One method of preventing the necessity of surging, by placing a horizontal roller beneath the messenger when it first enters on the capstan, adds considerably to the labour in turning the capstan, and the great friction which the messenger must suffer, must occasion a very great wear and injury to the messenger.

Another method to prevent surging was, that for which Mr Plucknet obtained a patent. In this way a number of upright lifters, placed round the capstan, were made to rise in succession as the capstan turned round by a circular inclined plane placed beneath them; a method Mr Boswell thinks superior to the former; but still the wear of the messenger from the lateral friction in rising against the whelps of the capstan remains undiminished.

A third method proposed by Captain Hamilton, left the lateral friction, and wear of the messenger against the whelps of the capstan, as great as in the others, having also the inconvenience of causing the coils to become loose as they ascend, the upper part of the barrel being nearly one third less in the diameter than the lower part.

In Mr Boswell's method of preventing the necessity of surging, none of the lateral friction of the messenger or cable against the whelps of the capstan, can possibly take place, and of course the wear of the messenger occasioned thereby will be entirely avoided, while it performs its purpose with a less moving power than any of them.

His method consists in the simple addition of a second smaller barrel or capstan of less dimensions to the large one; beside which it is to be placed in a similar manner, and which need not in general exceed the size of a half barrel cask. The coils of the messenger are to be passed alternately round the large capstan and this small barrel, but with their direction reversed in the different barrels, so that they may cross each other in the intervals between the barrels, in order to have the more extensive contact with, and better gripe on each barrel. To keep the coils distinct, and prevent their touching each other in passing from one barrel to the other, projecting rings are fastened round each barrel at a distance from each other equal to about two diameters of the messenger, and the thickness of the ring. Those rings should be so fixed on the two barrels that those on one barrel should be exactly opposite the middle of the intervals between those on the other barrel; the only circumstance which requires particular attention in the construction of this capstan. The rings should project about as much as the messenger from the barrels, which may be formed with whelps, and in every other respect, not before mentioned, in the usual manner for capstan barrels. The small barrel should be furnished with falling palls as well as the large one; a fixed iron spindle ascending from the deck will be the best for it, as it will take up less room. The spindle may be secured below the deck, so as to bear any strain, as the small barrel need not be much above half the height of the large barrel; the capstan bars can easily pass over it in heaving round, when it is thought fit to use capstan bars on the same deck with the small barrel. As two turns of the messenger round both barrels will be at least equivalent to three turns round the common capstan, it will scarcely ever be necessary to use more than four turns round the two barrels.

That which prevents the lateral friction of the messenger in Mr Boswell's double capstan is, that in it each coil is kept distinct from the rest, and must pass on to the second barrel before it can gain the next elevation on the first, by which no one coil can have any influence in raising or depressing another; and what each separate coil descends in a single revolution it regains as much as is necessary in its passage between the barrels when in the air, and free from all contact with any part of the apparatus, it attains a higher elevation without a possibility of friction or wear.

It is equally applicable in large and in smaller vessels, in the former of which messengers are necessary, from the size of the cables; but in the latter also, where cables can be managed with the same ease as messengers. The same principle may be also easily applied to windlasses, by having a small horizontal barrel placed parallel to the body of the windlass, and having both fitted with rings in the same way as is proposed for the capstan. The place for the small horizontal barrel is forward, just before the windlass, and it should also be furnished with catch polls.

Besides the advantages now stated, the improved capstan is simple in its construction, can be fitted up at small expence, is easily repaired, and requires but little room.

A represents the common capstan; B, another of smaller dimensions; C, the coils of the messenger passing alternately round the large and small capstans, but with the direction reversed on the different barrels, so that they may cross each other in the interval between them; DDDD, are projecting rings round each barrel, so fixed on the two barrels, that those on one barrel should be exactly opposite the middle of the intervals between those on the other barrel. Plate cccexciv.

Machine for measuring a SHIP'*s Way*.—We have already described a variety of machines or instruments which have been proposed for this purpose under the article LOG. In this place, therefore, we shall confine ourselves to the machine invented by Francis Hopkinson, Esq. Judge of the Admiralty in Pennsylvania.—After having shown the fallacies to which the common log, and also that particular kind of instrument invented by M. Saumarez, are liable, he proceeds to describe his own machine as follows: *Transactions of the American Philosophical Society*, vol. ii. p. 160.

This machine, in its most simple form, is represented by fig. 5. wherein AB is a strong rod of iron moveable on the fulcrum C. D is a thin circular palate of brass rivetted to the lower extremity of the rod. E a horizontal arm connected at one end with the top of the rod AB by a moveable joint F, and at the other end with the bottom of the index H, by a like moveable joint G. H is the index turning on its centre I, and travelling over the graduated arch K; and L is a strong spring, bearing against the rod AB, and constantly counteracting the pressure upon the palate D. Plate cccclxxxiii. fig. 5.

The

Ship.

The rod AB should be applied close to the cut-water or stem, and should be of such a length that the palate D may be no higher above the keel than is necessary to secure it from injury when the vessel is aground, or sails in shoal water. As the bow of the ship curves inward towards the keel M, the palate D will be thrown to a distance from the bottom of the vessel, although the perpendicular rod to which it is annexed lies close to the bow above; and therefore the palate will be more fairly acted upon. The arm E should enter the bow somewhere near the hawse hole, and lead to any convenient place in the forecastle, where a smooth board or plate may be fixed, having the index H, and graduated arch K, upon it.

It is evident from the figure, that as the ship is urged forward by the wind, the palate D will be pressed upon by the resisting medium, with a greater or less force, according to the progressive motion of the ship; and this will operate upon the levers so as to immediately affect the index, making the least increase or diminution of the ship's way visible on the graduated arch: the spring L always counteracting the pressure upon the palate, and bringing back the index, on any relaxation of the force impressed.

This machine is advantageously placed at the bow of the ship, where the current first begins, and acts fairly upon the palate, in preference to the stern, where the tumultuous closing of the water causes a wake, visible to a great distance. The palate D is sunk nearly as low as the keel, that it may not be influenced by the heaping up of the water, and the dashing of the waves at and near the water line. The arch K is to ascertain how many knots or miles she would run in one hour at her then rate of sailing. But the graduations on this arch must be unequal; because the resistance of the spring L will increase as it becomes more bent, so that the index will travel over a greater space from one to five miles than from five to twelve. Lastly, The palate, rod, spring, and all the metallic parts of the instrument, should be covered with a strong varnish, to prevent rust from the corrosive quality of the salt water and sea-air.

This machine may be considerably improved as follows: Let the rod or spear AB (fig. 5.) be a round rod of iron or steel, and instead of moving on the fulcrum or joint, as at C, let it pass through and turn freely in a socket, to which socket the moveable joint must be annexed, as represented in fig. 6. The rod must have a shoulder to bear on the upper edge of the socket, to prevent its slipping quite down. The rod must also pass through a like socket at F, fig. 5. The joint of the lower socket must be fixed to the bow of the ship, and the upper joint or socket must be connected with the horizontal arm E. On the top of the uppermost socket let there be a small circular plate, bearing the 32 points of the mariner's compass; and let the top of the rod AB come through the centre of this plate, so as to carry a small index upon it, as is represented in fig. 7. This small index must be fixed to the top of the rod on a square, so that by turning the index round the plate, the rod may also turn in the sockets, and of course carry the palate D round with it; the little index always pointing in a direction with the face of the palate. The small compass plate should not be fastened to the top of the socket, but only fitted tightly on, that it may be moveable at pleasure. Suppose then the intended port to bear S. W. from the place of departure, the palate must be turned on the socket till the south-west point therein looks directly to the ship's bow; so that the south-west and north-east line on the compass plate may be precisely parallel with the ship's keel, and in this position the plate must remain during the whole voyage. Suppose, then, the ship to be sailing in the direct course of her intended voyage, with her bowsprit pointing south-west. Let the little index be brought to the south-west point on the compass plate, and the palate D will necessarily present its broad face toward the port of destination; and this it must always be made to do, be the ship's course what it may. If, on account of unfavourable winds, the ship is obliged to deviate from her intended course, the little index must be moved so many points from the south-west line of the compass plate as the compass in the binnacle shall show that she deviates from her true course; so that in whatever direction the ship shall sail, the palate D will always look full to the south-west point of the horizon, or towards the port of destination, and consequently will present only an oblique surface to the resisting medium, more or less oblique as the ship deviates more or less from the true course of her voyage. As, therefore, the resistance of the water will operate less upon the palate in an oblique than in a direct position, in exact proportion to its obliquity, the index H will not show how many knots the vessel runs in her then course, but will indicate how many she gains in the direct line of her intended voyage.—Thus, in fig. 9. if the ship's course lies in the direction of the line AB, but she can sail by the wind no nearer than AC; suppose, then, her progressive motion such as to perform AC equal to five knots or miles in an hour, yet the index H will only point to four knots on the graduated arch, because she gains no more than at that rate on the true line of her voyage, viz. from A to B. Thus will the difference between her real motion and that pointed out by the index be always in proportion to her deviation from her intended port, until she sails in a line at right angles therewith, as AD; in which case the palate would present only a thin sharp edge to the resisting medium, the pressure of which should not be sufficient to overcome the friction of the machine and the bearing of the spring L. So that at whatever rate the ship may sail on that line, yet the index will not be affected, showing that she gains nothing on her true course. In this case, and also when the vessel is not under way, the action of the spring L should cause the index to point at O, as represented by the dotted lines in fig. 5. and 8.

