil less fruitful, and the whole tract unhealthy to man and beast. Near the towns and villages the fields are well cultivated, and enclosed with stone walls; but the rest for the most part are rocky, or covered with woods and thickets. There are some pools of standing water, but very few rivulets, which is the greatest defect about the island, as the inhabitants have scareely any wholesome water excepting what is saved from the elouds.

The soil is light, thin, and very stony, with a good deal of sea salt, and, in some places, of calcareous nitre intermixed. In most places there is so little earth, that the island appears to be but one large irregular rock, covered here and there with mould, and an infinite variety of stones. Notwithstanding this, however, it is not only extremely proper for vineyards, but produces more wheat and barley than could at first sight be imagined; and if the peasants may be credited, it would always yield a quantity of corn and wine sufficient for the natives, did not the violence of the winds, and the excessive drought of the weather, frequently spoil their crops. The fields commonly lie fallow for two years, and are sown the third. About the latter end of winter, or the beginning of spring, they are first broke up : and next autumn, as soon as the rains fall, they are again ploughed and prepared for receiving the proper seeds. The tillage is very easily performed; for a plough so light as to be transported from place to place on the ploughman's shoulder, and to be drawn by a heifer, or an ass sometimes assisted by an hog, is sufficient for opening so thin a soil. The later the harvest happens, the more plentiful it proves. The barley is usually cut down about the 20th of May and the wheat is reaped in June, so that the whole harvest is commonly got in by Midsummer day. The grain is not thrashed with flails as in this country, but trodden out on a smooth piece of rock by oxen and asses, according to the custom of the eastern nations.

The natives of Minorca are commonly lean, thin, and well-huilt, of a middle stature, and olive com-Vol. XIV. Part I. +

plexion; but their character is by no means agree- Minorea. able. Such is the natural impetuosity of their temper, " that the slightest cause provokes them to anger, and they seem to be incapable of forgiving or forgetting any injury. Hence quarrels break out daily, even among neighbours and relations : and family disputes are transmitted from father to son; and thus, though lawyers and pettifoggers are very numerous in this country, there are still too few for the clients. Both sexes are, by constitution, extremely amorous : they are often betrothed to each other while children, and marry at the age of 14. The women have easy labours, and commonly return in a few days to their usual domestic business; but, lest the family should become too numerous for their income, it is a practice among the poorer sort to keep their children at the breast for two or three years, that by this means the mothers may be hindered from breeding.

Bread of the finest wheat flour, well fermented and well baked, is more than half the diet of people of all ranks. Rice, pulse, vermicelli, herbs and roots from the garden, summer fruits, pickled olives and pods of the Guinea pepper, make up almost all the other half, so that scarce a fifth of their whole food is furnished from the animal kingdom, and of this fish makes by much the most considerable portion. On Fridays, and other fast days, they abstain entirely from flesh; and during Lent they live altogether on vegetables and fish, excepting Sundays, when they are permitted the use of eggs, cheese, and milk. Most of their dishes are high-seasoned with pepper, cloves, einnamon, and other spices; and garlic, opions, or leeks, are almost constant ingredients. They eat a great deal of oil, and that none of the sweetest or best flavoured ; using it not only with salads, but also with boiled and fried fish, greens, pulse, &c. instead of butter. A slice of bread soaked in boiled water, with a little oil and salt, is the common breakfast of the peasants, well known by the name of oleagua. Their ordinary meals are very frugal, and consist of very little variety; but on festivals and other solemn occasions their entertainments are to the last degree profuse and extravagant, insomuch that the bill of fare of a country farmer's wedding dinner would searce be eredited.

With regard to other matters, the Minorquins are accused of prodigious indolence in the way of business, and neglect of the natural advantages they possess. In the bowels of the earth are iron, copper, and lead ores, of none of which any use has been made except the last. A lead mine was worked to advantage some time ago, and the ore sent into France and Spain for the use of the potteries in those countries. The proprietor discontinued his work on some small discouragement; and indeed it is said, that these people are of all mankind the most easily put out of conceit with an undertaking that docs not bring them in mountains of present gain, or that admits of the slightest probability of disappointing their most sanguine expectations : nor will their purse admit of many disappointments; and thus their poverty co-operating with their natural despondence and love of ease, is the principal cause of their backwardness to engage in projects, though ever so promising for the improvement of their private fortune, and the advantage of the commerce of their Mm country.

Minorca. country. This lead ore went under the name of vernis among the natives, as it was wholly used by the potters in varnishing and glazing their earthen vessels.

There are few exports of any account, and they are obliged to their neighbours for near one-third of their corn, all their oil, and such a variety of articles of less consideration, that nothing could preserve them from a total bankruptey, but the English money eirculated by the troops, which is exchanged for the daily supplies of provisions, increased by the multiplication of vineyards, the breeding of ponltry, and the production of vegetables, in a proportion of at least five to one since the island has been in our possession. It will not require many words to enumerate their exports: they make a sort of eheese, little liked by the English, which sells in Italy at a very great price; this, perhaps, to the amount of 8001. per annum .- The wool they send abroad may produce 9001. more .- Some wine is exported; and, if we add to its value that of the home consumption, which has every merit of an export, being nine parts in ten taken off by the troops for ready money, it may well be estimated at 16,000l. a-year. In honey, wax, and salt, their yearly exports may be about 400l. and this comes pretty near the sum of their exports, which we estimate together at 18,1001. sterling per annum.

A vast balance lies against them, if we consider the variety and importance of the articles they fetch from other countries, for which they must pay ready cash. Here it may be necessary to withdraw some things from the heap, such as their cattle, sheep, and fowls, on which they get a profit; for the country does not produce them in a sufficient abundance to supply them, especially when we have a fleet of men of war stationed there.

Their imports are, corn, cattle, sheep, fowls, tobaeco, oil, rice, sugar, spices, hardware, and tools of all kinds; gold and silver lace; choeolate, or cocoa to make it; tobaeco, timber, plank, boards, millstones, tobacco pipes, playing cards, turnery ware, seeds, soap, saddles; all manner of eabinetmakers work, iron spikes, nails, fine earthen ware, glass lamps, brasiery; paper, and other stationary wares; copperas, galls, dye stuffs, painters brushes and colours; musical instruments, music, and strings; watches, wine, fruit, all manner of fine and printed linens, muslins, cambrics, and laces; bottles, corks, starch, indigo, fans, trinkets, toys, ribbands, tape, needles, pins, silk, mohair, lanthorns, eordage, tar, pitch, rosin, drugs, gloves, fire-arms, gunpowder, shot, and lead; hats, caps, velvet, cotton stuffs, woollen cloths, stockings, eapes, medals, vestments, lustres, pietures, images, agnus dei's, books, pardons, bulls, relicks, and 'indulgeneics.

The island is divided into what they style terminos, of which there were anciently five, now reduced to four, and resemble our counties. The termino of Ciudadella, at the north-western extremity of the island, is so styled from this place, which was once a city, and the capital of Minorca. It makes a venerable and majestic figure, even in its present state of decay, having in it a large Gothic cathedral, some other churches and convents, the governor's palace, and an exchange, which is no contemptible pilc .- There are in it 600 houses, which, before the seat of government and the courts of justice

were removed to Mahon, were fully inhabited; and Minor there are still more gentlemen's families here than in all the rest of the island. It hath a port coromodious enough for the vessels employed in the trade of this country, which, though in the possession of a maritime power, is less than it formerly was. It is still, in the style of our officers, the best quarters (and there are none bad) in the country; and if there was a civil government, and the place made a free port, the best judges are of opinion it would very soon become a flourishing place again; and the fortifications, if it should be found necessary, might then also be easily restored and improved.

The termino of Fererias is the next, a narrow slip reaching cross from sea to sea, and the country little cultivated ; it is therefore united to Mercandal. In this last termino stands Mont-toro in the very centre of the isle, and the highest ground, some say the only mountain in it; on the summit of which there is a convent, where even in the hottest months the monks enjoy a cool air, and at all times a most delightful prospect. About six miles north from Mont-toro stands the castle that eovers Port-Fornelles, which is a very spacious harbour on the east side of the island. There are in it shoals and foul ground, which, to those who are unacquainted with them, render it difficult and dangerous; yet the packets bound from Mahon to Marseilles frequently take shelter therein; and while the Spaniards were in possession of the isle, large ships and men of war frequented it. At a small distance from this lics another harbour called Adia, which runs far into the land; but being reputed unsafe, and being so near Fornelles, is at present useless. The country about it is, however, said to be the pleasantest and wholesomest spot in the island, and almost the only one plentifully supplied with excellent spring water; so that the gardens are well laid out, and the richest and finest fruits grow here in the highest perfection. Alaior is the next termino, in which there is nothing remarkable but the capital of the same name, well situated on an eminence, in a pleasant and tolerably cultivated country.

The termino of Mahon, at the south-east end of the island, is at present the most considerable of them all, containing about 60,000 English acres, and nearly onehalf of the inhabitants in Minorea. The town of Mahon derives its name from the Carthaginian general Mago, who is universally allowed to be its founder .--It stands on an eminence on the west side of the harbour, the ascent pretty steep. There are in it a large church, three convents, the governor's palaee, and some other public edifices. It is large, but the streets are winding, narrow, and ill paved. The fortress of St Philip stands near the entrance of the harbour, which it covers; is very spacious, of great strength, with subterranean works to protect the garrison from bombs, large magazines, and whatever else is necessary to render it a complete fortification, and hath a numerous and well disposed artillery. Port Mahon is allowed to be the finest harbour in the Mediterranean, about 90 fathoms wide at its entrance, but within very large and safe, stretching a league or more into the land. Beneath the town of Mahon there is a very fine quay, one end of which is reserved for the ships of war, and furnished with all the accommodations necessary for earcening and refitting them; the other serves for merchantmen. On arca

On the other side of the harbour is Cape Mola, where it is generally agreed a fortress might be constructed staur. which would be impregnable, as the castle of St Philip was esteemed before we took it, and bestowed so much money upon it, that though some works were erected at Cape Mola, it was not judged proper to proceed in the fortifications there at a fresh expence; at least this is the only reason that hath been assigned. Minorea was taken by the Spaniards during the American war, and is now in their possession.

MINORS, or FRIARS MINOR, an appellation which the Franciseans assume, out of show of humility ; calling themselves fratres minores, i. c. lesser brothers, and sometimes minorites. There is also an order of regular minors at Naples, which was established in the year 1 588, and confirmed by Sixtus V.

MINOS, in Fabulous History, a king of Crete, son of Jupiter and Europa. He flourished about 1432 years before the Christian era. He gave laws to his subjects, which still remained in full force in the age of the philosopher Plato, about 1000 years after the death of the legislator. His justice and moderation procured him the appellation of the favourite of the gods, the confidant of Jupiter, and the wise legislator, in every city of Greece; and, according to the poets, he was rewarded for his equity after death with the office of supreme and absolute judge in the infernal regions. In this capacity he is represented sitting in the middle of the shades, and holding a sceptre in his hand. The dead plead their different causes before him; and the impartial judge shakes the fatal urn, which is filled with the destinies of mankind. He married Ithona, by whom he had Lycastes, who was the father of Minos II.

MINOS II. was a son of Lycastes, the son of Minos I. and king of Crete. He married Pasiphae, the daughter of Sol and Perseis, and by her he had many children. He increased his paternal dominions by the conquest of the neighbouring islands ; but showed himself cruel in the war which he carried on against the Athenians, who had put to death his son Androgeus. He took Megara by the treachery of Scylla; and not satisfied with victory, he obliged the vanquished to bring him yearly to Crete seven chosen boys and the same number of virgins to be devoured by the MINO-TAUR. This bloody tribute was at last abolished when THESEUS had destroyed the monster. When DEDALUS, whose industry and invention had fabricated the labyrinth, and whose imprudence in assisting Pasiphae in the gratification of her unnatural desires, had offended Minos, fled from the place of his confinement with wings, and arrived safe in Sicily ; the incensed monarch pursued the offender, resolved to punish his infidelity. Cocalus, king of Sicily, who had hospitably received Dædalus, entertained his royal guest with dissembled friendship; and, that he might not deliver to him a man whose ingenuity and abilities he so well knew, he put Minos to death. Minos died about 35 years before the Trojan war. He was father of Androgeus, Glaucus, and Deucalion; and two daughters Phædra, and Ariadne. Many authors have confounded the two Minoses, the grandfather and the grandson ; but Homer, Plutarch, and Diodorus, prove plainly that they were two different persons.

MINOTAUR, in Fabulous History, a celebrated

MIN

monster, half a man and half a bull, according to this Minotaur verse of Ovid, Minstrel.

### Semibovçmque virum, semivirumque bovem.

It was the fruit of Pasiphae's amour with a bull. Minos refused to sacrifice a white bull to Neptune, an animal which he had received from the god for that purpose. This offended Neptune, and he made Pasiphae the wife of Minos enamoured of this fine bull, which had been refused to his altars. Dædalus prostituted his talents in being subservient to the queen's unnatural desires; and by his means, Pasiphae's horrible passions were gratified, and the Minotaur came into the world. Minos confined in the labyrinth this monster, which convinced the world of his wife's lasciviousness, and reflected disgrace upon his family. The Minotaur usually devoured the chosen young men and maidens which the tyranny of Minos yearly ex-acted from the Athenians. Theseus delivered his country from this tribute, when it had fallen to his lot to be sacrificed to the voracity of the Minotaur; and by means of Ariadne, the king's daughter, he dcstroyed the monster, and made his escape from the windings of the labyrinth .- The fabulous tradition of the Minotaur, and of the infamous commerce of Pasiphae with a favourite bull, has been often explained. Some suppose that Pasiphae was enamoured of one of her husband's courtiers called Taurus; and that Dxdalus favoured the passions of the queen, by suffering his house to become the retreat of the two lovers. Pasiphae some time after brought twins into the world, one of whom greatly resembled Minos and the other Taurus; and in the natural resemblance of their countenance with that of their supposed fathers, originated their name, and consequently the fable of the Minotaur.

MINOW, a very small species of cyprinus. See ICHTHYOLOGY Index.

MINSTER, (Saxon, Mynster or Mynstre), ancient. ly signified the church of a monastery or convent.

MINSTREL, an ancient term for a singer and instrumental performer.

The word minstrel is derived from the French mencstrier, and was not in use here before the Norman conquest. It is remarkable that our old monkish historians do not use the words citharædus, cantator or the like, to express a minstrel in Latin; but either mimus, histrio, joculator, or some other word that implies gesture. Hence it should seem that the minstrels set off their singing by mimicry or action; or, according to Dr Brown's hypothesis, united the powers of melody, poem, and dance.

The Saxons as well as the ancient Danes, had been accustomed to hold men of this profession in the highest reverence. Their skill was considered as something divine, their persons were deemed sacred, their attendance was solicited by kings, and they were everywhere loaded with honours and rewards. In short, poets and their art were held among them in that rude admiration which is ever shown by an ignorant people to such as excel them in intellectual accomplishments. When the Saxons were converted to Christianity, in proportion as letters prevailed among them this rude admiration began to abate, and poetry was no longer a peculiar profession. The poet and the minstrel be-Mm 2 came

Miastrel. came two persons. Poetry was cultivated by men of lctters indiseriminately, and many of the most popular ' rhymes were composed amidst the leisurc and retirement of monasteries. But the minstrels continued a distinct order of men, and got their livelihood by singing verses to the harp at the houses of the great. There they were still hospitably and respectfully received, and retained many of the honours shown to their predecessors the Bards and Sealds. And indeed, though some of them only recited the compositions of others, many of them still composed songs themselves : and all of them could probably invent a few stanzas on oecasion. There is no doubt but most of the old heroic ballads were produced by this order of men. For although some of the larger metrical romances might come from the pen of the monks or others, yet the smaller narratives were probably composed by the minstrels who sung them. From the amazing variations which occur in different copies of these old pieces, it is evident they made no scruple to alter each other's productions, and the reciter added or omitted whole stanzas according to his own faney or convenience.

In the early ages, as is hinted above, this profession was held in great reverence among the Saxon tribes, as well as among their Danish brethren. This appears from two remarkable facts in history, which show that the same arts of music and song were equally admired among both nations, and that the privileges and honours conferred upon the professors of them were common to both; as it is well known their eustoms, manners, and even language, were not in those times very dissimilar.

When King Alfred the Great was desirous to learn the true situation of the Danish army, which had invaded his realm, he assumed the dress and character of a minstrel; and taking his harp, and only one attendant (for in the earliest times it was not unusual for a minstrel to have a servant to carry his harp), he went with the utmost security into the Danish eamp. And though he could not but be known to be a Saxon, the character he had assumed procured him an hospitable reception; he was admitted to entertain the king at table, and staid among them long enough to contrive that assault which afterwards destroyed them. This was in the year 878.

About 60 years after, a Danish king made use of the same disguise to explore the eamp of King Athelstan. With his harp in his hand, and dressed like a minstrel, Anlass king of the Danes went among the Saxon tents, and taking his stand near the king's pavilion, began to play, and was immediately admitted. There he entertained Athelstan and his lords with his singing and his music; and was at length dismissed with an honourable reward, though his songs must have discovered him to have been a Dane. Athelstan was saved from the consequences of this stratagem by a soldier, who had observed Anlaff bury the money which had been given him, from some seruple of honour or motive of superstition. This occasioned a discovery.

From the uniform procedure of both these kings, it is plain that the same mode of entertainment prevailed among both peoples, and that the minstrel was a privileged character among both. Even as late as the M 1 N

reign of Edward II. the minstrels were easily admitted Minst into the royal presence, as appears from a passage in Stow, which also shows the splendour of their appear-

"In the year 1316, Edward II. did solemnize his feast of Pentecost at Westminster, in the great hall; where sitting royally at the table with his peers about him, there entered a woman adorned like a minstrel, sitting on a great horse trapped, as minstrels then used, who rode round about the tables, showing pastime ; and at length eams up to the king's table and laid before him a letter, and forthwith turning her horse, saluted every one, and departed."-The subject of this letter was a remonstrance to the king on the favours heaped by him on his minions, to the neglect of his knights and faithful servants.

The messenger was sent in a minstrel's habit, as what would gain an easy admission; and was a woman concealed under that habit, probably to disarm the king's resentment; for we do not find that any of the reat minstrels were of the female sex; and therefore conclude this was only an artful contrivance peculiar to that oecasion.

In the 4th year of Richard II. John of Gaunt erected at Tetbury in Staffordshire a court of minstrels, with a full power to receive suit and scrvice from the men of that profession within five neighbouring counties, to enact laws, and determine their controversies ; and to apprehend and arrest such of them as should refuse to appear at the said court, annually held on the 16th of August. For this they had a charter, by which they were empowered to appoint a king of the minstrels with four officers to preside over them. These were every year elected with great ceremony; the whole form of which is described by Dr Plott; in whose time, however, they seem to have become mere musicians.

Even so late as the reign of King Henry VIII. the reciters of verses or moral speeches learnt by heart, intruded without ceremony into all companies; not only in taverns, but in the houses of the nobility themselves. This we learn from Erasmus, whose argument led him only to describe a species of these men who did not sing their compositions; but the others that did, enjoyed without doubt the same privileges.

We find that the minstrels continued down to the reign of Elizabeth ; in whose time they had lost much of their dignity, and were sinking into contempt and neglect. Yet still they sustained a character far superior to any thing we can conceive at present of the singers of old ballads.

When Queen Elizabeth was entertained at Killingworth castle by the earl of Leicester in 1575, among the many devices and pageants which were exhibited for her entertainment, one of the personages introduced was that of an aneient minstrel, whose appearance and dress are so minutely described by a writer there present, and gives us so distinct an idea of the character, that we shall quote the passage at large.

"A person very meet seemed he for the purpose, of a xlv. years old, apparelled partly as he would himself. His cap off: his head seemingly rounded tonsterwise : fair kembed, that, with a sponge daintly dipt in a little eapon's grease, was finely smoothed, to make it shine like a mallard's wing. His beard snugly shaven :

I

lint.

MIN

ustrel, shaven : and yet his shirt after the new trink, with ruffs fair starched, sleeked, and glistering like a pair of new shoes, marshalled in good order with a setting stick, and strut, ' that' every ruff stood up like a wafer. A side [i. e. long] gown of Kendale green, after the freshness of the year now, gathered at the neek with a narrow gorget, fastened afore with a white clasp and a keeper close up to the chin; but easily, for heat, to undo when he list. Seemingly begirt in a red caddis girdle : from that a pair of capped Sheffield knives hanging a' two sides. Out of his bosom drawn from a lappet of his napkin edged with a blue lace, and marked with a D for Damian; for he was but a bachelor yet.

"His gown had side [i. e. long] sleeves down to midleg, slit from the shoulder to the hand, and lined with white cotton. His doublet sleeves of black worsted: upon them a pair of points of tawny chamlet laced along the wrist with blue threaden pointes. A wealt towards the hands of fustian-a-napes. A pair of red neather stocks. A pair of pumps on his feet, with a cross cut at his toes for eorns; not new indeed, yet eleanly blackt with soot, and shining as a shoing hom.

" About his neck a red ribband suitable to his girdle. His harp in good grace dependent before him. His wrest tyed to a green lace and hanging by : under the gorget of his gown a fair flaggon chain (pewter for) silver, as a Squire Minstrel of Middlesex, that travelled the country this summer season, unto fair and worshipful men's houses. From his chain hung a scutcheon, with metal and colour, resplendent upon his breast, of the aneient arms of Islington."

-This minstrel is described as belonging to that village. We suppose such as were retained by noble families wore their arms hanging down by a silver chain as a kind of badge. From the expression of Squire Minstrel above, we may conclude there were other inferior orders, as Yeomen Minstrels or the like.

This minstrel, the author tells us a little below, " after three lowly courtesies, cleared his voice with a hem ... and wiped his lips with the hollow of his hand for 'filing his napkin ; tempered a string or two with his wrist; and, after a little warbling on his harp for a prelude, came forth with a solemn song, warranted for story out of King Arthur's acts, &c."

Towards the end of the 16th century, this class of men had lost all credit, and were sunk so low in the public opinion, that in the 39th year of Elizabeth a statute was passed by which "minstrels," wandering abroad, were included among " rogues, vagabonds, and sturdy beggars," and were adjudged to be punished as such. This act seems to have put an end to the profession, for after this time they are no longer mentioned.

MINT, the place in which the king's money is coined. See COINAGE.

There were anciently mints in almost every county in England; but the only mint at present in the British dominions is that in the Tower of London. The officers of the mint are, 1. The warden of the mint, who is the chief; he oversees the other officers, and receives the bullion. 2. The master worker, who receives bullion from the wardens, causes it to be melted, delivers it to the moneyers, and, when it is eoined, receives it again. 3. The comptroller, who is the

overseer of all the inferior officers, and sees that all the Mint. money is made to the just assize. 4. The assay master, who weighs the gold and silver, and sees that it is according to the standard. 5. The two auditors who take the accounts. 6. The surveyor of the melting; who, after the assay master has made trial of the bullion, sees that it is cast out, and not altered after it is delivered to the melter. 7. The engraver; who engraves the stamps and dies for the coinage of the money. 8. The clerk of the irons; who sees that the irons are elean and fit to work with. 9. The melter, who melts the bullion before it be coined. 10. The provost of the mint; who provides for and oversees all the moneyers. 11. The blanchers, who anneal and eleanse the money. 12. The moneyers; some of whom forge the money, some share it, some round and mill it, and some stamp and coin it. 13. The porters who keep the gate of the mint.

MINT was also a pretended place of privilege, in Southwark, near the King's Bench, put down by statute. If any persons, within the limits of the mint, shall obstruct any officer in the serving of any writ or process, &c. or assault any person therein, so as he receive any bodily hurt, the offender shall be guilty of felony, and be transported to the plantations, &c. Stat. 9. Geo. I.

MINT Marks. It hath been usual, from old time, to oblige the masters and workers of the mint, in the indentures made with them, "to make a privy mark in all the money that they made, as well of gold as of silver, so that another time they might know, if need were, and witte which moneys of gold and silver among other of the same moneys, were of their own making, and which not." And whereas, after every trial of the pix at Westminster, the masters and workcrs of the mint, having there proved their moneys to be lawful and good, were immediately entitled to receive their quictus under the great seal, and to be discharged from all suits or actions concerning those moneys, it was then usual for the said masters and workers to ehange the privy mark before used for another, that so the moneys from which they were not yet discharged might be distinguished from those for which they had already received their quietus : which new mark they then continued to stamp upon all their moneys, until another trial of the pix gave them also their quietus concerning those.

The pix is a strong box with three locks, whose keys are respectively kept by the warden, master, and comptroller of the mint; and in which are deposited, sealed up in several pareels, certain pieces taken at random out of every journey as it is called; that is, out of every 15 pounds weight of gold, or 60 pounds weight of silver, before the same is delivered to the proprietors. And this pix is, from time to time, by the king's command, opened at Westminster, in the presence of the lord chancellor, the lords of the council, the lords commissioners of the treasury, the justices of the several benehes, and the barons of the exchequer; before whom a trial is made, by a jury of goldsmiths impanuelled and sworn for that purpose, of the collective weights of certain parcels of the several pieces of gold and silver taken at random from those contained in the pix; after which those pareels being severally melted, assays are then made of the bullion

Mint || Minuet. bullion of gold and silver so produced, by the melting certain small quantities of the same against equal weights taken from the respective trial pieces of gold and silver that are deposited and kept in the exchequer for that use. This is called the trial of the pix; the report made by the jury upon that trial is called the verdict of the pix for that time; and the indented trial pieces just above mentioned, arc certain plates of standard gold and standard silver, made with the greatest care, and delivered in upon oath, from time to time as there is occasion, by a jury of the most able and experienced goldsmiths, summoned by virtue of a warraut from the lords of the treasury to the wardens of the mystery of goldsmiths of the city of London for that purpose; and which plates being so delivered in, are divided each, at this time, into seven parts by indentures, one of which parts is kept in his majesty's court of exchequer at Westminster, another by the said company of goldsmiths, and two more by the officers of his majesty's mint in the Tower ; the remaining three being for the use of the mint, &c. in Scotland. The pix has sometimes been tried every year, or even oftencr, but sometimes not more than once in several years : and from hence is understood how it comes to pass, that, among the pieces that are dated as well as marked, three or more different dates are sometimes found upon pieces impressed with the same mark : and again, that different marks are found upon pieces bearing the same date. These marks are first observable upon the coins of King Edward III.; the words above quoted concerning those marks are from the indentures made with the lord Hastings, master and worker to King Edward IV; and the marks themselves continued to be stamped very conspicuously upon the moneys, till the coinage by the mill and screw was introduced and settled after the Restoration, in the year 1662; since which time, the moneys being made with far greater regularity and exactness than before, these marks have either been totally laid aside, or such only have been used as are of a more secret nature, and only known to the officers and engravers concerned in the coinage : and indeed the constant practice that has ever since prevailed, of dating all the several pieces, has rendered all such marks of much less consequence than before.

MINT. See MENTHA, BOTANY and MATERIA MEDICA Index.

MINTURNÆ, a town of Campania, between Sinuessa and Formiæ. It was in the marshes in this neighbourhood that Marius concealed himself in the mud to avoid the partizans of Sylla. The people condemned him to death; but when his voice alone had terrified the executioner, they showed themselves compassionate and favoured his escape.

MINUET, a very graceful kind of dance, consisting of a coupee, a high step, and a balance : it begins with a beat, and its motion is triple.

The invention of the minuet seems generally to be ascribed to the French, and particularly to the inhabitants of the province of Poictou. The word is said by Menage and Furetiere to be derived from the French *menue* or *menu*, "small or little;" and in strictness signifies a small space. The melody of this dance consists of two strains, which, as being repeated, are called *reprises*, each having eight or more bars, but

2

never an odd number. The measure is three crotchets Minuin a bar, and is thus marked  $\frac{3}{4}$ , though it is commonly performed in the time  $\frac{3}{8}$ . Walther speaks of a minuet in Lully's opera of *Roland*, each strain of which contains ten bars, the sectional number being 5; which renders it very difficult to dance.

MINUTE, in Geometry, the 60th part of a degree of a circle.

MINUTE of Time, the 60th part of an hour.

MINUTE, in Architecture, usually denotes the 60th, sometimes the 30th, part of a module. See ARCHI-TECTURE.

MINUTE is also used for a short memoir, or sketch of a thing taken in writing.

MINUTIUS FELIX. See FELIX.

MINYÆ, a name given to the inhabitants of Orchomenos in Bœotia, from Minyas king of the country. Orchomenos the son of Minyas gave his name to the capital of the country; and the inhabitants still retained their original appellation, in contradistinction to the Crchomenians of Arcadia. A colony of Orchomenians passed into Thessaly and settled in Iclehos; from which circumstance the people of the place, and particularly the Argonauts, were called Minyæ. This name they received, according to the opinion of some, not because a number of Orchomenians had settled among them, but because the chief and poblest of them were descended from the daughters of Minyas. Part of the Orchomenians accompanied the sons of Codrus when they migrated to Ionia. The descendants of the Argonauts, as well as the Argonauts themselves, received the name of Minyæ. They first inhabited Lemnos, where they had been born from the Lemnian women who had murdered their husbands. They were driven from Lemnos by the Pelasgi, about 1160 before the Christian era, and come to settle in Laconia, from whence they passed into Calliste with a colony of Lacedæmonians.

MIQUELETS, a name given to the Spaniards who inhabit the Pyrenean mountains on the frontiers of Arragon and Catalonia, and live by robbing.

MIQUELON, a small desert island to the southwest of Cape May in Newfoundland, ceded to the French by the peace of 1763, for drying and curing their fish. W. Long. 54. 30. N. Lat. 47. 22.

MIRABILIS, MARVEL OF PERU; a genus of plants belonging to the pentandria class; and in the natural method ranking with those of which the order is doubtful. See BOTANY *Index*.

MIRACLE, in its original sense, is a word of the same import with *wonder*; but in its usual and more appropriate signification, it denotes "an effect contrary to the established constitution and course of things, or a sensible deviation from the known laws of nature."

That the visible world is governed by stated general rules, or that there is an order of causes and effects established in every part of the system of nature which falls under our observation, is a fact which cannot be controverted. If the Supreme Being, as some have supposed, be the only real agent in the universe, we have the evidence of experience, that, in the particular system to which we belong, he acts by stated rules. If he employs inferior agents to conduct the various motions from which the phenomena result, we have the same evidence that he has subject. the laws of nature. On either hypothesis, effects which are produced by the regular operation of these laws, or which are conformable to the established course of events, are properly called natural; and every contradiction to this constitution of the natural system, and the correspondent course of events in it, is called a miracle.

If this definition of a miracle be just, no event can be deemed miraculous merely because it is strange, or even to us unaccountable; since it may be nothing more than a regular effect of some unknown law of nature. In this country earthquakes arc rare; and for monstrous births perhaps no particular and satisfactory account can be given: yet an earthquake is as regular an effect of the established laws of nature as any of those with which we are most intimately acquainted; and under circumstances in which there would always be the same kind of production, the monster is nature's genuine issue. It is therefore necessary, before we can pronounce any effect to be a true miracle, that the circumstances under which it is produced be known, and that the common course of nature be in some degree understood; for in all those cases in which we are totally ignorant of nature, it is impossible to determine what is, or what is not, a deviation from its course. Miracles, therefore, are not, as some have represented them, appeals to our ignorance. They suppose some antecedent knowledge of the course of nature, without which no proper judgement can be formed concerning them; though with it their reality may be so apparent as to prevent all possibility of a dispute.

Thus, were a physician to cure a blind man of a cataract, by anointing his eyes with a chemical preparation which we had never before seen, and to the nature and effects of which we are absolute strangers, the cure would undoubtedly be wonderful; but we could not pronounce it miraculous, because, for any thing known to us, it might be the natural effect of the operation of the unguent on the eye. But were he to recover his patient merely by commanding him to see, or by anointing his eyes with spittle, we should with the utmost confidence pronounce the cure to be a miracle ; because we know perfectly that neither the human voice nor human spittle have, by the established constitution of things, any such power over the diseases of the eye. No one is now ignorant, that persons apparently dead are often restored to their families and friends, by being treated in the manner recommended by the Humane Society. To the vulgar, and sometimes even to men of science, these effects appear very wonderful; but as they are known to be produced by physical agency, they can never be considered as miraculous deviations from the laws of nature. On the other hand, no one could doubt of his having witnessed. a real miracle who had seen a person that had been four days dead come alive out of his grave at the call of another, or who had even beheld a person exhibiting all the symptoms of death instantly resuscitated merely by being desired to live.

Thus easy is it, in all cases in which the course of nature is understood, to determine whether any particular event be really a miracle; whilst in circumstances where we know nothing of nature and its course, even If miracles be effects contrary to the established constitution of things, we are certain that they will never be performed on trivial occasions. The constitution of things was established by the Creator and Governor of the universe, and is undoubtedly the offspring of infinite wisdom pursuing a plan for the best of purposes. From this plan no deviation can be made but by God himself, or by some powerful being acting with his permission. The plans devised by wisdom are steady in proportion to their perfection, and the plans of infinite wisdom must be absolutely perfect. From this consideration, some men have ventured to conclude, that no miracle was ever wrought, or can rationally be expected; but maturer reflection must soon satisfy us that all such conclusions are hasty.

Man is unquestionably the principal creature in this world, and apparently the only one in it who is capable of being made acquainted with the relation in which he stands to bis Creator. We cannot, therefore, doubt, but that such of the laws of nature as extend not their operation beyond the limits of this earth were established chiefly, if not solely, for the good of mankind; and if, in any particular circumstances, that good can be more effectually promoted by an occasional deviation from those laws, such a deviation may be reasonably expected. Were man, in the exercise of his mental and corporeal powers, subjected to the laws of physical necessity, the circumstances supposed would indeed never occnr, and of course no miracle could be admitted. But such is not the nature of man.

Without repeating what has been said elsewhere (See METAPHYSICS, Part III. Chap. V.) of necessity and liberty, we shall here take it for granted, that the relation between motives and actions is different from that between cause and effect in physics; and that, mankind have such command over themselves, as that by their voluntary conduct, they can make themselves in a great degree either happy or miserable. We know likewise from history, that, by some means or other, almost all mankind were once sunk into the grossest ignorance of the mest important truths; that they knew not the Being by whom they were created and supported; that they paid divine adoration to stocks, stones, and the vilest reptiles; and that they were slaves to the most impious, cruel, and degrading superstitions.