As the truth of this instrument must depend on the equal pressure of the resisting medium upon the palate D, according to the ship's velocity, and the proportionable action of the spring L, there should be a pin or screw at the joints C and F, so that the rod may be readily unshipped and taken in, in order to clean the palate from any foulness it may contract, which would greatly increase its operation on the index H, and thereby render the graduated arch false and uncertain.

Further, the spring L may be exposed too much to injury from the salt water, if fixed on the outside of the ship's bow. To remedy this, it may be brought under cover, by constructing the machine as represented by fig. 8. where AB is the rod, C the fulcrum or centre of

Fig. 5. Fig. 6. Fig. 7. Fig. 9. Fig. 8.

of its motion, D the palate, E the horizontal arm leading through a small hole into the forecastle; M is a strong chain fastened at one end to the arm E, and at the other to a rim or barrel on the wheel G, which by means of its teeth gives motion to the semicircle I and index H. The spring L is spiral, and enclosed in a box or barrel, like the main-spring of a watch. A small chain is fixed to, and passing round the barrel, is fastened by the other end to the fuzee W. This fuzee is connected by its teeth with the wheel G, and counteracts the motion of the palate D. N, N, are the two sockets through which the rod AB passes, and in which it is turned round by means of the little index R. S is the small compass plate, moveable on the top of the upper socket N. The plate S hath an upright rim round its edge, cut into teeth or notches, so that when the index R is a little raised up, in order to bring it round to any intended point, it may fall into one of these notches, and be detained there; otherwise the pressure of the water will force the palate D from its oblique position, and turn the rod and index round to the direction in which the ship shall be then sailing.—Should it be apprehended that the palate D, being placed so far forward, may affect the ship's steerage, or obstruct her rate of sailing, it should be considered that a very small plate will be sufficient to work the machine, as one of three or four inches in diameter would probably be sufficient, and yet not large enough to have any sensible effect on the helm or ship's way.

The greatest difficulty, perhaps, will be in graduating the arch K, (if the machine is constructed as in fig. 5.); the unequal divisions of which can only be ascertained by actual experiment on board of each ship respectively, inasmuch as the accuracy of these graduations will depend on three circumstances, viz. the position of the fulcrum C with respect to the length of the rod, the size of the palate D, and the strength or bearing of the spring L. When these graduations however, are once ascertained for the machine on board of any one vessel, they will not want any future alterations, provided the palate D be kept clean, and the spring L retains its elasticity,

But the unequal divisions of the graduated arch will be unnecessary, if the machine is constructed as in fig. 8.; for as the chain goes round the barrel L, and then winds through the spiral channel of the fuzee W, the force of the main spring must operate equally, or nearly so, in all positions of the index, and consequently the divisions of the arch K may in such case be equal.

After all, it is not expected that a ship's longitude can be determined to a mathematical certainty by this instrument. The irregular motions and impulses to which a ship is continually exposed, make such an accuracy unattainable perhaps by any machinery: But if it should be found, as we flatter ourselves it will on fair experiment, that it answers the purpose much better than the common log, it may be considered as an acquisition to the art of navigation.

It should be observed, that in ascertaining a ship's longitude by a time-piece, this great inconvenience occurs, that a small and trifling mistake in the time makes a very great and dangerous error in the distance run: Whereas the errors of this machine will operate no farther than their real amount; which can never be great or dangerous, if corrected by the usual observations made by mariners for correcting the common log.

A like machine, made in its simple form (as at fig. 5), so constructed as to ship and unship, might occasionally be applied alongside about midships, in order to ascertain the leeway; which, if rightly shown, will give the ship's precise longitude. As to sea currents, this and all other machines hitherto invented must be subject to their influence; and proper allowances must be made according to the skill and knowledge of the navigator.

Lastly, some discretion will be necessary in taking observations from the machine to be entered on the log-book: that is, the most favourable and equable moment should be chosen for the observation; not whilst the ship is rapidly descending the declivity of a wave, or is suddenly checked by a stroke of the sea, or is in the very act of plunging. In all cases, periods may be found in which a ship proceeds with a true average velocity; to discover which, a little experience and attention will lead the skilful mariner.

It has been observed of the machine now described, that an ingenious mechanic would probably construct it to better advantage in many respects. The author only meant to suggest the principle; experiment alone can point out the best method of applying it. He is sensible of at least one deficiency, viz. that the little index R, fig. 4. will not be strong enough to retain the palate D in an oblique position when the ship is sailing by the wind; more especially as the compass plate S, in whose notched rim the index R is to fall, is not fixed to, but only fitted tight on the socket N. Many means, however, might be contrived to remedy this inconvenience.

Ship-Wreck. A French author has lately proposed some methods of saving the lives of persons shipwrecked near the coast. He observes, that the most proper means for saving the crews of shipwrecked vessels is, to establish a rope of communication from them to the shore. To a bomb or cannon ball should be fastened the end of a rope, extended afterwards in a zig-zag direction before the mortar or cannon, or suspended on a piece of wood raised several feet. But as it was necessary to know if the cord would not break by the force of the explosion and the velocity of the motion, the author thought it proper to consult professional men. He accordingly wrote to some officers of the artillery in garrison at La Fere in France, and they almost all replied that the rope would infallibly break.

Not deeming this answer satisfactory, he happily conceived the idea of making the experiment on a small scale. He caused a piece of the barrel of a musket to be filed into the form of a small mortar of 18 lines in length internally; and having tied a packthread to a common ball of lead, he made an experiment which perfectly succeeded, as did many others which he afterwards repeated, even with the strongest charges of powder. This success he communicated to the officers of artillery, who replied, that there was a great difference between a quarter of an ounce of powder and four or five pounds employed for a bomb; and were still of opinion that the rope would break.

Having already made experiments, he was still disposed to doubt the truth of this assertion, and therefore tried a four-inch mortar with a ball of the same calibre, and 18 ounces of powder with a rope only three or four

four lines in diameter, and his success was equally flattering as before. These experiments were repeated by order of government at La Fere, four times with an eight-inch mortar, and three times with one of twelve inches, all of which happily succeeded. The same author goes on to observe;

"It ought to be remembered, that a vessel is never cast away, or perishes on the coast, but because it is driven thither against the will of the captain, and by the violence of the waves and the wind, which almost always blows from the sea towards the shore, without which there would be no danger to be apprehended: consequently in these circumstances, the wind comes always from the sea, either directly or obliquely, and blows towards the shore.

"1st, A common paper kite, therefore, launched from the vessel and driven by the wind to the shore, would be sufficient to save a crew of 1500 seamen, if such were the number of a ship of war. This kite would convey to the shore a strong packthread, to the end of which might be affixed a cord, to be drawn on board by means of the string of the kite; and with this cord a rope, or as many as should be necessary, might be conveyed to the ship.

"2d, A small balloon, of six or seven feet in diameter, and raised by rarefied air, would be also an excellent means for the like purpose. Being driven by the wind from the vessel to the shore, it would carry thither a string capable of drawing a cord with which several ropes might be afterwards conveyed to the vessel. Had not the discovery of Montgolfier produced any other benefit, it would be entitled on this account to be considered as of great importance.

"3dly, A sky-rocket, of a large diameter, would be of equal service. It would also carry, from the vessel to the shore a string capable of drawing a rope after it.

"Lastly, A fourth plan for saving the crew of a shipwrecked vessel, is that of throwing from the vessel into the sea an empty cask with a cord attached to it. The wind and the waves would drive the cask to the shore, and afford the means of establishing that rope of communication already mentioned."

The author just quoted says, that he announced his discovery in a French journal in January 1794. It is, however, to be observed, that the method he proposes of conveying a rope to the shore, by fastening it to a bullet or bomb, to be afterwards fired from a cannon or mortar, was proposed some years ago by a serjeant or officer of artillery at Woolwich, and it is said, similar experiments were made at Portsmouth and succeeded *.