From this depraved state it was surely not unworthy of the common "Father of all" to rescue his helpless creatures, to enlighten their understandings that they might perceive what is right, and to present to them motives of sufficient force to engage them in the practice of it. But the understandings of ignorant barbarians cannot be enlightened by arguments ; because of the force of such arguments as regard moral science they are not qualified to judge. The philosophers of Athens and Rome inculcated, indeed, many excellent moral precepts, and they sometimes ventured to expose the absurdities of the reigning superstition : but their lectures had no influence upon the multitude;. and they had themselves imbibed such erroncous notions respecting the attributes of the Supreme Being, and the nature of the human soul, and converted those notions into first principles, of which they would not permit

R MI

Miracle. permit an examination, that even among them a thorough reformation was not to be expected from the powers of reasoning. It is likewise to be observed, that there are many truths of the utmost importance to mankind, which unassisted reason could never have discovered. Amongst these we may confidently reckon the immortality of the soul, the terms upon which God will be reconciled to sinners, and the manner in which that all-perfect Being may be acceptably worshipped; about all of which philosophers were in such uncertainty, that, according to Plato, "Whatever is set right, and as it should be, in the present evil state of the world, can be so only by the particular interposition of God (A).

An immediate revelation from Heaven, therefore, was the only method by which infinite wisdom and perfect goodness could reform a bewildered and vicious race. But this revelation, at whatever time we suppose it given, must have been made directly either to some chosen individuals commissioned to instruct others, or to every man and woman for whose benefit it was ultimately intended. Were every person instructed in the 'knowledge of his duty by immediate inspiration, and were the motives to practise it brought home to his mind by God himself, human nature would be wholly changed : men would not be masters of their own actions: they would not be moral agents, nor by consequence be capable either of reward or of punishment. It remains, therefore, that if God has been graciously pleased to cnlighten and reform mankind, without destroying that moral nature which is essential to virtue, he can have done it only by revealing his truth to certain chosen instruments, who were the immediate instructors of their contemporaries, and through them have been the instructors of succeeding ages.

Let us suppose this to have been actually the case, and consider how those inspired teachers could communicate to others every truth which had been revealed to themselves. They might casily, if it was part of their duty, deliver a sublime system of natural and moral science, and establish it upon the common basis of experiment and demonstration; but what foundation could they lay for those truths which unassisted reason cannot discover, and which, when they are revealed, appear to have no necessary relation to any thing previously known? To a bare affirmation that they had been immediately received from God, no rational being could be expected to assent. The teachers might be men of known veracity, whose simple assertion would be admitted as sufficient evidence for any fact in conformity with the laws of nature; but as every man has the evidence of his own consciousness and experience that revelations from heaven are deviations from these laws, an assertion so apparently extravagant would be rejected as false, unless supported by some better proof than the mere affirmation of the teacher. In this state of things, we can conceive no evidence sufficient to make such doctrines be received as the truths of God, but the power of working miracles committed to him who taught them. This would,

#### M R

280

indeed, be fully adequate to the purpose. For if there Mirach were nothing in the doctrines themselves impious, immoral, or contrary to truths already known, the only thing which could render the teacher's assertion incredible, would be its implying such an intimate communion with God as is contrary to the cstablished course of things, by which men are left to acquire all their knowledge by the exercise of their own faculties .----Let us now suppose one of those inspired teachers to tell his countrymen, that he did not desire them, on his ipse dixit, to believe that he had any preternatural communion with the Deity, but that for the truth of his assertion he would give them the evidence of their own senses; and after this declaration let us suppose him immediately to raise a person from the dead in their presence, merely by calling upon him to come out of his grave. Would not the only possible objection to the man's veracity be removed by this miracle? and his assertions that hc had received such and such doctrines from God be as fully credited, as if it related to the most common occurrence? Undoubtedly it would; for when so much preternatural power was visibly communicated to this person, no one could have reason to question his having received an equal portion of preternatural knowledge. A palpable deviation from the known laws of nature, in one instance, is a sensible proof that such a deviation is possible in another; and in such a case as this, it is the witness of God to the truth of a man.

Miracles, then, under which we include prophecy, are the only direct evidence which can be given of divine inspiration. When a religion, or any religious truth, is to be revealed from heaven, they appear to be absolutely necessary to enforce its reception among men; and this is the only case in which we can suppose them necessary, or believe for a moment that they ever have been or will be performed.

The history of almost every religion abounds with relations of prodigies and wonders, and of the intercourse of men with the gods; but we know of no religious system, those of the Jews and Christians excepted, which appealed to miracles as the sole evidence of its truth and divinity. The pretended miracles mentioned by Pagan historians and poets are not said to have been publicly wrought to enforce the truth of a new religion contrary to the reigning idolatry. Many of them may be clearly shown to have been mere natural events; (see MAGIC). Others of them are represented as having been performed in secret on the most trivial occasions, and in obscure and fabulous ages long prior to the era of the writers by whom they are recorded. And such of them as at first view appear to be best attested, are evidently tricks contrived for interested purposes; to flatter power, or to promote the prevailing superstitions. For these reasons, as well as on account of the immoral character of the divinities by whom they are said to have been wrought, they are altogether unworthy of examination, and carry in the very nature of them the completest proofs of falsehood and imposture. But

Macles.

But the miracles recorded of Moses and of Christ bear a very different character. None of them is represented as wrought on trivial occasions. The writers who mention them were eye witnesses of the facts ; which they affirm to have been performed publicly, in attestation of the truth of their respective systems. They are indeed so incorporated with these systems, that the miracles eannot be separated from the doctrines; and if the miracles were not really performed, the doctrines cannot possibly be true. Besides all this, they were wrought in support of revelations which opposed all the religious systems, superstitions, and prejudices, of the age in which they were given : a circumstance which of itself sets them, in point of authority, infinitely above the Pagan prodigies, as well as the lying wonders of the Romish church.

It is indeed, we believe, universally admitted, that the miracles mentioned in the book of Exodus and in the four Gospels, might, to those who saw them performed, be sufficient evidence of the divine inspiration of Moses and of Christ; but to us it may be thought that they are no evidence whatever, as we must believe in the miracles themselves, if we believe in them at all, upon the barc authority of human testimony. Why, it has been sometimes asked, are not miracles wrought in all ages and eountries? If the religion of Christ was to be of perpetual duration, every generation of men ought to have complete cvidence of its truth and divinity.

To the performance of miraeles in every age and in every country, perhaps the same objections lic as to the immediate inspiration of every individual. Were those miracles universally received as such, men would be so overwhelmed with the number rather than with the force of their authority, as hardly to remain masters of their own conduct; and in that case the very end of all miracles would be defeated by their frequency. The truth, however, seems to be, that miracles so frequently repeated would not be received as such, and of course would have no authority; because it would be difficult, and in many cases impossible, to distinguish them from natural events. If they recurred regularly at certain intervals, we could not prove them to be deviations from the known laws of nature, because we should have the same experience for the one series of events as for the other; for the regular succession of preternatural effects, as for the established constitution and course of things.

Be this, however, as it may, we shall take the liberty to affirm, that for the reality of the Gospel miracles we have cvidence as convincing to the reflecting mind, though not so striking to vulgar apprehension, as those had who were contemporary with Christ and his apostles, and actually saw the mighty works which he performed. To the admirers of Mr Humc's philosophy this assertion will appear an extravagant paradox ; but we hope to demonstrate its truth from principles which, consistently with himself, that author could not have denied. He has indeed endcavoured say on to prove \*, that " no testimony is sufficient to establish a miracle;" and the reasoning employed for this purpose is, that " a miracle being a violation of the laws of nature which a firm and unalterable experience has established, the proof against a miracle, from the very nature of the fact, is as entire as any argu-VOL. XIV. Part I.

MIR

ment from experience can be ; whereas our experience Miraele. of human veracity, which (according to him) is the sole foundation of the evidence of testimony, is far from being uniform, and can therefore never preponderate against that experience which admits of no exception." This hoasted and plausible argument has with equal candour and acuteness been examined by Dr Campbell \*, who justly observes, that so far is \* Disserta. experience from being the sole foundation of the cvi-tion on dence of testimony, that, on the contrary, testimony Miracles. is the sole foundation of by far the greater part of what Mr Hume calls firm and unalterable experience; and that if in certain circumstances we did not give an implicit faith to testimony, our knowledge of events would be confined to those which had fallen under the immediate observation of our own senses. For a short view of this celebrated controversy in which the Christian so completely vanquishes the philosopher, see the word ABRIDGMENT.

But though Dr Campbell has exposed the sophistry of his opponent's reasoning, and overturned the principles from which he reasons, we are persuaded that he might safely have joined issue with him upon those very principles. To us, at least, it appears that the testimony upon which we receive the Gospel miracles is precisely of that kind which Mr Hume has acknowledged sufficient to establish even a miracle. " No testimony (says he) is sufficient to establish a miracle, unless the testimony be of such a kind that its falsehood would be more miraculous than the fact which it endeavours to establish. When one tells me that he saw a dead man restored to life, I immediately consider with myself whether it be more probable that this person should cither deceive or be deceived, or that the fact which he relates should really have happened. I weigh the one miracle against the other; and according to the superiority which I discover, I pronounce my decision, and always reject the greater miracle." In this passage every reader may remark what did not escape the perspicacious eye of Dr Campbell, a strange confusion of terms; but as all miracles are equally easy to the Almighty; and as Mr Hume has elsewhere ohserved, that "the raising of a feather, when the wind wants ever so little of a force requisite for that purpose, is as real a miracle as the raising of a house or a ship into the air;" candour obliges us to suppose, that by talking of greater and less miraeles and of always rejecting the greater, he meant nothing more, but that of two deviations from the known laws of nature he always rejects that which in itself is least probable.

If, then, we can show that the testimony given by the apostles and other first preachers of Christianity to the miraeles of their Master would, upon their supposition that those miracles were not really performed, have been as great a deviation from the known laws of nature as the miracles themselves, the balance must be considered as evenly poised by opposite miracles; and whilst it continues so, the judgment must remain in a state of suspense. But if it shall appear, that in this case the false testimony would have been a deviation from the laws of nature less probable in itself than the miracles recorded in the Gospels, the balance will be instantly destroyed; and hy Mr Humc's maxim we shall be obliged to reject the supposition of falsehood in the testimony Nn of

Miracle. of the apostles, and admit the miracles of Christ to

In this argument we need not waste time in proving that those miracles, as they are represented in the writings of the New Testament, were of such a nature, and performed before so many witnesses, that no imposition could possibly be practised on the senses of those who affirm that they were present. From every page of the Gospels this is so evident, that the philosophical adversaries of the Christian faith never suppose the apostles to have been themselves deceived, but boldly accuse them of bearing false witness. But if this aceusation be well founded, their testimony itself is as great a miracle as any which they record of themselves or of their Master.

It has been shown elsewhere (see METAPHYSICS, Nº 138.), that by the law of association, which is one of the laws of nature, mankind, in the very process of learning to speak, necessarily learn to speak the truth; that ideas and relations are in the mind of every man so closely associated with the words by which they are expressed in his native tongue, and in every other language of which he is master, that the one eannot be entirely scparated from the other; that therefore no man can on any occasion speak falsehood without some effort ; that by no effort can a man give consistency to an unpremeditated detail of falsehood, if it be of any length, and include a number of particulars ; and that it is still less possible for several men to agree in such a detail, when at a distance from each other, and cross questioned by their enemies.

This being the case, it follows, if the testimony of the apostles to their own and their Master's miraeles be false, either that they must have concerted a consistent scheme of falsehood, and agreed to publish it at every hazard; or that God, or some powerful agent appointed by him, must have dissolved all the associations formed in their minds between ideas of scnse and the words of language, and arbitrarily formed new associations, all in exact conformity to each other, but all in direct contradiction to truth. One or other of these events must have taken place; because, upon the supposition of falsehood, there is no other alternative. But such a dissolution and formation of associations as the latter implies, must, to every man who shall attentively consider it, appear to be as real a miracle, and to require as great an exertion of power, as the resurrection of the dead. Nor is the supposed voluntary agreement of the apostles in a scheme of falsehood an event less miraculous. When they sat down to fabricate their pretended revelation, and to contrive a series of miracles to which they were unanimously to appeal for its truth, it is plain, since they proved successful in their daring enterprise, that they must have elearly foreseen every possible eireumstance in which they could be placed, and have prepared consistent answers to every question that could be put to them by their most invetcrate and most enlightened encmies; by the statesman, the lawyer, the philosopher, and the priest. That such foreknowledge as this would have been miraeulous, will not surely be denied; since it forms the very attribute which we find it most difficult to allow even to God himself. It is not, however, the only miraele which this supposition would compel us to swallow. The very resolution of the apostles to propagate the belief of false miracles

in support of such a religion as that which is taught in Miraci the New Testament, is as great a miracle as human <u>with a support</u> imagination can easily conceive.

When they formed this design, either they must have hoped to succeed, or they must have foreseen that they should fail in their undertaking; and in either ease, they chose evil for its own sake. They could not, if they foresaw that they should fail, look for any thing but that contempt, disgrace, and persecution, which were then the inevitable consequences of an unsuccessful endeavour to overthrow the established religion. Nor could their prospects be brighter upon the supposition of their success. As they knew themselves to be false witnesses and impious dcceivers, they could have no hopes beyond the grave; and by determining to oppose all the religious systems, superstitions, and prejudices of the age in which they lived, they wilfully exposed themselves to inevitable misery in the present life, to insult, and imprisonment, to stripes and death. Nor can it be said that they might look forward to power and affluence when they should, through sufferings, have converted their countrymen; for so desirous were they of obtaining nothing but misery, as the end of their mission, that they made their own persecution a test of the truth of their doctrines. They introduced the Master from whom they pretended to have received these doctrines as telling them, "that they were sent forth as sheep in the midst of wolves; that they should be delivered up to councils, and scourged in synagogues ; that they should be hated of all men for his name's sake; that the brother should deliver up the brother to death, and the father the child ; and that he who took not up his cross and followed after him was not worthy of him." The very system of religion, therefore, which they invented and resolved to impose upon mankind, was so contrived, that the worldly prosperity of its first preachers, and even their exemption from persecution, was incompatible with its success. Had these clear predictions of the Author of that religion, under whom the apostles acted only as ministers, not been verified, all mankind must have instantly perceived that their pretenee to inspiration was false, and that Christianity was a scandalous and impudent imposture. All this the apostles could not but foresee when they formed their plan for deluding the world. Whence it follows, that when they resolved to support their pretended revelation by an appeal to forged miracles, they wilfully, and with their eyes open, exposed themselves to inevitable misery, whether they should succeed or fail in their enterprise; and that they concerted their measures so as not to admit of a possibility of recompense to themselves, either in this life or in that which is to come. But if there be a law of nature, for the reality of which we have better evidence than we have for others, it is, that "no man can choose misery for its own sake," or make the acquisition of it the ultimate end of his pursuit. The existence of other laws of nature we know by testimony and our own observation of the regularity of their effects. The existence of this law is made known to us not only by these means, but also by the still elcarer and more conclusive evidence of our own conseiousness.

Thus, then, do miraeles force themselves upon our assent in every possible view which we can take of this interesting subject. If the testimony of the first preachers

acle preachers of Christianity was true, the miracles recorded in the Gospel were certainly performed, and the docindola. trines of our religion are derived from heaven. On the other hand, if that testimony was false, either God must have miraculously effaced from the minds of those by whom it was given all the associations formed between their sensible ideas and the words of language, or he must have endowed those men with the gift of presci-" ence, and have impelled them to fabricate a pretended revelation for the purpose of deceiving the world, and involving themselves in certain and foreseen destruction.

The power necessary to perform the one series of these miracles may, for any thing known to us, be as great as that which would be requisite for the performance of the other; and, considered merely as exertions of preternatural power, they may seem to balance each other, and to hold the mind in a state of suspense. But when we take into consideration the different purposes for which these opposite and contending miracles were wrought, the balance is instantly destroyed. The miracles recorded in the Gospels, if real, were wrought in support of a revelation which, in the opinion of all by whom it is received, has brought to light many important trnths which could not otherwise have been made known to men; and which, by the confession of its adversaries, contains the purest moral precepts by which the conduct of mankind was over directed. The opposite series of miracles, if real, was performed to enable, and even to compel, a company of Jews, of the lowest rank and of the narrowest education, to fabricate, with the view of inevitable destruction to themselves, a consistent scheme of falsehood, and by an appeal to forged miracles to impose it upon the world as a revelation from heaven. The object of the former miracles is worthy of a God of infinite wisdom, goodness, and power. The object of the latter is absolutely inconsistent with wisdom and goodness, which are demonstrably attributes of that Being by whom alone miracles can be performed. Whence it follows, that the supposition of the apostles bearing false testimony to the miracles of their Master, implies a series of deviations from the laws of nature, infinitely lcss probable in themselves than those miracles: and therefore by Mr Hume's maxim, we must necessarily reject the supposition of falsehood in the testimony, and admit the reality of the miracles. So true it is, that for the reality of the Gospel miracles we have evidence as convincing to the reflecting mind, as those had who were contemporary with Christ and his apostles, and were actual witnesses to their mighty works.

MIRANDA-DE-EBRO, a town of Spain, in Old Castile, with a strong castle; seated in a country that produces excellent wine. W. Long. 3. 10. N. Lat.

42. 52. MIRANDO-DE-DOURO, or Duero, a strong town of Portugal, and capital of the province of Tra-los-Montes, with a bishop's see. It is well fortified, and seated on a rock near the confluence of the rivers Douro and Fresna. W. Long. 5. 40. N. Lat. 41. 30.

MIRANDOLA, a town of Italy, and capital of a duchy of the same name, situated between the duchies of Mantua and Modena; is well fortified, and has also a strong citadel and fort. It has been several times taken and retaken. E. Long. 11. 5. N. Lat. 44. 52.

283

MIRIAM, sister of Aaron and Moscs, makes two Miniam or three remarkable appearances in Scripturc. It was owing to her that her mother was employed by Pha- Misadvenraoh's daughter as nurse to Moses. She put herself at the head of the women of Israel after their passage through the Red sea, in order to sing the song which the men had sung before. She joined with her brother Aaron in murmuring against Moses, and was severely chastised for that action ; for she became leprous, and continued separate from the rest without the camp for seven days. She died before her brothers, though in the same year with them, and was buried at the public expence

MIRROR, a name for a looking glass, or any polished body, whose use is to form the images of distant objects, by reflection of the rays of light. See REFLEC-TION.

Mirrors are either plane, convex, or concave. The first reflect the rays of light in a direction exactly similar to that in which they fall upon them, and therefore represent bodies of their natural magnitude. The convex ones make the rays diverge much more than before reflection, and therefore greatly diminish the images of those objects which they show : while the concave ones, by collecting the rays into a focus, not only magnify the objects they show, but will burn very ficrcely when exposed to the rays of the sun; and hence they are commonly known by the name of burning mirrors. See BURNING Mirrors.

In ancient times the mirrors were made of some kind of metal; and from a passage of the Mosaic writings we learn that the mirrors used by the Jcwish women were made of brass. The Jews certainly had been taught to use that kind of mirrors by the Egyptians; from whence it is probable that brazen mirrors were the first kind used in the world. Any kind of metal, indeed, when well polished, will reflect very powerfully; but of all others silver reflects the most, though it has been in all countries too expensive a material for common use. Gold also is very powerful; and metals, or even wood, gilded and polished, will act very powerfully as burning mirrors. Even polished ivory, or straw nicely plaited together, will form mirrors capable of burning, if on a large scale.

Since the invention of glass, and the application of quicksilver to it, became generally known, it hath been universally employed for those plane mirrors used as ornaments to houses; hut in making reflecting telescopes, they have been found much inferior to metallic ones. It does not appear that the same superiority belongs to the metalline burning mirrors, considered merely as burning glasses; since the mirror with which M. Macquer melted platina, though only 22 inches diameter, and which was made of quicksilvered glass, produced much greater effects than M. Vilette's metalline speculum, which considerably exceeded it in size. It is very probable, however, that this mirror of M. Vilette's was by no means so well polished as it ought to have heen; as the art of preparing the metal for taking the finest polish has but lately been discovered and published in the Philosophical Transactions by Mr Mudge. See GLASS-Grinding.

MIRE-CROW, SEA-CROW, or Pewit. Sce LARUS, ORNITHOLOGY Index.

MISADVENTURE, in common language, signi-Nn 2 fies

ture.

Misadven. fies any unlucky accident which takes place without beture ing foreseen.

Mischna.

MISADVENTURE, in Law, has an especial signification for the killing a man partly by negligence, and partly by chance. See HOMICIDE.

MISANTHROPY (from μισος, hatred, and αγθεωπος, a man); a general dislike or aversion to man, and mankind. In which sense it stands opposed to philanthropy, or the love of mankind.

MISCARRIAGE. See Abortion and Midwife-Ry.

MISCHNA, or MISNA, (from *iteravit*), a part of the Jewish Talmud.

The Mischna contains the text; and the Gemara, which is the second part of the Talmud, contains the commentarics: so that the Gemara is, as it were, a glossary on the Mischna.

The Mischna consists of various traditions of the Jews, and of explanations of several passages of Scripture: these traditions serving as an explication of the written law, and supplement to it, are said to have been delivered to Moses during the time of his abode on the Mount; which he afterwards communicated to Aaron, Eleazar, and his servant Joshua. By these they were transmitted to the 70 elders, by them to the prophets, who communicated them to the men of the great sanhedrim, from whom the wise men of Jerusalem and Babylon received them. According to Prideaux's account, they passed from Jeremiah to Baruch, from him to Ezra, and from Ezra to the men of the great synagogue, the last of whom was Simon the Just; who delivered them to Antigonus of Socho; and from him they came down in regular succession to Simeon, who took our Saviour in his arms; to Gamaliel, at whose feet Paul was educated; and last of all to Rabbi Judah the Holy, who committed them to writing in the Mischna. But Dr Prideaux, rejecting this Jewish hction, observes, that after the death of Simon the Just, about 299 years before Christ, the Mischnical doctors arose, who, by their comments and conclusions, added to the number of those traditions which had been received and allowed by Ezra and the men of the great synagogue; so that towards the middle of the second century after Christ, under the empire of Antoninus Pius, it was found necessary to commit these traditions to writing; more especially, as their country had considerably suffered under Adrian, and many of their schools had been dissolved, and their learned men cut off; and therefore the usual method of preserving their traditions had failed. Rabbi Judah on this occasion being rector of the school at Tiberias, and president of the sanhedrim in that place, undertook the work, and compiled it in six books, each consisting of several tracts, which altogether make up the number of 63. Prid. Connex. vol. ii. p. 468, &c. edit. 9. This learned author computes, that the Mischna was composed about the 150th year of our Lord; but Dr Lightfoot says, that Rabbi Judah compiled the Mischna about the year of Christ 190, in the latter end of the reign of Commodus; or, as some compute, in the year of Christ 220. Dr Lardner is of opinion, that this work could not have been finished before the year 190, or later. Collect. of Jewish and Heathen Testimonies, &c. vol. i. p. 178. Thus the book called the Mischna was formed; a book which the Jews have generally received

with the greatest veneration. The original has been Misch published with a Latin translation by Surenhusius, with notes of his own, and others from the learned Maimonides, &c. in 6 vol. fol. Amsterd. A. D. 1698—1703. (See TALMUD). It is written in a much purer style, and is not near so full of dreams and visions as the Gemara.

MISDEMEANOUR, in *Law*, signifies a crime. Every crime is a misdemeanour; yet the law has made a distinction between crimes of a higher and a lower nature; the latter being denominated *misdemeanours*, the former *felonies*, &c. For the understanding of which distinction, we shall give the following definition from Blackstone's Commentaries, vol. iv. 5.

"A crime, or misdemeanour, is an act committed or omitted, in violation of a public law, either forbidding or commanding it. This general definition comprehends both crimes and misdemcanours; which, properly speaking, are mere synonymous terms; though, in common usage, the word crime is made to denote such offences as are of a deeper and more atrocious dye; while smaller faults, and omissions of less consequence, are comprised under the gentler name of misdemeanours only."

MISE, in law books, is used in various senses: thus it sometimes signifies costs or expences; in which sense it is commonly used in entering of judgments in actions personal. It is also used for the issue to be tried on the grand assize; in which case, joining of the mise upon the mere right, is putting in issue between the tenant and demandant, Who has the best or clearest right.

MISE, also signifies a tax or tallage, &c. An honorary gift, or customary present from the people of Wales to every new king or prince of Wales, anciently given in cattle, wine, and corn, but now in money, being 5000l. or more, is denominated a *mise*: so was the usual tribute or fine of 3000 merks paid by the inhabitants of the county palatine of Chester at the change of every owner of the said earldom, for enjoying their liberties. And at Chester they have a mise-book, wherein every town and village in the county is rated what to pay towards the mise. The 27 Hen. VIII. c. 26. ordains that lords shall have all such mises and profits of their lands as they had in times past, &c.

MISE, is sometimes also corruptly used for mease, in law French mecs, "a messuage;" as a mise place, in some manors, is such a messuage or tenement as answers the lord a heriot at the death of its owner.— 2 Inst. 528.

MISENUM, or MISENUS, in Ancient Geography; a promontory, port, and town in Campania, situated to the south-west of Baiæ, in the Sinus Puteolanus, on the north side. Here Augustus had a fleet, called *Classis Misenensis*, for guarding the Mare Inferum; as he had another at Ravenna for the Superum.

On this peninsula a villa was built by Caius Marius, with a degree of elegance that gave great offence to the most austere among the Romans, who thought it ill suited to the character of so rough a soldier. Upon the same foundation Lucullus the plunderer of the eastern world, erected an edifice, in comparison of which the former house was a cottage; but even his magnificence was eclipsed by the splendour of the palace which the emperors raised upon the same spot. To these proud abodes iser.

enum, abodes of herocs and monarchs, which have long been levelled to the ground, a few fishing huts, as Mr Swinburne informs ns, and a lonely public house, have succeeded : hither boatmen resort to tipple perhaps on the identical site where the voluptuous masters of the world quaffed Chian and Falernian wines.

MISER, a parsimonious person who is at the same time rich; or a wretch covetous to extremity, whom avariee has divested of all the charities of human nature, and made even an enemy to himself.

Of this most unaccountable of all characters, many instances occur; some of them so extraordinary as almost to surpass belief. The following are here selected, as being of recent date, perfectly authentic, and the last of them in particular exhibiting an assemblage of qualities the most singular perhaps that ever existed in the same person. 'Too little dignified to merit a place in regular biography, yet too curious a variety of human character to pass unnoticed in this work, the present seemed the only title under which it could with propriety be introduced.

1. In December 1790, died at Paris, literally of want, Mr Ostervald, a well known banker. This man, originally of Neufchatel, felt the violence of the disease of avarice (for surely it is rather a disease than a passion of the mind) so strongly, that within a few days of his death, no importunities eould induce him to buy a few pounds of meat for the purpose of making a little soup for him. "'Tis true (said he), I should not dislike the soup, but I have no appetite for the meat; what then is to become of that ?" At the time that he refused this nourishment, for fear of being obliged to give away two or three pounds of meat, there was tied round his neck a silken bag, which contained 800 assignat's of 1000 livres each. At his outset in life, he drank a pint of beer which served him for supper, every night at a house much frequented, from which he carried home all the bottle corks he could come at. Of these, in the course of eight years, he had collected as many as sold for 12 louis d'or, a sum that had laid the foundation of his future fortune, the superstructure of which was rapidly raised by his uncommon success in stock jobbing. He died possessed of three millions of livres (125,000l. sterling.)

2. The late John Elwcs, Esq. was member for Berkshire in three successive parliaments. His family name was Meggot; and his father was a brewer of great eminence, and distinguished by no peculiarity of eharaeter: but his mother, though she was left nearly 100,000l. by her husband, starved herself to death! At an early period of life he was sent to Westminster school, where he remained for 10 or 12 years. During that time he certainly had not misapplied his talents; for he was a good classical scholar to the last: and it is a circumstance not a little remarkable, though well authenticated, that he never read afterwards, nor had he ever any knowledge in accounts; to which may in some measure be attributed the total ignorance he was always in as to his affairs. From Westminster school Mr Meggot removed to Geneva, where he soon entercd upon pursuits more agreeable to him than study. The riding master of the academy there had then to boast perhaps of three of the best riders in Europe, Mr Worsley, Mr Elwes, and Sir Sidney Meadows. Of the three, Elwes was reckoned the most desperate; the

young horses were always put into his hands, and he Miser. was the rough rider to the other two.

On his return to England, after an absence of two or three years, he was to be introduced to his uncle the late Sir Harvey Elwes, who was then living at Stoke in Suffolk, perhaps the most perfect picture of human penury that ever existed. The attempts at saving money were in him so extraordinary, that Mr Elwes perhaps never quite reached them, even at the last period of his life .- Of what temperanee can do, Sir Harvey was an instance. At an early period of life he was given over for a consumption, and he lived till betwixt 80 and 95 years of age. On his death, his fortune, which was at least 250,000l. fell to his nephew Mr Meggot, who by will was ordered to assume the name and arms of Elwes. To this uncle, and this property, Mr Elwes succeeded when he had advanced beyond the 40th year of his age. For 15 years previous to this period, he was well known in the more fashionable eircles of London. He had always a turn for play; and it was only late in life, and from paying always and not always being paid, that he conceived disgust at it. The theory which he professed, " that it was impossible to ask a gentleman for money," he perfectly confirmed by the practice; and he never violated this feeling to the latest hour of his life.

The manners of Mr Elwes were such-so gentle, so attentive, so gentlemanly, and so engaging-that rudeness could not ruffle them, or strong ingratitude break their observance. He retained this peculiar feature of the old court to the last; but he had a praise beyond this : He had the most gallant disregard of his own person, and all care about himself that can be imagined. The instances in younger life, in the most imminent personal hazard, are innumerable; but when age had despoiled him of his activity, and might have rendered care and attention about himself natural, he knew not what they were: He wished no one to assist him: "He was as young as ever; he could walk; he could ride, and he could dance ; and he hoped he should not give trouble even when he was old :" He was at that. time 75.

It is eurious to remark how he contrived to mingle small attempts at saving with objects of the most unbounded dissipation. After sitting up a whole night at play for thousands with the most fashionable and profligate men of the time, amidst splendid rooms, gilt sofas, wax lights, and waiters attendant on his call, he would walk out about four in the morning, not towards home. but into Smithfield, to meet his own eattle, which were coming to market from Thaydonhall, a farm of his in Essex! There would this same man, forgetful of the scenes he had just left, stand in the cold or rain, bartering with a carcass butcher for a shilling! Sometimes when the cattle did not arrive at the hour he expected, he would walk on in the mire to meet them; and more than once has gone on foot the whole way to his farm without stopping, which was 17 miles from London, after sitting up the whole night. Had every man been of the mind of Mr Elwcs, the race of innkeepers must have perished, and post-chaises have been returned back to those who made them; for it was the business of his life to avoid both. He always travelled on horseback. To see him setting out on a journey, was a matter truly curious; his first care was to put two or three eggs,

Miser. boiled hard, into his great coat pocket, or any scraps of bread which he found ; haggage he never took ; then mounting one of his hunters, his next attention was to get out of London into that road where turnpikes were the fewest ; then stopping under any hedge where grass presented itself for his horse, and a little water for himself, he would sit down and refresh himself and his horse together.

The chief residence of Mr Elwes at this period of his life was in Berkshire, at his own seat at Marcham. Here it was he had two natural sons born, who inherit the greatest part of his property by a will made about the year 1785. The keeping of fox hounds was the only instance in the whole life of Mr Elwes of his ever sacrificing money to pleasure; and may be selected as the only period when he forgot the cares, the perplexities, and the regret, which his wealth occasioned. But even here every thing was done in the most frugal manner. Scrub, in the Beaux Stratagem, when compared with Mr Elwes's huntsman, had an idle life of it. This famous huntsman might have fixed an epoch in the history of servants: for in a morning, getting up at four o'clock, he milked the cows; he then prepared breakfast for Mr Elwes or any friends he might have with him: then slipping on a green coat, he hurried into the stable, saddled the horses, got the hounds out of the kennel, and away they went into the field. After the fatigues of hunting, he refreshed himself by rubbing down two or three horses as quickly as he could; then running into the house to lay the cloth, and wait at dinner; then hurrying again into the stable to feed the horses-diversified with an interlude of the cows again to milk, the dogs to feed, and cight hunters to litter down for the night.

In the penury of Mr Elwes there was something that seemed like a judgment from heaven. All earthly comforts he voluntarily denied himself: he would walk home in the rain in London rather than pay a shilling for a coach; he would sit in wet clothes sooner than have a fire to dry them; he would eat his provisions in the last stage of putrefaction sooner than have a fresh \* Mr Top- joint from the butchers; and he wore a wig for above \* Mr 10p- a fortnight, which his biographer \* saw him pick up out whose Life of a rnt in a lane where they were riding. This was the last extremity of laudable economy; for to all ap-Elwes, Esq. pearance it was the cast-off wig of some beggar !

Mr Elwes had now resided about 13 years in Suffolk, article are when the contest for Berkshire presented itself on the extracted. dissolution of the parliament; and when, to preserve the peace of that county, he was nominated by Lord Craven. Mr Elwes, though he had retired from public business for some years, had still left about him some of the seeds of more active life, and he agreed to the proposal. It came farther enhanced to him, hy the agrecment, that he was to be brought in by the freeholders for nothing. All he did on the occasion was dining at the ordinary at Reading; and he got into parliament for 18 pence!

Though a new man, Mr Elwes could not be called a young member; for he was at this time nearly 60 years old when he thus entcred on public life. But he was in possession of all his activity; and, preparatory to his appearance on the boards of St Stephen's Chapel, he used to attend constantly during the races and other public meetings all the great towns where his 2

voters resided. At the different assemblies he would Mise dance among the youngest to the last, after riding over on horsehack, and frequently in the rain, to the place of meeting. A gentleman who was one night standing hy, observed on the extraordinary agility of so old a man .- O! that is nothing (replied another); for Mr Elwes, to do this, rode 20 miles in the rain, with his shoes stuck into his boots and his bag-wig in his pocket."

The honour of parliament made no alteration in the dress of Mr Elwes : on the contrary, it seemed at this time to have attained additional meanness; and nearly to have reached that happy climax of poverty, which has more than once drawn on him the compassion of those who passed by him in the street. For the speaker's dinners, however, he had one suit, with which the speaker in the course of the sessions became very familiar. The minister likewise was well acquainted with it; and at any dinner of opposition still was his apparel the same. The wits of the minority used to say, " that they had full as much reason as the minister to be satisfied with Mr Elwes, as he had the same habit with every body." At this period of his life Mr Elwes wore a wig. Much about the time when his parliamentary life ceased, that wig was worn out; so then, being older and wiser as to expence, he wore his own hair, which like his expences was very small.

All this time the income of Mr Elwes was increasing hourly, and his present expenditure was next to nothing; for the little pleasures he had once engaged in he had now given up. He kept no house, and only one old servant and a couple of horses : he resided with his nephew : his two sons he had stationed in Suffolk and Berkshire, to look after his respective estates : and his dress certainly was no expence to him; for had not other people been more careful than himself, he would not have had it even mended.

When he left London, he went on horseback to his country seats with his couple of hard eggs, and without once stopping upon the road at any house. He always took the most unfrequented road, and used every shift to avoid turnpikes. Marcham was the seat he now chiefly visited; which had some reason to be flattered with the preference, as his journey into Suffolk cost him only twopence-halfpenny, while that into Berkshire amounted to fourpence !

As Mr Elwes came into parliament without expence, he performed his duty as a member would have done in the pure days of our constitution. What he had not bought he never attempted to sell; and he went forward in that straight and direct path, which can alone satisfy a reflecting mind. Amongst the smaller memorials of the parliamentary life of Mr Elwes may be noted, that he did not follow the custom of members in general by sitting on any particular side of the house, but sat as occasion presented itself on either indiscriminately; and he voted much in the same manner, but never rose to speak. In his attendance at the house, he was always early and late; and he never left it for dinner, as he had accustomed himself to fasting, sometimes for 24 hours in continuance.

When he quitted parliament, he was, in the common phrase, " a fish out of water !" The style of Mr Elwes's

of John the particuiser.

Elwes's life had left him no domestic scenes to which he could retire-his home was dreary and poor-his rooms received no eheerfulness from fire; and while the outside had all the appearance of a "House to be Let," the inside was a desert; but he had his penury alone to thank for this, and for the want of all the little eonsolations which should attend old age, and smooth the passage of deelining life. At the close of the spring of 1785, he wished again to visit, which he had not done for some years, his seat at Stoke. But then the journey was a most serious object to him. The famous old servant was dead; all the horses that remained with him were a couple of worn-out brood mares; and he himself was not in that vigour of body in which he could ride 60 or 70 miles on the sustenance of two boiled eggs. The mention of a post chaise would have been a crime-" He afford a post chaise, indeed! where was he to get the money ?" would have been his exclamation. At length he was carried into the country as he was earried into parliament, free of expence, by a gentleman who was certainly not quite so rich as Mr Elwes. When he reached Stoke-the seat of more active scenes, of somewhat resembling hospitality, and where his fox hounds had spread somewhat like vivaeity around-he remarked, " he had expended a great deal of money once very foolishly; but that a man grew wiser by time."

The rooms at this seat, which were now much out of repair, and would have all fallen in but for his son John Elwes, Esq. who had resided there, he thought too expensively furnished, as worse things might have served. If a window was broken, there was to be no repair but that of a little brown paper, or that of piecing in a bit of broken glass; which had at length been done so frequently, and in so many shapes, that it would have puzzled a mathematician to say " what figure they described." To save fire, he would walk about the remains of an old greenhouse, or sit with a servant in the kitchen. During the harvest he would amuse himself with going into the fields to glean the corn on the grounds of his own tenants; and they used to leave a little more than common to please the old gentleman, who was as eager after it as any pauper in the parish. In the advance of the season, his morning employment was to pick up any stray chip, bones, or other things, to earry to the fire, in his pocket-and he was one day surprised by a neighbouring gentleman in the act of pulling down, with some difficulty, a crow's nest for this purpose. On the gentleman wondering why he gave himself this trouble -" Oh, Sir, (replied old Elwes), it is really a shame that these ereatures should do so. Do but see what waste they make! They don't care how extravagant they are !"

As no gleam of favourite passion, or any ray of amusement, broke through this gloom of penury, his insatiable desire of saving was now become uniform and systematie. He used still to ride about the country on one of these mares—but then he rode her very economically, on the soft turf, adjoining the road, without putting himself to the expence of shoes, as he observed, "The turf was so pleasant to a horse's foot!" And when any gentleman called to pay him a visit, and the boy who attended in the stables, was profuse enough to put a little hay before his horse, old Elwes

would slily steal back into the stable, and take the hay very earefully away. That very strong appetite which Mr Elwes had in some measure restrained during the long sitting of parliament, he now indulged most voraciously, and on every thing he could find. To save, as he thought, the expense of going to a butcher, he would have a whole sheep killed, and so cat mutton to the-end of the chapter. When he occasionally had his river drawn, though sometimes horse loads of small fish were taken, not one would he suffer to be thrown in again; for he observed, "He should never see them again!" Game in the last state of putrefaction, and meat that walked about his plate. would he continue to eat, rather than have new things killed before the old provision was finished. With this diet-the charnel house of sustenance-his dress kept pace-equally in the last stage of absolute dissolution. Sometimes he would walk about in a tattered browneoloured hat, and sometimes in a red and white woollen eap, like a prisoner confined for debt. His shoes he never would suffer to be eleaned, lest they should be worn out the sooner. But still, with all this self-denial-that penury of life to which the inhabitant of an alms house is not doomed-still did he think he was profuse, and frequently say, " He must be a little more careful of his property." His disquietude on the subject of money was now continual. When he went to bed, he would put five or ten guineas into a bureau; and then, full of his monev, after he had retired to rest, and sometimes in the middle of the night, he would come down to see if it was there.

The scene of mortification at which Mr Elwes was now arrived was all but a denial of the common necessaries of life; and indeed it might have admitted a doubt, whether or not, if his manors, his fish ponds, and some grounds in his own hands, had not furnished a subsistence, where he had not any thing actually to buy, he would not, rather than have bought any thing, have starved. Strange as this may appear, it is not exaggerated .- He one day, during this period, dined upon the remaining part of a moor hen, which had been brought out of the river by a rat! and at another ate an undigested part of a pike which a larger one had swallowed, but had not finished, and which were taken in this state in a net. At the time this last eircumstance happened, he discovered a strange kind of satisfaction; for he said to a friend, " Aye! this was killing two birds with one stone !" In the room of all commentof all moral-let it be remarked, that at this time Mr Elwes was perhaps worth nearly eight hundred thousand pounds! and, at this period, he had not made his will, of course was not saving from any sentiment of affection for any person.

The summer of 1788 Mr Elwes passed at his house in Welbeck street, London; and he passed that summer without any other society than that of two maid servants; for he had now given up the expence of keeping any male domestic. His chief employment used to be that of getting up carly in a morning to visit some of his houses in Mary-le-bone, which during the summer were repairing. As he was there generally at four o'clock in a morning, he was of course on the spot before the workmen; and he used contentcdly to sit down on the steps before the door, to scold them Miser.

Mise

sance

them when they did come. The neighbours who used to see him appear thus regularly every morning, and who concluded, from his apparel, that he was one of the workmen, observed, " there never was so punctual a man as the old carpenter." During the whole morning he would continue to run up and down stairs to see the men were not idle for an instant, with the same anxiety as if his whole happiness in life had been centered in the finishing of this house, regardless of the greater property he had at stake in various places, and for ever employed in the minutiæ only of affairs. Indeed such was his anxiety about this house, the rent of which was not above 50l. a-year, that it brought on a fever which nearly cost him his life : but the fate which dragged him on thus strangely to bury him under the load of his own wealth, seemed as resistless as it was unaecountable.

In the museular and unencumbered frame of Mr Elwcs there was every thing that promised extreme length of life; and he lived to above 70 years of age without any natural disorder attacking him : but, as Lord Bacon has well observed, " the minds of some men are a lamp that is continually burning;" and such was the mind of Mr Elwes. Removed from those occasional public avocations which had once engaged his attention, money was now his only thought. He rose upon money-upon money he lay down to rest; and as his capacity sunk away from him by degrees, he dwindled from the real cares of his property into the puerile concealment of a few guineas. This little store he would carefully wrap up in various papers, and depositing them in different corners, would amuse himself with running from one to the other, to see whether they were all safe. Then forgetting, perhaps, where he had concealed some of them, he would become as seriously afflicted as a man might be who had lost all his property. Nor was the day alone thus spent-he would frequently rise in the middle of the night, and be heard walking about different parts of the house, looking after what he had thus hidden and forgotten.

During the winter of 1789, the last winter Mr Elwes was fated to see, his memory visibly weakened every day; and from the unceasing wish to save money, he now began to fear he should die in want of it. Mr Gibson had been appointed his builder in the room of Mr Adams; and one day, when this gentleman waited upon him, he said with apparent eoneern, "Sir, pray consider in what a wretched state I am : you see in what a good house I am living; and here are five guineas, which is all I have at present; and how I shall go on with such a sum of money puzzles me to death. I dare say you thought I was rich; now you see how it is !"

Mr George Elwes having now settled at his seat at Marcham in Berkshire, he was naturally desirons that, in the assiduities of his wife, his father might at length find a comfortable home. In London he was certainly most uncomfortable : but still, with these temptations before and behind him, a journey with any expence annexed to it was insurmountable. This, however, was luckily obviated by an offer from Mr Partis, a gentleman of the law, to take him to his ancient seat in Berkshire with his purse perfectly whole. But there was one circumstance still very distressing—the

old gentleman had now nearly worn out his last coat, and he would not buy a new one; his son, therefore, with a pious fraud, contrived to get Mr Partis to buy him a coat and make him a present of it. Thus formerly having had a good coat, then a bad one, and at last no coat at all, he was kind enough to accept one from a neighbour.

Mr Elwes carried with him into Berkshire five guineas and a half, and half a crown. Lest the mention of this sum may appear singular, it should be said, that previous to his journey he had carefully wrapped it up in various folds of paper, that no part of it might be lost. On the arrival of the old gentleman, Mr George Elwcs and his wife did every thing they could to make the country a scene of quiet to him. But " he had that within" which baffled every effort of this kind. Of his heart it might be said, " there was no peace in Israel." His mind, cast away upon the vast and troubled ocean of his property, extending beyond the bounds of his calculation, returned to amuse itself with fetching and carrying about a few guineas, which in that ocean was indeed a drop. But nature had now carried on life nearly as far as she was able, and the sand was almost run out. The first symptom of more immediate decay was his inability to enjoy his rest at night. Frequently would he be heard at midnight as if struggling with some one in his chamber, and erying ont, " I will keep my money, I will ; nobody shall rob me of my property." On any one of the family going into his room, he would start from this fever of anxiety, and, as if waking from a troubled dream, again hurry into bed, and seem unconseious of what had happened. At length, on the 26th November 1789, expired this miserably rich man, whose property, nearly reaching to a million, extended itself almost through every county in England.

MISERICORDIA, in Law, is an arbitrary fine imposed on any person for an offence; this is called *misericordia*, because the amercement ought to be but small, and less than that required by magna eharta. If a person be outrageously amerced in a court that is not of record, the writ called *moderata misericordia* lies for moderating the amercement according to the nature of the fault.

MISFORTUNE. An unlucky accident.

MISFORTUNE, or chance, in Law, a deficiency of the will; or committing of an unlawful act by misfortune or chance, and not by design. In such case, the will observes a total neutrality, and does not co-operate with the dced; which therefore wants one main ingredient of a crime. See CRIME.

Of this, when it affects the life of another, we have spoken under the article HOMICIDE; and in this place have only occasion to observe, that if any aecidental mischief happens to follow from the performance of a lawful act, the party stands excused from all guilt: but if a man be doing any thing unlawful, and a consequence ensues which he did not foresee or intend, as the death of a man or the like, his want of foresight shall be no excuse; for, being guilty of one offenee, in doing antecedently what is in itself unlawful, he is eriminally guilty of whatever consequence may follow the first misbehaviour.

MISFEASANCE, in law books, signifies a trespass.

MISLETOE,

lisletoe

MIS

which the principal is the mal-administration of such Misprisions

MISLETOE. See VISCUM, BOTANY Index.

MISNOMER, in *Law*, a misnaming or mistaking prisions: a person's name. The Christian name of a person should always be perfect; but the law is not so strict in regard to surnames, a small mistake in which will be dispensed with to make good a contract, and support the act of the party. See PLEA to Indictment.

MISPRISIONS, (a term derived from the old French, mespris, a negleet or contempt), are, in the acceptation of our law, generally understood to be all such high offences as are under the degree of capital, but nearly bordering thereon : and it is said, that a misprision is contained in every treason and felony whatsoever; and that, if the king so please, the offender may be proceeded against for the misprision only. And upon the same principle, while the jurisdiction of the starchamber subsisted, it was held that the king might remit a prosecution for treason, and cause the delinquent to be censured in that court, merely for a high misdemeanor ; as happened in the case of Roger earl of Rutland, in 43 Eliz. who was concerned in the earl of Essex's rebellion. Misprisions are generally divided into two sorts ; negative, which consist in the concealment of something which ought to be revealed; and positive, which consist in the commission of something which ought not to be done.

1. Of the first, or negative kind, is what is called misprision of treason; consisting in the barc knowledge and eoncealment of treason, without any degree of assent thereto ; for any assent makes the party a principal traitor; as indeed the concealment, which was construed aiding and ahetting, did at the common law; in like manner as the knowledge of a plot against the state, and not revealing it, was a capital crime at Florence, and other states of Italy. But it is now en-acted by the statute I & 2 Ph & Mar. c. 10. that a bare concealment of treason shall be only held a misprision. This concealment becomes criminal, if the party apprised of the treason does not, as soon as conveniently may be, reveal it to some judge of assize or justice of the peace. But if there be any probable circumstances of assent, as if one goes to a treasonable meeting, knowing heforehand that a conspiracy is intended against the king; or, being in such company onee by aecident, and having heard such treasonable conspiracy, meets the same company again, and hears more of it, but conceals it; this is an implied assent in law, and makes the concealer guilty of actual high treason.

Misprision of felony is also the conccalment of a felony which a man knows, but never assented to; for, if he assented, this makes him either principal or accessory. And the punishment of this, in a public officer, by the statute Westm. I. 3 Edw. I. c. 9. is imprisonment for a year and a day; in a common person, imprisonment for a less discretionary time; and, in both, fine and ransom at the king's pleasure : which pleasure of the king must be observed, once for all, not to signify any extrajudicial will of the sovereign, but such as is declared by his representatives, the judges in his courts of justice; voluntas regis in curia, non in camera.

2. Misprisions, which are merely positive, are generally denominated *contempt* or *high misdemeanours*; of Vol. XIV. Part I. †

high officers as are in public trust and employment. If This is usually punished by the method of parliamen. Mississippi. tary impeachment; wherein such penalties, short of death, are inflicted, as to the wisdom of the house of peers shall seem proper; consisting usually of banishment, imprisonment, fines, or perpetual disability. Hither also may be referred the offence of embezzling the public money, called among the Romans peculatus ; which the Julian law punished with death in a magistrate, and with deportation, or banishment, in a private person. With us it is not a capital crime, but subjects the committer of it to a discretionary fine and imprisonment .- Other misprisions are, in general, such contempts of the executive magistrate as demonstrate themselves by some arrogant and undutiful behaviour towards the king and government: for a detail of which, vide Blackstone's Comment. iv. 22.

MISSAL, the Romish mass-book, containing the several masses to be said on particular days. It is derived from the Latin word *missa*, which, in the ancient Christian church, signified every part of divine service.

MISSEL-BIRD, a species of TURDUS. See TUR-DUS, ORNITHOLOGY Index.

MISSIO, among the Romans, was a full discharge given to a soldier after 20 years service, and differed from the *exauctoratio*, which was a discharge from duty after 17 years service. Every soldier had a right to claim his *missio* at the end of 20 years.

MISSION, in *Theology*, denotes a power or commission to preach the gospel. Jesus Christ gave his disciples their mission in these words, *Go and teach all nations*, &c. The Romanists reproach the Protestants, that their ministers have no mission, as not being authorized in the exercise of their ministry, either by an uninterrupted succession from the apostles, or by miraracles, or by any extraordinary proof of a vocation. Many among us deny any other mission necessary for the ministry than the talents necessary to discharge it.

MISSION is also used for an establishment of people zealous for the glory of God and the salvation of souls; who go and preach the gospel in remote countries and among infidels.

MISSIONARY, an ecclesiastic who devotes himself and his labours to some mission, either for the instruction of the orthodox, the conviction of heretics, or the conversion of infidels. See JESUITS.

MISSISSIPPI, a river of North America, and onc of the largest in the world. It rises in some lakes about the latitude of 48°, and runs in a direction nearly south to the gulf of Mexico. Its course, including windings, is about 2500 miles in length, and it is navigable from the sea to the falls of St Anthony in latitude 44° 50'. Its width is from 800 yards to a mile and a half. Its depth above New Orleans has been found to be 150 feet; but there is only from 12 to 17 feet water on the bars at its mouth. Its current is from three to four miles an hour, but varies with the rise and fall of the waters. In low water a boat will float down at the rate of 45 or 50 miles a day, and in high water at 90 or 100. Towards the mouth the current is much less rapid than farther up. The usual progress of a hoat up the river is about 15 miles a day; but the steam-boats, of which there are now great num-00bers

MIS

MIS

Mississippi, bers on this river, go against the stream at the rate of Missouri. 60 miles a-day. This river has an annual swell, which begins in November, and increases till May, from which period it again diminishes till October. The greatest rise from the mouth of the Ohio to Natchez is about 50 feet; but at New Orleans is only about 12 feet. During this annual flood a part of the waters pass over the western banks, inundate the country to a considerable extent, and never return into the bed of the river, but either form marshes, or pass off to the sea by different channels. In the lower part of its course the banks are higher than the surrounding country; and, besides the waters that overflow during the floods, a part always escapes by lateral branches, which intersect the country towards its mouth in various directions, and form a delta about 200 miles long by 100 broad. This tract, inclosed within the branches of the river, is, for the greater part, a morass nearly on a level with high water. It has evidently been formed by alluvial matter brought down and deposited by the river, and it is observed to be continually en-

larging. The Mississippi receives in its course a great many very large rivers, the Illinois and Ohio on the east; the Missouri, Arkansaw, Red River, &c. on the west. Including all its branches, Mr Bradbury computes that it waters a country eleven times as large as Great Britain and Ireland.

MISSISSIPPI, one of the United States of North America, is situated on the east side of the river of the same name, between 30° and 35° N. Lat. and 87° and 91° W. Long. It is about 350 miles long, and 150 broad, and has an area of about 45,000 square miles. The southern parts on the gulf of Mexico are low, sandy, or marshy, and unhealthy; but the middle and northern parts are pretty well watered, and very fertile. The great articles of culture are cotton and Indian eorn; rice and sugar, however, are also raised. Lemons and other fruits thrive well. Horned eattle are raised in great numbers, but are sometimes destroyed by the wolf and cougouar. Labour is generally performed by slaves. Natchez, the principal town, and the only place of trade, is about 300 miles above New Orleans. There are some tanneries in the state, and some domestic manufactures of woollen, cotton, flax, and hemp. The principal rivers are the Tombigbee, Pascagoula, Pearl, and Yazoo. This state was admitted into the Union in 1817. Its population the year before was 44,206, of whom 20,567 were slaves, and 191 free blacks. The Choctaws, Cherokees, and some other of the Indian tribes who have made considerable advances in eivilization, reside in this state. The legislative power of this state is vested in a house of representatives and a senate, chosen by all free white males of 21 years of age.

MÍSSOURI, a river in Louisania, which falls into the Mississippi from the west, 195 miles above the mouth of the Ohio, and about 1160 miles from the Balize in the gulf of Mexico. Though the united rivers take the name of the Mississippi, the Missouri is much the largest branch. It was first explored by Captains Lewis and Clerk in 1804, 1805, and 1806. It is navigable for boats to the great falls 2848 miles from its junction with the Mississippi, and even beyond

2

this almost to its source at the distance of 3096 miles Missour from the Mississippi, making the total extent of navigation from the sea in one line above 4000 miles. Its width varies from 200 yards to a mile. Its velocity was found by the log to be about five miles an hour. It receives many large streams, the Yellowstone, Kansas, Platte, &c. chiefly on its south side; and it is computed that, including these branches, it affords an inland navigation of 15,000 miles. It earries down great quantities of earth, and has an annual swell like the Mississippi. Its sources in the Stony mountains are not far from those of the Columbia, which flows into the Pacific ocean. The distance to the South sea from the Mississippi by this route is 3555 miles.

MISSOURI, a territory of the United States of North America, including the greater part of the country formerly known under the name of Louisiana. It extends from the Mississippi to the Rocky mountains, and from the gulf of Mexico to Canada. Its length from north to south is about 1400 miles, and its breadth from east to west 886, comprising an area of 985,250 square miles. It is watered by the Missouri river and its numerous tributary streams, and by some other branches of the Mississippi. The surface is generally uneven, but not mountainous. The soil is rich and well watered ; but, unlike that of the eastern parts of America, it produces little natural wood, except on the banks of the rivers. Lime is abundant in this vast region; coal and iron ore were observed in many places; and salt is found in great quantities. Near St Louis lead ore abounds, and is wrought to a great extent. As the country extends through 20 degrees of latitude, the climate is various; warm and unhealthy in the south; colder and more salubrious towards the north. There are as yet but a small number of white settlers in this country, the greater part of which is still occupied by savage tribes.

MISSUS, in the Circensian games, were the matches in horse or chariot races. The usual number of *missus* or matches in one day was 24; though the emperor Domitian presented the people with 100. The last match was generally made at the expense of the people, who made a collection for the purpose; hence it was ealled *missus ærarius*, a subscription plate.

MIST, or Fog. See Fog.

MISTAKE, any wrong action committed, not through an evil design, but through an error of judgment.

MISUSER, in *Law*, is an abuse of any liberty or henefit; as "He shall make fine for his MISUSER." Old. Nat. Br. 149. By misuser a charter of a corporation may be forfeited; so also an office, &c.

MITCHELSTOWN, a post town of Ireland, in the county of Cork and province of Munster in Ireland, where there is a college founded by the earl of Kingston for the support of 12 decayed gentlemen and 12 decayed gentlewomen, who have 40l. yearly, and handsome apartments.

MITE, a small piece of money mentioned Luke xii. 59. and xxi. 2. In the Greek it is ysdewins, i. e. quadrans, or a quarter of the Roman denarius; so that the mite was worth about seven farthings, or twopence of our money.

MITE. See ACARUS, ENTOMOLOGY Index. MITELLA, itella

ates.

MITELLA, BASTARD AMERICAN SANICLE; a genus of plants belonging to the decandria class, and in ithri- the natural method ranking under the 13th order, Succulenta. See BOTANY Index.

MITHRA, feasts of, in antiquity, were feasts celebrated among the Romans in honour of Mithras or the sun. The most ancient instance of this Mithras among the Romans occurs in an inscription dated in the third consulate of Trajan, or about the year of Christ 101. This is the dedication of an altar to the sun under the above name, thus inscribed, Deo Soli Mithræ. But the worship of Mithras was not known in Egypt and Syria in the time of Origen, who died about the year of Christ 263; though it was common at Rome for more than a century before this time. The worship of Mithras was proscribed at Rome in the year 378, by order of Graechus, prefect of the prætorium. According to M. Freret, the feasts of Mithras were derived from Chaldea, where they had been instituted for celebrating the entrance of the sun into the sign Taurus.

MITHRAS, or MITHRA, a god of Persia and Chal-dea, supposed to be the sun. His worship was introduced at Rome. He is generally represented as a young man, whose head is covered with a turban after the manner of the Persians. He supports his knee upon a bull that lies on the ground, and one of whose horns he holds in one hand, while with the other he plunges a dagger in his neck.

MITHRIDATE, an old term, in Pharmacy; an antidote or composition, in form of an electuary, supposed to serve either as a remedy or a preservative against poisons; so named from the inventor, Mithridates, king of Pontus, who is said to have so fortified his body against poisons with antidotes and preservatives, that when he had a mind to dispatch himself he could not find any poison that would take effect. MITHRIDATES, the name of several kings of

Pontus. See PONTUS.

MITHRIDATES VII. surnamed Eupator and the Great, succeeded to the throne at the age of II years, about 123 years before the Christian era. The beginning of his reign was marked by ambition, cruelty, and artifice. He murdered his own mother, who had been left by his father co-heircss of the kingdom; and he fortified his constitution by drinking antidotes against the poison with which his enemies at court attempted to destroy him. He carly inured his body to hardship, and employed himself in the most manly exercises, often remaining whole months in the country, and making frozen snow and the earth the place of his repose. Naturally ambitious and cruel, he spared no pains to acquire himself power and dominion. He murdered the two sons whom his sister Laodice had by Ariarathes king of Cappadocia, and placed one of his own children, only eight years old, on the vacant throne. These violent proceedings alarmed Nicomedes king of Bithynia, who had married Laodice the widow of Ariarathes, and ultimately involved Mithridates in a quarrel with the Romans. Mithridates never lost an opportunity by which he might lessen the influence of his adversaries; and the more effectually to destroy their power in Asia, he ordered all the Romans that were in his dominions to be massaered. This was done in one night, and no less than 150,000, according to Plutarch, or 80,000 Romans, as Appian mentions, were

was made prisoner; but Sylla obtained a victory over the king's generals; and another decisive engagement rendered him master of all Greece, Macedonia, Ionia, and Asia Minor. This ill fortune was aggravated by the loss of about 200,000 men, who were killed in the several engagements that had been fought; and Mithridates, weakened by repeated ill success by sea and land, sued for peace from the conqueror, which he obtained on hard terms. But he soon took the field again with an army of 140,000 infantry, and 16,000 horse, consisting of his own forces and those of his son-in-law Tigranes king of Armenia. With this army he made himself master of the Roman provinces in Asia; none dared to oppose his conquests; and the Romans, relying on his fidelity, had withdrawn the greatest part of their armics from the country. The news of his warlike preparations were no sooner heard, than Lucullus the consul marched into Asia; and without delay lue blocked up the camp of Mithridates who was then besieging Cyzicus. The Asiatic monarch escaped from him, and fled into the heart of his kingdom. Lucullus pursued him with the utmost celerity ; and would have taken him prisoner after a battle, had not the avidity of his soldiers preferred the plundering of a mule loaded with gold to the taking of a monarch who had exercised such cruelties against their countrymen. The appointment of Glabrio to the command of the Roman forces, instead of Lucullus, was favourable to Mithridates, who recovered the greatest part of his dominions. The sudden arrival of Pompey, however, soon put an end to his victories. A battle in the night was fought near the Euplirates. An universal overthrow ensued, and Mithridates, bold in his misfortunes, rushed through the thick ranks of the enemy at the head of 800 horsemen, 500 of whom perished in the attempt to follow him. He fled to Tigranes ; but that monarch refused an asylum to his father-in-law, whom he had before supported with all the collected forces of his kingdom. Mithridates found a safe retreat among the Scythians; and though destitute of power, friends, and resources, yet he meditated the overthrow of the Roman empire, by penetrating into the heart of Italy by land. These wild projects were rejected by his followers, and he sued for peace. It was denied to his ambassadors ; and the victorious Pompey declared, that, to obtain it, Mithridates must ask it in person. He scorned to trust himself in the hands of his enemy, and resolved to conquer or to die. His subjects refused to follow him any longer; and revolting from him, made his son Pharnaces king. The son showed himself ungrateful to his father; and even, according to some writers, he ordered him to be put to death. This unnatural treatment broke the heart of Mithridates; he obliged his wife to poison herself, and attempted to do the same himself. It was in vain : the frequent antidotes he had taken in the early part of his life, strengthened his constitution against the poison ; and when this was unavailing, he attempted to stab himself. The blow was not mortal; and a Gaul who was then present, at his own request, gave him the fatal stroke, a-

misfortunes, abilities, and miserable end, of a man, who 0 0 2

bout 64 years before the Christian cra. Such were the

supported

Mithridates [] Mittimus. supported himself so long against the power of Rome, and who, according to the declarations of the Roman authors, proved a more powerful and indefatigable adversary to the capital of Italy than the great Hannibal, Pyrrhus, Perseus, cr Antiochus. It is said that Mithridates conquered 24 nations, whose different languages he knew and spoke with the same case and fluency as his own. As a man of letters he also deserves attention. He was acquainted with the Greek language, and even wrote in that dialect a treatise on botany. His skill in physic is well known; and even now there is a celebrated antidote which bears his name, and is called *mithridate*.

MITRA, was a cap or covering for the head, worn by the Roman ladies, and sometimes by the men; but it was looked upon as a mark of effeminaey in the last, especially when it was tied upon their heads.

MITRE, a sacerdotal ornament worn on the head, by bishops and certain abbots on solenn occasions; being a sort of cap, pointed and cleft at top. The high priest among the Jews wore a mitre or bonnet on his head. The inferior priests of the same nation had likewise their mitres; but in what respect they differed from that of the high priest, is uncertain. Some contend that the ancient bishops wore mitres; but this is by no means certain.

MITRE, in Architecture, is the workmen's term for an angle that is just 45 degrees, or half a right one. If the angle be a quarter of a right angle, they call it a half mitre.

To describe such angles, they have an instrument called the *mitre square*; with this they strike mitre lines on their quarters or battens; and for despatch, they have a *mitre box*, as they call it, which is made of two pieces of wood, each about an inch thick, one nailed upright on the edge of the other; the upper piece hath the mitre lines struck upon it on both sides, and a kerf to direct the saw in cutting the mitre joints readily, by only applying the piece into this box.

MITRE is used by the writers of the Irish history for a sort of base money, which was very common there about the year 1270, and for 30 years before and as many after.

There were besides the mitre several other pieces, called, according to the figures impressed upon them, rosaries, lionades, eagles, and by the like names. They were imported from France and other countries, and were so much below the proper currency of the kingdom, that they were not worth so much as a halfpenny cach. They were at length decryed in the year 1300, and good coins struck in their place. These were the first Irish coins in which the sceptre was left out. They were struck in the reign of Edward, the son of our Henry III. and are still found among the other antiquities of that country. They have the king's head in a triangle full faced. The penny, when well preserved, weighs 22 grains ; the halfpenny  $10\frac{1}{2}$  grains.

MITTAU, the capital of the duchy of Courland. It is strongly fortified; but was taken by the Swedes in 1701, and by the Museovites in 1706. E. Long. 23. 51. N. Lat. 56. 44.

MITTIMUS, as generally used, hath two significations. 1. It signifies a writ for removing or transferring of records from one court to another. 2. It signifies a precept, or command in writing, under the hand and seal of a justice of the peace, directed to the

gaoler or keeper of some prison, for the receiving and Mitting safe keeping of an offender charged with any crime, until he be delivered by due course of law.

MITYLENE, or MYTELENE, in Ancient Geography, a celebrated, powerful, and affluent city, capital of the island of Lesbos. It received its name from Mitylene, the daughter of Macareus, a king of the country. It is greatly commended by the aneients for the stateliness of its buildings and the fruitfulness of its soil, but more particularly for the great men it produced : Pit-taeus, Aleæus, Sappho, Terpander, Theophanes, Hellanieus, &te. were all natives of Mitylene. It was long a seat of learning; and, with Rhodes and Athens, it had the honour of having educated many of the great men of Rome and Greece. In the Peloponnesian war, the Mitylenians suffered greatly for their revolt from the power of Athens; and in the Mithridatie wars, they had the boldness to resist the Romans, and disdain the treaties which had been made between Mithridates and Sylla. See METELIN.

MIXT, or MIXT BODY, in *Chemistry*, that which is compounded of different elements or principles.

MIXTURE, a compound or assemblage of several different bodies in the same mass. Chemical mixture is attended with many phenomena which are never observed in simple mixtures; such as heat, efferveseence, &c. To chemical mixture belong the union of acids and alkalies, the amalgamation of metals, solution of gums, &c. and upon it depend many of the principal operations of CHEMISTRY. See that article, passim.

MIXTURE, in *Pharmacy*, a medicine which differs from a julep in this respect, that it receives into its composition not only salts, extracts, and other substances dissoluble in water; but also earths, powders, and such substances as cannot be dissolved.

MIZEN, in the sea language, is a particular mast or sail. The mizen mast stands in the sternmost part of the ship. In some great ships there are two of these; when that next the main-mast is called the main-mizen, and that next the poop the bonaventure mizen.

MIZRAIM, or MISRAIM, the dual name of Egypt, used in Seripture to denote the Higher and Lower Egypt, which see. It sometimes occurs singular, Mazor: 2 Kings xix. Isaiah xix. Micah vii.

MNEMOSYNE, in fabulous history, a daughter of Cœlus and Terra. She married Jupiter, by whom she had the nine Muses. The word *mnemosyne* signifies "memory;" and therefore the poets have rightly called Memory the mother of the Muses, because it is to that mental endowment that mankind are indebted for their progress in science.

MNIUM, MARSHMOSS; a genus of the natural order of musci, belonging to the cryptogamia class of plants. See BOTANY Index.

MOAB, in Ancient Geography, a country of Arabia Petræa; so called from Moab the son of Lot, to whose posterity this country was allotted by divine appointment, Deut. xi. 9. It was originally occupied by the Emim, a race of giants extirpated by the Moabites, *ibid*. Moab anciently lay to the south of Ammon, before Sihon the Amorite stripped both nations of a part of their territory, afterwards occupied by the Israclites, Numb. xxi.; and then Moab was bounded by the river Arnon to the north, the Lacus Asphaltites to the west, the loab

the brook Zared to the south, and the mountains Abarim to the east.

MOAT, or DITCH, in *Fortification*, a deep trench dug round the rampart of a fortified place, to prevent surprises.

The brink of the moat, next the rampart, is called the *scarpe*; and the opposite one, the *counterscarpe*.

A dry moat round a large place, with a strong garrison, is preferable to one full of water; because the passage may be disputed inch by inch, and the besiegers, when lodged in it, are continually exposed to the bombs, grenades, and other fire works, which are thrown ineessantly from the rampart into their works. In the middle of dry moats, there is sometimes another small one, ealled *cunette*; which is generally dug so deep till they find water to fill it.

The deepest and broadest moats are accounted the best; but a deep one is preferable to a broad one : the ordinary breadth is about 20 fathoms, and the depth about 16.

To drain a moat that is full of water, they dig a trench deeper than the level of the water, to let it run off; and then throw hurdles upon the mud and slime, covering them with earth or bundles of rushes, to make a sure and firm passage.

MOATAZALITES, or SEPARATISTS, a religions sect among the Turks, who deny all forms and qualities in the Divine Being; or who divest God of his attributes.

There are two opinions among the Turkish divines concerning God. The first admits metaphysical forms or attributes; as, that God has wisdom, by which he is wise; power, by which he is powerful; cternity, by which he is eternal, &e. The second allows God to be wise, powerful, eternal; but will not allow any form or quality in God, for fear of admitting a multiplicity. Those who follow this latter opinion are called *Moatazalites*; they who follow the former, *Scphalites*.

This sect is said to have first invented the scholastic divinity, and is subdivided into no less than 20 inferior sects, which mutually brand one another with infidelity.

MOBILE, a town in the United States, in the territory of Alabama, situated on a bay of the same name in the gulf of Mexico. It has but an indifferent port. Its population in 1817, was from 1000 to 1500 persons.

MOBILE, *Moveable*, any thing susceptible of motion, or that is disposed to be moved either by itself or by some other prior *mobile* or mover.