* Phil. Mag. vol. iv. p. 247.

SHIRAUZ, See SCHIRAS.

SHIRE, is a Saxon word signifying a division; but a county, *comitatus*, of the same import, is plainly derived from *comes*, "the count of the Franks;" that is, the earl or alderman (as the Saxons called him) of the shire, to whom the government of it was entrusted. This he usually exercised by his deputy, still called in Latin *vice-comes*, and in English the *sheriff*, *shrieve*, or *shire-reeve*, signifying the "officer of the shire;" upon whom, in process of time, the civil administration of it totally devolved. In some counties there is an intermediate division between the shire and the hundred; as lathes in Kent and rapes in Sussex, each of them containing about three or four hundred a-piece. These had formerly their lathe-reeves and rape-reeves, acting in subordination to the shire-reeve. Where a county is divided into three of these intermediate jurisdictions, they are called *trithings*, which were anciently governed by a trithing reeve. These trithings still subsist in the large county of York, where, by an easy corruption, they are denominated *ridings;* the north, the east, and the west ridings.

SHIRL, SHORL, or COCKLE, a species of mineral. See SCHORL, MINERALOGY *Index*.

SHIRT, a loose garment, commonly of linen, worn next the body.—Some doubt the propriety of changing the linen when a person is sick. Clean linen promotes perspiration; and it may be renewed as often as the patient pleases, whether the disorder be of the acute or the chronical kind. Except during a crisis in fevers, whilst the patient is in a sweat, a change of linen, if well dried and warmed, may be daily used.

Shirts were not worn by the Jews, Greeks, or Romans, but their place was supplied by thin *tunicæ* of wool. The want of linen among the ancients made frequent washings and ablutions necessary.

SHIVER, a name given by miners to some of the strata which accompany coal. See SCHISTUS, MINERALOGY *Index*.

SHIVERS, in the sea language, names given to the little rollers, or round wheels of pulleys.

SHOAD, among miners, denotes a train of metalline stones, serving to direct them in the discovery of mines.

SHOAD-Stones, a term used by the miners of Cornwall and other parts of this kingdom, to express such loose masses of stone as are usually found about the entrances into mines, sometimes running in a straight course from the load or vein of ore to the surface of the earth.

These are stones of the common kinds, appearing to have been pieces broken from the strata or larger masses; but they usually contain mundic, or marcasitic matter, and more or less of the ore to be found in the mine. They appear to have been at some time rolled about in water, their corners being broken off, and their surface smoothed and rounded.

The antimony mines in Cornwall are always easily discovered by the shoad-stones, these usually lying up to the surface, or very nearly so; and the matter of the stone being a white spar, or debased crystal, in which the native colour of the ore, which is a shining bluish black, easily discovers itself in streaks and threads.

Shoad-stones are of so many kinds, and of such various appearances, that it is not easy to describe or know them; but the miners, to whom they are of the greatest use in the tracing or searching after new mines, distinguish them from other stones by their weight; for if very ponderous, though they look ever so much like common stones, there is great reason to suspect that they contain some metal. Another mark of them is their being spongy and porous; this is a sign of especial use in the tin countries; for the tin shoad-stones are often so porous and spongy, that they resemble large bodies thoroughly calcined. There are many other appearances of tin shoads, the very hardest and firmest stones often containing this metal.

When the miners, in tracing a shoad up hill, meet with such odd stones and earths that they know not well what to make of them, they have recourse to vanning, that is, they calcine and powder the stone, clay, or whatever else is supposed to contain the metal; and then

then washing it in an instrument, prepared for that purpose, and called a *vanning shovel*, they find the earthy matter washed away, and of the remainder, the stony or gravelly matter lies behind, and the metalline matter at the point of the shovel. If the person who performs this operation has any judgment, he easily discovers not only what the metal is that is contained in the shoad, but also will make a very probable guess at what quantity the mine is likely to yield of it in proportion to the ore.

SHOAL, in the sea language, denotes a place where the water is shallow; and likewise a great quantity of fishes, such as a *shoal of herrings*.

SHOCK, in *Electricity*. The effect of the explosion of a charged body, that is, the discharge of its electricity on any other body, is called the *electric shock*.

SHOE, a covering for the foot, usually of leather.

SHOES, among the Jews, were made of leather, linen, rush, or wood; those of soldiers were sometimes of brass or iron. They were tied with thongs which passed under the soles of the feet. To put off their shoes was an act of veneration; it was also a sign of mourning and humiliation: to bear one's shoes, or to untie the latchets of them, was considered as the meanest service.

Among the Greeks shoes of various kinds were used. Sandals were worn by women of distinction. The Lacedemonians wore red shoes. The Grecian shoes generally reached to the middle of the leg. The Romans used two kinds of shoes; the *calceus*, which covered the whole foot somewhat like our shoes, and was tied above with latchets or strings; and the *solea* or slipper, which covered only the sole of the foot, and was fastened with leathern thongs. The calceus was always worn along with the *toga* when a person went abroad: slippers were put on during a journey and at feasts, but it was reckoned effeminate to appear in public with them. Black shoes were worn by the citizens of ordinary rank, and white ones by the women. Red shoes were sometimes worn by the ladies, and purple ones by the coxcombs of the other sex. Red shoes were put on by the chief magistrates of Rome on days of ceremony and triumphs. The shoes of senators, patricians, and their children, had a crescent upon them which served for a buckle; these were called *calcei lunati*. Slaves wore no shoes; hence they were called *cretati* from their dusty feet. Phocion also and Cato Uticensis went without shoes. The toes of the Roman shoes were turned up in the point; hence they were called *calcei rostrati*, *repandi*, &c.

In the 9th and 10th centuries the greatest princes of Europe wore wooden shoes, or the upper part of leather and the sole of wood. In the reign of William Rufus, a great beau, Robert, surnamed *the horned*, used shoes with long sharp points, stuffed with tow, and twisted like a ram's horn. It is said, the clergy, being highly offended, declaimed against the long-pointed shoes with great vehemence. The points, however, continued to increase till, in the reign of Richard II. they were of so enormous a length that they were tied to the knees with chains, sometimes of gold, sometimes of silver. The upper parts of these shoes in Chaucer's time were cut in imitation of a church window. The long-pointed shoes were called *crackowes*, and continued in fashion for three centuries in spite of the bulls of popes, the decrees of councils, and the declamations of the clergy. At length the parliament of England interposed by an act A. D. 1463, prohibiting the use of shoes or boots with pikes exceeding two inches in length, and prohibiting all shoemakers from making shoes or boots with longer pikes under severe penalties. But even this was not sufficient: it was necessary to denounce the dreadful sentence of excommunication against all who wore shoes or boots with points longer than two inches. The present fashion of shoes was introduced in 1633, but the buckle was not used till 1670.

In Norway they use shoes of a particular construction, consisting of two pieces, and without heels; in which the upper leather sits close to the foot, the sole being joined to it by many plaits or folds.

The shoes or slippers of the Japanese, as we are informed by Professor Thunberg, are made of rice-straw woven, but sometimes for people of distinction of fine slips of ratan. The shoe consists of a sole, without upper leather or hind-piece; forwards it is crossed by a strap, of the thickness of one's finger, which is lined with linen; from the tip of the shoe to the strap a cylindrical string is carried, which passes between the great and second toe, and keeps the shoe fast on the foot. As these shoes have no hind-piece, they make a noise when people walk in them like slippers. When the Japanese travel, their shoes are furnished with three strings made of twisted straw, with which they are tied to the legs and feet, to prevent them from falling off. Some people carry one or more pairs of shoes with them on their journeys, in order to put on new, when the old ones are worn out. When it rains, or the roads are very dirty, these shoes are soon wetted through, and one continually sees a great number of worn-out shoes lying on the roads, especially near the brooks, where travellers have changed their shoes after washing their feet. Instead of these, in rainy or dirty weather they wear high wooden clogs, which underneath are hollowed out in the middle, and at top have a band across like a stirrup, and a string for the great toe; so that they can walk without soiling their feet. Some of them have their straw shoes fastened to these wooden clogs. The Japanese never enter their houses with their shoes on; but leave them in the entry, or place them on the bench near the door, and thus are always barefooted in their houses, so as not to dirty their neat mats. During the time that the Dutch live at Japan, when they are sometimes under an obligation of paying visits at the houses of the Japanese, their own rooms at the factory being likewise covered with mats of this kind, they wear, instead of the usual shoes, red, green, or black slippers, which, on entering the house, they pull off: however, they have stockings on, and shoes made of cotton stuff with buckles in them, which shoes are made at Japan, and can be washed whenever they are dirty. Some have them of black satin, in order to avoid washing them.