**Primum MOBILE**, in the ancient astronomy, was a ninth heaven or sphere, imagined above those of the planets and fixed stars. This was supposed to be the first mover, and to carry all the lower spheres round along with it; by its rapidity communicating to them a motion whereby they revolved in 24 hours. But the diurnal revolution of the planets is now accounted for without the assistance of any such primum mobile.

Perpetuium MOBILE. See Perpetual MOTION.

MOCHO, Moco, or *Mokha*; by some supposed to be the Musa or Muza of Ptolemy, is a port and town on the Red Sea, of considerable trade; contains about 10,000 inhabitants, Jews, Armenians, and Mohammedans; and it gives name to a kingdom extending

part which lies next the sea is a dry barren desert, in some places 10 or 12 leagues over; but bounded by, mountains, which being well watered, enjoy an almost perpetual spring; and besides coffee, the peculiar produce of this country, yields eorn, grapes, myrrh, frankincense, cassia, balm, gums of several sorts, mangos, dates, pomegranates, &c. The weather here is so hot and sultry in summer, especially when the south wind blows, that it would be insupportable, if it was not mitigated by the cool breezes that generally blow from the mountains on the north, or the Red and Arabic seas on the west and east. The heat in winter is equal to that of our warmest summers; and it is very seldom that either clouds or rain are seen. The city of Mocho is now the emporium for the trade of all India to the Red sea. The trade was removed hither from Aden. in consequence of the prophecy of a sheik, much revered by the people, who foretold that it would soon bccome a place of extensive commerce notwithstanding its disadvantageous situation. The buildings here are lofty, and tolerably regular, having a pleasant aspect from Mecca. The steeples of several mosques are very high, presenting themselves to view at a great distance. Their markets are well stored with beef, mutton, lamb, kid, camels and antelopes flesh, common fowls, Guinea hens, partridges, and pigeons. The sea affords plenty of fish, but not savoury; which some think proceeds from the extreme saltness of the water and the nature of their aliment. The markets are also stocked with fruit, such as grapes, peaches, apricots, quinces, and nectarines; although neither shrub nor tree is to be seen near the town, except a few date trees. Frequently no rain falls here in two or three years, and seldom more than a shower or two in a year; but in the mountains, at the distance of about 20 miles from Mocha, the earth is watered with a gentle shower every morning, which makes the valleys fertile in eorn and the fruits natural to the climate. The Arab inhabitants, though remarkably grave and superstitious, are said to be extremely eovetous and hypoeritical; robbing, thieving, and committing piracy, without the least scruple or remorse. The English and Dutch companies have handsome houses here, and carry on a great trade in eoffce, olibanum, myrrh, aloes, liquid storax, white and yellow arscnic, gum arabic, mummy, balm of Gilead, and other drugs. One inconvenience, however, they sustain from the violence and exactions of the Arabian princes; but the king's customs are easy, being fixed at three per cent. to Europcans. Of the coins at Mocha, the most current is the camassie, which rises and falls in value at the banker's discretion : they are from 50 to 80 for a current. dollar, which is but an imaginary species, being always reckoned one and a half per cent. lower than Spanish dollars.

# MOCKING BIRD. See TURDUS, ORNITHOLOGY Index.

MOCOCO. See LEMUR, MAMMALIA Index.

MODE, which is a word of the same general import with MANNER, is used as a technical term in grammar, metaphysics, and music. For its import in GRAM-MAR, see that article, N° 80.

MODE, in *Metaphysics*, seems properly to denote the manner of a thing's existence : but Locke, whose language

along the most southern coast of Arabia; of which that Mocho part which lies next the sea is a dry barren desert, in II Mode.

language in that science is generally adopted, uses the word in a sense somewhat different from its ordinary and proper signification. "Such complex ideas, which, however compounded, contain not in them the supposition of subsisting by themselves, but are considered as dependencies on, or affections of, substances," he calls modes. Of these modes, there are, according to him, two sorts, which deserve distinct consideration. First, There are some "which are only variations, or different combinations of the same simple idea, without the mixture of any other, as a dozen or a score; which are nothing but the ideas of so many distinct units added together :" and these he calls simple modes. Secondly, "There are others compounded of simple ideas of scveral kinds put together to make one complex one; v. g. beauty, consisting of a certain composition of colour and figure, causing delight in the beholder; theft, which being the concealed change of the possession of any thing without the consent of the proprietor, contains, as is visible, a combination of several ideas of several kinds ;" and these he calls mixed modes. For the just distinction between ideas and notions, as well as between ideas and the qualities of external objects, which in this account of modes are all confounded together, sce METAPHYSICS.

MODE, in Music, a regular disposition of the air and accompaniments, relative to certain principal sounds upon which a piece of music is formed, and which are called the essential sounds of the mode.

Our modes are not, like those of the ancients, characterized by any sentiment which they tend to excite, but result from our system of harmony alone. The sounds essential to the mode are in number three, and form together one perfect chord. I. The tonic or key, which is the fundamental note both of the tone and of the mode. 2. The dominant, which is a fifth from the tonic. 3. The mediant, which properly constitutes the mode, and which is a third from the same tonic. As this third may be of two kinds, there are of conscaucnee two different modes. When the mediant forms a greater third with the tonic, the mode is major; when the third is lesser, it is minor. Sce Music.

MODEL, in a general sense, an original pattern, proposed for any one to copy or imitate.

I Different kinds of models.

2

General

making

models.

Mode,

Model.

This word is particularly used, in building, for an artificial pattern made in wood, stone, plaster, or other matter, with all its parts and proportions, in order for the better conducting and executing some great work, and to give an idea of the effect it will have in large. In all great buildings, it is much the surest way to make a model in relievo, and not to trust to a bare design or draught. There are also models for the building of ships, &c. and for extraordinary staircases,

They also use models in painting and sculpture; whence, in the academics, they give the term model to a naked man or woman, disposed in several postures, to afford an opportunity to the scholars to design them in various views and attitudes.

Models in imitation of any natural or artificial substance, are most usually made by means of moulds method of composed of plaster of Paris. For the purpose of making these moulds, this kind of plaster is much more fit than any other substance, on account of the power it has of absorbing water, and soon condensing

into a hard substance, even after it has been rendered bold so thin as to be of the consistence of cream. This happens in a shorter or longer time as the plaster is of a better or worse quality; and its good or bad properties depend very much upon its age, to which, therefore, particular regard ought to be had. It is sold in the shops at very different prices ; the finest being made use of for casts, and the middling sort for moulds. It may be very easily coloured by means of almost any kind of powder excepting what contains an alkaline salt; for this would chemically decompose the substance of it, and render it unfit for use. A very considerable quantity of chalk would also render it soft and useless, but lime hardens it to a great degree. The addition of common size will likewise render it much harder than if mere water is made use of. In making either moulds or models, however, we must be careful not to make the mixture too thick at first; for if this is done, and more water added to thin it, the composition must always prove brittle and of a bad quality.

The particular manner of making models (or casts, as they are also called) depends on the form of the subject to be taken. The process is easy, where the parts are elevated only in a slight degree, or where they form only a right or obtuse angle with the principal surface from which they project; but where the parts project in smaller angles, or form curves inclined towards the principal surface, the work is more diffi-This observation, however, holds good only cult. with regard to hard and inflexible bodies; for such as are soft may often be freed from the mould, even though they have the shape last mentioned. But though this be the case with the soft original substance, it is not so with the inflexible model when once it is cast.

The moulds are to be made of various degrees of thickness, according to the size of the model to be cast; and may be from half an inch to an inch, or, if very large, an inch and a half. Where a number of models arc to be taken from one mould, it will likewise be necessary to have it of a stronger contexture than where only a few arc required, for very obvious reasons.

It is much more easy to make a mould for any soft Anatom substance than a rigid one, as in any of the viscera of models the animal body; for the fluidity of the mixture makes it easily accommodate itself to the projecting parts of the substance ; and as it is necessary to inflate these substances, they may be very readily extracted again by letting out the air which distended them.

When a model is to be taken, the surface of the original is first to be greased, in order to prevent the plaster from sticking to it; but if the substance itself is slippery, as is the case with the internal parts of the human body, this need not be done: when necessary, it may be laid over with lintseed oil by means of a painter's brush. The original is then to be laid on a Pole's. smooth table, previously greased or covered with a tomical cloth, to prevent the plaster sticking to it; then surround the original with a frame or ridge of glaziers putty, at such a distance from it as will admit the plaster to rest upon the table on all sides of the subject for about an inch, or as much as is sufficient to give the proper degree of strength to the mould. A sufficient

odel. cient quantity of plaster is then to he poured as uniformly as possible over the whole substance, until it be everywhere covered to such a thickness as to give a proper substance to the mould, which may vary in proportion to the size. The whole must then be suffered to remain in this condition till the plaster has attained its hardness; when the frame is taken away, the mould may be inverted, and the subject removed from it: and when the plaster is thoroughly dry let it be well scasoned.

Having formed and seasoned the moulds, they must next he prepared for the casts by greasing the inside of them with a mixture of olive oil and lard in equal parts, and then filled with fine fluid plaster, and the plane of the mould formed by its resting on the surface of the table covered to a sufficient thickness with coarse plaster, to form a strong basis or support for the cast where this support is requisite, as is particularly the case where the thin and membranous parts of the body are to be represented. After the plaster is poured into the mould, it must be suffered to stand until it has acquired the greatest degree of hardness it will receive; after which the mould must be removed : but this will be attended with some difficulty when the shape of the subject is unfavourable; and in some cases the mould must be separated by means of a small mallet and chissel. If hy these instruments any parts of the model should be broken off, they may be cemented by making the two surfaces to be applied to each other quite wet; then interposing betwixt them a little liquid plaster; and lastly, the joint smoothed after being thoroughly dry. Any small holes that may be made in the mould can be filled up with liquid plaster, after the sides of them have been thoroughly wetted, and smoothed over with the edge of a knife.

In many cases it is altogether impracticable to prepare a mould of one piece for a whole subject; and therefore it must be considered how this can be done in such a manner as to divide the mould into the fewest pieces. This may be effected by making every piece cover as much of the pattern as possible, without surrounding such projecting parts, or running into such hollows as would not admit a separation of the mould. It is impossible, however, to give any particular directions in this matter which can hold good in every instance, the number of pieces of which the mould is to consist being always determined from the shape of the pattern. Thus the mould of the human calculus will require no more than three pieces, but that of an os femoris could scarce have fewer than ten or twelve .---Where any internal pieces are required, they are first to be made, and then the outer pieces after the former have become hard.

To make a mould upon a hard and dry substance, we must, in the first place, rub the surface of it smoothly over with the mixture of oil and lard above mentioned. Such hollows as require internal pieces are then to be filled up with fluid plaster; and while it continues in this state, a wire loop must be introduced into it, by which, when hardcned, it can be pulled off. The plaster should be somewhat raised in a pyramidal form around this wire, and afterwards cut smooth with a knife while yet in its soft state; preserving two or three angular ridges from the loop to the outer edge, that it may fix the more steadily

in the outer piece of the mould to be afterwards made Model. upon it. Let the outer piece then be well greased, to prevent the second piece from adhering; the loop being enclosed with some glaziers putty, both to prevent the second piece from adhering and to preserve a hollow place for the cord.

To form the second or outside piece, mix a quantity of plaster proportioned to the extent of surface it is to cover and the intended thickness of the mould: when it is just beginning to thicken, or assumes such a consistence as not to run off very casily, spread it over the internal piece or pieces as well as the pattern, taking care at the same time not to go too far lest it should not deliver safely; and as the plaster becomes more tenacious, add more upon the pattern until it has become sufficiently thick, keeping the edges square and smooth like the edge of a board. The plaster should be spread equally upon all parts, which is best done by a painter's pallet knife or apothecary's bolus knife : but for this the instrument should be somewhat less pliable than it is commonly made.

When the outside piece is hardened, the edges are to be pared smooth, and nearly made square with a small pointed knife. Little holes of a conical shape are to be made with the point of a knife about an inclu distant from one another, according to the size of the piece. These are designed to receive the fluid plaster in forming the adjacent parts of the mould, and occasion points corresponding to the hollows; and are intended to preserve the edges of the different pieces steadily in their proper relative situations. The third piece is then to be formed in a manner similar to the second; greasing the edges of the former plentifully with hog's lard and oil, to prevent the pieces from adhering to each other. Thus the pattern is to be wholly enclosed, only leaving a proper orifice for pouring in the plaster to form the model; small holes being also bored in the mould opposite to the wireloops fixed in the inside pieces, through which a cord is to be conveyed from the loop to confine such pieces during the time of casting. In some cases, however, it is not necessary that the mould should totally enclose the pattern; for instance, where a model is to be made of a pedestal, or a bust of any part of the human body. The bottom of such moulds being left open, there is accordingly ample room for pouring in . the plaster.

After the mould is completely formed, it is next to be dried either naturally or by a gentle artificial heat, and then seasoned in the following manner :---Having been made thoroughly dry, which, if the mould is large, will require two or three weeks, it is to be brushed over plentifully with linseed oil boiled with sugar of lead, finely levigated litharge, or oil ofvitriol. The inside and joints of the mould should beparticularly well supplied with it. If the mould be large, it is needless to attend to the outside ; but when the moulds arc small, it will not be improper to hoil them in the oil; by which means their porcs arc more exactly filled than could otherwise be done. After the moulds have undergone this operation, they are again set by to dry, when, being greased with olive oil and hog's lard, they are fit for use. If linsecd oil be used for greasing the moulds, it will in a short time impart a disagreeable yellow colour to the casts.

Model.

The mould being properly prepared and seasoned, nothing more is requisite to form the model than to pour the finest liquid plaster of Paris into it. After a layer of this, about half an inch in thickness, has been formed all round the mould, we may use the coarser kind to fill it up entirely, or to give to the model what thickness we please.

Models subjects.

Besides the models which are taken from inanimate from living bodies, it has been frequently attempted to take the exact resemblance of pcople while living, by using their face as the original of a model, from whence to take a mould; and the operation, however disagrecable, has been submitted to by persons of the highest ranks in life. A considerable difficulty occurs in this, however, by reason of the person's being apt to shrink and distort his features when the liquid is poured upon him; neither is he altogether without danger of suffocation, unless the operator well understands his business.

To avoid the former inconvenience, it will be proper to mix the plaster with warm instead of cold water, by which means the person will be under no temptation to shrink; and to prevent any danger of a fatal accident, the following method is to be practised : Having laid the person horizontally on his back, the head must first be raised by means of a pillow to the exact position in which it is naturally carried when the body is erect; then the parts to be represented must be very thinly covered over with fine oil of almonds by means of a painter's brush; the face is then to be first eovered with fine fluid plaster, beginning at the upper part of the forehead, and spreading it over the eyes, which are to be kept close, that the plaster may not come in contact with the globe ; yet not closed so strongly as to cause any unnatural wrinkles. Cover then the nose and ears, plugging first up the meatus auditorii, with cotton, and the nostrils with a small quantity of tow rolled up, of a proper size, to exclude the plaster. During the time that the nose is thus stopped, the person is to breathe through the mouth : in this state the fluid plaster is to be brought down low enough to cover the upper lip, observing to leave the rolls of tow projecting out of the plaster. When the operation is thus far carried on, the plaster must be suffered to harden ; after which the tow may be withdrawn, and the nostrils left free and open for breathing. The mouth is then to be closed in its natural position, and the plaster brought down to the extremity of the chin. Begin then to cover that part of the breast which is to be represented, and spread the plaster to the outsides of the arms and upwards, in such a manner as to meet and join that which is previously laid on the face: when the whole of the mass has acquired its due hardness, it is to be cautiously lifted, without breaking, or giving pain to the person. After the mould is constructed, it must be seasoned in the manner already directed; and when the mould is cast, it is to be separated from the mould by means of a small mallet and chissel. The eyes, which are necessarily shown closed, are to be carved, so that the eyelids may be represented in an elevated posture; the nostrils hollowed out, and the back part of the head, from which, on account of the hair, no mould can be taken, must be finished according to the skill of the artist. The edges of the I

model are then to be neatly smoothed off, and the bust Mod fixed on its pedestal.

The method of making models in the plaster of S Paris is undoubtedly the most easy way of obtaining phiced them. When models, however, are made of such dels, & large objects that the model itself must be of considerable size, it is vain to attempt making it in the way above described. Such models must be constructed by the hand with some soft substance, as wax, clay, putty, &c. and it being necessary to keep all the proportions with mathematical exactness, the construc. tion of a single model of this kind must be a work of great labour and expence as well as of time. Of all those which have been undertaken by human industry, however, perhaps the most remarkable is that constructed by General Psiffer, to represent the mountainous parts of Switzerland. It is composed of 142 compartments, of different sizes and forms, respectively numbered, and so artfully put together, that they can be separated and replaced with the greatest case. The model itself is  $20\frac{1}{2}$  feet long and 12 broad, and formed on a scale which represents two English miles and a quarter by an English foot : comprehending part of the cantons of Zug, Zurich, Schweitz, Underwalden, Lucern, Berne, and a small part of the mountains of Glarus ; in all, an extent of country of 18% leagues in length and 12 in breadth, The highest point of the model, from the level of the centre (which is the lake of Lucerne), is about ten inches; and as the most elevated mountain represented therein rises 1475 toises or 9440 feet above the lake of Lucerne, at a gross calculation, the height of an inch in the model is about 900 feet. The whole is painted of different colours, in such a manner as to represent objects as they exist in nature; and so exactly is this done, that not only the woods of oak, beech, pine, and other trees, arc distinguished, but even the strata of the several rocks are marked, each being shaped upon the spot, and formed of granite, gravel, or such other substances as compose the natural mountain. So minute also is the accuracy of the plan, that it comprises not only all the mountains, lakes, rivers, towns, villages, and forests, but every cottage, bridge, torrent, road, and even every path is distinctly marked.

The principal material employed in the construction of this extraordinary model, is a mixture of charcoal, lime, clay, a little pitch, with a thin coat of wax; and is so hard that it may be trod upon without any damage. It was begun in the year 1766, at which time the general was about 50 years of age, and it employed him till the month of August 1785; during all which long space of time he was employed in the most laborious and even dangerous tasks .---He raised the plans with his own hands on the spot, took the elevation of mountains, and laid them down in their several proportions. In the prosecution of this laborious employment, he was twice arrested for a spy; and in the popular cantons was frequently forced to work by moon light, in order to avoid the jealousy of the peasants, who imagined that their liberty would be endangered should a plan of their country be taken with such minute exactness. Being obliged frequently to remain on the tops of some of the Alps, where no provisions could be procured, he

Jodel.

"odena.

he took along with him a few milk goats, who supplied him with nourishment. When any part was finished, he sent for the people residing near the spot, and desired them to examine each mountain with accuracy, whether it corresponded, as far as the smallness of the scale would admit, with its natural appearance; and then, by frequently retouching, corrected the deficiencies. Even after the model was finished, he continued his Alpine expeditions with the same ardour as ever, and with a degree of vigour that would fatigue a much younger person. All his elevations were taken from the level of the lake Lucerne; which, according to M. Saussure, is 1408 feet above the level of the Mcditerranean.

MODENA, a duchy of Italy, bounded on the south by Tuscany and the republic of Lucca, on the north by the duchy of Mantua, on the east by the Bolognese and the territorics of the Church, and on the west by the duchy of Parma; extending in length from south to north about 56 English miles, and in breadth between 24 and 36, and yielding plenty of corn, wine, and fruits, with mineral waters. In some places also petroleum is skimmed off the surface of the water of deep wells made on purpose; and in others is found a kind of earth or tophus, which, when pulverized, is said to be an excellent remedy against poison, fevers, dysenteries, and hypochoodriac against poison, levers, dysenteries, and hypothologiae disorders. The country of La Salsa affords several kinds of petrifactions. The principal rivers are the Crostolo, Secchia, and Panaro. The family of Esté, dukes of Modena, is very ancient. They had their name from Esté, a small city in the district of Padua. They retained the sovereignty of this duchy till it was conquered by the French in 1795. After this it formed a part of the Cisalpine republic, and latterly of the kingdom of Italy. But since the peace of Paris in 1814 it has regained its independence. The duke, though a vassal of the empire, has an unlimited power within his own dominions.

MODENA, an ancient city, in Latin Mutina, which gives name to a duchy of Italy, and is its capital. It stands in a rich plain 28 miles east of Parma, 44 almost south of Mantua, and 20 west of Bologna; and is a pretty large, but not a handsome city, with a population of 23,000. It is much celebrated by Roman authors for its grandeur and opulence; but was a great sufferer by the siege it underwent during the troubles of the triumvirate. Mr Keysler says, that when Decius Brutus was besieged here by Mark Antony, Hirtius the consul made use of carrier pigeons; and that, even at this day, pigeons are trained up at Modena to carry letters and bring back answers. This city hath given birth to several celebrated persons, particularly Tasso the poet, Corregio the great painter, Sigonius the civilian and historian, Da Vignola the architect, and Montecuculi the imperial general. The tutelary saint of it is named Geminianus. The ducal palace is a very noble edifice ; but the collection of pictures and curiosities it formerly contained is no longer there. The only manufacture for which this city is noted, is that of masks, of which great numbers are exported. The women have a singular costume; they cover the head and body with a large silk cloak or veil, which gives them the appearance of old women or masked dominos. The churches of the Jesuits, of the Thea-Vol. XIV. Part I.

tines, and of St Dominic, are well worth viewing. The Modena university, now called the Lyceum, has produced scveral good scholars in the belles lettres, sciences, and po- Modesty. litics. There is also a neat theatre here, and an excellent library. St Beatrix, who was of the family of Esté, is said to knock always at the gate of the palace three days before any of the family dies. Before most of the houses are covered walks or porticoes, as at Bologna. The city is fortified, and on its south side stands the citadel. E. Long. 11. O. N. Lat. 44. 34.

MODERATION, in Ethics, is a virtue consisting in the proper government of our appetites, passions, and pursuits, with respect to honours, riches, and pleasures; and in this sense it is synonymous with temperance : it is also often used to denote candour.

MODERATOR, in the schools, the person who presides at a dispute, or in a public assembly : thus the president of the annual assembly of the church of Scotland is styled moderator.

MODERN, something new, or of our time; in opposition to what is antique or ancient.

MOVERN Authors, according to Naude, are all those who have wrote since Boethius. The modern philosophy commences with Galileo; the modern astronomy with Copernicus.

MODESTY, in Ethics, is sometimes used to dcnote humility; and sometimes to express chastity, or purity of sentiments and manners .- Modesty, in this last sense, and as particularly applied to women, is defined by the authors of the Encyclopédie Methodique, as a natural, chary, and honest shame; a secret fear; a feeling on account of what may be accompanied with disgrace. Women who possess only the remains of a suspicious modesty, make but feeble efforts to resist: those who have obliterated every trace of modesty from their countenance, soon extinguish it completely in their soul, and throw aside for ever the veil of decency. She, on the contrary, who truly possesses modesty, passes over in silence attempts against her honour, and forbears speaking of those from whom she has received an outrage, when in doing so she must reveal actions and expressions that might give alarm to virtue.

The idea of modesty is not a chimera, a popular prejudice, or an illusion arising from laws and education. Nature, which speaks the same language to all men, has, with the unanimous consent of nations, annexcd contempt to female incontinence. To resist and to attack are laws of her appointment : and while she bestows desires on both parties, they are in the one accompanied with boldness, in the other with shame. To individuals she has allotted long spaces of time for the purposes of self-preservation, and but moments for the propagation of their species. What arms more gentle than Modesty could she have put into the hands of that sex which she designed to make resistance.

If it were the custom for both sexes to make and receive advances indiscriminately, vain importunity would not be prevented : the fire of passion would never be stirred up, but languish in tedious liberty ; the most amiable of all feelings would scarcely warm the human breast; its object would with difficulty be attained. That obstacle which seems to remove this ob-. ject to a distance, in fact brings it nearer. The veil, of shame only makes the desires more attractive. Modesty kindles that flame which it endeavours to sup-Pp press ;

4

Modesty press : its fears, its evasions, its caution, its timid avowals, its pleasing and affecting finesses, speak more Modula- plainly what it wishes to conceal, than passion can do without it : it is MODESTY, in short, which enhances tion the value of a favour, and mitigates the pain of a refusal.

Since modesty is the secret fear of ignominy; and since all nations, ancient or modern, have confessed the obligation of its laws; it must be absurd to violate them in the punishment of crimes, which should always have for its object the re-establishment of order. Was it the intention of those oriental nations, who exposed women to clephants, trained for an abominable species of punishment, to violate one law by the observance of another? By an ancient practice among the Romans a girl could not be put to death before she was marriageable. Tiberius found means to evade this law, by ordering them to be violated by the executioner previous to the infliction of punishment; the refinement of a cruel tyrant, who sacrificed the morals to the customs of his people ! When the legislature of Japan caused women to be exposed naked in the market places, and obliged them to walk on all fours like brutes, modesty was shocked : but when it wanted to force a mother-when it wanted to compel a son-nature received an outrage.

Such is the influence of climate in other countries, that the physical part of love possesses an almost irresistible force. The resistance is feeble; the attack is accompanied with a certainty of success. This is the case at Patana, at Bantam, and in the small kingdoms on the coast of Guinea. When the women in these countries (says Mr Smith) meet with a man, they lay hold of him and threaten to inform their husbands if he despises their favours. But here the sexes seem to have abolished the laws peculiar to each. It is fortunate to live in a temperate climate like ours, where that sex which possesses the most powerful charms exerts them to embellish society; and where modest women, while they reserve themselves for the pleasures of one, contribute to the amusement of all.

MODIFICATION, in Philosophy, that which modifies a thing, or gives it this or that manner of being. Quantity and quality are accidents which modify all bodies.

Decree of MODIFICATION, in Scots Law, a decree ascertaining the extent of a minister's stipend, without proportioning it among the persons liable in payment.

MODILLIONS, in Architecture, ornaments in the corniche of the lonic, Corinthian, and Composite columns.

MODIUS, a Roman dry measure for all sorts of grain, containing 32 heminæ, or 16 sextarii, or onethird of the amphora; amounting to an English peck. Sce MEASURE.

MODULATION, the art of forming any thing to certain proportion.

MODULATION, in reading or speaking. See READ-ING

MODULATION, in Music, derived from the Latin modulari. This word, in our language, is susceptible of several different significations. It frequently means no more than an air, or a number of musical sounds properly connected and arranged. Thus it answers

to what Mr Malcolm understands by the word tune, Modul when he does not expressly treat concerning the tuning of instruments. Thus likewise it expresses the Mogoda French word *chant*; for which reason, in the article Music, we have frequently expressed the one word by the other. But the precise and technical acceptation to which it ought to be confined, is the art of composing melody or harmony agreeably to the laws prescribed by any particular key, that of changing the key, or of regularly and legitimately passing from one key to another. See Music.

MODULE, in Architecture, a certain measure, or bigness, taken at pleasure, for regulating the proportions of columns, and the symmetry or disposition of the whole building. Architects generally choose the semidiameter of the bottom of the column for their module, and this they subdivide into parts or minutes.

MOEONIA, or MEONIA. See MEONIA and LY-DIA.

MOESIA, or MYSTA, in Ancient Geography, a country of Europe, extending from the confluence of the Savus and the Danube to the shores of the Euxine. It was divided into Upper and Lower Mœsia. Lower Mœsia was on the borders of the Euxine, and comprehended that tract of country which received the name of Pontus from its vicinity to the sea. Upper Mæsia lay beyond the other in the inland country.

MOFFAT, a village of Scotland, in Annandale, in the county of Dumfries, 50 miles south-west of Edinburgh ; famous for its sulphureous well, which has been in just estimation for near 1 50 years as a remedy in all cutaneous and scrofulous complaints; and for its chalybeate spring, called Hartfell spaw, which was discovered above 50 years ago, and is of a very bracing quality .- The place is chiefly supported by the company who resort thither for the benefit of its waters and air; but it has also a manufacture of coarse woollen stuffs. It is a well-built clean village; and contains many good and even elegant lodgings, a tolerable assembly room, a bowling green and walks, and a good inn. The population of the parish in 1811 amounted to 1834.

MOFFETTA. See AMPSANCTI.

MOGODORE, or MAGADORE, a large, uniform, and well built town in the kingdom of Morocco, situated about 350 miles from Tangier on the Atlantic ocean, and surrounded on the land side by deep and heavy sands. The European factory here consists of about a dozen mercantile houses of different nations, whose owners, from the protection granted them by the emperor, live in full security from the Moors, whom indeed they keep at a rigid distance. They export, to America, mules; to Europe, Morocco leather, hides, gum arabic, gum sandaric, ostrich feathers, copper, wax, wool, elephants teeth, fine mats, beautiful carpeting, dates, figs, raisins, olives, almonds, oil, &c. In return, they import timber, artillery of all kinds, gunpowder, woollen cloths, linens, lead, iron in bars, all kinds of hardware and trinkets, such as looking glasses, snuff boxes, watches, small knives, &c. tea, sugar, spices, and most of the useful articles which are not otherwise to be procured in this empire. The town is regularly fortified on the sca side; and on the land, batteries are so placed as to prevent any incursion from the southern Arabs, who 318

tion

ninated

et.

ogodore, are of a turbulent disposition, and who, from the great wealth which is known to be always in Mogodore, would gladly avail themselves of any opportunity that offered to pillage the town. The entrance, both by sea and land, consists of elegant stone arch-ways, with double gates. The market place is handsomely built, with piazzas of the same materials; and at the water port there is a customhouse and powder magazine, both of which are neat stone huildings. Besides these public edifices, the emperor has a small but handsome palace for his occasional residence. The streets of the town, though very narrow, are all in straight lines; and the houses, contrary to what we meet with in the other towns of the empire, are lofty and regular. The bay, which is a little better than a road, and is very much exposed when the wind is at north west, is formed by a curve in the land, and a small island about a quarter of a mile from the shore. -Its entrance is defended by a fort well furnished with guns.

MOGULS, a celebrated nation of Asia, whose conquests formerly were the most rapid and extensive of any people recorded in history. They themselves deduce their origin from Japhet, or, as they call him, Japhis, the son of Noah. His son Turk, they say, was the first king, or khan, of those nations who are now known by the separate names of Turks, Tartars, and Moguls; and the Tartars especially assert, that their proper designation is Turks. To this prince is attributed many of those inventions which barbarons nations commonly ascribe to their first sovereigns. He was succeeded by Taunak ; in whose reign the whole posterity of Turk were divided into four large tribes, denominated the orda's of Erlat, Gialair, Kaugin, Berlas or Perlas; of which last came the famous Timur Beg, or Tamerlane .- From this time to that of Alanza Khan, we meet with nothing remarkable. In his reign the Turks being immersed in all kinds of luxury, universally apostatized into idolatry. Having two sons, Tartar and Mogul, he divided his dominions among them, and thus gave rise to the two empires of the Tartars and Moguls.

The two nations had not long existed before they began to make war upon each other; and after long contention, the event at last was, that Il Khan, emperor of the Moguls, was totally overthrown by Siuntz post ex- Khan, emperor of the Tartars; and so great was the defeat, that the Mogul nation seems to have been almost exterminated. Only two of Il Khan's family survived this disaster. These were Kajan his youngest son, and Nagos his nephew, who were both of an age, and had both been married the same year. These two princes, with their wives, had been taken prisoners by Siuntz Khan, but found means to make their escape to their own country. Here they seized upon all the cattle which had not been carried off by the Tartars; which was easily done, as having none to dispute the property with them; then stripping some of the slain, they took their clothes, and retired into the mountains. They passed several mountains without much difficulty; but at last advanced to the foot of one exceedingly high, which had no way over it but a very small path made by certain animals, called in the Tartar language archara. This path they found themselves obliged to

make use of, though it was so strait, that only one Mogula. could pass at a time, and he was in the most imminent 4 danger of breaking his neck at the least false step. Having ascended the mountain on one side by this They arpath, they descended by the same on the other side ; rive in a and were agreeably surprised to find themselves in a delightful most delightful tract, interspersed with rivulets and valley. charming meadows, abounding with a vast variety of delicious fruits, and enclosed on all sides by inaccessible mountains, in such a manner as to shelter them from all future pursnits of the Tartars. Here they lived some time, and gave this beautiful country the name of Irgana-kon, in allusion to its situation ; Irgana signifying, in the old language of the Moguls, a " valley," and .Kon a "steep height."

In process of time these two families very much increased. Kajan, whose posterity was the most numerous, called his descendants Kujath; but the people springing from Nagos were divided into two tribes; one of which received the appellation of Nagosler, and the other that of Durlagan.

These two Mogul princes and their descendants lived. in this place for more than 400 years; but the latter then finding it too narrow for them, meditated a return to the country from which their forefathers had been driven. For some time, however, they found this impracticable, as the path that conducted their ancestors had been long since destroyed. At last they discovered, that one part of the high mountain above mentioned was not very thick in a certain place; and also, that it consisted entircly of iron ore. To this, having before set fire to a layer of wood, and another of charcoal, laid along the foot of the mountain, they applied 70 large bellows, and at last melted the mountain in such a manner, that an opening was made large enough for a loaded camel to pass; and through this passage they all marched out with great joy.