SHOE of an Anchor, a small block of wood, convex on the back, and having a small hole, sufficient to contain the point of the anchor fluke, on the foreside. It is used to prevent the anchor from tearing or wounding the planks on the ship's bow, when ascending or descending; for which purpose the shoe slides up and down along the bow between the fluke of the anchor and the planks, as being pressed close to the latter by the weight of the former.

To SHOE an Anchor, is to cover the flukes with a broad

Shoe, Shoemakers. broad triangular piece of plank, whose area or superficies is much larger than that of the flukes. It is intended to give the anchor a stronger and surer hold of the bottom in very soft and oozy ground.

SHOEMAKERS MACHINE for working at in a standing posture. A machine for this purpose was invented by Mr Thomas Parker, who on the 22d of November, 1804, attended a committee appointed by the Society of Arts, and informed them that he had made use of this apparatus for twelve months, and found it very useful. He observed that all the work of shoemaking may be done with it standing; but that in some parts thereof he found an advantage in using along with it a high stool; and that prior to the use of this machine, he never saw or heard of a similar invention; and that he found it of great service to his health.

He estimated the cost of such a machine at two guineas.

Plate cccxcv. fig. 1. Plate CCCCXCVI. fig. 1. T, a bench standing on four legs, about four feet from the ground.

V, A circular cushion affixed to the bench, in the centre of which cushion is an open space quite through the bench, through which hole a leather strap U is brought up from below. This strap holds the work and last firm upon the cushion in any position required, by means of the workman's foot placed upon the treadle W.

X, Shews the last upon the cushion, with the strap holding it firm.

Y, An implement used in closing boots.

Z, A small flat leather cushion, useful in adjusting the last and strap.

L, The shoe last shewn separate from the cushion. The round cushion is formed of a circular piece of wood, covered with leather or stuffed with wool or hair to give it some elasticity.

Another machine for the same purpose has been invented by Mr Holden of Fettleworth in Sussex, and the following account of it was presented to the Society of Arts. He observes that the sitting posture had so greatly injured his health, as to render it necessary to give up his business, and in this difficulty he invented the machine which he found to answer the purpose fully, as it enabled him to resume his work with the recovery of his health. He recommends it as the quickest way of closing all the thread work, and he adds, that he has made 1800 or 2000 pairs of shoes with the machine, and still contines to employ it. The followine is a description of the maching.

Fig. 2. Fig. 2. A, the bed for the closing block, and to lay the shoe in, whilst sewing.

B, The closing block.

C, A loose bed to lay the shoe in whilst stitching; the lower part of which is here exhibited reversed, to show how it is placed in the other bed A.

D, The hollow or upper part of the loose bed C, in which the shoe is laid while stitching.

E, A table on which the tools wanted are to be laid.

F, An iron semicircle, fixed to each end of the bed A, to allow the bed to be raised or depressed. This half circle moves in the block G.

H, Another iron semicircle, with notches, which catch upon a tooth in the centre of the block, to hold the bed in any angle required. This semicircle moves sidewise on two hooks in staples at each end of the bed.

I, the tail or stem of the bed A, moving in a cylindrical hole in the pillar, enabling the bed to be turned in any required direction, and which, with the movement F, enables the operator to place the shoe in any position necessary.

Shoemakers ‖ Shooting.

K, the pillar, formed like the pillar of a claw-table, excepting the two side legs being in a direct line, and the other leg at a right angle with them.

L, The semicircle H, shewn separately, to explain how it is connected with the staples, and how the notches are formed.

M, The tail or stem of the bed A, and the lower part of the bed N, shewn separately, to explain how the upper part of the bed is raised or depressed occasionally.

SHOOTING, in the military art. See ARTILLERY, GUNNERY, and PROJECTILES.

1 Shooting in sportmanship.

SHOOTING, in sportmanship, the killing of game by the gun, with or without the help of dogs.

Under this article we shall lay down all the rules which are necessary to be observed in order to render one accomplished and successful in the art of shooting.

2 Directions for choosing a fowling piece.

The first thing which the sportsman ought to attend to is the choice of his fowling-piece. Conveniency requires that the barrel be as light as possible, at the same time it ought to possess that degree of strength which will make it not liable to burst. Experience has proved, that a thin and light barrel, which is of equal thickness in every part of its circumference, is much less liable to burst than one which is considerably thicker and heavier, but which, from being badly filed or bored, is of unequal strength in different places.

It is also of importance to determine of what length the barrel ought to be, in order to acquire that range which the sportsman has occasion for. On this subject we have received the following information from an experienced sportsman. We have, at different times, compared barrels of all the intermediate lengths between 28 and 40 inches, and of nearly the same caliber, that is to say, from 22 to 26; and these trials were made both by firing the pieces from the shoulder, and from a firm block, at an equal distance, and with equal weights of the same powder and of the same shot.

To avoid every possibility of error, the quires of paper at which we fired were fixed against planks instead of being placed against the wall. From these trials frequently repeated, we found that the shot pierced an equal number of sheets, whether it was fired from a barrel of 28, 30, 32, 34, 36, 38, or 40, inches in length. Nay more, we have compared two barrels of the same caliber, but one of them 33, and the other 66 inches long, by repeatedly firing them in the same manner as the others, at different distances from 45 to 100 paces, and the results have always been the same, i. e. the barrel of 33 inches drove its shot through as many sheets of paper as that of 66 did. The conclusion from all this is, that the difference of 10 inches in the length of the barrel, which seems to be more than is ever insisted upon among sportsmen, produces no sensible difference in the range of the piece; and therefore, that every one may please himself in the length of his barrel, without either detriment or advantage to the range.

It may appear as an objection to this, that a duck-gun which is five or six feet long kills at a greater distance than

Fig. 1.

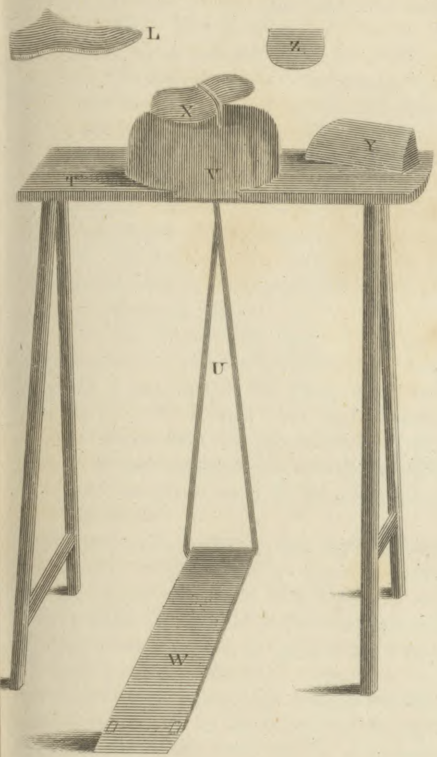

Fig. 2.