The Moguls having thus issued as it were from a From new world, overthrew the Tartars in their turn; and whence continued to be a very considerable nation till the time they at last of their great hero Temujin, afterwards called Jenghiz issue and defeat the Khan, whom they extol in the most extravagant man-Tartars. ner. It is difficult, however, to say, at the time Temujin made his appearance, how fur the dominions of the Moguls extended, or in what estimation they were held by their neighbours. It seems to be pretty certain that great part of the vast region, now known by the name of Tartary, was then in a state of considerable civilization, and likewise extremely populous, as we find mention made of many cities which the Moguls destroyed; and the incredible multitudes whom they slaughtered, abundantly show the populousness of the country. On the east, the country of the Moguls and Tartars had the great desert which divides Tartary from China ; on the west, it had the empire of Karazm, State of Afounded by Mahmud Gazni; and on the south were sia at the the countries now known by the name of Indostan, time of Siam, Pegu, Tonquin, and Cochin China. Thus it com- Jenghiz prehended the eastern part of modern Tartary, and Khan. all Siberia. This whole region was divided among a great number of Aymacks, or tribes ; who had each one or more khans, according as it was more or less numerous, or divided into branches. Among these that of the Kara-its was the most powerful : their Pp2 prince

Mogu's. prince assumed the title of Grand Khan, and among the rest the Mogals were tributary to him; but, according to the Chinese historians, both the one and the other were tributary to the emperor of Kitay or Katay. China was divided into two parts : the nine southern provinces were in the hands of the Chinese emperors of the Song dynasty, who kept their court at Hang-chew, the capital of the province of Chekyang; the five northern provinces, excepting part of Shensi, were possessed by the Kin, a people of Eastern Tartary, from whom are descended the Manchew Tartars, at present masters of China. This vast dominion was named Kitay or Katay, and was divided into two parts : that which belonged to China, was properly ealled Kitay; and the part which belonged to Tartary was called Karakitay, in which some even include the territorics of the Moguls, Karaits, and other tribes which are the subject of the present history. The western part of the empire of Kitay was possessed by a Turkish prince, who had lately founded a new kingdom there called Hya; whose capital city was Hyachew, now Ninghya in Shensi, from whence the kingdom took its name. To the west of Hya lay Tangut; a country of great extent, and formerly very powerful; but at that time reduced to a low state, and divided among many princes; some of whom were subject to the emperor of Hya, and others to the emperor of China. All Tartary to the westward as far as the Caspian sea, with the greater part of Little Buckharia, which then passed under the general name of Turkestan, was subject to Ghurkhan, Khurkhan, or Kaver Khan; to whom even the Gazni monarchs are said to have been tributary. This Ghurkhan had been prince of the Western Kitan or Lyau; who, driven out of Kitay by the king, settled in Little Buckharia, and the country to the north, where they founded a powerful state about

6 Descent and birth

means of

Vang

Khan.

the year 1124. Thus the Moguls, properly so called, had but a very small extent of empire which could be called their own, of Temujin. if indeed they had any, when Temujin made his appear-

ance. This hero is said by the Tartars to have been of divine origin, since his family could be traced no farther back than ten generations, the mother of whom was got with child by a spirit. The names and transactions of his predecessors are equally uncertain and unimportant : he himself, however, was born in the year 1163, and is said to have come into the world with congealed blood in his hands; from whence it was prognosticated that he would be a great warrior, and obtain the victory over all his enemies.

This prediction, if any such there was, Temujin most literally fulfilled. At the time of his father's decease, his subjects amounted to between 30,000 and 40,000 families; but of these two-thirds quickly deserted, and Temujin was left almost without subjects. When only 13 years of age, he fought a bloody battle against these revolters; but either was defeated, or gained an indecisive victory; so that he remained in obscu-7 rity for 27 years longer. His good fortune at last he Subdues his owed to the friendship of Vang Khan, who ruled over subjects by a great number of Tartar tribes to the north of Kitay, and has been heard of under the name of Prester John among the Europeans. This prince took Temujin under his protection; and a rebellion being afterwards raised against himself, Temujin was made his general,

and the khan was kept in possession of his throne : soon Mogula after which Temujin subdued the tribes which had revolted from himself, treating them at the same time with the utmost barbarity.

This happened in the year 1201; but Vang Khan, Who be. instead of continuing the triend of Temujin, now became comes je jealous, and resolved to destroy him by treachery. With lous, and this view he proposed a marriage between Temujin's son contrive Juji and his own daughter, and another between Temu-tion. jin's daughter and his own son. Temujin was invited to the camp of Vang Khan, in order to eelebrate this double marriage; but receiving intelligence of some evil intention against him, he excused himself to Vang Khan's messengers, and desired that the ceremony might be put off to some other time.

A few days after the departure of these messengers, Badu and Kishlik, two brothers, who kept the horses of one of Vang Khan's chief domesties, eame and informed Temujin, that the grand Khan finding he had missed his aim, was resolved to set out instantly, and surprise him next morning, before he could suspect any danger. Temujin, alarmed at this intelligence, quitted his camp, in the night time, and retired with all his people to some distance. He was searce gone when Vang Khan's troops arrived, and discharged an incredible number of arrows among the empty tents; but finding nobody there, they pursued Temujin in such haste that they fell into great disorder. In this coudition they were suddenly attacked and routed by Temujin; after which an open war with Vang Khan took place.

By this quarrel almost all the princes of Tartary 9 were put in motion, some siding with Temujin, and overcom others with Vang Khan. But at last fortune deelared all his in favour of the former: Vang Khan was overthrown mies. in a battle, where he lost 40,000 men, and obliged to fly for refuge to a prince named Tayyan Khan, who was Temujin's father-in-law, and his own enemy, and by whom he was ungenerously put to death. Temujin immediately began to seize on his dominions, great part of which voluntarily submitted : but a confederacy was formed against him by a number of Vang Khan's tributaries, at the head of whom was Jamuka, a prince who had already distinguished himself by his enmity to Temujin ; and even Tayyan Khan himself was drawn into the plot, through jealousy of his son-in-law's good fortune. But Temujin was well prepared ; and in the year 1204 attacked Tayyan Khan, entirely routed his army, killed himself, and took Jamuka prisoner, whose head he cansed instantly to be struck off; after which he marched against the other tribes who had conspired against him. Them he quickly reduced ; took a city called Kashin, where he put all to the sword who had borne arms against him; and reduced all the Mogul tribes in 1205.

Temujin now, having none to oppose him, called a general diet, which he appointed to be held on the first day of the spring 1206; that is, on the day in which the sun entered Aries. To this diet were summoned all the great lords both Moguls and Tartars; and in the mean time, to establish good order in the army, he divided his soldiers into bodies of 10,000, 1000, 100, and 10 men, with their respective officers, all subordinate to the generals, or those who commanded the bodies of 10,000; and these were to act under his OWN

oguis. own sons. On the day of holding the diet, the princes of the blood and great lords appeared dressed in white. Temujin dressed in the same manner, with his crown on his head, sat down on his throne, and was complimented by the whole assembly, who wished him the continuance of his health and prosperity. After this they confirmed the Mogul empire to him and his successors, adding all those kingdoms which he had subdued, the descendants of whose vanquished khans were deprived of all right or title to them; and after this he was proclaimed emperor with much ceremony. During this inauguration, a pretended prophet declared that he came from God to tell the assembly, that from thenceforth Tcmujin should assume the name of Jenghiz Khan, or the most Great Khan of khans; prophesying also, that all his posterity should be khans from generation to generation. This prophecy, which was no doubt owing to Temujin himself, had a surprising effect on his subjects, who from that time concluded that all the world belonged of right to them, and even thought it a crime against heaven for any body to pretend to resist them.

8.c.

Jenghiz Khan having now reduced under his subjection all the wandering tribes of Moguls and Tartars, began to think of reducing those countries to the south and south-west of his own, where the inhabitants were much more civilized than his own subjects : and the countries being full of fortified cities, he must of course expect to meet with more resistance. He began with the emperor of Hya, whose dominions he invaded in 1209, who at last submitted to become his tributary. But in the mean time Jenghiz Khan himself was supposed to be tributary to the emperor of Kitay: who, in 1210, sent him an officer demanding the customary tribute. This was refused with the utmost indignation, and a war commenced, which ended not but with the dissolution of the empire of Kitay, as mentioned under the article CHINA.

In the year 1216, Jenghiz Khan resolved to carry his arms westward, and therefore left his general Muchuli to pursue his conquests in Kitay. In his journey westward he overthrew an army of 300,000 Tartars who had revolted against him; and, in 1218, sent ambassadors desiring an alliance with Mohammed: Karazm Shah, emperor of Gazna. His ambassador was haughtily treated : however, the alliance was concluded; but soon after broken, through the treachery, . as it is said, of the Karazmian monarch's subjects. This brought on a war attended with the most dreadful devastations, and which ended with the entire destruction of the empire of Karazm or Gazna, as related under the article GAZNA.

After the reduction of Karazm, part of the Moguls broke into Iran or Persia, where also they made large conquests, while others of their armies invaded Georgia and the countries to the west; all this time committing such enormities, that the Chinese historians say both men and spirits burst with indignation. In 1225, Jenghiz Khan returned to Hya, where he made war on the emperor for having sheltered some of his enemies. The event was, that the emperor was slain, and his kingdom conquered, or rather destroyed; which, however, was the last exploit of this most cruel conqueror, who died in 1227, as he marched to complete the destruction of the Chinese.

## MOG

The Mogul empire, at the death of Jenghiz Khan, Moguls. extended over a prodigious tract of country; being more than 1800 leagues in length from east to west, and <sup>12</sup> upwards of 1000 in breadth from north to south. Its of his emprinces, however, were still insatiable, and pushed on pire. their conquests on all sides. Oktay was acknowledged emperor after Jenghiz Khan; and had under his immediate government Mogulestan (the country of the Moguls properly so called), Kitay, and the countries easward to the Tartarian sea. Jagaty his brother govern-ed under him a great part of the western conquests. The country of the Kipjacks, and others to the east and north-east, north and north-west, were governed by Batu or Patu the son of Juji, who had been killed in the wars ; while Tuli or Toley, another son of Jenghiz Khan, had Khorassan, Persia, and what part of India was conquered. On the east side the Mogul arms were still attended with success; not only the empire of Kitay, but the southern part of CHINA, was conquered, as already related under that article, N° 24–42. On the west side matters continued much in the same way till the year 1254, when Magu, or Menkho, the fourth khan of the Moguls, (the same who was afterwards killed at the sicge in China\*), raised a great army, \* See Chiwhich he gave to his brother Hulaku or Hulagu, to ex-na, Nº 38. tend his dominions westward. In 1255, he entered Iran, where he suppressed the Ismaelians or Assassins, of whom an account is given under the article Assas-SINS, and two years afterwards he advanced to Bagdad, which he took, and cruelly put the caliph to death, treating the city with no more lenity than the Moguls usually treated those which fell into their hands. Every Bagdad rething was put to fire and sword; and in the city and duced, its neighbourhood the number of slain, it is said, amounted to 1,600,000. The next year he invaded Syria; the city of Damascus was delivered up, and, as it made no resistance, the inhabitants were spared ; but Aleppo being taken by storm, a greater slaughter ensued there than had taken place at Bagdad, not even the children in their cradles being spared. Some cities of this country revolted the next year, or the year after ; but falling again into the hands of the Moguls, they were plundered, and the inhabitants butchered without mercy, or carried into slavery.

Hulaku died in 1264, and at his death we may fix the greatest extent of the Mogul empire. It now comprehended the whole of the continent of Asia, excepting part of Indostan, Siam, Pegu, Cochin China, and a few of the countries of Lesser Asia, which had not been attacked by them ; and during all these vast con-quests no Mogul army had ever been conquered, except one by Jaloloddin, as mentioned under the article GAZNA .- From this period, however, the empire be-It begins to gan to decline. The ambition of the khans having decline. prompted them to invade the kingdoms of Japan and Cochin China, they were miserably disappointed in their attempts, and lost a great number of men. The same bad success attended them in Indostan; and in a short time this mighty empire broke into several smaller ones. The governors of Persia being of the family of Jenghiz Khan, owned no allegiance to any superior; those of Tartary did the same. The Chinese threw off the yoke; and thus the continent of Asia wore much the same face that it had done before Jenghiz Khan began his conquests.

The

## The successors of Hulaku reigned in Persia till the year 1335; but that year Abusaid Khan, the eighth from Hulaku, dying, the affairs of that country fell into confusion for want of a prince of the race of Jenghiz Khan to succeed to the throne. The empire, therefore, was divided among a great number of petty princes who fought against each other almost without intermission, till in the year 1369 Timur Bek, or Ta-Tamerlane merlane, one of these princes, having conquered a number of others, was crowned at Balkh, with the pompous title of Saheb Karan; that is, " the emperor of the age, and the conqueror of the world." As he had just before taken that city, and destroyed one of his most formidable rivals who had shut himself up in it, the new emperor began his reign with beheading some of the inhabitants, imprisoning others, burning their houses, and selling the women and children for slaves. In 1370 he crossed the Sihun, made war on the Getes, Becomes a and attacked Karazm. Next year he granted a peace great con-queror. to his enemies; but two years after, he again invaded queror. the country of the Getes, and by the year 1379 had fully conquered that country as well as Korazan; and from that time he continued to extend his conquests in much the same manner as Jenghiz Khan had done, though with less cruelty .- In 1387 he had reduced Armenia, Georgia, and all Persia; the conquest of which last was completed by the reduction of Ispahan, 70,000 of the inhabitants of which were slaughtered on account of a sedition raised by some rash or evil disposed

persons. After the reduction of Persia, Timur turned his arms northward and westward, subduing all the countries to the Euphrates. He took the city of Bagdad; subdued Syria; and having ravaged great part of Russia, returned to Persia in 1396, where he splendidly feasted his whole army. In 1398 he invaded Indostan, crossed the Indus on the 17th of September, reduquers Indoced several fortresses, and made a vast number of captives. However, as he was afraid that, in case of any emergency, these prisoners might take part with the enemy, he gave orders to his soldiers to put all their Indian slaves to death; and in consequence of this inhuman order, more than 100,000 of these poor wretches were slaughtered in less than an hour.

In the beginning of the year 1399 Timur was met by the Indian army; whom, after a desperate battle, he defeated with great slaughter, and soon after took the city of Delhi the capital of the country. Here he seated himself on the throne of the Indian emperors, and here the sharifs, kadis, the principal inhabitants of the city, came to make their submission, and begged for mercy. The tame elephants and rhinoceroses likewise were brought to kneel before him as they had been accustomed to do to the Indian emperors, and made a great cry as if they implored his clemency. These war elephants, 120 in number, were, at his return, sent to Samarcand, and to the province where his sons resided. After this, at the request of the lords of the court, Timur made a great feast; at which he distributed presents to the princes and principal officers.

18 The city of Delhi destroved ed.

Delhi at this time consisted of three cities, called Seyri, Old Delhi, and Jehan Penah. Seyri was surand the in rounded with a wall in form of a circle. Old Delhi habitants was the same, but much larger, lying south-west of the slaughter- other. These two parts were joined on each side by

a wall : and the third, lying between them, was called Mogu Jehan Penah, which was larger than Old Delhi. Penah had ten gates; Seyri had seven, three of which looked towards Jehan Penah; this last had 13 gates, six to the north-west, and seven to the south-east. Every thing seemed to be in a quiet posture; when, on the 12th of January 1399, the soldiers of Timur being assembled at one of the gates of Delhi, insulted the inhabitants of the suburbs. The great emirs were ordered to put a stop to these disorders; but their endeavours were not effectual. The sultanas having a curiosity to sce the rarities of Delhi, and particularly a famous palace adorned with 1000 pillars, built by an ancient king of India, went in with all the court ; and the gate being on that occasion left open for every body, above 15,000 soldiers got in unperceived. But there was a far greater number of troops in a large place between Delhi, Seyri, and Johan Penah, who committed great disorders in the two last cities. This made the inhabitants in despair fall on them; and many, setting fire to their houses, burnt their wives and children. The soldiers seeing this confusion, did nothing but pillage the houses ; while the disorder was increased by the admission of more troops, who seized the inhabitants of the neighbouring places who had fled thither for shelter. The emirs, to put a stop to this mischief, caused the gates to be shut: but they were quickly opened by the soldiers within, who rose in arms against their officers; so that by the morning of the 13th the whole army was entered, and this great city was totally destroyed. Some soldiers carried out 150 slaves, men, women, and children; nay, some of their boys had 20 slaves a piece to their share. The other spoils, in jewels, plate, and manufactures, were immense; for the Indian women and girls were adorned with precious stones, and had bracelets and rings on their hands, feet, and even toes, so that the soldiers were loaded with them. On the 15th, in Old Delhi, the Indians retired into the great mosque to defend themselves; but being attacked by the Tartars they were all slaughtered, and towers erected with their heads. A dreadful carnage now ensued throughout the whole city, and scveral days were employed before the inhabitants could be made to quit it entirely; and as they went, the emirs took a number of them for their service. The artisans were also distributed among the princes and commanders; all but the masons, who were reserved for the emperor, in order to build him a spacious stone mosque at Samarcand.

After this terrible devastation, Timur marched into the different provinces of Indostan, everywhere defeating the Indians who opposed him, and slaughtering the Ghebrs or worshippers of fire. On the 25th of March he set out on his return, and on the 9th of May arrived at Samarcand. In a few months after his arrival, he was obliged to undertake an expedition into Persia, where affairs were in the utmost disorder on account of the misconduct of his son, whom he had appointed sovereign of that empire. Here Timur soon settled matters; after which he again set out on an expedition westward, reduced many places in Georgia which had not submitted before, and invaded and conquered Sy-Timur ria. At the same time he quarrelled with Bajazet the quarre Turkish sultan, then busied in an enterprise against with I Constantinople, in which he would probably have suc. zet th ceeded had not Timur interposed. The cause of this sultan

3

quarrel

303

aguls. quarrel at first was, that Bajazet had demanded tribute from a prince who was under Timur's protection, and is said to have returned an insulting answer to the Tartar ambassadors who were sent to him on that account. Timur, however, who was an enthusiast in the cause of Mahometanism, and considered Bajazet as engaged in the cause of heaven when besieging a Christian city, was very unwilling to disturb him in so pious a work ; and therefore undertook several expeditions against the princes of Syria and Georgia, in order to give the Turkish monarch time to cool and return to reason. Among other places, he again invested the city of Bagdad, which had cast off its allegiance to him; and having taken it by storm, made such a dreadful massacre of the inhabitants, that 120 towers were erected with the heads of the slain. In the mean time Bajazet continued to give fresh provocation, by protecting one Kara Yusef a robber, who had even insulted the caravan of Mecca; so that Timur at length resolved to make war upon him. The sultan, however, foreseeing the danger of bringing such a formidable enemy against himself, thought proper to ask pardon, by a letter, for what was past, and promise obedience to Timmr's will for the future. This embassy was graciously received ; and Timur returned for answer, that he would forbear hostilitics, provided Bajazet would either put Kara Yusef to death, send him to the Tartar camp, or expel him out of his dominions. Along with the Turkish ambassadors he sent one of his own; telling Bajazet that he would march into the confines of Anatolia, and there wait his final answer.

Though Bajazet had seemed at first willing to come to an agreement with Timur, and to dread his superior power; yet he now behaved in such an unsatisfactory manner, that the Tartar monarch desired him to prepare for war; upon which he raised the siege of Constantinople, and having met Timur with an army great-Ba et de-ly inferior to the Tartars, was utterly defeated and taken prisoner. According to some accounts, he was treated with great humanity and honour ; while others inform us, that he was shut up in an iron cage, against which he dashed out his brains the following year. At any rate, it is certain that he was not restored to liberty, but died in confinement.

tal pri-

This victory was followed by the submission of many places of the Lesser Asia to Timur; the Greek emperor owned himself his tributary, as did also the sultan of Egypt. After this Timur once more returned to Georgia, which he cruelly ravaged ; after which he marched to Samarcand, where he arrived in the year 1405. Here, being now an old man, this mighty conqueror began to look forward to that state which at one time or other is the dread of all living creatures; and Timur, in order to quiet the remorses of his own conscience, came to the following curious resolution, which he communicated to his intimate friends ; namely, that " as the vast conquests he had made were not obtained without some violence, which had occasioned the destruction of a great number of God's creatures, he was resolved, by way of atonement for his past crimes, to of perform some good action; namely. to make war on me, the infidels, and exterminate the idolaters of China." This atonement, however, he did not live to accomplish; for he died the same year of a burning fever, in the 71st year of his age and 36th of his reign.

On the death of Timur, his empire fell immediately. Moguls into great disorder, and the civil wars continued for five or six years; but at last peace was restored, by the Mohilof. settlement of Shah Rukh, Timur's son, on the throne. He did not, however, enjoy the empire in its full extent, or indeed much above one half of it ; having only Karazm, Khorassan, Kandahar, Persia, and part of Hindostan. Neither was he able, though a brave and warlike prince, to extend his dominions, though he transmitted them to his son Ulug Beg. He proved a wise and learned monarch ; and is famous for the astronomical tables which he caused to be composed, and which are well known at this day. He was killed in 1448 by his son Abdollatif, who six months after was put to death by his own soldiers. After the death of Abdollatif, Abdollah, a grandson of Shah Rukh, seized the throne ; but, after reigning one year, was expelled by Abusaid Mirza, the grandson of Miran Shah the son of Timur. His reign was one continued scene of wars and tumults; till at last he was defeated and taken prisouer by one Hassan Beg, who put him to death in 1468. From this time we may look upon the empire of Timur as entirely dissolved, though his descendants still reigned in Persia and Indostan, the latter of which is still known by the name of the Mogul's empirc.

On the death of the above-mentioned monarch, his History of son Babr or Babor succeeded him, but was soon driven Hindostan. ont by the Usbeck Tartars ; after which he resided some time in Gazna, whence he made incursions into Hindostan, and at length became master of the whole empire, excepting the kingdoms of Dekan, Guzerat, and Bengal .- For the transactions subsequent to this period, see HINDOSTAN and INDIA.

MOHAIR, in commerce, the hair of a kind of goat frequent about Angora in Turkey; the inhabitants of which city are all employed in the manufacture of camblets made of this hair.

Some give the name mohair to the camblets or stuffs made of this hair; of these there are two kinds; the one smooth and plain, the other watered like tabbics : the difference between the two only consists in this, that the latter is callendered, the other not. There are also mohairs both plain and watered, whose woof is of wool, cotton, or thread.

MOHAIR Shell, in Conchology, a name given to a species of voluta, which seems of a closely and finely reticulated texture, and resembles on the surface a piece of mohair or a very close silkworm's web.

MOHAWK, a river of North America, which rises near lake Oneida, and runs a south-east course of about 1 30 miles to its junction with the Hudson, 8 miles above Abany, in the state of New York.

MOHAWKS. See MUCK.

MOHILA, or MOELIA, one of the Comora islands in the Indian sea, between the north end of Madagascar and the continent of Africa. The inland parts are mountainous and woody; but the lands adjoining to the sea are watered by several fine streams. The island abounds with provisions of all kinds; and the East India ships of different nations sometimes touch here for refreshment.

MOHILOF, a large and strong city of Russian Poland, in the province of Lithuania. It is well built, populous, and has a considerable trade. Near this place

Mol

place the Swedes obtained a great victory over the Mohilof Russians in 1707. Lat. 53. 50. Long. 30. 14. MOIDORE, a Portuguese gold coin, value 11. 7s.

Moivre.

sterling. MOIETY (Medietas), the balf of any thing.

MOIRA, a town of Ireland, in the county of Down and province of Ulster, 69 miles from Dublin; noted for its linen manufacture. It gives title of earl to the family of Rawdon.

MOISTURE. Sce HUMIDITY.

The moisture of the air has considerable effects on the human body. For the quantity and quality of the food, and the proportion of the meat to the drink, being given, the weight of a human body is less, and consequently its discharges greater in dry weather than in wet weather; which may be thus accounted for: the moisture of the air moistens the fibres of the skin and lessens perspiration by lessening their vibratory motion. When perspiration is thus lessened by the moisture of the air, urine indeed is by degrees increased, but not equally. Hence, according to Dr Bryan Robinson, we learn, that to keep a body of the same weight in wet weather as in dry, cither the quantity of food must be lessened, or the proportion of the meat to the drink increased; and both these may be done by lessening the drink without making any change in the meat.

The instrument used for determining the degree of moisture in the air, is called an hygrometer. See Hy-GROMETER.

MOIVRE, ABRAHAM, a learned mathematician, was born at Vitri in Champagne, in France, 1667, where his father was a surgeon. At the revocation of the edict of Nantes, he came to England. Before he left France, he had begun the study of mathematics; and having perfected himself in that science in London, he was obliged, by necessity, to teach it. Newton's Principia, which accidentally fell into his hands, showed him how little progress he had made in a science of which he thought himself master. From this work he acquired a knowledge of the geometry of infinites with as great facility as he had learned the elementary geometry; and in a short time be was fit to be ranked with the most celebrated mathematicians. His success in these studies procured him a seat in the Royal Society of London and in the Academy of Sciences at Paris. His merit was so well understood in the former, that he was thought capable of deciding in the famous dispute between Leibnitz and Newton concerning the differential calculus .- He published a Treatise on Chances in 1738, and another on Annuities in 1752; both extremely accurate. The Philosophical Transactions contain many interesting memoirs of his composition .---Some of them treat of the method of fluxions; others arc on the lunula of Hippocrates; others on physical astronomy, in which he resolved many important problems; and others, in short, on the analysis of the games of chance, in which he followed a different course from that of Montmort. Towards the close of his life he lost his sight and hearing; and the demand for sleep became so great that he required 20 hours of it in a day. He died at London, 1754, aged 87. His knowledge was not confined to mathematics ; but he retained to the last a taste for polite literature. He was intimately acquainted with the best authors of anti-

quity; and he was frequently consulted about difficult Moin passages in their works. Rabelais and Moliere were his favourite French authors : he had them by heart ; and he one day observed to one of his acquaintance, " that he would rather have been Moliere than Newton." He recited whole scenes of the Misanthrope, with that delicacy and force with which he remembered to have heard them recited at Paris 70 years before, by Moliere's own company. The character indeed was somewhat similar to his own. He judged severely of mankind; and could never conceal his disgust at the conversation of a fool, or his aversion to cunning and dissimulation. He was free from the affectation of science, and no one could know him to be a mathematician but from the accuracy of his thoughts. His conversation was general and instructive. Whatever he said was well digested and clearly expressed. His style possessed more strength and solidity than ornament and animation ; but he was always correct, and he bestowed as much pains on his sentences as on his calculations. He could never endure any bold assertions or indecent witticisms against religion.

MOLA, an aucient town of Italy, in the kingdom of Naples, and in the Terra di Lavoro, where they pretend to show the ruins of Cicero's house. It is seated on the gulf of Venice, in E. Long. 17. 50. N. Lat. 41.5.

MOLA Salsa (Salt Cake), in antiquity, was barley parched, and afterwards ground to meal or flour, then mixed with salt and frankincense, with the addition of a little water. Thus prepared, it was sprinkled between the borns of the victim before it was killed in sacrifice. This act was called immolatio, and was common to the Greeks as well as Romans; with this difference, that the mola of the Romans was of wheat. The Greeks called it shn or shoxeln.

MOLARES, or DENTES MOLARES, in Anatomy, the large teeth, called in English the grinders. See ANATOMY Index.

MOLASSES, or MOLOSSES. See MOLOSSES.

MOLDAVIA, a province of Turkey in Europe, bounded on the north-east by the river Niester, which divides it from Russia; on the cast, by Bessarabia; on the south, by Walachia; and on the west, by Transylvania. It is 240 miles in length, and 1 50 in breadth. It has a good air and fruitful soil, producing corn, wine, rich pastures, a good breed of horses, oxen, sheep, plenty of game, fish, fowl, honey, wax, and all European fruits. Its principal rivers are the Danube, Niester, Pruth, Bardalach, and Sereth. The inhabitants are Christians of the Greek church, and Jassy is the principal town. It has been tributary to the Turks since the year 1574; who appoint a prince who is a native of the country, but have no regard to his being of the principal families. The prince is called Hospodar. The province pays a large yearly tribute to the Turkish government; besides raising a great body of horse at its own expence.

MOLE, a river in Surry, which has taken its name from running under ground. It first disappears at Boxhill, near Darking, in the county of Surry, and emerges again near Leatherhead.

MOLE. See TALPA, MAMMALIA Index; and for methods of destroying, see VERMIN, Destruction of.

Mole, in Midwifery, a mass of fleshy matter, of a spherical

spherical figure, generated in the uterus, and sometimes Mole, Moliere. mistaken for a child. See MIDWIFERY.

MOLE, or Mark. See NÆVUS.

MOLE, in Architecture, a massive work formed of large stones laid in the sea by means of coffer dams, extended either in a right line or an areh of a circle, before a port, which it serves to close; to defend the vessels in it from the impetuosity of the waves, and to prevent the passage of ships without leave. Thus we say the mole of the harbour of Messina, &c.

MOLE is sometimes also used to signify the harbour itself.

MOLE, (moles), among the Romans, was also used for a kind of mausolcum, built in manner of a round tower on a square base, insulate, encompassed with columns, and eovered with a dome .- The mole of the emperor Adrian, now the eastle of St Angelo, was the greatest and most statcly of all the moles. It was crowned with a brazen pine apple, wherein was a golden urn containing the ashes of the emperor.

MOLE Cricket, See GRYLLOTALPA, ENTOMOLOGY Index.

MOLE Hills. These little hillocks of earth are a very great prejudice to the pasture lands, not only in wasting so much of the land as they cover, but in obstructing the scythe in mowing. In the west of England they use a peculiar instrument for the breaking up of these. It is a flat board, very thick, and of about eight inches in diameter, into, which there is fastened a perpendicular handle of three or four feet long. It has four broad and sharp iron teeth at the front, which readily eut through the hill, and spread the earth it consists of; and behind there is a large knob proper for breaking the clods with, if there are any. Some use a spade, or other common instrument, in the place of this, but not so well. There is, however, a much better instrument even than this, for destroying these hills, where they are in very great numbers. This is a kind of horse machine; it has a sharp iron about three feet over, and with a strong back .- It is about four or five inches broad, and has two long handles for a horse to be harnessed to, and a cross bar of iron to strengthen it at the bottom of the handles, reaching from the one handle to the other. The middle of this cross bar is furnished with one, two, or more sharp pieces of iron like small ploughshares, to cut the mole hills into two, three, or more parts. The iron behind is of a semicircular figure. A single horse is harnessed to this machine, and a boy must be employed to drive it, and a man to hold and guide it; the sharp irons or shares are the first things that meet the hill, they run through it, break its texture, and eut it into several parts ; and the circular iron following immediately behind them, euts up the whole by the roots, and leaves the land level. This instrument will destroy as many mole hills in one day as a common labourer can do in eight, and would be of very-great advantage to the kingdom if brought into general use.

MOLIERE, JOHN BAPTIST, a celebrated French comedian and dramatic writer, whose true name was Pocquelin, which for some reason he changed to that of Molierc. He was the son of a valet de chambre, and was born at Paris about the year 1620. He went through the study of the classics under the Jesuits in the college of Clermont, and was designed for the bar; but at his quitting the law schools, he made choice of the actor's

Vol. XIV. Part I.

#### MO L

profession. From a strong attachment to the drama, Molicre his whole study and application were directed to the stage, and he continued till his death to exhibit plays, Mollugó. which were greatly applauded. It is said the first motive of his going upon the stage was to enjoy the company of an actress for whom he had contracted a violent fondness. His comedies are highly esteemed. And it is no wonder he so justly represented domestie feuds, and the torments of jealous husbands, or of those who have reason to be so; for it is asserted that no man ever experienced this more than Moliere. His last comedy was Le Malade Imaginaire, which was brought on the stage in 1673; and Moliere died on the fourth night of its representation ; some say in acting the very part. of the pretended dead man, which gave some excreise for the wits of the time; but according to others he died in his bed that night, from the bursting of a vein in his lungs by coughing. The king, as a last mark of his favour, prevailed with the archbishop of Paris to suffer him to be buried in consecrated ground; though he had irritated the elergy by his *Tartuff*. The most esteemed editions of his works are that of Amsterdam, 5 vols. 1 2mo, 1699; and that of Paris, 6 vols. 4to, 1734.

MOLINISTS, in ecclesiastical history, a sect in the Romish church, who follow the doetrinc and sentiments of the Jcsuit Molina, relating to sufficient and efficacious grace. He taught that the operations of divine grace were entirely consistent with the freedom of human will; and he introduced a new kind of hypothesis to remove the difficulties attending the doctrines of predestination and liberty, and to reconcile the jarring opinions of Augustines, Thomists, Semi-Pelagians, and other contentious divines. He affirmed that the decrcc of predestination to eternal glory was founded upon a previous knowledge and consideration of the merits of the cleet; that the grace, from whose operations these merits are derived, is not efficacious by its own intrinsic power only, but also by the consent of our own will, and because it is administered in those eircumstances, in which the Deity, by that branch of his knowledge which is ealled scientia media, foresces that it will be officacious. The kind of preseience, denominated in the schools scientia media, is that foreknowledge of future eontingents that arises from an acquaintance with the nature and faculties of rational beings, of the eircumstances in which they shall be placed, of the objects that shall be presented to them, and of the influence which their circumstances and objects must have on their actions.

MOLINOSISTS, a scet among the Romanists, who adhere to the doetrine of Molinos. These are the same with what are otherwise called Quietests, whose chief principle was, that men ought to annihilate themselves in order to be united to God, and afterwards remain in quietness of mind, without being troubled for what shall happen to the body. Molinos, the author of those opinions, was a Spanish pricst, and was born in 1627. His 68 propositions were examined in 1687 by the pope and inquisitors, who decreed that his doctrine was false and pernicious, and that his books should be burned. He was foreed to recant his errors publicly in the Dominican church, and was condemned to perpetual imprisonment. He was then 60 years old, and had been spreading his doetrine 22 years before. He died in prison in 1692.

MOLLUGO, AFRICAN CHICKWEED; a genus of Qq plants

Molingo plants belonging to the triandria class, and in the natural method ranking under the 22d order, Caryophyllei. Molosser. See BOTANY Index.

~

MOLLUSCA, in the Linnæan system, one of the orders of vermes or worms. These are simple naked animals, not included in a shell, but furnished with limbs. See HELMINTHOLOGY Index.

MOLOCH, a false god of the Ammonites, who dedicated their children to him, by making them "pass through the fire," as the Scriptures express it. There are various opinions concerning this method of consecration. Some think, the children leaped over a fire sacred to Moloch; others, that they passed between two fires; and others, that they were really burnt in the fire, by way of sacrifice to this god. There is foundation for each of these opinions. For, first, it was usual among the pagans to lustrate or purify with fire; and, in the next place, it is expressly said, that the inhabitants of Sepharvaim burnt their children in the fire to Anamelech and Adramelech; much such deities as Moloch of the Ammonites.

Moses, in several places, forbids the Israelites to dedicate their children to this god as the Ammonites did, and threatens death and utter extirpation to such persons as were guilty of this abominable idolatry. And there is great probability that the Hebrews were much addicted to the worship of this deity : since Amos, and after him St Stephen, reproaches them with having carried along with them into the wilderness the tabernacle of their god Moloch.

Solomon built a temple to Moloch upon the mount of Olives; and Manasseh, a long time after, imitated his impiety, by making his son pass through the fire in honour of Moloch. It was chiefly in the valley of Top!et and Hinnom, to the cast of Jerusalem, that the Israelites paid their idolatrous worship to this false god of the Ammonites.

There are various sentiments concerning the relation which Moloch had to the other pagan divinities. Some believe he was the same with Saturn, to whom it is well known that human sacrifices were offered. Others suppose him to be Mercury; others, Mars; others, Mithras; and others, Venus. Lastly, Others take Moloch to be the sun, or the king of heaven. Moloch was likewise called *Milcom*; as appears from what is said of Solomon, that he went after Ashtaroth the abomination of the Zidonians, and Milcom the abomination of the Ammonites.

MOLOSSES, MOLASSES, or *Melasses*, that gross fluid matter remaining of sugar after refining, and which no boiling will bring to a consistence more solid than that of syrup; hence also called *syrup of sugar*.