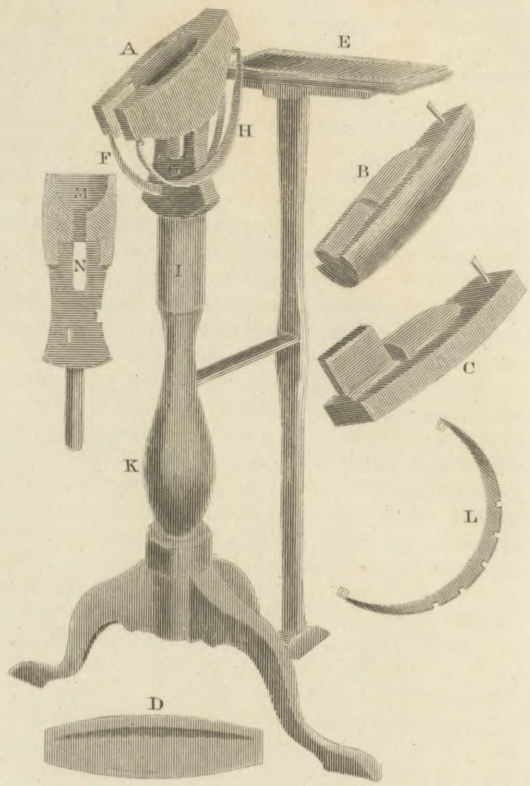
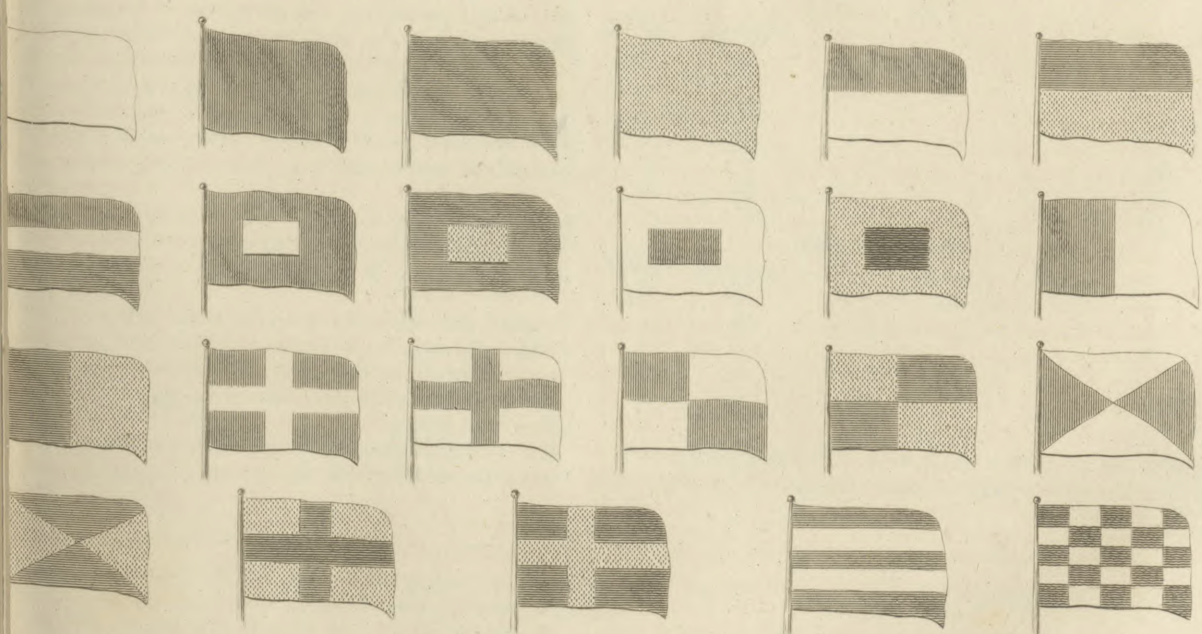


NAVAL SIGNALS.



E. Mitchell sculp^t.

Shooting. than a fowling-piece; but this is not owing to its length, but to its greater weight and thickness, which give it such additional strength, that the shot may be increased, and the charge of powder doubled, trebled, and even quadrupled. But a barrel of five or six feet length would be very inconvenient for fowling. Those who consult the appearance of the piece, lightness, and the ease with which it is managed, will find that a barrel from 32 to 38 inches will answer best.

3 Proper length of the barrel.

4 Caliber.

The next thing to be considered is, of what dimensions the caliber or bore of a fowling-piece ought to be. This matter has been subjected to experiment, and it has been found, that a barrel of 22 or 24, which is the largest caliber usually employed in fowling-pieces, throws its shot as closely as one of the smallest caliber, viz. of 30 or 32 (A).

5 Length and form of the stock.

As to the length and form of the stock, it may be laid down as a principle, that a long stock is preferable to a short one, and at the same time rather more bent than usual; for a long stock sits firmer to the shoulder than a short one, and particularly so when the shooter is accustomed to place his left hand, which principally supports the piece, near to the entrance of the ramrod into the stock.

It is certain, however, that the stock may be so formed as to be better suited to one man than another. For a tall, long-armed man, the stock of a gun should be longer than for one of a less stature and shorter arm. That a straight stock is proper for him who has high shoulders and a short neck; for, if it be much bent, it would be very difficult for him, especially in the quick motion required in shooting at a flying or running object, to place the butt of the gun-stock firmly to the shoulder, the upper part alone would in general be fixed; which would not only raise the muzzle, and consequently shoot high, but make the recoil much more sensibly felt, than if the whole end of the stock were firmly placed on his shoulder. Besides, supposing the shooter to bring the butt home to his shoulder, he would scarcely be able to level his piece at the object. On the contrary, a man with low shoulders, and a long neck, requires a stock much bent; for if it is straight, he will, in the act of lowering his head to that place of the stock at which his cheek should rest in taking aim, feel a constraint which he never experiences, when by the effect of the proper degree of bent, the stock lends him some assistance, and, as it were, meets his aim half way.

Having now described the fowling-piece which has been found to answer best, it will next be proper to give some instructions for the choice of gunpowder, shot, and wadding.

6 Best gunpowder.

The various kinds of gunpowder are well known; but, in the opinion of some experienced sportsmen, Hervey's battle-powder is the best. Those who wish to examine the strength of powder, may determine it by drying some of it very well, and then trying how many sheets of paper it will drive the shot through, at the distance of 10 or 12 yards. In this trial we should be careful to employ the same sized shot in each experiment, the quantity both of the shot and the powder being regulated by exact weight; otherwise we cannot, even in this experiment, arrive at any certainty in comparing the strength of different powders, or of the same powder at different times.

7 To be kept dry.

Powder ought to be kept very dry, for every degree of moisture injures it; and if considerable, the saltpetre is dissolved, and the intimate combination of the several ingredients is entirely destroyed. It is observed, that after firing with damp powder the piece becomes very foul, which seems to arise from the diminution of the activity of the fire in the explosion. Flasks of copper or tin are much better for keeping powder in than those made of leather, or than small casks. Their necks ought to be small and well stopped with cork.

8 Size of shot.

The *patent milled shot* is now very generally used, and is reckoned superior to any other. The size of the shot must vary according to the particular species of game which is the object of the sportsman's pursuit, as well as be adapted to the season. In the first month of partridge shooting, N° 1. is most proper; for since at this time the birds spring near at hand, and we seldom fire at more than the distance of 40 paces, if the shooter takes his aim but tolerably well, it is almost impossible for a bird at this distance to escape in the circle which the shot forms.

As hares sit closer, and are thinly covered with fur at this season, they may easily be killed with this shot at 30 or 35 paces. N° 1. is equally proper for shooting snipes or quails. About the beginning of October, when the partridges are stronger, N° 3. is the most proper shot to be used. Many sportsmen use no other during the whole season. The directions which have now been given refer only to the patent shot.

We shall now subjoin a table, which will shew at one view the number of pellets composing an ounce weight of each sort of shot, the patent and the common, beginning with the smallest size.

PATENT SHOT.

2	id.	110
1	id.	95

9 Proportion of powder and shot in the charge.

For a fowling-piece of a common caliber, which is from 24 to 30 balls to the pound weight, a dram and a quarter,

(A) In speaking of the size of the caliber, we mean by 22 or 24, that so many balls exactly fitting it weigh just one pound; and every caliber is marked in the same way.

(B) The reader will observe that the patent shot has no N° 6, the × being substituted in its place, and that the numbers do not follow each other in the order of progression: The reason of this we cannot assign.

Shooting. quarter, or at most a dram and a half, of good powder; and an ounce, or an ounce and a quarter of shot, is sufficient. But when shot of a larger size is used, such as N° 5. the charge of shot may be increased one-fourth, for the purpose of counterbalancing in some degree what the size of the shot loses in the number of pellets, and also to enable it to garnish the more. For this purpose the sportsman will find a measure marked with the proper gauges very convenient to him. An instrument of this nature has been made by an ingenious artist of London, Egg of the Haymarket.

A consequence of overloading with shot, is the powder has not sufficient strength to throw it to its proper distance; for if the object fired at be distant, one-half of the pellets composing the charge, by their too great quantity and weight, will strike against each other, and fall by the way; and those which reach the mark will have small force, and will produce but little or no effect.

10 Wadding. The use of the *wadding* is to carry the shot in a body to a certain distance from the muzzle of the piece. It ought to be of soft and pliable materials. The best kind of wadding, in the opinion of an experienced fowler, is a piece of an old hat; but this cannot be obtained in sufficient quantity. Next to it nothing is better than soft brown paper, which combines suppleness with consistence, moulds itself to the barrel, and never falls to the ground within 12 or 15 paces from the muzzle of the piece. Tow answers very well, and cork has been extolled for possessing the peculiar virtue of increasing the range and closeness of the shot.

The wadding ought to be quite close in the barrel, but not rammed too hard; for if it be rammed too close, or be of a rigid substance, the piece will recoil, and the shot will spread too much. On the other hand, if the wadding be very loose, or is composed of too soft materials, such as wool or cotton, the discharge will not possess proper force.