Properly, molosses are only the sediment of one kind of sugar called *chypre*, or brown sugar, which is the refuse of other sugars not to be whitened or reduced into loaves.

Molosses are much used in Holland for the preparation of tobacco, and also among poor people instead of sugar. There is a kind of brandy or spirit made of molosses; but by some held exceedingly unwholesome. See below.

Artificial MOLOSSES. There has been found a method of making molosses from apples without the addition of sugar. The apple that succeeds best in this operation is a summer sweeting of a middle size, plea.

sant to the taste, and so full of juice that seven bushels Molor will yield a barrel of cyder.

M

The manner of making it is this: the apples are to be ground and pressed, then the juice is to be boiled in a large copper, till three quarters of it be evaporated: this will be done with a moderate fire in about six hours, with the quantity of juice above mentioned; by this time it will be of the consistence and taste as well as of the colour of molosses.

This new molosses serves all the purposes of the common kind, and is of great use in preserving cyder. Two quarts of it put into a barrel of racked cyder, will preserve it, and give it an agreeable colour.

The invention of this kind of molosses was owing to Mr Chandler of Woodstock in New England, who living at a distance from the sea, and where the common molosses was very dear and searce, provided this for the supply of his own family, and introduced the practice among people of the neighbourhood. It is to be observed, that this sort of apple, the sweeting, is of great use in making cyder; one of the very best kinds we know being made of it. The people in New England also feed their hogs with the fallings of their orchards of these apples; and the consequence of this is, that their pork is the finest in the world.

MoLOSSES Spirit; a very clean and pure spirit, much used in England, and made from molosses or common treacle dissolved in water, and fermented in the same manner as malt or the common malt spirit. See DI-STILLATION.

MOLOSSI, a people of Epirus, who inhabited that part of the country which was called *Molossia*, or *Molossus*, from King Molossus, a son of Pyrrhus and Andromache. This country had the bay of Ambracia on the south, and the country of the Perrhæbeans on the east. The dogs of the place were famous, and received the name of *Molossi* among the Romans. Dodona was the capital of the country, according to some writers. Others, however, reckon it as the chief eity of Thesprotia.

MOLOSSUS, in the Greek and Latin poetry, a foot consisting of three long syllables. As audiri, cantabant, virtutem.

It takes its name either from a dance in use among the people called *Molossi* or *Epirotæ*; or from the temple of Jupiter Molossus, where odes were sung, in which this foot had a great share; or else because the march of the Molossi, when they went to the combat, was composed of these feet, or had the cadence thereof. The same foot was also called among the ancients, *Vertumnus*, extensipes, hippius, et cannius.

MOLUCILLA, a genus of plants belonging to the didynamia class, and in the natural method ranking under the 42d order, Verticillate. See BOTANY Index. MOLTEN-GREASE. See FARRIERY, Nº 499.

MOLTERV-GREASE. See Finkthere of the Molter Stands, lie in the East Indian sea under the line; of which there are five principal, namely, Ternate, Tydor, Machian, Motyr, and Bachian. The largest of them is hardly 30 miles in circumference. They produce neither corn, rice, nor cattle, except goats: but they have oranges, lemons, and other finits; and are most remarkable for spices, especially cloves. They have large snakes, which are not venomous, and very dangerous land crocodiles. At present they have three kings; and the Dutch, who are

O L

Monius.

MOLWITZ, a town of Silesia, in the province of Grotska, remarkable for a hattle gained by the Prussians over the Austrians in 1741. E. Long. 16. 45. N. Lat. 50. 26.

MOLY. The name of this plant is rendered famous by Homer: and hence has been much inquired into, as to its true sense, by the hotanists of almost all times. The old interpreters of Homer explain this word by the " wild rue ;" and the only reason for this is, that at some time, probably long after the days of Homer, the people of Cappadocia called the wild rue moly. But this plant is wholly different from the moly of Homer, which Theophrastus affirms grew in his time in Areadia in great plenty, and had a round bulbons root like an onion, and long and grassy leaves like the squill. On the whole, the moly of Homer seems to have been a species of allium or garlie.

MOLYBDENA, a mctal. See CHEMISTRY and MINERALOGY Index.

MOMBAZA, or MONBAZA, a town of Africa. in an island of the same name, with a castle and a fort; seated on the eastern coast, opposite to the country of Mombaza in Zanguchar, 75 miles south of Melinda, and subject to Portugal. E. Long. 39. 30. S. Lat. 3. 15.

MOMBAZA, a country of Africa in Zauguebar, subject to the Portugese, from whence they export slaves, gold, ivory, rice, flesh, and other provisions, with which they supply the settlements in Brasil. The king of this country being a Christian, had a quarrel with the Portuguese governor, took the castle by assault in 1631, turned Mahometan, and murdered all the Christians; but in 1729 they became masters of the territory again.

MOMENT, in the doctrine of time, an instant, or the most minute and indivisible part of duration.

MOMENTUM, in Mechanics, signifies the same with impetus, or the quantity of motion in a moving body; which is always equal to the quantity of matter multiplied into the velocity; or, which is the same thing, it may be considered as a rectangle under the quantity of matter and velocity. See MECHANICS.

MOMORDICA, MALE BALSAM APPLE; a genus of plants belonging to the monœeia class; and in the natural method ranking under the 34th order, Cucurbitacea. See BOTANY Index.

MOMUS, in fabulous history, the god of raillery, or the jester of the eelestial assembly, and who ridiculed both gods and men. Being chosen by Vulean, Neptune, and Minerva, to give his judgment concerning their works, he blamed them all: Neptune for not making his bull with horns before his eyes, in order that he might give a surer blow; Minerva for building a house that could not be removed in case of bad neighbours; and Vulcan, for making a man without a window in his breast, that his treacheries might be seen. For his free reflections upon the gods, Momus was driven from heaven. He is generally represented raising a mask from his face, and holding a small figure in his hand.

MONA, in Ancient Geography, two islands of this Mona name in the sea lying between Britain and Ireland. Ш The one described by Cæsar, as situated in the middle Monarchy. passage between both islands, called Monaæda (Ptolemy); Monapia, or Monabia (Pliny), is supposed to be the isle of Man.-Another Mona (Taeitus); an island more to the south, separated from the coast of the Ordovices by a narrow strait. The ancient seat of the Druids. New ealled Anglescy, the island of the Angles or English.

MONA, an island of the Baltic sea, south-west of the island of Zealand, subject to Denmark. E. Long. 12. 30. N. Lat. 55. 20.

MONA. See INCHCOLM.

MONACA, a small but handsome and strong town of Italy, in the territory of Genoa, with a eastle, citadel, and a good harbour. It is seated on a eraggy rock, and had its own prince, under the protection of France. It was united to France early in the Revolution, but its independence was restored by the peace of Paris in 1814. E. Long. 7. 33. N. Lat. 43. 48.

MONAD. See LEIBNITZIAN Philosophy.

MONADELPHIA, (from provos, alone, and ader Qia, a brotherhood;) a "single brotherhood:" The name of the 16th elass in Linnæus's sexual system, consisting of plants with hermaphrodite flowers; in which all the stamina are united below into one body or cylinder, through which passes the pistillum. See BOTANY Inder.

MONAGHAN, a county of Ireland, situated in the province of Ulster, is bounded by Tyrone on the north, Armagh on the cast, Cavan and Louth on the south, and Fermanagh on the west. It is a mountainous tract, but in some places is well improved. It contains 170,090 Irish plantation aeres, and is about 30 miles long and 22 broad. It has a considerable linen trade, and sends two members to parliament.

MONAGHAN, the capital town of the county of that name, is distant 62 miles from Dublin, and gives title of baron to the family of Blayney. It was aneiently called Muinechan. An abbey was founded here in a very early age, of which Moelodius the son of Aodh was abbot. In 1462, a monastery for conventual Franciscans was erected on the site of this abbey, which was granted on the general suppression of monasteries to Edward Withe, and a eastle has been since creeted on the site by Edward Lord Blayney.

MONANDRIA, (from proves, alone, and arme, a man or husband), the name of the first class in Linnæns's sexual system; eonsisting of plants with hermaphrodite flowers, which have only one stamen.

MONARCHY, a large state governed by one; or a state where the supreme power is lodged in the hands of a sing'e person. The word comes from the Greek provagyns, " one who governs alone ;" formed of provos, solus, and agyn, imperium, "government." Of the three forms of government, viz. democracy, aristocracy, and monarchy, the last is the most powerful, all the sinews of government being knit tegether, and united in the hand of the prince; but then there is imminent danger of his employing that strength to improvident or oppressive purposes. As a democracy is the best calculated to direct the end of a law, and an aristocracy to invent the means by which that end shall be obtained, a monarchy is most fit for earrying those means into execution.

Qq 2

The

The most ancient monarchy was that of the Assy-Monarchy. rians, which was founded soon after the deluge. We usually reckon four grand or universal monarchies ; the Assyrian, Persian, Grecian, and Roman ; though St Augustine makes them but two; viz. those of Babylon and Rome. Belus is placed at the head of the series of Assyrian kings who reigned at Babylon, and is by profane authors esteemed the founder of it, and by some the same whom the Scriptures call Nimrod. The principal Assyrian kings after Belus were Ninus, who built Nineveli, and removed the seat of empire to it; Semiramis, who disguising her sex, took possession of the kingdom instead of her son, and was killed and succeeded by her son Ninyas; and Sardanapalus, the last of the Assyrian monarchs, and more effeminate than a woman. After his death the Assyrian empire was split into three separate kingdoms, viz. the Median, Assyrian, and Babylonian. The first king of the Median kingdom was Arbaces ; and this kingdom lasted till the time of Astyages, who was subdued and divested of his kingdom by Cyrus.

In the time of Cyrus there arose a new and second monarchy called the Persian, which stood upwards of 200 years from Cyrus, whose reign began A. M. 3468, to Darius Codomannus, who was conquered by Alexander, and the empire translated to the Greeks A. M. 3674 .- The first monarch was Cyrus, founder of the empire. 2. Cambyses, the son of Cyrns. 3. Smerdis. 4. Darius, the son of Hystaspis, who reigned 521 years before Christ. 5. Xerxes, who reigned 485 years before Christ. 6. Artaxerxes Longimanus, who reigned 464 years before Christ. 7. Xerxes, the second. 8. Ochus, or Darius, called Nothus, 424 years before Christ. 9. Artaxerxes Mnemon, 405 years before Christ. 10. Artaxerxcs Ochus, 359 years before Christ. 11. Arses, 338 years before Christ. 12. Darius Codomannus, 336 years before Christ, who was defeated by Alexander the Great, and deprived of his kingdom and life about 331 years before Christ: the dominion of Persia after his death was translated to the Greeks.

The third monarchy was the Grecian. As Alexander, when he dled, did not declare who should succeed him, there started up as many kings as there were commanders. At first they governed the provinces that were divided among them under the title of viceroys; hut when the family of Alexander the Great was extinct, they took upon them the name of kings. Hence, in process of time, the whole empire of Alexander produced four distinct kingdoms, viz. 1. The Macedonian; the kings of which, after Alexander, were Antipater, Cassander, Demetrius Poliorcetes, Seleucus Nicanor, Meleager, Antigonus Doson, Philip, and Perseus, under whom the Macedonian kingdom was reduced to the form of a Roman province. 2. The Asiatic kingdom, which upon the death of Alexander fell to Antigonus, comprehending that country now called Natolia, together with some other regions beyond Mount Taurus. From this kingdom proceeded two lesser ones, viz. that of Pergamus, whose last king, Attalus, appointed the Roman people to be his heir; and Pontus, reduced by the Romans into the form of a province, when they had subdued the last king, Mithridates. 3. The Syrian, of whose twenty-two kings the most celebrated were, Seleucus Nicanor, founder of

kingdom; Antiochus Deus; Antiochus the Great; Monard Antiochus Epiphanes; and Tigranes, who was conquered by the Romans under Pompey, and Syria reduced into the form of a Roman province. 4. The Egyptian, which was formed by the Greeks in Egypt, and flourished near 240 years under 12 kings, the principal of whom were, Ptolemy Lagus, its founder; Ptolemy Philadelphus, founder of the Alexandrian library; and Queen Cleopatra, who was overcome by Augustus, in consequence of which Egypt was added to the dominion of the Romans.

The fourth monarchy was the Roman, which lasted 244 years, from the building of the city until the time when the royal power was abrogated. The kings of Rome were Romulus, its founder; Numa Pompilius; Tullus Hostilius; Ancus Martius; Tarquinius Priscus; Servins Tullius; and Tarquin the Proud, who was banished, and with whom terminated the regal power.

There seems in reality no necessity to make the Medes, Persians, and Greeks, succeed to the whole power of the Assyrians, to multiply the number of the monarchies. It was the same empire still; and the several changes that happened in it did not constitute different monarchies. Thus the Roman empire was successively governed by princes of different nations, yet without any new monarchy being formed thereby. Rome, therefore, may be said to have immediately succeeded Babylon in the empire of the world. See EMPIRE.

Of monarchies some are absolute and despotic, where the will of the monarch is uncontroulable; others are limited, where the prince's authority is restrained by laws, and part of the supreme power lodged in other hands, as in Britain. See GOVERNMENT.

Some monarchies again are hereditary, where the succession devolves immediately from father to son; and others are clective, where, on the death of the monarch, his successor is appointed by election, as in Poland.

Fifth-MONARCHY Men, in the ecclesiastical history of England, were a set of wronged-headed and turbulent enthusiasts who arose in the time of Cromwell, and who expected Christ's sudden appearance upon earth to establish a new kingdom; and, acting in consequence of this illusion, aimed at the subversion of all human government.

MONARDA, INDIAN HOREHOUND, a genus of plants belonging to the diandria class; and in the natural method ranking under the 42d order, Verticillatæ. See BOTANY Index.

MONASTEREVAN, a post town of Ireland, in the county of Kildare and province of Leinster, 36 miles from Dublin, so called from a magnificent abbey which was founded here, in which St Evan in the beginning of the 7th century placed a number of mouks from South Munster, and which had the privilege of being a sanctuary. The consecrated bell, which belonged to this saint, was on solemn trials sworn upon by the whole tribe of the Eoganachts, and was always committed to the care of the Mac Evans, hereditary chief justices of Munster. The abbot of this house sat as a baron in parliament.—At the general suppression of monasteries, this abbey was granted to Lord Audley, who assigned it to Viscount Ely. It afterwards came into

4

1971.

astere-into the family of Moor, earls of Drogheda, and has been beautifully repaired by the present Lord Drogheda, stery. still wearing the venerable appearance of an abbey. There is a nursery at Monasterevan for the charter schools of the province of Leinster; and the grand canal has been carried up to this town from Dublin, since which it has been much improved and enlarged with several new buildings.

> MONASTERY, a convent or house built for the reception of religious; whether it be abbey, priory, nunnery, or the like.

> MONASTERY is only properly applied to the houses of monks, mendicant friars, and nuns. The rest are more properly called *religious houses*. For the origin of monasterics, sec MONASTIC and MONK.

> The houses belonging to the several religious orders which obtained in England and Wales were, cathedrals, colleges, abbeys, priories, preceptories, commandries, hospitals, friaries, hermitages, chantries, and free chapels. These were under the direction and management of various officers. The dissolution of houses of this kind began so early as the year 1312, when the Templars were suppressed ; and in 1323 their lands, churches, advowsons, and liberties, here in England, were given by 17 Ed. II. st. 3. to the prior and brethren of the hospital of St John at Jernsalem. In the years 1390, 1437, 1441, 1459, 1497, 1505, 1508, and 1515, several other houses were dissolved, and their revenues settled on different colleges in Oxford and Cambridge. Soon after the last period, Cardinal Wolsey, by license of the king and pope, obtained a dissolution of above 30 religious houses for the founding and endowing his colleges at Oxford and Ipswich. About the same time a bull was granted by the same pope to Cardinal Wolsey to suppress monasteries, where there were not above six monks, to the value of 8000 ducats a-year, for endowing Windsor and King's College in Cambridge; and two other bulls were granted to Cardinals Wolsey and Campeius, where there were less than twelve monks, and to annex them to the greater monasteries; and another bull to the same cardinals to inquire about abbeys to be suppressed in order to be made eathedrals. Although nothing appears to have been done in consequence of these bulls, the motives which induced Wolsey and many others to suppress these houses was the desire of promoting learning; and Archbishop Cranmer engaged in it with a view of earrying on the Reformation. There were other eauses that concurred to bring on their ruin: many of the religious were loose and vicious; the monks were generally thought to be in their hcarts attached to the pope's supremacy; their revenues were not employed according to the intent of the donors; many clieats in images, feigned miracles, and counterfeit relicks, had been discovered, which brought the monks into disgrace; the Observant friars had opposed the king's divorce from Queen Catharine; and these circumstances operated, in concurrence with the king's want of a supply and the people's desire to save their money, to forward a motion in parliament, that in order to support the king's state and supply his wants, all the religious houses might be conferred upon the crown which were not able to spend above 200l. a-year; and an act was passed for that purpose 27

Hen. VIII. c. 28. By this act about 380 houses were Monastery. dissolved, and a revenue of 30,000l. or 32,000l. a-year came to the erown; besides about 100,000l. in plate and jewels. The suppression of these houses oceasioned discontent, and at length an open rebellion : when this was appeased, the king resolved to suppress the rest of the monasteries, and appointed a new visita= tion: which caused the greater abbeys to be surrendered apaee; and it was enacted by 31 Henry VIII. c. 13. that all monasteries, & e. which have been sur-rendered since the 4th of February, in the 27th year of his majesty's reign, and which hereafter shall be surrendered, shall be vested in the king. The knights of St John of Jerusalem were also suppressed by the 32 Henry VIII. e. 24. The suppression of these greater houses by these two acts produced a revenue to the king of above 100,000l. a year, besides a large sum in plate and jewels. The last aet of dissolution in this king's reign was the act of 37 Henry VIII. c. 4. for dissolving colleges, free chapels, chantries, &c. which act was farther enforced by I Edw. VI. e. 14. By this act were suppressed 90 colleges, 110 hospitals, and 2374 chantries and free chapels. The number of houses and places suppressed from first to last, so far as any calculations appear to have been made, seems to be as follow:

Of lesser monasteries, of which we have the va-

| luation, -                     | - 100 |   | 374  |
|--------------------------------|-------|---|------|
| Of greater monasteries,        | -     | - | 186  |

|           |         |       |         |     |     |   |    |

Total L.140,784 19 34

If proper allowanecs are made for the lesser monasteries and houses not included in this estimate, and for the plate, &c. which came into the hands of the king by the dissolution, and for the value of money at that time, which was at least six times as much as at present, and also consider that the estimate of the lands was generally supposed to be much under the real worth, we must conclude their whole revenues to have been immense.

It does not appear that any computation hath been made of the number of persons contained in the religious houses.

| onastery. | Those of the lesser monasteries dissolved by 27  | 111 |

One for each chantry and free chapel, 2374

Total, 47,721

But as there were probably more than one person to officiate in several of the free chapels, and there were other houses which are not included within this calculation, perhaps they may be computed in one general estimate at about 50,000. As there were pensions paid to almost all those of the greater monasteries, the king did not immediately come into the full enjoyment of their whole revenues : however, by means of what he did receive, he founded six new bishoprics, viz. those of Westminster (which was changed by Queen Elizabeth into a deanery, with twelve prebends and a school), Peterborough, Chester, Gloucester, Bristol, and Oxford. And in eight other sees he founded deaneries and chapters, by converting the priors and monks into deans and prebendaries, viz. Canterbury, Winchester, Durham, Worcester, Rochester, Norwich, Ely, and Carlisle. He founded also the colleges of Christ-church in Oxford and Trinity in Cambridge, and finished King's college there. He likewise founded professorships of divinity, law, physic, and of the Hebrew and Greek tongues, in both the said universities. He gave the house of Greyfriars and St Bartholomew's hospital to the city of London, and a perpetual pension to the poor knights of Windsor, and laid out great sums in building and fortifying many ports in the channel. It is observable, upon the whole, that the dissolution of these houses was an act, not of the church, but of the state; in the period preceding the Reformation, by a king and parliament of the Roman catholic communion in all points except the king's supremacy; to which the pope himself, by his bulls and licenses, had led the way.

MONASTIC, something belonging to monks, or the monkish life. The monastic profession is a kind of civil death, which in all worldly matters has the same effect with the natural death. The council of Trent, &c. fix sixteen years for the age at which a person may be admitted into the monastical state.

St Anthony is the person who, in the fourth century, first instituted the monastic life; as St Pachomius, in the same century, is said to have first set on foot the cœnobitic life, i. e. regular communities of religious. In a short time the deserts of Egypt became inhabited with a set of solitaries, who took upon them the monastic profession. St Basil carried the monkish humour into the east, where he composed a rule which afterwards obtained through a great part of the west.

In the 11th century the monastic discipline was grown very remiss. St Odo first began to retrieve it

the monastery of Cluny; that monastery, by the Mona onditions of its erection, was put under the immediate rotection of the holy see; with a prohibition to all Mone owers, both secular and ecclesiastical, to disturb the onks in the possession of their effects or the election of neir abbot. In virtue hereof they pleaded an exempon from the jurisdiction of the bishop, and extended is privilege to all the houses dependent on Cluny. his made the first congregation of several houses, nder one chief immediately subject to the pope, so s to constitute one body, or, as they now call it, one ligious order. Till then, each monastery was independent and subject to the bishop. See MONK.

MONDA, or MUNDA, in Ancient Geography, a river of Lusitania, running mid-way from east to west into the Atlantic, between the Durius and Tagns, and washing Conimbrica. Now the Mondego, a river of Portugal, which running by Coimbra, falls into the Atlantic, 30 miles below it.

MONDAY, the second day of the week, so called as being anciently sacred to the moon ; q. d. moon-day.

MONDOVI, a considerable town of Italy, in Piedmont; with a citadel, university, and bishop's sec. It belongs to the king of Sardinia, is large and populous, and is seated in E. Long. 7. 40. N. Lat.

44. 33. MONEMUGI, an empire in the south of Africa, has Zanguebar on the east, Monomotapa on the south, Motamba and Makoko on the west, and Abyssinia on the north and partly to the east, though its boundaries that way cannot be ascertained. It is divided into the kingdoms of Mujaco, Makoko or Ansiko, Gingiro, Cambate, Alaba, and Monemugi Proper. This last lies in the middle of the torrid zone, and about the equinoctial line, south of Makoko, west of Zanguebar, north of Monomotapa, and east of Congo and of the northern parts of Monomotapa. The country known, abounds with gold, silver, copper mines, and elephants. The natives clothe themselves in silks and cottons, which they buy of strangers, and wear collars of transparent amber beads, brought them from Cambaya : which beads scrve also instead of money ; gold and silver being too common, and of little value among them.

Their monarch always endeavours to be at peace with the princes round about him, and to keep an open trade with Quitoa, Melinda, and Mombaza, on the east, and with Congo on the west : from all which places the black merchants resort thither for gold. The Portuguese merchants report, that on the cast side of Monemugi there is a great lake full of small islands, abounding with all sorts of fowl and cattle, and inhabited by negroes. They relate also, that on the main land eastward they heard sometimes the ringing of bells, and that one could observe buildings very much like churches; and that from these parts came men of a brown and tawney complexion, who traded with those islanders, and with the people of Monemugi. This country abounds in palm wine, oil, and honey.

MONETARIUS, or MONEYER, a name which antiquaries and medallists give to those who struck the ancient coins or moneys.

Many of the old Roman, &c. coins have the name of the monetarius, either written at length, or at least the initial letters of it. See MEDAL.

M

L 3II

#### MON E Y.

MONEY, a piece of matter, commonly metal, to which public authority has affixed a certain value and weight to serve as a medium in commerce. See COIN, COMMERCE, MEDALS, and BANK; also the artieles BANKING, COINAGE, and EXCHANGE, in the SUPPLEMENT.

Money is usually divided into real or effective, and imaginary or money of account,

I. REAL Money.

1. History of real money. Real money includes all coins, or species of gold, silver, copper, and the like; which have course in common, and do really exist. Such are guineas, pistoles, pieces of eight, ducats, &e. Real money, civilians observe, has three essential

qualities, viz. matter, form, and weight or value.

For the matter, copper is that thought to have been first coined; afterwards silver; and lastly gold, as being the most beautiful, scaree, cleanly, divisible, and pure of all metals.

The degrees of goodness are expressed in gold by carats; and in silver by pennyweights, &e. For there are several reasons for not coining them pure and without alloy, viz. the great loss and expense in refining them, the necessity of hardening them to make them more durable, and the scarcity of gold and silver in most countries. See ALLOY.

Among the ancient Britons, iron rings, or, as some say, iron plates, were used for money ; among the Laeedæmonians, iron bars quenched with vinegar, that they might not serve for any other use. Seneca observes, that there was anciently stamped money of leather, corium forma publica impressum. And the same thing was put in practice by Frederic II. at the siege of Milan; to say nothing of an old tradition among ourselves, that in the confused times of the barons wars the like was done in England : but the Hollanders, we know, coined great quantities of pasteboard in the year 1574.

As to the form of money, it has been more various than the matter. Under this arc comprehended the weight, figure, impression, and value.

For the impression, the Jews, though they detested images, yet stamped on the one side of their shekel the golden pet which held the manna, and on the other Aaron's rod. The Dardans stamped two cocks fighting. The Athenians stamped their coins with an owl, or an ox; whenee the proverb on bribed lawyers, Bos in lingua. They of Ægina, with a tortoise ; whence, that other saying, Virtutem et sapientiam vincunt testudines. Among the Romans, the monetarii sometimes impressed the images of men that had been eminent in their families on the coins : but no living man's head was ever stamped on a Roman coin till after the fall of the commonwealth. From that time they bore the emperor's head on one side. From this time the practice of stamping the prince's image on coins has obtained among all civilized nations; the Turks and other Mahometans alone excepted, who, in detestation of images, inscribe only the prince's name, with the year of the transmigration of their prophet.

As to the figure, it is either round as in Britain; multangular or irregular, as in Spain; square, as in some parts of the Indies; or nearly globular, as in Money. most of the rest.

After the arrival of the Romans in this island, the Britons imitated them, coining both gold and silver with the images of their kings stamped on them. When the Romans had subdued the kings of the Britons, they also suppressed their coins, and brought in their own; which were eurrent here from the time of Claudius to that of Valentinian the Younger, about the space of 500 years.

Mr Camden observes, that the most aneient English coin he had known was that of Ethelbert king of Kent, the first Christian king in the island ; in whose time all money accounts begin to pass by the names of pounds, shillings, pence, and mancuses. Pence seems borrowed from the Latin pecunia, or rather from pendo, on account. of its just weight, which was about threepence of our money. These were coarsely stamped with the king's image on the one side, and either the mint master's, or the city's where it was coined, on the other. Five of these pence made their schilling, probably so called from scilingus, which the Romans used for the fourth part of an ounce. Forty of these schillings made their pound ; and 400 of these pounds were a legaey, or portion for a king's daughter, as appears by the last will of King Alfred. By these names they translated all sums of money in their Old English testament; talents by pundes ; Judas's thirty pieces of silver by thirtig scillinga; tribute money, by pennining; the mite by feorthling.

But it must be observed, they had no other real money, but pence only; the rest being imaginary moneys, i. e. names of numbers or weights. Thirty of these pence made a maneus, which some take to be the same with a mark: manca, as appears by an old MS. was quinta pars unciæ. These maneas or maneuses were reekoned both in gold and silver. For in the year 680 we read that Ina king of the West Saxons obliged the Kentishmen to buy their peace at the price of 30,000 mancas of gold. In the notes on King Canute's laws, we find this distinction, that mancusa was as much as a mark of silver, and manca, a square piece of gold, valued at 30 pence.

The Danes introduced a way of reckoning money by ores, per oras, mentioned in Domesday book ; but whether they were a several coin, or a certain sum, does not plainly appear. This, however, may be gathered from the Abbey book of Burton, that 20 ores were equivalent to two marks. They had also a gold coin ealled byzantine, or b zant, as being coined at Constantinople, then called Byzantium. The value of which coin is not only now lost, but was so entirely forgot even in the time of King Edward III. that whereas the bishop of Norwich was fined a byzantine of gold to be paid the abbot of St Edmund's Bury for infringing his liberties (as it had been enacted by parliament in the time of the Conqueror), no man then living could tell how much it was; so it was referred to the king to rate how much he should pay. Which is the more unaecountable, because but 100 years before, 200,000 bezants were exacted by the soldan for the ransom of St Louis of. France: which were then valued at 100,000 livres.

Though the coining of money be a special preroga-

tive

tive of the king, yet the ancient Saxon princes communicated it to their subjects; insomuch that in every good town there was at least one mint; but at London eight; at Canterbury four for the king, two for the archbishop, one for the abbot at Winchester, six at Rochester, at Hastings two, &c.

The Norman kings continued the same custom of coining only pence, with the prince's image on one side, and on the other the name of the city where it was coined, with a cross so deeply impressed, that it might be easily parted and broke into two halves, which, so broken, they called *halfpence*; or into four parts, which they called *fourthings* or *farthings*.

In the time of King Richard I. money coined in the east parts of Germany came in special request in England on account of its purity, and was called *casterling money*, as all the inhabitants of those parts were called *Easterlings*. And shortly after, some of those people skilled in coining were sent for hither, to bring the coin to perfection; which since has been called *sterling* for *Easterling*. See STERLING.

King Edward I. who first adjusted the measure of an ell by the length of his arm, herein imitating Charles the Great, was the first also who established a certain standard for the coin, which is expressed to this effect by Greg. Rockley, mayor of London, and mint master.—" A pound of money containeth twelve ounces : in a pound there ought to be eleven ounces, two easterlings, and one farthing ; the rest alloy. The said pound ought to weigh twenty shillings and three pence in account and weight. The ounce ought to weigh twenty pence, and a penny twenty-four grains and a half. Note, That eleven ounces two pence sterling ought to be of pure silver, called *leaf silver*; and the penny farthing, if the silver be so pure."

About the year 1320, the states of Europe first began to coin gold; and among the rest, our King Edward III. The first pieces he coined were called *florences*, as being coined by Florentines: afterwards he coined nobles; then rose-nobles, current at 6s. 8d. half nobles called *half pennics*, at 3s. 4d. of gold; and quarters at 20d. called *farthings of gold*. The succeeding kings coined rose-nobles, and double rose-nobles, great sovereigns, and half Henry nobles, angels, and shillings.

King James I. coined units, double crowns, Britain crowns : then crowns, half-crowns, &c.

2. Comparative value of Money and Commodities at different periods. The English money, though the same names do by no means correspond with the same quantity of precious metal as formerly, has not changed so much as the money of most other countries. From the time of William the Conqueror, the proportion between the pound, the shilling, and the penny, seems to have been uniformly the same as at present.

Edward III. as already mentioned, was the first of our kings that coined any gold; and no copper was coined by authority before James I. These pieces were not called farthings, but *farthing tokens*, and all people were at liberty to take or refuse them. Before the time of Edward III. gold was exchanged, like any other commodity, by its weight; and before the time of James I. copper was stamped by any one person who chose to do it.

In the years 712 and 727, a ewe and lamb were

rated at 15. Saxon money till a fortnight after Easter. Mou Between the years 900 and 1000, two hydes of land, each containing about 120 acres, were sold for 100 shillings. In 1000, by King Ethelred's laws, a horse was rated at 305. a mare or a colt of a year old, at 205. a mule or young ass, at 125. an ox at 305. a cow at 245. a swine at 8d. a sheep at 15. In 1043, a quarter of wheat was sold for 60d. Hence it is computed, that in the Saxon times there was ten times less money, in proportion to commodities, than at present. Their nominal specie, therefore, being about three times higher than ours, the price of every thing, according to our present language, must be reekoned thirty times cheaper than it is now.

In the reign of William the Conqueror, commodities were ten times cheaper than they are at present; from which we cannot help forming a very high idea of the wealth and power of that king: for his revenue was 400,000. per annum, every pound being equal to that weight of silver, consequently the whole may be estimated at 1,200,000. of the present computation; a sum which, considering the different value of money between that period and the present, was equivalent to 12,000,000. of modern estimation.

The most necessary commodities do not seem to have advanced their price from William the Conqueror to Richard I.

The price of corn in the reign of Henry III. was near half the mean price in our times. Bishop Fleetwood has shown, that in the year 1240, which was in this reign, 4l. 138. 9d. was worth about 50l. of our present money. About the latter end of this reign, Robert de Hay, rector of Souldern, agreed to receive 100s. to purchase to himself and successor the annual rents of 5s. in full compensation of an aere of corn.

Butchers meat, in the time of the great searcity in the reign of Edward II. was, by a parliamentary ordinance, sold three times cheaper than our mean price at present; poultry somewhat lower, because being now considered as a delicacy, it has risen beyond its proportion. The mean price of corn at this period was half the present value, and the mean price of cattle one-eighth.

In the next reign, which was that of Edward III. the most necessary commodities were in general about three or four times cheaper than they are at present.

In these times, knights, who served on horseback in the army, had 2s. a-day, and a foot areher 6d. which last would now be equal to a crown a-day. This pay has continued nearly the same nominally (only that in the time of the commonwealth the pay of the horse was advanced to 2s. 6d. and that of the foot 1s. though it was reduced again at the Restoration), but soldiers were proportionably of a better rank formerly.

In the time of Henry VI. corn was about half its present value, other commodities much cheaper. Bishop Fleetwood has determined, from a most accurate consideration of every circumstance, that 31. in this reign was equivalent to 281. or 301. now.

In the time of Henry VII. many commodities were three times as cheap here, and in all Europe, as they are at present, there having been a great increase of gold and silver in Europe since his time occasioned by the discovery of America.

The commodities whose price has risen the most since before the time of Henry VII. are butchers meat, fowls,

SI2 Money. fowls, and fish, especially the latter. And the reason why corn was always much dearer in proportion to other eatables, according to their prices at present, is, that in carly times agriculture was little understood. It required more labour and expence, and was more precarious than it is at present. Indeed, notwithstanding the high price of corn in the times we are speaking of, the raising of it so little answered the expence, that agriculture was almost universally quitted for grazing; which was more profitable, notwithstanding the low price of butchers meat. So that there was constant occasion for statutes to restrain grazing, and to promote agriculture; and no effectual remedy was found till the bounty upon the exportation of corn; since which, above ten times more corn has been raised in this country than before.

oney.

The price of corn in the time of James I. and consequently that of other necessaries of life, was not lower, but rather higher, than at present: wool is not two-thirds of the value it was then; the finer manufactures having sunk in price by the progress of art and industry, notwithstanding the increase of money. Butchers meat was higher than at present. Prince Henry made an allowance of near 4d. per pound for all the beef and mutton used in his family. This may be true with respect to London; but the price of butchers meat in the country, which does not even now much exceed this price at a medium, has certainly greatly increased of late years, and particularly in the northern counties.

The prices of commodities are higher in England than in France; besides that the poor people of France live upon much less than the poor in England, and their armies are maintained at less expence. It is computed by Mr Hume, that a British army of 20,000men is maintained at near as great an expence as 60,000 in France, and that the English fleet, in the war of 1741, required as much money to support it as all the Roman legions in the time of the emperors. However, all that we can conclude from this is, that money is much more plentiful in Europe at present than it was in the Roman empire.

In the 13th century, the common interest which the Jews had for their money, Voltaire says, was 20 per cent. But with regard to this, we must consider the great contempt that nation was always held in, the large contributions they were frequently obliged to pay, the risk they ran of never receiving the principal, the frequent confiscations of all their effects, and the violent persecutions to which they were exposed; in which eircumstances it was impossible for them to lend money at all, unless for most extravagant interest, and much disproportioned to its real value. Before the discovery of America, and the plantation of our colonies, the interest of money was generally 12 per cent. all over Enrope ; and it has been growing gradually less since that time, till it is now generally about four or five.

When sums of money are said to be raised by a whole people, in order to form a just estimate of it, we must take into consideration not only the quantity of the precious metal according to the standard of the coin, and the proportion of the quantity of coin to the commodities, but also the number and riches of the people who raise it; for populous and rich coun-

Vol. XIV. Part I.

tries will much more easily raise any certain sum of money than one that is thinly inhabited, and chiefly by poor people. This circumstance greatly adds to our surprise at the vast sums of money raised by William the Conqueror, who had a revenue nearly in value eqnal to 12,000,000l. of our money (allowance being made for the standard of coin and the proportion it bore to the commodities), from a country not near so populous or rich as England is at present. Indeed, the accounts historians give us of the revenues of this prince, and the treasure he left behind him, are barely credible.

II. IMAGINARY Money, or Money of Account, is that which has never existed, or at least which does not exist in real specie, but is a denomination invented or retained to facilitate the stating of accounts, by keeping them still on a fixed footing, not to be changed, like current coins, which the authority of the sovereign raises or lowers according to the exigencies of the state. Of which kind are pounds, livres, marks, maravedies, &c. See the annexed Table, where the fictitious money is distinguished by a dagger (†).

Moneys of Account among the Ancients .- The Grecians reckoned their sums of money by drachma, minæ, and talenta. The drachma was equal to  $7\frac{3}{4}$ d. sterling; 100 drachmæ made the mina, cqual to 31. 4s. 7d. sterling; 60 minæ made the talent, equal to 1931. 155. sterling; hence 100 talents amounted to 19,375l. sterling. The mina and talentum, indeed, were different in different provinces : their proportions in Attic drachms are as follow: The Syrian mina contained 25 Attic drachms; the Ptolemaic 331; the Antiochic and Eubœan 100; the Babylonic 116; the greater Attic and Tyrian 133; the Æginean and Rhodian 166?. The Syrian talent contained 15 Attic minæ; the Ptolemaic 20; the Antiochic 60; the Eubœan 60; the Babylonic 70; the greater Attic and Tyrian 80; the Æginean and Rhodian 100.

2. Roman moneys of account were the scstertius and sestertium. The sestertius was equal to 1d.  $3\frac{3}{4}q$ . sterling. One thousand of these made the sestertium, equal to 8l. 1s. 5d. 2q. sterling. One thousand of these sestertia made the decies sestertium (the adverb centics being always understood) equal to 80721. 18s. 4d. sterling. The decies sestertium they also called decies centena millia nummum. Centies sestertium, or centies HS, were equal to 80,7291. 3s. 4d. Millies HS to 807,2911. 13s. 4d. Millies centies HS to 888,0201. 16s. 8d.

### THEORY OF MONEY.

### 1. Of Artificial or Material Money.

I. As far back as our accounts of the transactions of mankind reach, we find they had adopted the precious metals, that is, silver and gold, as the common measure of value, and as the adequate equivalent for every thing alienable.

The metals are admirably adapted for this purpose: they are perfectly homogeneous: when pure, their masses, or bulks, are exactly in proportion to their weights; no physical difference can be found between two pounds of gold, or silver, let them be the production of the mines of Europe, Asia, Africa, or America: they are perfectly malleable, fusible, and suffer Rr the the most exact division which human art is eapable to give them: they are capable of being mixed with one another, as well as with metals of a baser, that is, of a less homogeneous nature, such as copper: by this mixture they spread themselves uniformly through the whole mass of the composed lump, so that every atom of it becomes proportionally possessed of a share of this noble mixture; by which means the subdivision of the precious metals is rendered very extensive.

Their physical qualities are invariable: they lose nothing by keeping; they are solid and durable; and though their parts are separated by friction, like every other thing, yet still they are of the number of those which suffer least by it.

If money, therefore, can be made of any thing, that is, if the proportional value of things vendible can be measured by any thing material, it may be measured by the metals.

II. The two metals being pitched upon as the most proper substances for realizing the ideal scale of money, those who undertake the operation of adjusting a standard, must constantly keep in their eye the nature and qualities of a scale, as well as the principles upon which it is formed.

The unit of the scale must constantly be the same, although realized in the metals, or the whole operation fails in the most essential part. This realizing the unit is like adjusting a pair of compasses to a geometrical scale, where the smallest deviation from the exact opening once given must occasion an incorrect measure. The metals, therefore, are to money what a pair of compasses is to a geometrical scale.

This operation of adjusting the metals to the money of account implies an exact and determinate proportion of both metals to the money unit, realized in all the species and denominations of coin, adjusted to that standard.

The smallest particle of either metal added to, or taken away from, any coins, which represent certain determinate parts of the scale, overturns the whole system of material money. And if, notwithstanding such variation, these coins continue to bear the same denominations as before, this will as effectually destroy their usefulness in measuring the value of things, as it would overturn the usefulness of a pair of compasses, to suffer the opening to vary, after it is adjusted to the scale representing feet, toises, miles, or leagues, by which the distances upon the plan arc to be measured.

III. Debasing the standard is a good term, because it conveys a clear and distinct idea. It is diminishing the weight of the pure metal contained in that denomination by which a nation reekons, and which we have called the *money unit*. Raising the standard requires no farther definition, being the direct contrary.

IV. Altering the standard (that is, raising or debasing the value of the money unit) is like altering the national measures or weights. This is best discovered by comparing the thing altered with things of the same nature which have suffered no alteration. Thus, if the foot of measure was altered at once over all Engtand, by adding to it, or taking from it, any propor-

4

tional part of its standard length, the alteration would be best discovered by comparing the new foot with that of Paris, or of any other country, which had suffered no alteration. Just so, if the pound sterling, which is the English unit, shall be found anyhow changed, and if the variation it has met with be difficult to ascertain because of a complication of circumstances, the best way to discover it, will be to compare the former and the present value of it with the money of other nations which has suffered no variation. This the course of exchange will perform with the greatest exactness.

V. Artists pretend, that the precions metals, when absolutely pure from any mixture, are not of sufficient hardness to constitute a solid and lasting eoin. They are found also in the mines mixed with other metals of a baser nature; and the bringing them to a state of perfect purity occasions an unnecessary expense. To avoid, therefore, the inconvenience of employing them in all their purity, people have adopted the expedient of mixing them with a determinate proportion of other metals, which hurts neither their fusibility, mallcability, beauty, nor lustre. This metal is ealled alloy : and, being considered only as a support to the principal metal, is accounted of no value in itself. So that eleven ounces of gold, when mixed with one ounce of silver, acquires by that addition no augmentation of value whatever.

This being the case, we shall, as much as possible, overlook the existence of alloy, in speaking of money, in order to render language less subject to ambiguity.

# 2. Incapacities of the metals to perform the office of an invariable Measure of Value.

I. Were there but one species of such a substance as we have represented gold and silver to be; were there but one metal possessing the qualities of purity, divisibility, and durability; the inconveniences in the use of it for money would be fewer by far than they are found to be as matters stand.

Such a metal might then, by an unlimited division into parts exactly equal, be made to serve as a tolerably steady and universal measure. But the rivalship between the metals, and the perfect equality which is found between all their physical qualities, so far as regards purity and divisibility, render them so equally well adapted to serve as the common measure of value, that they are universally admitted to pass current as money.

What is the consequence of this? that the one measures the value of the other, as well as that of every other thing. Now the moment any measure begins to be measured by another, whose proportion to it is not physically, perpetually, and invariably the same, all the usefulness of such a measure is lost. An example will make this plain.

A foot of measure is a determinate length. An English foot may be compared with the Paris foot, or with that of the Rhine; that is to say, it may be measured by them: and the proportion between their lengths may be expressed in numbers, which proportion will be the same perpetually. The measuring the one by the other will occasion no uncertainty; and we may speak of length by Paris feet, and be be

314

Money.

Toney. be perfectly well understood by others who are used to measure by the English foot, or by the foot of the Rhine.

But suppose that a youth of 12 years old takes it into his head to measure from time to time, as he advances in age, by the length of his own foot, and that he divides this growing foot into inches and decimals : what ean be learned from his account of measures ? As he increases in years, his foot, inches, and subdivisions, will be gradually lengthening; and were every man to follow his example, and measure by his own foot, then the foot of a measure now established would totally cease to be of any utility.

This is just the case with the two metals. There is no determinate invariable proportion between their value; and the consequence of this is, that when they are both taken for measuring the value of other things, the things to be measured, like lengths to be measured by the young man's foot, without changing their relative proportion between themselves, change, however, with respect to the denominations of both their measures. An example will make this plain.

Let us suppose an ox to be worth 3000 pounds weight of wheat, and the one and the other to be worth an ounce of gold, and an ounce of gold to be worth exactly 15 ounces of silver: if the case should happen, that the proportional value between gold and silver should come to be as 14 is to 1, would not the ox, and consequently the wheat, be estimated at less in silver, and more in gold, than formerly? Farther, Would it be in the power of any state to prevent this variation in the measure of the value of oxen and wheat, without putting into the unit of their money less silver and more gold than formerly?

If therefore any particular state should fix the standard of the unit of their money to one species of the metals, while in fact both the one and the other are actually employed in measuring value; does not such a state resemble the young man who measures all by his growing foot? Fc: if silver, for example, be retained as the standard, while it is gaining upon gold one-fifteenth additional value : and if gold continue all the while to determine the value of things as well as silver; it is plain, that, to all intents and purposes, this silver measure is lengthening daily like the young man's foot, since the same weight of it must become every day equivalent to more and more of the same commodity; notwithstanding that we suppose the same proportion to subsist, without the least variation, bctween that commodity and every other species of things alienable.

Buying and selling are purely conventional, and no man is obliged to give his merchandise at what may be supposed to be the proportion of its worth. The use, therefore, of an universal measure, is to mark, not only the relative value of the things to which it is applied as a measure, but to discover in an instant the proportion between the value of those, and of every other commodity valued by a determinate measure in all the countries of the world.

Were pounds sterling, livres, florins, piastres, &c. which are all money of account, invariable in their values, what a facility would it produce in all conversions ! what an assistance to trade ! But as they are all limited or fixed to coins, and consequently vary from time to time, this example shows the utility of the invariable measure which we have described.

There is another circumstance which incapacitates the metals from performing the office of money; the substance of which the coin is made, is a commodity which rises and sinks in its value with respect to other commodities, according to the wants, competition, and caprices of mankind. The advantage, therefore, found in putting an intrinsic value into that substance which performs the function of money of account, is compensated by the instability of that intrinsic value; and the advantage obtained by the stability of paper, or symbolical money, is compensated by the defect it commonly has of not being at all times susceptible of realization into solid property or intrinsic value.

In order, therefore, to render material money more perfect, this quality of metal, that is, of a commodity, should be taken from it; and in order to render paper money more perfect, it ought to be made to circulate upon metallic or land security.

II. There are several smaller inconveniences accompanying the use of the metals, which we shall here shortly enumerate.

1 mo, No money made of gold or silver can eirculate long, without losing its weight, although it all along preserves the same denomination. This represents the contracting a pair of compasses which had been rightly adjusted to the scale.

2do, Another inconvenience proceeds from the fabrication of money. Supposing the faith of princes who coin money to be inviolable, and the probity as well as capacity of those to whom they commit the inspection of the business of the metals to be sufficient, it is hardly possible for workmen to render every piece exactly of a proper weight, or to preserve the due proportion between pieces of different denominations, that is to say, to make every ten sixpences exactly of the same weight with every crown piece and every five shillings struck in a coinage. In proportion to such inaccuracies, the parts of the seale become unequal.

*3tio*, Another inconvenience, and far from being inconsiderable, flows from the expence requisite for the coining of money. This expence adds to its value as a manufacture, without adding any thing to its weight.

4to, The last inconvenience is, that by fixing the money of account entirely to the coin, without having any independent common measure, (to mark and controul these deviations from mathematical exactness, which are either inseparable from the metals themselves, or from the fabrication of them), the whole measure of value, and all the relative interests of debtors and creditors, become at the disposal not only of workmen in the mint, of Jews who deal in money, of clippers and washers in coin ; but they are also entirely at the mercy of princes who have the right of coinage, and who have frequently also the right of raising or debasing the standard of the coin, according as they find it most for their present and temporary interest.

3. Methods which may be proposed for lessening the several Inconveniences to which Material Money is liable.

The inconveniences from the variation in the relative R r 2 value Money. value of the metals to one another, may in some measure be obviated by the following expedients.

1mo, By considering one only as the standard, and leaving the other to seek its own value like any other commodity.

2do, By considering one only as the standard, and fixing the value of the other from time to time by authority, according as the market price of the metals shall vary.

3tio, By fixing the standard of the unit according to the mean proportion of the metals, attaching it to neither; regulating the coin accordingly; and upon every considerable variation in the proportion between them, either to make a new coinage, or to raise the denomination of one of the species, and lower it in the other in order to preserve the unit exactly in the mean proportion between the gold and silver.

4to, To have two units and two standards, one of gold and one of silver, and to allow every body to stipulate in either.

5to, Or last of all, To oblige all debtors to pay one half in gold, and one half in the silver standard.

## 4. Variations to which the Value of the Money unit is exposed from every Disorder in the Coin.

Let us suppose, at present, the only disorder to consist in a want of the due proportion between the gold and silver in the coin.

This proportion can only be established by the market price of the metals; because an augmentation and rise in the demand for gold or silver has the effect of augmenting the value of the metal demanded. Let us suppose, that to-day one pound of gold may buy fifteen pounds of silver: if to-morrrow there be a high demand for silver, a competition among merchants to have silver for gold will ensue: they will contend who shall get the silver at the rate of 15 pounds for one of gold : this will raise the price of it; and in proportion to their views of profit, some will accept of less than the 15 pounds. This is plainly a rise in the silver, more properly than a fall in the gold; because it is the competition for the silver which has occasioned the variation in the former proportion between the metals.

Let us now suppose, that a state, having with great exactness examined the proportion of the metals in the market, and having determined the precise quantity of each for realizing or representing the money unit, shall execute a most exact coinage of gold and silver coin. As long as that proportion continues unvaried in the market, no inconvenience can result from that quarter in making use of metals for money of account.

But let us suppose the proportion to change; that the silver, for example, shall rise in its value with regard to gold: will it not follow, from that moment, that the unit realized in the silver, will become of more value than the unit realized in the gold coin?

But as the law has ordered them to pass as equivalents for one another, and as debtors have always the option of paying in what legal coin they think fit, will they not all choose to pay in gold; and will not then the silver coin be melted down and exported, in order to be sold as bullion, above the value it bears when it circulates in coin? Will not this paying in

gold also really diminish the value of the money unit, Monor since upon this variation every thing must sell for more gold than before, as we have already observed.

Consequently, merchandises, which have not varied in their relative value to any other thing but to gold and silver, must be measured by the mean proportion of the metals: and the application of any other measure to them is altering the standard. If they are measured by the gold, the standard is debased; if by silver, it is raised.

If, to prevent the inconvenience of melting down the silver, the state shall give up affixing the value of their unit to both species at once, and shall fix it to one, leaving the other to seek its price as any other commodity; in that case, no doubt, the melting down of the coin will be prevented : but will this ever restore the value of the money unit to its former standard? Would it, for example, in the foregoing supposition, raise the debased value of the money unit in the gold coin, if that species were declared to be the standard ? It would, indeed, render silver coin purely a merchandise, and, by allowing it to seek its value, would certainly prevent it from being melted down as before ; because the pieces would rise conventionally in their denomination; or an agio, as it is called, would be taken in payments made in silver; but the gold would not, on that account, risc in its value, or begin to purchase any more merchandise than before. Were therefore the standard fixed to the gold, would not this be an arbitrary and a violent revolution in the value of the money unit, and a debasement of the standard?

If, on the other hand, the state should fix the standard to the silver, which we suppose to have risen in its value, would that ever sink the advanced value which the silver coin had gained above the worth of the former standard unit? and would not this be a violent and an arbitrary revolution in the value of the money unit, and a raising of the standard?

The only cxpedient, therefore, is, in such a case, to fix the numerary unit to neither of the metals, but to contrive a way to make it fluctuate in a mean proportion between them; which is in effect the introduction of a pure ideal money of account.

The regulation of fixing the unit by the mean proportion, ought to take place at the instant the standard unit is fixed with exactness both to the gold and silver. If it be introduced long after the market proportion between the metals has deviated from the proportion established in the coin; and if the new regulation is made to have a retrospect, with regard to the acquitting of permanent contracts entered into while the value of the money unit had attached itself to the lowest currency in consequence of the principle above laid down : then the restoring the money unit to that standard where it ought to have remained (to wit, to the mean proportion) is an injury to all debtors, who have contracted since the time that the proportion of the metals began to vary.

This is clear from the former reasoning. The moment the market price of the metals differs from that in the coin, every one who has payments to make, pays in that species which is the highest rated in the coin; consequently, he who lends, lends in that species. If after the contract, therefore, the unit is carried

316
ried up to the mean proportion, this must be a loss to Maney. him who had borrowed.

From this we may perceive, why there is less inconvenience from the varying of the proportion of the metals, where the standard is fixed to one of them. than when it is fixed to both. In the first case, it is at least uncertain whether the standard or the merchandise species is to rise; consequently, it is uncertain whether the debtors or the creditors are to gain by a variation. If the standard species should rise, the creditors will gain; if the merchandise species rises, the debtors will gain; but when the unit is attached to both species, then the creditors never can gain, let the metals vary as they will; if silver rises, then debtors will pay in gold; if gold rises, the debtors will pay in silver. But whether the unit be attached to one or to both species, the infallible consequence of a variation is, that one half of the difference is either gained or lost by debtors and creditors. The invariable unit is constantly the mean proportional between the two measures.

## 5. How the Variations of the intrinsic value of the Unit of Moncy must affect all the domestic Interests of a Nation.

If the changing the content of the bushel by which grain is measured, would affect the interest of those who are obliged to pay, or who are entitled to receive, a certain number of bushels of grain for the rent of lands; in the same manner must every variation in the value of the unit of account affect all persons who, in permanent contracts, are obliged to make payments, or who are obliged to receive sums of money stipulated in multiples or in fractions of that money unit.

Every variation, therefore, upon the intrinsic value of the money unit, has the effect of bcucfiting the class of creditors at the expence of debtors, or vice versa.

This consequence is deduced from an obvious principle. Money is more or less valuable in proportion as it can purchase more or less of every kind of merchandise. Now, without entering anew into the causes of the rise and fall of prices, it is agreed upon all hands, that whether an augmentation of the general mass of money in circulation has the effect of raising prices in general or not, any augmentation of the quantity of the metals appointed to be put into the money unit, must at least affect the value of that money unit, and make it purchase more of any commodity than before: that is to say, 113 grains of fine gold, the present weight of a pound sterling in gold, can buy 113 pounds of flour; were the pound sterling raised to 114 grains of the same metal, it would buy 114 pounds of flour; consequently, were the pound sterling augmented by one grain of gold, every miller who paid a rent of ten pounds a-year, would be obliged to sell 1140 pounds of his flour, in order to procure ten pounds to pay his rent, in place of 1130 pounds of flour, which he sold formerly to procure the same sum; consequently, by this innovation, the miller must lose yearly ten pounds of flour, which his master consequently must gain. From this example, it is plain, that every augmentation of

metals put into the pound sterling, either of silver or Money. gold, must imply an advantage to the whole class of " creditors who are paid in pounds sterling, and consequently must be a proportional loss to all debtors who must pay by the same denomination.

6. Of the Disorder in the British Coin, so far as it occasions the melting down or the exporting of the Specie.

The defects in the British coin are three.

1mo, The proportion between the gold and silver in it is found to be as 1 to  $15\frac{2}{10}$ , whereas the market price may be supposed to be nearly as 1 to  $14\frac{1}{2}$ .

2do, Great part of the current money is worn and light.

3tio, From the second defect proceeds the third, to wit, that there are several currencies in circulation which pass for the same value, without being of the same weight.

4to, From all these defects results the last and greatest inconvenience, to wit, that some innovation must be made, in order to set matters on a right footing.

The English, besides the unit of their money which they call the pound sterling, have also the unit of their weight for weighing the precious metals.

This is called the pound troy, and consists of 12 ounces, every ounce of 20 pennyweights, and every pennyweight of 24 grains. The pound troy, therefore, consists of 240 pennyweights and 5760 grains.

The fineness of the silver is reckoned by the number of ounces and pennyweights of the pure metal in the pound troy of the composed mass; or, in other words, the pound troy, which contains 5760 grains of standard silver, contains 5328 grains of finc silver, and 432 grains of copper, called alloy.

Thus standard silver is II ounces 2 pennyweights of fine silver in the pound troy to 18 pennyweights copper, or III parts fine silver to nine parts alloy.

Standard gold is 11 ounces fine to 1 ounce silver or copper employed for alloy, which together make the pound troy; consequently, the pound troy of standard gold contains 5280 grains fine, and 480 grains alloy, which alloy is reckoned of no value.

This pound of standard silver is ordered, by statute of the 43d of Elizabeth, to be coincd into 62 shillings, 20 of which make the pound sterling; consequently, the 20 shillings contain 1718.7 grains of fine silver, and 1858.06 standard silver.

The pound troy of standard gold, TT fine, is ordered, by an act of King Charles II. to be cut into 441 guincas : that is to say, every guinea contains 129.43 grains of standard gold, and 118.644 of fine gold; and the pound sterling, which is  $\frac{20}{2T}$  of the guinea, contains 112.994, which we may state at 113 grains of fine gold.

The coinage in England is entirely defrayed at the expence of the state. The mint price for the metals is the very same with the price of the coin. Whoever carries to the mint an ounce of standard silver, receives for it in silver coin 5s. 2d. or 62d. : whoever carries an ounce of standard gold receives in gold coin 31. 175. 101 d. the one and the other making exactly an ounce of the same fineness with the bullion. Coin, therefore, can have

Money.

have no value in the market above bulliou; consequently, no loss can be incurred by those who melt it down.

When the guinea was first struck, the government (not inclining to fix the pound sterling to the gold coin of the nation) fixed the guinea at 20 shillings, (which was then below its proportion to the silver), leaving it to seek its own price above that value, according to the course of the market.

By this regulation no harm was done to the English silver standard; hecause the guinea, or 118.644 grains fine gold, being worth more, at that time, than 20 shillings, or 1718.7 grains fine silver, no debtor would pay with gold at its standard value; and whatever it was received for above that price was purely conventional.

Accordingly guineas sought their own price until the year 1728, that they were fixed a-new, not below their value as at first, but at what was then reckoned their exact value, according to the proportion of the metals, viz. at 21 shillings; and at this they were ordered to pass current in all payments.

This operation had the effect of making the gold a standard as well as the silver. Debtors then paid indifferently in gold as well as in silver, because both were supposed to be of the same intrinsic as well as current value; in which case no inconvenience could follow upon this regulation. But in time silver came to be more demanded; the making of plate began to prevail more than formerly, and the exportation of silver to the East Indies increasing yearly, made the demand for it greater, or perhaps brought its quantity to be proportionally less than before. This changed the proportion of the metals; and by slow degrees they have come from that of I to 15.2 (the proportion they werc supposed to have when the guineas werc fixed and made a lawful money at 21 shillings) to that of 14.5, the present supposed proportion.

The consequence of this has been, that the same guinea which was worth 1804.6 grains fine silver, at the time it was fixed at 21s. is now worth no more than 1719.9 grains of fine silver according to the proportion of  $14\frac{1}{2}$  to 1.

Consequently debtors, who have always the option of the legal species in paying their debts, will pay pounds sterling no more in silver but in gold; and as the gold pounds they pay in are not intrinsically worth the silver pounds they paid in formerly according to the statute of Elizabeth, it follows that the pound sterling in silver is really no more the standard, since nobody will pay at that rate, and since nobody can be compelled to do it.

Besides this want of proportion between the metals, the silver coined before the reign of George I. is now become light by circulation; and the guineas coined by all the princes since Charles II. pass by tale, though many of them are considerably diminished in their weight.

Let us now examine what profit the want of proportion and the want of weight in the coin can afford to the money-jobbers in melting it down or exporting it.

Did every body consider coin only as the measurc for reckoning value, without attending to its value as a metal, the deviations of gold and silver coin from perfect

exactness, either as to proportion or weight, would oc- Mone casion little inconvenience.

Great numbers, indeed, in every modern society, consider coin in no other light than that of money of account; and have great difficulty to comprehend what difference any one can find between a light shilling and a heavy one, or what inconvenience there can possibly result from a guinea's being some grains of fine gold too light to be worth 21 shillings standard weight. And did every one think in the same way, there would be no occasion for coin of the precions metals at all; leather, copper, iron, or paper, would keep the reckoning as well as gold and silver.

But although there be many who look no farther than at the stamp on the coin, there are others whose sole business it is to examine its intrinsic worth as a commodity, and to profit of every irregularity in the weight and proportion of metals.

By the very institution of coinage, it is implied, that every piece of the same metal, and same denomination with regard to the money-unit, shall pass current for the same value.

It is, therefore, the employment of money-jobbers, to examine, with a scrupulous exactness, the precise weight of every piece of coin which comes into their hands.

The first object of their attention is, the price of the metals in the market : a jobber finds, at present, that with 14.5 pounds of fine silver bullion, he can buy one pound of fine gold bullion.

He therefore buys up with gold coin all the new silver as fast as it is coined, of which he can get at the rate of 15.2 pounds for one in gold; these 15.2 pounds silver coin he melts down into bullion, and converts that back into gold bullion, giving at the rate of only 14.5 pounds for onc.

By this operation he remains with the value of  $\frac{\tau}{\tau_0}$  of one pound weight of silver bullion clear profit upon the  $15\frac{\tau}{2}$  pounds he bought; which is  $\frac{\tau}{\tau_0}$  is really lost by the man who inadvertently coined silver at the mint, and gave it to the moncy-jobber for his gold. Thus the state loses the expense of the coinage, and the public the convenience of change for their guineas.

lic the convenience of change for their guineas. But here it may be asked, Why should the moneyjobber melt down the silver coin ? can he not buy gold with it as well without melting it down ? He cannot; because when it is in coin he cannot avail himself of its being new and weighty. Coin gocs by tale, not by weight; therefore, were he to come to market with his new silver coin, gold bullion being sold at the mint price, we shall suppose, viz. at 31. 175. 10<sup>±</sup>/<sub>2</sub>d. sterling money per ounce, he would be obliged to pay the price of what he bought with heavy money, which he can do with light.

He therefore melts down the new silver coin, and sells it for bullion, at so many pence an ounce; the price of which bullion is, in the English market, always above the price of silver at the mint, for the reasons now to be given.

When you sell standard silver bullion at the mint, you are to be paid in weighty money; that is, you receive for your bullion the very same weight in standard coin; the coinage costs nothing: but when you sell bullion in the market you are paid in worn-out silver,

silver, in gold, in bank notes, in short, in every species of lawful current money. Now all these payments have some defect: the silver you are paid with is worn and light; the gold you are paid with is overrated, and perhaps also light; and the bank notes must have the same value with the specie with which the bank pays them; that is, with light silver or overrated gold.

Money.

It is for these reasons, that silver bullion, which is bought by the mint at 5s. 2d. per ounce of heavy silver money, may be bought at market at 65 pence the ounce in light silver, overrated gold, or bank notes, which is the same thing.

Further, We have seen how the imposition of coinage has the effect of raising coin above the value of bullion, by adding a value to it which it had not as a metal.

Just so, when the unit is once affixed to certain determined quantities of both metals, if one of the metals should afterwards rise in value in the market, the coin made of that metal must lose a part of its value as coin, although it retains it as a metal. Consequently, as in the first case it acquired an additional value by being coined, it must now acquire an additional value by being melted down. From this we may conclude that when the standard is affixed to both the metals in the eoin, and when the proportion of that value is not made to follow the price of the market, that species which rises in the market is melted down, and the bullion is sold for a price as much exceeding the mint price as the metal has risen in its value.

If, therefore, in England, the price of silver bullion is found to be at 65 pence the ounce, while at the mint it is rated at 62; this proves that silver has risen  $\frac{3}{35}$ above the proportion observed in the coin, and that all coin of standard weight may consequently be melted down with a profit of  $\frac{3}{55}$ . But as there are several other circumstances to be attended to which regulate and influence the price of bullion, we shall here pass them in review, the better to discover the nature of this disorder in the English coin, and the advantages which money-jobbers may draw from it.

The price of bullion, like that of every other merchandise, is regulated by the value of the money it is paid with.

If bullion, therefore, sells in England for 65 pence an ounce paid in silver coin, it must sell for 65 shillingsthe pound troy; that is to say, the shillings it is commonly paid with do not exceed the weight of  $\frac{1}{65}$  of a pound troy; for if the 65 shillings with which the pound of bullion is paid weigh more than a pound troy, it will be a shorter and better way for him who wants bullion to melt down the shillings and make use of the metal, than to go to market with them in order to get less.

We may, therefore, be very certain, that no man will buy silver bullion at 65 pence an ounce, with any shilling which weighs above  $\frac{1}{63}$  of a pound troy.

We have gone upon the supposition that the ordinary price of bullion in the English market is 65 pence per ounce. This has been done upon the authority of some late writers on this subject: it is now proper to point out the causes which may make it deviate from that value. I. It may, and certainly will vary, in the price, according as the currency is better or worse. When the expence of a war, or a wrong balance of trade, have carried off a great many heavy guineas, it is natural that bullion should rise; because then it will be paid for more commonly in light gold and silver; that is to say, with pounds sterling, below the value of 113 grains fine gold, the worth of the pound sterling in new guineas.

II. This wrong balance of trade, or a demand for bullion abroad, becoming very great, may oceasion a scarcity of the metals in the market, as well as a scarcity of the coin ; consequently, an advanced price must be given for it in proportion to the greatness and height of the demand. In this ease, both the specie and the bullion must be bought with paper. But the rise in the price of hullion proceeds from the demand for the metals and the competition between merchants to procure them, and not because the paper given as the price is at all of inferior value to the specie. The least discredit of this kind would not tend to diminish the value of the paper; it would annihilate it at once. Therefore, since the metals must be had, and that the paper cannot supply the want of them when they are to be exported, the price rises in proportion to the difficulties in finding metals elsewhere than in the English market.

III. A sudden call for bullion, for the making of plate. A goldsmith can well afford to give 67 pence for an ounce of silver, that is to say, he cau afford to give one pound of gold for 14 pounds of silver, and perhaps for less, notwithstanding that what he gives be more than the ordinary proportion between the metals, because he indemnifies himself amply by the price of his workmanship; just as a tavern keeper will pay any price for a fine fish, because, like the goldsmith, he buys for other people.

IV. The mint price has as great an effect in bringing down the price of hullion, as exchange has in raising it. In countries where the metals in the coin are justly proportioned, where all the currencies are of legal weight, and where coinage is imposed, the operations of trade make the price of bullion constantly to fluctuate between the value of the coin and the mint price of the metals.

Now let us suppose that the current price of silver bullion in the market is 65 pence the ounce, paid in lawful money, no matter of what weight or of what metal. Upon this the money-jobher falls to work. All shillings which are above  $\frac{1}{63}$  of a pound troy, he throws into his melting pot, and sells them as bullion for 65d. per ounce; all those which are below that weight he carries to market, and buys bullion with them at 65d. per ounce.

What is the consequence of this ?

That those who sell the bullion, finding the shillings which the money-jobber pays with perhaps not above  $\frac{r}{66}$  of a pound troy, they on their side raise the price of the bullion to 66d. the ounce.

This makes new work for the money-jobber; for he must always gain. He now weighs all shillings as they come to hand; and as formerly he threw into his melting pot those only which were worth more than  $\frac{1}{53}$ of a pound troy, he now throws in all that are in vaMoney.

Money. Itie above  $\frac{x}{6\sigma}$ . He then sells the melted shillings at 66d. the ounce, and buys bullion with the light ones at the same price.

This is the consequence of ever permitting any species of coin to pass by the authority of the stamp, without controlling it at the same time by the weight : and this is the manner in which money-jobbers gain by the currency of light money.

It is no argument against this exposition of the matter to say, that silver bullion is seldom bought with silver coin; because the pence in new guineas are worth no more than the pence of shillings of 65 in the pound troy: that is to say, that 240 penec contained in 20 of a new guinea, and 240 pence contained in 28 shillings of 65 to the pound troy, differ no more in the intrinsie value than 0.83 of a grain of fine silver upon the whole, which is a mere trifle.

Whenever, therefore, shillings come below the weight of  $\frac{1}{63}$  of a pound troy, then there is an advantage in changing them for new guineas; and when that is the case, the new guineas will be melted down, and profit will be found in selling them for bullion, upon the principles we have just been explaining.

We have already given a specimen of the domestic operations of the money-jobbers; but these are not the most prejudicial to national concerns. The jobbers may be supposed to be Englishmen; and in that case the profit they make remains at home : but whenever there is a call for bullion to pay the balance of trade, it is evident that this will be paid in silver coin ; never in gold, if heavy silver can be got; and this again carries away the silver coin, and renders it at home so rare, that great inconveniences are found for want of the lesser denominations of it. The loss, however, here is confined to an inconvenience; because the balance of trade being a debt which must be paid, we do not consider the exportation of the silver for that purpose as any consequence of the disorder of the coin. But besides this exportation which is necessary, there are others which are arbitrary, and which are made only with a view to profit of the wrong proportion.

When the money-jobbers find difficulty in carrying on the traffic we have described, in the English market, because of the competition among themselves, they carry the silver coin of the country, and sell it abroad for gold, upon the same principles that the East India Company send silver to China in order to purchase gold.