11 Powder and shot to be slightly rammed down. In loading a piece, the powder ought to be slightly rammed down by only pressing the ramrod two or three times on the wadding, and not by drawing up the ramrod and then returning it into the barrel with a jerk of the arm several times. For when the powder is violently compressed, some of the grains must be bruised, which will prevent the explosion from being quick, and will spread the shot too wide. In pouring the powder into the barrel, the measure ought to be held so as that the powder may fall most readily to the bottom. That no grains may adhere to the sides of the barrel, the butt-end of the piece may be struck against the ground. The shot ought never to be rammed down with force: it is sufficient to strike the butt-end of the gun against the ground as before. Then the wadding is to be put down gently. A sportsman ought never to carry his gun under his arm with the muzzle inclined downwards, for this practice loosens the wadding and charge too much.

12 Directions for loading and firing. Immediately after the piece is fired it ought to be reloaded; for while the barrel is still warm, there is no danger of any moisture lodging in it to hinder the powder from falling to the bottom. As it is found that the coldness of the barrel, and perhaps the moisture condensed in it, diminishes the force of the powder in the first shot; it is proper to fire off a little powder before the piece is loaded. Some prime before loading, but this is not proper unless the touch-hole be very large. After every discharge the touch-hole ought to be pricked, or a small feather may be inserted to clear away any humidity or foulness that has been contracted.

The sportsman having loaded his piece, must next prepare to fire. For this purpose he ought to place his hand near the entrance of the ramrod, and at the same time grasp the barrel firmly. The muzzle should be a little elevated, for it is more usual to shoot low than high. This direction ought particularly to be attended to when the object is a little distant; because shot as well as ball only moves a certain distance point blank, when it begins to describe the curve of the parabola.

13 Distance which the sportsman ought to kill. Practice soon teaches the sportsman the proper distance at which he should shoot. The distance at which he ought infallibly to kill any kind of game with patent shot, N° 3. provided the aim be well taken, is from 25 to 35 paces for the footed, and from 40 to 45 paces for the winged, game. Beyond this distance even to 50 or 55 paces, both partridges and hares are sometimes killed; but in general the hares are only slightly wounded, and carry away the shot; and the partridges at that distance present so small a surface, that they frequently escape untouched between the spaces of the circle. Yet it does not follow that a partridge may not be killed with N° 3, patent shot at 60 and even 70 paces distance, but then these shots are very rare.

14 How the aim is to be taken. In shooting at a bird flying, or a hare running across, it is necessary to take aim before the object in proportion to its distance at the time of firing. If a partridge flies across at the distance of 30 or 35 paces, it will be sufficient to aim at the head, or at most but a small space before it. If it be 50, 60, or 70 paces distant, it is then requisite to aim at least half a foot before the head. The same practice ought to be observed in shooting at a hare, rabbit, or fox, when running in a cross direction; at the same time making due allowance for the distance and swiftness of the pace. Another thing to be attended to is, that the shooter ought not involuntarily to stop the motion of the arms at the moment of pulling the trigger; for the instant the hand stops in order to fire, however inconsiderable the time be, the bird gets beyond the line of aim, and the shot will miss it. A sportsman ought therefore to accustom his hand while he is taking aim to follow the object. When a hare runs in a straight line from the shooter, he should take his aim between the ears, otherwise he will run the hazard either of missing, or at least not of killing dead, or as it is sometimes called *clean*.

15 Every part of the piece to be kept clean and dry. A fowling-piece should not be fired more than 20 or 25 times without being washed; a barrel when foul neither shoots so ready, nor carries the shot so far as when clean. The flint, pan, and hammer, should be well wiped after each shot; this contributes greatly to make the piece go off quick; but then it should be done with such expedition, that the barrel may be reloaded whilst warm, for the reasons we have before advanced. The flint should be frequently changed, without waiting until it misses fire before a new one is put in. Fifteen or eighteen shots, therefore, should only be fired with the same flint; the expence is too trifling to be regarded, and by changing it thus often much vexation will be prevented.

Shooting.

A gun also should never be fired with the prime of the preceding day; it may happen that an old priming will sometimes go off well, but it will more frequently contract moisture and fuze in the firing; then the object will most probably be missed, and that because the piece was not fresh primed.

When and how game is to be sought for.

For the information of the young sportsman we shall add a few more general directions. In warm weather he ought to seek for game in plains and open grounds, and in cold weather he may search little hills exposed to the sun, along hedges, among heath, in stubbles, and in pastures where there is much furze and fern. The morning is the best time of the day, before the dew is exhaled, and before the game has been disturbed. The colour of the shooters dress ought to be the same with that of the fields and trees; in summer it ought to be green, in winter a dark gray. He ought to hunt as much as possible with the wind, not only to prevent the game from perceiving the approach of him and his dog, but also to enable the dog to scent the game at a greater distance.

He should never be discouraged from hunting and ranging the same ground over and over again, especially in places covered with heath, brambles, high grass, or young coppice wood. A hare or rabbit will frequently suffer him to pass several times within a few yards of its form without getting up. He should be still more patient when he has marked partridges into such places, for it often happens, that after the birds have been sprung many times, they lie so dead that they will suffer him almost to tread upon them before they will rise. Pheasants, quails, and woodcocks, do the same.

He ought to look carefully about him, never passing a bush or tuft of grass without examination; but he ought never to strike them with the muzzle of his gun, for it will loosen his wadding. He who patiently beats and ranges his ground over again, without being discouraged, will always kill the greatest quantity of game; and if he is shooting in company, he will find game where others have passed without discovering any.

When he has fired he should called in his dog, that he may not have the mortification to see game rise which he cannot shoot. When he has killed a bird, instead of being anxious about picking it up, he ought to follow the rest of the covey with his eye till he see them settle.

17
Dogs fit for sport.

Three species of dogs are capable of receiving the proper instruction, and of being trained. These are the smooth pointer, the spaniel, and the rough pointer. The last is a dog with long curled hair, and seems to be a mixed breed of the water-dog and the spaniel. The smooth pointer is active and lively enough in his range, but in general is proper only for an open country.

The greatest part of these dogs are afraid of water, brambles, and thickets; but the spaniel and the rough pointer are easily taught to take the water, even in cold weather, and to range the woods and rough places as well as the plain. Greater dependence may therefore be had on these two last species of dogs than on the smooth pointer.

18
Directions for training a pointer.

The education of a pointer may commence when he is only five or six months old. The only lessons which he can be taught at this time are to *fetch* and *carry* any thing when desired; to come in when he runs far off, and to go behind when he returns; using, in the one case, the words *here, come in*, and in the other *back* or *behind*. It is also necessary at this period to accustom him to be tied up in the kennel or stable; but he ought not at first to be tied too long. He should be let loose in the morning, and fastened again in the evening. When a dog is not early accustomed to be chained, he disturbs every person in the neighbourhood by howling. It is also of importance that the person who is to train him should give him his food.

When the dog has attained the age of 10 or 12 months, he may be carried into the field to be regularly trained. At first he may be allowed to follow his own inclination, and to run after every animal he sees. His indiscriminating eagerness will soon abate, and he will pursue only partridges and hares. He will soon become tired of following partridges in vain, and will content himself after having flushed them to follow them with his eyes. It will be more difficult to prevent him from following hares.

All young dogs are apt to *rake;* that is, to hunt with their noses close to the ground, to follow birds rather by the track than by the wind. But partridges lie much better to dogs that *wind* them, than to those that follow them by the track. The dog that winds the scent approaches the birds by degrees and without disturbing them; but they are immediately alarmed when they see a dog tracing their footsteps. When you perceive that your dog is committing this fault, call to him in an angry tone *hold up;* he will then grow uneasy and agitated, going first to the one side and then to the other, until the wind brings him the scent of the birds. After finding the *game* four or five times in this way, he will take the wind of himself, and hunt with his nose high. If it be difficult to correct this fault, it will be necessary to put the *puzzle peg* upon him. This is of very simple construction, consisting only of a piece of oak or deal inch board, one foot in length, and an inch and a half in breadth, tapering a little to one end; at the broader end are two holes running longitudinally, through which the collar of the dog is put, and the whole is buckled round his neck; the piece of wood being projected beyond his nose, is then fastened with a piece of leather thong to his under jaw. By this means the peg advancing seven or eight inches beyond his snout, the dog is prevented from putting his nose to the ground and raking.

As soon as the young dog knows his game, you must bring him under complete subjection. If he is tractable, this will be easy; but if he is stubborn, it will be necessary to use the *trash cord*, which is a rope or cord of 20 or 25 fathoms in length fastened to his collar. If he refuse to come back when called upon, you must check him smartly with the cord, which will often bring him upon his haunches. But be sure you never call to him except when you are within reach of the cord. After repeating this several times he will not fail to come back when called; he ought then to be caressed, and a bit of bread should be given him. He ought now constantly to be tied up, and never unchained, except when you give him his food, and even then only when he has done something to deserve it.