It may be demanded, What hurt this trade can do to Britain, since those who export silver bring back the same value in gold? Were this trade carried on by natives, there would be no loss; because they would bring home gold for the whole intrinsic value of the silver. But if we suppose foreigners sending over gold to be coined at the English mint, and changing the gold into English silver coin, and then carrying off this coin, it is plain that they must gain the difference, as well as the money-jobbers. But it may be answered, That having given gold for silver at the rate of the mint, they have given value for what they have received. Very right; but so did Sir Hans Sloane, when he paid five guineas for an overgrown toad : he got value for his money; but it was value only to himself. Just so, whenever the English government shall be obliged to restore the proportion of the metals (as they must do),

this operation will annihilate that imaginary value which Money they have hitherto set upon gold ; which imagination is ~ the only thing which renders the exchange of their silver against the foreign gold equal.

But it is farther objected, that foreigners cannot carry off the heavy silver; because there is none to cary off, Very true; but then they have carried off a great quantity already : or if the English Jews have been too sharp to allow such a profit to fall to strangers, (which may or may not have been the ease), then this disorder is an effectual stop to any more coinage of silver for eirculation.

## 7. Of the Disorder in the British Coin, so far as it affects the Value of the Pound Sterling Currency.

From what has been said, it is evident, that there must be found in England two legal pounds sterling, of different values; the one worth 113 grains of fine gold, the other worth 1718.7 grains of fine silver. Wc call them different : because these two portions of the precious metals are of different values all over Europe.

But besides these two different pounds sterling, which the change in the proportion of the metals has created, the other defects of the circulating coin produce similar effects. The guineas coined by all the princes since King Charles II. have been of the same standard weight and fineness,  $44\frac{1}{2}$  in a pound troy of standard gold  $\frac{11}{12}$ fine : these have been constantly wearing ever since they have been coined; and in proportion to their wearing they are of less value.

If, therefore, the new guineas are below the value of a pound sterling in silver, standard weight, the old must be of less value still. Here then is another currency, that is, another pound sterling ; or indeed, more properly speaking, there are as many different pounds sterling as there are guineas of different weights. This is not all; the money-jobbers having carried off all the weighty silver, that which is worn with use, and reduced even below the standard of gold, forms one currency more, and totally destroys all determinate proportion between the money unit and the currencies which are supposed to represent it.

It may be asked, how, at this rate, any silver has remained in England? It is answered, that the few weighty shillings which still remain in circulation, have marvellously escaped the hands of the money-jobbers: and as to the rest, the rubbing and wearing of these pieces has done what the state might have done; that is to say, it has reduced them to their due proportion with the lightest gold.

The disorder, therefore, of the English coin has rendered the standard of a pound sterling quite uncertain. To say that it is 1718.7 grains of fine silver, is quite ideal. Who are paid in such pounds ? To say that it is 113 grains of pure gold, may also not be true; because there are many curreneics worse than the new guineas.

What then is the consequence of all this disorder? What effect has it upon the current value of a pound sterling ? And which way can the value of that be determined ?

The operations of trade bring value to an equation, notwithstanding the greatest irregularities possible; and

value over all the world by the means of foreign ex-Money. change. This is a kind of ideal scale for measuring the British coin, although it has not all the properties of that described above.

Exchange considers the pound sterling as a value determined according to the combination of the values of all the different currencies, in proportion as payments are made in the one or the other; and as debtors generally take care to pay in the worst species they can, it consequently follows, that the value of the pound sterling should fall to that of the lowest currency

Were there a sufficient quantity of worn gold and silver to acquit all bills of exchange, the pound sterling would come down to the value of them; but if the new gold be also necessary for that purpose, the value of it must he proportionably greater.

All these combinations are liquidated and compensated with one another, by the operations of trade and exchange; and the pound sterling, which is so different in itself, becomes thereby, in the eyes of commerce, a determinate unit; subject, however to variations, from which it never can be exempted.

Exchange, therefore, is one of the best measures for valuing a pound sterling, present currency. Here occurs a question :

Does the great quantity of paper money in England tend to diminish the value of the pound sterling?

We answer in the negative. Paper money is just as good as gold or silver money, and no better. The variation of the standard, as we have already said, must influence the interest of debtors and creditors proportionally everywhere. From this it follows, that all augmentation of the value of the money unit in the specie must hurt the debtors in the paper money; and all diminutions, on the other hand, must hurt the creditors in the paper money as well as everywhere else. The payments, therefore, made in paper money, never can contribute to the regulation of the standard of the pound sterling; it is the specie received in liquidation of that paper money which alone can contribute to mark the value of the British unit; because it is affixed to nothing else.

From this we may draw a principle, "That in countries where the money unit is entirely affixed to the coin, the actual value of it is not according to the legal standard of that coin, but according to the mean proportion of the actual worth of those currencies in which debts are paid.

From this we see the reason why the exchange between England and all other trading towns in Europe has long appeared so unfavourable. People calculate the real par, upon the supposition that a pound sterling is worth 1718.7 grains troy of fine silver, when in fact the currency is not perhaps worth 1638, the value of a new guinea in silver, at the market proportion of I to 14.5; that is to say, the currency is but 95.3 per cent. of the silver standard of the 43d of Elizabeth. No wonder then if the exchange be thought unfavourable.

From the principle we have just laid down, we may gather a confirmation of what we advanced concerning the cause of the advanced price of bullion in the English market.

When people buy bullion with current money at a VOL. XIV. Part I.

determinate price, that operation, in conjunction with Money. the course of exchange, ought naturally to mark the actual value of the pound sterling with great exact-

If therefore the price of standard bullion in the English market, when no demand is found for the exportation of the metals, that is to say, when paper is found for paper upon exchange, and when merchants versed in these matters judge exchange (that is remittances) to be at par, if then silver bullion cannot be bought at a lower price than 65 pence the ounce, it is evident that this bullion might be bought with 65 pence in shillings, of which 65 might be coined out of the pound troy English standard silver; since 65 per ounce implies 65 shillings for the 12 ounces or pound troy.

This plainly shows how standard silver bullion should sell for 65 pence the ounce, in a country where the ounce of standard silver in the coin is worth no more than 62; and were the market price of bullion to stand uniformly at 65 pence per ounce, that would show the value of the pound sterling to be tolerably fixed. All the heavy silver coin is now carried off; because it was intrinsically worth more than the gold it passed for in currency. The silver therefore which remains is worn down to the market proportion of the metals, as has been said; that is to say, 20 shillings in silver currency are worth 113 grains of fine gold, at the proportion of 1 to 14.5 between gold and silver. Now.

## as I is to 14.5, so is 113 to 1638:

so the 20 shillings current weigh but 1638 grains fine silver, instead of 1718.7, which they ought to do according to the standard.

Now let us speak of standard silver, since we are examining how far the English coin must be worn by

The pound troy contains 5760 grains. This, according to the standard, is coined into 62 shillings; consequently, every shilling ought to weigh 92.9 grains. Of such shillings it is impossible that ever standard bullion, should sell at above 62 pence per ounce. If therefore such bullion sells for 65 pence, the shillings with which it is bought must weigh no more than 88.64 grains standard silver; that is, they must lose 4.29 grains, and are reduced to I of a pound troy.

But it is not necessary that bullion be bought with shillings : no stipulation of price is ever made farther, than at so many pence sterling per ounce. Does not this virtually determine the value of such currency with regard to all the currencies in Europe? Did a Spaniard, a Frenchman, or a Dutchman, know the exact quantity of silver bullion which can be bought in the London market for a pound sterling, would he inform himself any farther as to the intrinsic value of that money unit? would be not understand the value of it far better from that circumstance than by the course of any exchange, since exchange does not mark the intrinsic value of money, but only the value of that money transported from one place to another ?

The price of bullion, therefore, when it is not influenced by extraordinary demand, (such as for the payment of a balance of trade, or for making an ex-Ss traordinary

Money. traordinary provision of plate), but when it stands at what every body knows to be meant by the common market price, is a very tolerable measure of the value of the actual money standard in any country.

If it be therefore true, that a pound sterling eannot purchase above 1638 grains of fine silver bullion, it will require not a little logie to prove that it is really, or has been for these many years, worth any more ; notwithstanding that the standard weight of it in England is regulated by the laws of the kingdom at 1718.7 grains of fine silver.

If to this valuation of the pound sterling drawn from the price of bullion, we add the other drawn from the course of exchange; and by this we find that when paper is found for paper upon exchange, a pound sterling cannot purchase above 1638 grains of fine silver in any country in Europe : upon these two authorities we may very safely conclude (as to the matter of fact at least) that the pound sterling is not worth more, either in London or in any other trading city ; and if this be the ease, it is just worth 20 shillings of 65 to the pound troy.

If therefore the mint were to coin shillings at that rate, and pay for silver bullion at the market price, that is, at the rate of 65 pence per ounce in those new coined shillings, they would be in proportion to the gold; silver would be carried to the mint equally with gold, and would be as little subject to be exported or melted down.

It may be inquired in this place, how far the coining the pound troy into 65 shillings is contrary to the laws of England ?

The moment a state pronounces a certain quantity of gold to be worth a certain quantity of silver, and orders these respective quantities of each metal to be received as equivalents of each other, and as lawful money in payments, that moment gold is made a standard as much as silver. If therefore too small a quantity of gold be ordered or permitted to be considered as an equivalent for the unit, the silver standard is from that moment debased ; or indeed, more properly speaking, all silver money is from that moment proscribed; for who, from that time, will ever pay in silver, when he can pay cheaper in gold ? Gold, therefore, by such a law, is made the standard, and all deelarations to the contrary are against the matter of fact.

Were the king, therefore, to coin silver at 65 shillings in the pound, it is demonstration, that by such an aet he would commit no adulteration upon the stand-The ard: the adulteration is already committed. standard has descended to where it is by slow degrees, and by the operation of political eauses only; and nothing prevents it from falling lower but the standard of the gold coin. Let guineas be now left to seek their value as they did formerly, and let light silver continue to go by tale, we shall see the guineas up at 30 shillings in 20 years time, as was the case in 1695.

It is as absurd to say that the standard of Queen Elizabeth has not been debased by enacting that the English unit shall be acquitted with 113 grains of fine gold, as it would be to affirm that it would not be debased from what it is at present by enacting that a pound of butter should everywhere be received in pay-

ment for a pound sterling; although the pound ster- Moner ling should continue to consist of three ounces, 17 penny-weights, and 10 grains of standard silver, according to the statute of the 43d of Elizabeth. In that case, most debtors would pay in butter; and silver would, as at present, acquire a conventional value as a metal, but would be looked upon no longer as a standard, or as money.

If therefore, by the law of England, a pound sterling must consist of 1718.7 grains troy of fine silver ; by the law of England also, 113 grains of gold must be of the same value : but no law can establish that proportion ; consequently, in which ever way a reformation be brought about, some law must be reversed ; consequently, expediency, and not compliance with law, must be the motive in reforming the abuse.

From what has been said, it is not at all surprising that the pound sterling should in fact be reduced nearly to the value of the gold. Whether it ought to be kept at that value is another question. All that we here decide is, that coining the pound troy into 65 shillings would restore the proportion of the metals, and render both species common in circulation. But restoring the weight and proportion of the coin is not the difficulty which prevents a reformation of the English eoinage.

## 8. Circumstances to be attended to in a New Regulation of the British Coin.

To people who do not understand the nature of such operations, it may have an air of justice to support the unit at what is commonly believed to be the standard of Queen Elizabeth, viz. at 1718.7 grains of fine silver.

The regulating the standard of hoth silver and gold to II fine, and the pound sterling to four ounces standard silver, as it stood during the reign of Queen Mary I. has also its advantages, as Mr Harris has observed. It makes the crown-piece to weigh just one ounce, the shilling four pennyweights, and the penny eight grains: eonsequently, were the new statute to bear, that the weight of the coin should regulate its eurrency upon certain occasions, the having the pieces adjusted to certain aliquot parts of weight would make weighing easy, and would accustom the common people to judge of the value of money by its weight, and not by the stamp.

In that case, there might be a conveniency in striking the gold coins of the same weight with the silver; because the proportion of their values would then constantly be the same with the proportion of the metals. The gold crowns would be worth at present, 3l. 12s. 6d. the half-crowns 11. 16s. 3d. the gold shillings 14s. 6d. and the half 7s. 3d. This was anciently the practiee in the Spanish mints.

The interests within the state can be nowise perfectly protected, but by permitting conversions of value from the old to the new standard, whatever it be, and by regulating the footing of such conversions by act of parliament, according to circumstances.

For this purpose, we shall examine those interests which will chiefly merit the attention of government, when they form a regulation for the future of acquitting

Money. ting permanent contracts already entered into. Such as may be contracted afterwards will naturally follow the new standard.

The landed interest is no doubt the most considerable in the nation. Let us therefore examine, in the first place, what regulations it may be proper to make, in order to do justice to this great class, with respect to the land tax on one hand, and with respect to their lessees on the other.

The valuation of the lands of England was made many years ago, and reasonably ought to be supported at the real value of the pound sterling at that time, according to the principles already laid down. The general valuation, therefore, of the whole kingdom will rise according to this scheme. This will be considered as an injustice; and no doubt it would be so, if for the future, the land tax be imposed as herectofore, without attending to this circumstance; but as that imposition is annual, as it is laid on by the landed interest itself, who compose the parliament, it is to be supposed that this great class will at least take care of their own interest.

Were the valuation of the lands to be stated according to the valuation of the pound sterling of 1718.7 grains of silver, which is commonly supposed to be the standard of Elizabeth, there would be no great injury done; this would raise the valuation only 5 per cent. and the land tax in proportion.

There is no class of inhabitants in all England so much at their ease, and so free from taxes, as the class of farmers. By living in the country, and by consuming the fruits of the earth without their suffering any alienation, they avoid the effect of many excises, which, by those who live in corporations, are felt upon many articles of their consumption, as well as on those which are immediately loaded with these impositions. For this reason it will not, perhaps, appear unreasonable, if the additional 5 per cent. on the land tax were thrown upon this class, and not upon the landlords.

With respect to leases, it may be observed, that we kave gone upon the supposition that the pound sterling in the year 1728 was worth 1718.7 grains of fine silver, and 113 grains of fine gold.

There would be no injustice done the lessees of all the lands in the kingdom, were their rents to be fixed at the mean proportion of these values. We have observed how the pound sterling has been gradually diminishing in its worth from that time by the gradual rise of the silver. This mean proportion, therefore, will nearly answer to what the value of the pound sterling was in 1743; supposing the rise of the silver to have been uniform.

It may be farther alleged in favour of the landlords, that the gradual debasement of the standard has been more prejudicial to their interest in letting their lands, than to the farmers in disposing of the fruits of them. Proprietors cannot so easily raise their rents upon new leases, as farmers can raise the prices of their grain according to the debasement of the value of the currency.

The pound sterling, thus regulated at the mean proportion of its worth, as it stands at present, and as it stood in 1728, may be realized in 1678.6 grains of fine eilver, and 115.76 grains fine gold; which is 2.4 per cent. above the value of the present currency. No injury, therefore, would be done to lessees, and no unreasonable gain would accrue to the landed interest, in appointing conversions of all land rents at  $2\frac{1}{2}$  per cent. above the value of the present currency.

Without a thorough knowledge of every circumstance relating to Great Britain, it is impossible to lay down any plan. It is sufficient here briefly to point out the principles upon which it must be regulated.

The next interest to be considered is that of the nation's creditors. The right regulation of their concerns will have a considerable influence in establishing public eredit upon a solid basis, by making it appear to all the world, that no political operation upon the money of Great Britain can in any respect either benefit or prejudice the interest of those who lend their money upon the faith of the nation. The regulating also the interest of so great a body, will serve as a rule for all creditors who are in the same circumstances, and will upon other accounts be productive of greater advantages to the nation in time coming.

In 1749, a new regulation was made with the public creditors, when the interest of the whole redeemable national debt was reduced to 3 per cent. This circumstance infinitely facilitates the matter with respect to this elass, since by this innovation of all former contracts, the whole national debt may be considered as contracted at, or posterior to, the 25th December 1749.

Were the state, by an arbitrary operation upon money (which every reformation must be), to diminish the value of the pound sterling in which the parliament at that time bound the nation to acquit those eapitals and the interest upon them, would not all Europe say, That the British parliament had defrauded their creditors? If therefore the operation proposed to be performed should have a contrary tendency, viz. to augment the value of the pound sterling with which the parliament at that time bound the nation to acquit those eapitals and interests, must not all Europe also agree, that the British parliament had defrauded the nation ?

The convention with the ancient creditors of the state, who, in consequence of the debasement of the standard, might have justly claimed an indemnification for the loss upon their capitals, lent at a time when the pound sterling was at the value of the heavy silver, removes all causes of complaint from that quarter. There was in the year 1749 an innovation in all their contracts; and they are now to be considered as creditors only from the 25th of December of that year.

Let the value of the pound sterling be inquired into during one year preceding and one posterior to the transaction of the month of December 1749. The great sums borrowed and paid back by the nation during that period, will furnish data sufficient for that calculation. Let this value of the pound be specified in troy grains of fine silver and fine gold bullion, without mentioning any denomination of money according to the exact proportion of the metals at that time. And let this pound be called the *pound of national credit*.

This first operation being determined, let it be enacted, that the pound sterling, by which the state is to S s 2 borrow 324 Money.

borrow for the future, and that in which the creditors are to be paid, shall be the exact mean proportion between the quantities of gold and silver above specified, according to the actual proportion of the metals at the time such payments shall be made: or that the sums shall be borrowed or acquitted, one half in gold and one half in silver, at the respective requisitions of the creditors or of the state, when borrowing. All debts contracted posterior to 1749 may be made liable to conversions.

The consequence of this regulation will be the insensible establishment of a bank money. Nothing would be more difficult to establish, by a positive revolution, than such an invariable measure; and nothing will be found so easy as to let it establish itself by its own ad-vantages. This bank money will be liable to much vantages. fewer inconveniences than that of Amsterdam. There the persons transacting must be upon the spot; herc, the sterling currency may, every quarter of a year, be adjusted by the exchequer to this invariable standard, for the benefit of all debtors and creditors who incline to profit of the stability of this measure of value.

This scheme is liable to no inconvenience from the variation of the metals, let them be ever so frequent or hard to be determined; because upon every occasion where there is the smallest doubt as to the actual proportion, the option competent to creditors to be paid half in silver and half in gold will remove.

Such a regulation will also have this good effect, that it will give the nation more just ideas of the nature of money, and consequently of the influence it. ought to have upon prices.

If the value of the pound sterling shall be found to have been by accident less in December 1749 than it is at present; or if at present the currency be found below what it has commonly been since 1749; in justice to the creditors, and to prevent all complaints, the nation may grant them the mean proportion of the value of the pound sterling from 1749 to 1760, or any other which may to parliament appear reasonable.

This regulation must appear equitable in the eyes of all Europe; and the strongest proof of it will be, that it will not produce the smallest effect prejudicial to the interest of the foreign creditors. The course of exchange with regard to them will stand precisely as before.

A Dutch, French, or German creditor, will receive the same value for his interest in the English stocks as heretofore. This must silence all clamours at home, being the most convincing proof, that the new regulation of the coin will have made no alteration upon the real value of any man's property, let him be debtor. or creditor.

The interest of every other denomination of creditors, whose contracts are of a fresh date, may be regulated upon the same principles. But where debts are of an old standing, justice demands, that attention be had to the value of money at the time of contracting. Nothing but the stability of the English coin, when compared with that of other nations, can make such a proposal appear extraordinary. Nothing is better known in France than this stipulation added to obli-

gations, Argent au cours de ce jour ; that is to say, That Mone the sum shall be paid in coin of the same intrinsic value with what has been lent. Why should such a clause be thought reasonable for guarding people against arbitrary operations upon the numerary value of the coin, and not be found just upon every occasion where the numerary value of it is found to be changed, let the cause be what it will ?

The next interest we shall examine is that of trade. When men have attained the age of 21, they have no more occasion for guardians. This may be applied to traders; they can parry with their pen every inconvenience which may result to other people from the changes upon money, provided only the laws permit them to do themselves justice with respect to their engagements. This class domands no more than a right to convert all reciprocal obligations into denominations of coin of the same intrinsic value with those they have contracted in.

The next interest is that of buyers and sellers; that is, of manufacturers with regard to consumers, and of servants with respect to those who hire their personal service.

The interest of this class requires a most particular attention. They must, literally speaking, be put to school, and taught the first principles of their trade, which is buying and selling. They must learn to judge of price by the grains of silver and gold they receive : they are children of a mercantile mother, however warlike the father's disposition. If it be the interest of the state that their bodies be rendered robust and active, it is no less the interest of the state that their minds be instructed in the first principles of the trade they exercise

For this purpose, tables of conversion from the old standard to the new must be made, and ordered to be put up in every market, in every shop. All duties, all excises, must be converted in the same manner. Uniformity must be made to appear everywhere. The smallest deviation from this will be a stumbling block to the multitude.

Not only the interest of the individuals of the class we are at present considering, demands the nation's care and attention in this particular; but the prosperity of trade, and the wellbeing of the nation, are also deeply intcrested in the execution,

The whole delicacy of the intricate combinations of commerce depends upon a just and equable vibration of prices, according as circumstances demand it. The more, therefore, the industrious classes are instructed in the principles which influence prices, the more easily will the machine move. A workman then learns to sink his price without regret, and can raise it without avidity. When principles are not understood, prices cannot gently fall, they must be pulled down : and merchants dare not suffer them to rise, for fear of abuse, even although the perfection of an infant manufacture should require it.

The last interest is that of the bank of England, which naturally must regulate that of every other.

Had this great company followed the example of other banks, and established a bank-money of an invariable standard as the measure of all their debts and credits, they would not have been liable to any inconvenience upon a variation of the standard.

The bank of England was projected about the year 1694, at a time when the current money of the nation was in the greatest disorder, and government in the greatest distress both for money and for credit. Commerce was then at a very low ebb; and the only, or at least the most profitable, trade of any, was jobbing in coin, and carrying backwards and forwards the precious metals from Holland to England. Merchants profited also greatly from the effects which the utter disorder of the coin produced upon the price of merehandise.

Ioney.

At such a juncture the resolution was taken to make a new coinage; and upon the prospect of this, a company was found, who, for an exclusive charter to hold a bank for 13 years, willingly lent the government upwards of a million sterling at 8 per cent. (in light money we suppose), with a prospect of being repaid both interest and capital in heavy. This was not all : part of the money lent was to be applied for the establishment of the bank; and no less than 4000l. a-year was allowed to the company, above the full interest, for defraying the charge of the management.

Under such eireumstances the introduction of bankmoney was very superfluous, and would have been very impolitie. That invention is ealculated against the raising of the standard : but here the hank profited of that rise in its quality of creditor for money lent; and took eare not to commence debtor by circulating their paper until the effect of the new regulation took place in 1695; that is, after the general re-coinage of all the elipped silver.

From that time till now, the bank of England has been the basis of the nation's credit, and with great reason has been constantly under the most intimate protection of every minister.

The value of the pound sterling, as we have seen, has been declining ever since the year 1601, the standard being fixed to silver during all that century, while the gold was constantly rising. No sooner had the proportion taken another turn, and silver begun to rise, than the government of England threw the standard virtually upon the gold, by regulating the value of the guineas at the exact proportion of the market. By these operations, however, the hank has constantly been a gainer (in its quality of debtor) upon all the paper in circulation; and therefore has lost nothing by not having established a bank-money.

The interest of this great company being established upon the principles we have endeavoured to explain, it is very evident, that the government of England never will take any step in the reformation of the eoin which in its consequences can prove hurtful to the bank. Such a step would be contrary both to justice and to common sense. To make a regulation which, by raising the standard, would prove beneficial to the public creditors, to the prejudice of the bank (which we may call the *public debtor*), would be an operation upon public eredit like that of a person who is at great pains to support his house by props on all sides, and who at the same time blows up the foundation of it with gunpowder.

We may therefore conclude, that with regard to the bank of England, as well as every other private banker, the notes which are constantly payable upon demand must be made liable to a conversion at the actual

3

value of the pound sterling at the time of the new re- Money.

## That the bank will gain by this, is very certain; but the circulation of their notes is so swift, that it would be absurd to allow to the then possessors of them that indemnification which naturally should be shared by all those through whose hands they have passed, in proportion to the debasement of the standard during the time of their respective possession.

Besides these considerations, which are in common to all states, the government of Great Britain has one peculiar to itself. The interest of the hank, and that of the creditors, are diametrically opposite; every thing which raises the standard hurts the bank; every thing which can sink it hurts the creditors : and upon the right management of the one and the other, depends the solidity of public eredit. For these reasons, without the most certain prospect of conducting a restitution of the standard to the general advantage as well as approbation of the nation, no minister will probably ever undertake so dangerous an operation.

We shall now propose an expedient which may remove at least some of the inconveniences which would result from so extensive an undertaking as that of regulating the respective interests in Great Britain by a positive law, upon a change in the value of their money of account.

Suppose then, that, before any change is made in the coin, government should enter into a transaction with the public creditors, and ascertain a permanent value for the pound sterling for the future, specified in a determined proportion of the fine metals in common bullion, without any regard to money of account, or to any coin whatever.

This preliminary step being taken, let the intended alteration of the standard be proclaimed a certain time before it is to commence. Let the nature of the change be clearly explained, and let all such as are engaged in contracts which are dissolvable at will upon the prestations stipulated, be acquitted between the parties, or innovated as they shall think proper; with certification, that, posterior to a certain day, the stipulations formerly entered into shall be binding according to the denominations of the money of account in the new standard.

As to permanent contracts, which cannot at once be fulfilled and dissolved, such as leases, the parliament may cither prescribe the methods and terms of conversion; or a liberty may be given to the parties to annul the contract, upon the debtor's refusing to perform his agreement according to the new standard. Contracts, on the other hand, might remain stable, with respect to creditors who would be satisfied with payments made on the footing of the old standard. If the rise intended should not be very considerable, no great injustice can follow such a regulation.

Annuities are now thoroughly understood, and the value of them is brought to so nice a calculation, that nothing will be easier than to regulate these upon the footing of the value paid for them, or of the subject affected hy them. If by the regulation, land rents are made to rise in denomination, the annuities charged upon them ought to rise in proportion; if in intrinsic\_value, the annuity should remain as it was. 9. Regulations which the Principles of this Inquiry point out as expedient to be made by a new Statute for regulating the British Coin.

Let us now examine what regulations it may be proper to make by a new statute concerning the coin of Great Britain, in order to preserve always the same exact value of the pound sterling realized in gold and in silver, in spite of all the incapacities inherent in the metals to perform the functions of an invariable scale or measure of value.

1. The first point is to determine the exact number of grains of fine gold and fine silver which are to compose it, according to the then proportion of the metals in the London market.

2. To determine the proportion of these metals with the pound troy; and in regard that the standard of gold and silver is different, let the mint price of both metals be regulated according to the pound troy fine.

3. To fix the mint price within certain limits; that is to say, to leave to the king and council, by proclatnation, to carry the mint price of bullion up to the value of the coin, as is the present regulation, or to sink it to per cent. below that price, according as government shall incline to impose a duty upon-coinage.

4. To order, that silver and gold coin shall be struck of such denominations as the king shall think fit to appoint; in which the proportion of the metals above determined shall be constantly observed through every denomination of the coin, until necessity shall make a new general coinage unavoidable.

5. To have the number of grains of the fine metal in every piece marked upon the exergue, or upon the legend of the coin, in place of some initial letters of titles, which not one person in a thousand can decypher; and to make the coin of as compact a form as possible, diminishing the surface of it as much as is consistent with beauty.

6. That it shall be lawful for all contracting parties to stipulate their payments either in gold or silver coin, or to leave the option of the species to one of the parties.

7. That where no particular stipulation is made, creditors shall have power to demand payment, half in one species, half in the other; and when the sum cannot fall equally into gold and silver coins, the fractions to be paid in silver.

8. That in buying and selling, when no particular species has been stipulated, and when no act in writing has intervened, the option of the species shall be competent to the buyer.

9. That all sums paid or received by the king's receivers, or by bankers, shall be delivered by weight, if demanded.

10. That all money which shall be found under the legal weight, from whatever cause it may proceed, may be rejected in every payment whatsoever; or if offered in payment of a debt above a certain sum, may be taken according to its weight, at the then mint price, in the option of the creditor.

11. That no penalty shall be incurred by those who melt down or export the nation's coin; but that washing, clipping, or diminishing the weight of any part

2

of it shall be deemed felony, as much as any other Mone theft, if the person so degrading the coin shall afterwards make it circulate for lawful money.

To prevent the inconveniences proceeding from the wariation in the proportion between the metals, it may be provided,

12. That upon every variation of proportion in the market price of the metals, the price of both shall be changed, according to the following rule:

Let the price of the pound troy fine gold in the coin be called G.

Let the price of ditto in the silver be called S.

Let the new proportion between the market price of the metals be called *P*.

Then state this formula :

 $\frac{G}{2P} + \frac{S}{2} =$ to a pound troy fine silver, in sterling currency.

 $\frac{S}{2} + P + \frac{G}{2} =$  to a pound troy fine gold, in sterling currency.

This will be a rule for the mint to keep the price of the metals constantly at par with the price of the market; and coinage may be imposed, as has been described, by fixing the mint price of them at a certain rate below the value of the fine metals in the coin.

13. As long as the variation of the market price of the metals shall not carry the price of the rising metal so high as the advanced price of the coin above the bullion, no alteration need be made on the denomination of either species.

14. So soon as the variation of the market price of the metals shall give a value to the rising species, above the difference between the coin and the bullion; then the king shall alter the denominations of all the coin, silver and gold, adding to the coins of the rising metal exactly what is taken from those of the other. An example will make this plain :

Let us suppose that the coinage has been made according to the proportion of 14.5 to 1; that 20 shillings, or 4 crown-pieces, shall contain, in fine silver, 14.5 times as many grains as the guinea, or the gold pound, shall contain grains of fine gold. Let the new proportion of the metals be supposed to be 14 to 1. In that case, the 20 shillings, or the 4 crowns, will contain  $\frac{1}{20}$  more value than the guinea. Now since there is no question of making a new general coinage upon every variation, in order to adjust the proportion of the metals in the weight of the coins, that proportion might be adjusted by changing their respective denominations according to this formula :

Let the 20 shillings, or 4 crowns, in coin, be called S. Let the guinea be called G. Let the difference between the old proportion and the new, which is  $\frac{1}{2}$  be called P. Then say.

$$S - \frac{P}{2} = a$$
 pound sterling, and  $G + \frac{P}{2} = a$  pound

sterling.

By this it appears that all the silver coin must be raised in its denomination  $\frac{1}{3B}$ , and all the gold coin must be lowered in its denomination  $\frac{1}{3B}$ ; yet still S+G will be equal to two pounds sterling, as before, whether

326 Money ther they be considered according to the old or according to the new denominations.

But it may be observed, that the imposition of coinage rendering the value of the coin greater than the value of the bullion, that circumstance gives a certain latitude in fixing the new denominations of the coin, so as to avoid minute fractions. For, providing the deviation from the exact proportion shall fall within the advanced price of the coin, no advantage can be taken by melting down one species preferably to another; since, in either case, the loss incurred by melting the coin must be greater than the profit made upon selling the bullion. The mint price of the metals, however, may be fixed exactly, that is, within the value of a farthing upon a pound of fine silver or gold. This is easily reckoned at the mint; although upon every piece in common circulation the fractions of farthings would be inconvenient.

15. That notwithstanding of the temporary variations made upon the denomination of the gold and silver coins, all contracts formerly entered into, and all stipulations in pounds, shillings, and pence, may continue to be acquitted according to the old denominations of the coins, paying one half in gold and onehalf in silver : unless in the case where a particular species has been stipulated; in which case, the sums must be paid according to the new regulation made upon the denomination of that species, to the end that neither profit or loss may result to any of the partics.

16. That notwithstanding the alterations on the mint price of the metals, and in the denomination of the coins, no change shall be made upon the weight of the particular pieces of the latter, except in the case of a general re-coinage of one denomination at least : that is to say, the mint must not coin new guineas, crowns, &c. of a different weight from those already in currency, although by so doing the fractions might be avoided. This would occasion confusion, and the remedy would cease to be of any use upon a new change in the proportion of the metals. But it may be found convenient, for removing the small fractions in shillings and sixpences, to recoin such denominations altogether, and to put them to their integer numbers of twelve and of six pence, without changing in any respect their proportion of value to all other denominations of the coin : this will be no great expence, when the bulk of the silver coin is put into 5 shilling pieces.

By this method of changing the denomination of the coin, there never can result any alteration in the value of the pound sterling, and although fractions

of value may now and then be introduced, in order to Money. prevent the abuses to which the coin would otherwise " be exposed by the artifice of those who melt it down, yet still the inconvenience of such fractions may be avoided in paying, according to the old denominations, in both species, by equal parts. This will also prove demonstratively, that no change is thereby made in the true value of the national unit of money.

17. That it be ordered, that shillings and sixpences shall only be current for 20 years; and all other coins, both gold and silver, for 40 years, or more. For ascertaining which term, there may be marked, upon the exergue of the coin, the last year of their currency, in place of the date of their fabrication. This term elapsed, or the date effaced, that they shall have no more currency whatsoever; and, when offered in payment, may be received as bullion at the actual price of the mint, or refused, at the option of the creditor.

18. That no forcign coin shall have any legal currency, except as bullion at the mint price.

By these and the like regulations may be prevented, 1mo, The melting or exporting of the coin in general. 2do; The melting or exporting one species, in order to sell it as bullion at an advanced price. 3tio, The profit in acquitting obligations preferably in one species to another. 4to, The degradation of the standard, by the wearing of the coin, or by a change in the proportion between the metals. 5to, The circulation of the coin below the legal weight. 6to, The profit that other nations reap by paying their debts more cheaply to Great Britain than Great Britain can pay her's to them.

And the great advantage of it is, that it is an uniform plan, and may serve as a perpetual regulation, . compatible with all kinds of denominations of coins, variations in the proportion of the metals, and with the imposition of a duty upon coinage, or with the prcserving it free; and further, that it may in time be adopted by other nations, who will find the advantage of having their money of account preserved perpetually at the same value, with respect to the denominations of all foreign money of account established on the same principles. — But for a fuller discussion of this subject we must refer our readers to the articles BANKING and-EXCHANGE in the SUPPLEMENT, and to Mr Wheatley's Essay on the Theory of Money and Principles of Commerce, London 1807; and to a Treatise on the Coinsof the Realm, in a letter to the king, by the Earl of Liverpool, London 1805.

The number of grains of fine metal in every coin is sought for in the regulations of the mint of the country where it is coined, and is expressed in the ZI grains in use in that mint. From that weight it is converted into those of other countries according to the following proportions : 2840 Troy grains, 4676.35 Paris grains, 5192.8 Holland aces or mains and a

|                 |                                                                                                                                                                                                                                                                     | M                                                        | ONEY.                                                                                             | Toronto and                                                                                             |