The next step will be to throw down a piece of bread on the ground, at the same moment taking hold of

Shooting. of the dog by the collar, calling out to him, "take heed,—softly." After having held him in this manner for some space of time, say to him, "seize—lay hold." If he is impatient to lay hold of the piece of bread before the signal is given, correct him gently with a small whip. Repeat this lesson until he "takes heed" well, and no longer requires to be held fast to prevent him from laying hold of the bread. When he is well accustomed to this manége, turn the bread with a stick, holding it in the manner you do a fowling-piece, and having done so, cry *seize*. Never suffer the dog to eat either in the house or field without having first made him take heed in this manner.

Then, in order to apply this lesson to the game, fry small pieces of bread in hogs lard, with the dung of partridge; take these in a linen bag into the fields, stubbles, ploughed grounds, and pastures, and there put the pieces in several different places, marking the spots with little cleft pickets of wood, which will be rendered more distinguishable by putting pieces of card in the nicks. This being done, cast off the dog and conduct him to these places, always hunting in the wind. After he has caught the scent of the bread, if he approaches too near, and seems eager to fall upon it, cry to him in a menacing tone, "take heed;" and if he does not stop immediately, correct him with the whip. He will soon comprehend what is required of him, and will stand.

At the next lesson, take your gun charged only with powder, walk gently round the piece of bread once or twice, and fire instead of crying *seize*. The next time of practising this lesson, walk round the bread four or five times, but in a greater circle than before, and continue to do this until the dog is conquered of his impatience, and will stand without moving until the signal is given him. When he keeps his point well, and stands steady in this lesson, you may carry him to the birds; if he run in upon them, or bark when they spring up, you must correct him; and if he continue to do so, you must return to the fried bread; but this is seldom necessary.

When the dog has learned by this use of the bread to take heed, he may be carried to the fields with the trash-cord dragging on the ground. When he springs birds for the first time, if he runs after them or barks, check him by calling out to him, *take heed*. If he point properly, caress him; but you ought never to hunt without the cord until he point staunch.

19 and preventing his running after sheep. If the dog runs after sheep, and it be difficult to cure him, couple him with a ram, and then whip the dog as long as you can follow him. His cries will at first alarm the ram; he will run with all his speed, and drag the dog along with him; but he will at length take courage, turn upon the dog, and butt him severely with his horns. When you think the dog is sufficiently chastised, untie him: he will never run at sheep again.

Having now given a few general instructions concerning the best method of training pointers, we shall subjoin a few observations respecting the most common species of game, the partridge, pheasant, grouse, woodcock, snipe, and wild duck.

20 Observations concerning the partridge. Partridges pair in the spring, and lay their eggs (generally from 15 to 20) during May and part of June. The young begin to fly about the end of June, and their plumage is complete in the beginning of October. The male has a conspicuous horse shoe upon his breast, an obtuse spur on the hinder part of the leg, which distinguish him from the female. He is also rather larger.

When a sportsman is shooting in a country where the birds are thin, and he no longer chooses to range the field for the bare chance of meeting with them, the following method will show him where to find them on another day. In the evening, from sunset to nightfall, he should post himself in a field, at the foot of a tree or a bush, and there wait until the partridges begin to call or juck, which they always do at that time; not only for the purpose of drawing together when separated, but also when the birds composing the covey are not dispersed. After calling in this manner for some little space of time, the partridges will take to flight; then, if he mark the place where they alight, he may be assured they will lie there the whole night, unless disturbed. Let him return to the same post the next morning by break of day, and there watch a while; being careful to keep his dog in a string, if he is not under perfect command.

As soon as the dawn begins to peep, the partridges will begin to call, and soon afterwards will perform the same manœuvre as on the preceding evening; that is, after having called a while, they will take their flight, and will most commonly settle at a little distance. There in a few minutes they will call again, and sometimes take a second flight, but that will be to no great distance. Then as soon as the sun is risen, and the sportsman can see to shoot, he may cast off his dog and pursue them.

The *pheasant* is of the size of a common dunghill cock, and lays its eggs generally in the woods, the number of which is 10 or 12. 21 Pheasant.

Pheasants are accounted stupid birds; for when they are surprised they will frequently squat down like a rabbit, supposing themselves to be in safety as soon as their heads are concealed; and in this way they will sometimes suffer themselves to be killed with a stick. They love low and moist places, and haunt the edges of those pools which are found in woods, as well as the high grass of marshes that are near at hand; and above all, places where there are clumps of alders.

Grouse, or moor-game, are found in Wales, in the northern counties of England, and in great abundance in Scotland. They chiefly inhabit those mountains and moors which are covered with heath, and seldom descend to the low grounds. They fly in companies of four or five braces, and love to frequent mossy places, particularly in the middle of the day or when the weather is warm. In pursuing this game, when the pointer sets, and the sportsman perceives the birds running with their heads erect, he must run after them as fast as he can, in the hope that he may get near enough to shoot when they rise upon the wing; for he may be pretty certain they will not lie well that day. As these birds are apt to grow soon putrid, they ought to be drawn carefully the instant they are shot and stuffed with any heath, and if the feathers happen to be wetted they must be wiped dry. 22 Grouse.

The *woodcock* is a bird of passage; it commonly arrives about the end of October, and remains until the middle of March. Woodcocks are fattest in December and January, but from the end of February they are lean. At their arrival they drop anywhere, but afterwards 23 Woodcock.

Shooting. wards take up their residence in copses of nine or ten years growth. They seldom, however, stay in one place longer than 12 or 15 days. During the day, they remain in those parts of the woods where there are void spaces or glades, picking up earth-worms and grubs from the fallen leaves. In the evening they go to drink and wash their bills at pools and springs, after which they repair to the open fields and meadows for the night. It is remarkable, that when a woodcock springs from a wood to go into the open country, he always endeavours to find some glade or opening, which he follows to the boundaries of the wood. At his return he pursues the same path a good way, and then turns to the right or left opposite to some glade, in order to drop into a thick part of the wood, where he may be sheltered from the wind. He may therefore be watched with advantage in these narrow passes and little alleys on the edges of woods which lead to a pool or spring, or he may be watched in the dusk of the evening near the pools which he frequents.

24 Snipe. The *snipe* is a bird of passage as well as the woodcock. This bird is scarcely worth shooting till the frost commences. In the month of November they begin to grow fat. Snipes, like woodcocks, frequent springs, bogs, and marshy places, and generally fly against the wind. The slant and cross shots are rather difficult, as the birds are small and fly very quickly. The sportsman ought to look for them in the direction of the wind; because then they will fly towards him, and present a fairer mark.

25 Wild duck. The *wild duck* is also a bird of passage, and arrives here in great flocks from the northern countries in the beginning of winter. Still, however, a great many remain in our marshes and fens during the whole year, and breed.

The wild duck differs little in plumage from the tame duck, but is easily distinguished by its size, which is less; by the neck, which is more slender; by the foot, which is smaller; by the nails, which are more black; and above all, by the web of the foot, which is much finer and softer to the touch.

In the summer season, when it is known that a team of young ducks are in a particular piece of water, and just beginning to fly, the sportsman is sure to find them early in the morning dabbling at the edges of the pool, and amongst the long grass, and then he may get very near to them: it is usual also to find them in those places at noon.

In the beginning of autumn almost every pool is frequented by teams of wild ducks, which remain there during the day, concealed in the rushes. If these pools are of small extent, two shooters, by going one on each side, making a noise and throwing stones into the rushes, will make them fly up; and they will in this way frequently get shots, especially if the pool is not broad, and contracts at one end. But the surest and most successful way, is to launch a small boat or trow on the pool, and to traverse the rushes by the openings which are found; at the same time making as little noise as possible. In this manner the ducks will suffer the sportsmen to come sufficiently near them to shoot flying; and it often happens that the ducks, after having flown up, only make a circuit, return in a little time, and again alight upon the pool. Then the sportsmen endeavour a second time to come near them. If several shooters are in company, they should divide; two should go in the boat, whilst the others spread themselves about the edge of the pool, in order to shoot the ducks in their flight. In pools which will not admit a trow, water-spaniels are absolutely necessary for this sport.

Shooting || Shore.

In winter they may be found on the margins of little pools; and when pools and rivers are frozen up, they must be watched for in places where there are springs and waters which do not freeze. The sport is then much more certain, because the ducks are confined to these places in order to procure aquatic herbs, which are almost their only food at this period.

SHOP-LIFTERS, are those that steal goods privately out of shops; which, being to the value of 5s. though no person be in the shop, is felony without the benefit of clergy by the 10 and 11 W. III. c. 23.

SHORE, a place washed by the sea, or by some large river.

Count Marsigli divides the sea shore into three portions: the first of which is that tract of land which the sea just reaches in storms and high tides, but which it never covers; the second part of the shore is that which is covered in high tides and storms, but is dry at other times; and the third is the descent from this, which is always covered with water.

The first part is only a continuation of the continent, and suffers no alteration from the neighbourhood of the sea, except that it is rendered fit for the growth of some plants, and wholly unfit for that of others, by the saline steams and impregnations; and it is scarce to be conceived by any, but those who have observed it, how far on land the effects of the sea reach, so as to make the earth proper for plants which will not grow without this influence; there being several plants frequently found on high hills and dry places, at three, four, and more miles from the sea, which yet would not grow unless in the neighbourhood of it, nor will ever be found elsewhere.

The second part or portion of the shore is much more affected by the sea than the former, being frequently washed and beaten by it. Its productions are rendered salt by the water, and it is covered with sand, or with the fragments of shells in form of sand, and in some places with a tartarous matter deposited from the water; the colour of this whole extent of ground is usually dusky and dull, especially where there are rocks and stones, and these covered with a slimy matter.

The third part of the shore is more affected by the sea than either of the others; and is covered with an uniform crust of the true nature of the bottom of the sea, except that plants and animals have their residence in it, and the decayed parts of these alter it a little.

SHORE, *Jane*, the celebrated concubine of the licentious King Edward IV. was the wife of Mr Matthew Shore, a goldsmith in Lombard-street, London. Kings are seldom unsuccessful in their amorous pursuits; therefore there was nothing wonderful in Mrs Shore's removing from Lombard-street to shine at court as the royal favourite. Historians represent her as extremely beautiful, remarkably cheerful, and of most uncommon generosity. The king, it is said, was no less captivated with her temper than with her person: she never made use of her influence over him to the prejudice of any person; and if ever she importuned him, it was in favour of the unfortunate. After the death of Edward, she

Shore ‖ Short.

she attached herself to the lord Hastings; and when Richard III. cut off that nobleman as an obstacle to his ambitious schemes, Jane Shore was arrested as an accomplice, on the ridiculous accusation of witchcraft. This, however, terminated only in a public penance; excepting that Richard rifled her of all her little property: but whatever severity might have been exercised towards her, it appears that she was alive, though sufficiently wretched, under the reign of Henry VIII. when Sir Thomas More saw her poor, old, and shrivelled, without the least trace of her former beauty. Mr Rowe, in his tragedy of Jane Shore, has adopted the popular story related in the old historical ballad, of her perishing by hunger in a ditch where Shoreditch now stands. But Stow assures us that street was so named before her time.

SHORL. See SCHORL, MINERALOGY *Index*.

SHORLING and MORLING, are words to distinguish fells of sheep *shorling* being the fells after the fleeces are shorn off the sheep's back; and *morling* the fells flead off after they die or are killed. In some parts of England, they understand by a *shorling*, a sheep whose face is shorn off; and by a *morling*, a sheep that dies.

SHORT, JAMES, an eminent optician, was born in Edinburgh on the 10th of June O. S. in the year 1710. At ten years of age, having lost his father and mother, and being left in a state of indigence, he was received into Heriot's hospital, (see *EDINBURGH*, *Public Buildings*, N° 16.) where he soon displayed his mechanical genius, in constructing for himself, little chests, book-cases, and other conveniences, with such tools as fell in his way. At the age of twelve he was removed from the Hospital to the High School, where he showed a considerable taste for classical literature, and generally kept at the head of his forms. In the year 1726 he was entered into the university, where he passed through the usual course of education, and took his master's degree with great applause.

By his friends he was intended for the church; but after attending a course of theological lectures, his mind revolted from a profession which he thought little suited to his talents; and he devoted his whole time to mathematical and mechanical pursuits. He had been fortunate enough to have the celebrated M'Laurin for his preceptor; who having soon discovered the bent of his genius, and made a proper estimate of the extent of his capacity, encouraged him to prosecute those studies in which nature had qualified him to make the greatest figure. Under the eye of that eminent master, he began in 1732 to construct Gregorian telescopes; and, as the professor observed in a letter to Dr Jurin, "by taking care of the figure of his specula, he was enabled to give them larger apertures, and to carry them to greater perfection than had ever been done before him." (See OPTICS, N° 89.).

In the year 1736 Mr Short was called to London, at the desire of Queen Caroline, to give instructions in mathematics to William duke of Cumberland; and immediately on his appointment to that very honourable office he was elected a fellow of the royal society, and patronized by the earls of Morton and Macclesfield. In the year 1739 he accompanied the former of those noble lords to the Orkney isles, where he was employed in adjusting the geography of that part of Scotland: and

Short ‖ Shortford.

happy it was for him that he was so employed, as he might otherwise have been involved in a scuffle which took place between the retainers of Sir James Stewart of Barra and the attendants of the earl, in which some of the latter were dangerously wounded.

Mr Short having returned to London, and finally established himself there in the line of his profession was in 1742 employed by Lord Thomas Spencer to make for him a reflector of 12 feet focus, for which he received 600 guineas. He made several other telescopes of the same focal distance with greater improvements and higher magnifiers; and in 1752 finished one for the king of Spain, for which, with its whole apparatus, he received 1200l. This was the noblest instrument of the kind that had then been constructed, and perhaps it has never yet been surpassed except by the astonishing reflectors of Herschel. See TELESCOPE.

Mr Short used to visit the place of his nativity once every two or three years during his residence in London, and in 1766 he visited it for the last time. On the 15th of June 1768 he died, after a very short illness, at Newington Butts, near London, of a mortification in his bowels, and was buried on the 22d of the same month, having completed, within a few days, his fifty-eighth year. He left a fortune of about 20,000l. of which 15,000l. was bequeathed to two nephews, and the rest in legacies to his friends. In gratitude for the steady patronage of the earl of Morton, he left to his daughter the lady Mary Douglas, afterwards countess of Aboyne, 1000l. and the reversion of his fortune, should his nephews die without issue; but this reversionary legacy the lady, at the desire of her father, generously relinquished by a deed in favour of Mr Short's brother Mr Thomas Short and his children. Mr Short's eminence as an artist is universally known, and we have often heard him spoken of by those who were acquainted with him from his youth, as a man of virtue and of very amiable manners.

SHORT-Hand Writing. See STENOGRAPHY.

SHORT-Jointed, in the *Manege*. A horse is said to be short-jointed that has a short pastern; when this joint, or the pastern is too short, the horse is subject to have his fore legs from the knee to the cornet all in a straight line. Commonly your short-jointed horses do not manege so well as the long-jointed; but out of the manege the short-jointed are the best for travel or fatigue.

SHORT-Sightedness, a certain defect in vision by which objects cannot be distinctly seen, unless they are very near the eye. See OPTICS, N° 142.

SHORTFORD, q. d. *fore-close*, an ancient custom in the city of Exeter, when the lord of the fee cannot be answered rent due to him out of his tenement, and no distress can be levied for the same. The lord is then to come to the tenement, and there take a stone, or some other dead thing off the tenement, and bring it before the mayor and bailiff, and thus he must do seven quarter days successively; and if on the seventh quarter-day the lord is not satisfied of his rent and arrears, then the tenement shall be adjudged to the lord to hold the same a year and a day; and forthwith proclamation is to be made in the court, that if any man claims any title to the same tenement, he must appear within the year and day next following, and satisfy the lord of the said rent and arrears: but if no appearance be made, and the rent not paid, the lord comes again to the court, Showerd, Shot.

court, and prays that, according to the custom, the said tenement be adjudged to him in his demesne as of fee, which is done accordingly, so that the lord hath from thenceforth the said tenement, with the appurtenances to him and his heirs.

SHOT, a denomination given to all sorts of balls for fire-arms: those for cannon being of iron, and those for guns, pistols, &c. of lead. See SHOOTING.

Case Shot formerly consisted of all kinds of old iron, nails, musket-balls, stones, &c. used as above.

Shot of a Cable, on ship-board, is the splicing of two cables together, that a ship may ride safe in deep waters and in great roads; for a ship will ride easier by one shot of a cable, than by three short cables out ahead.

Grape-Shot. See *Grape-Shot.*

Patent-milled Shot is made thus: Sheets of lead, whose thickness corresponds with the size of the shot required, are cut into small pieces, or cubes, of the form of a die. A great quantity of these little cubes are put into a large hollow iron cylinder, which is mounted horizontally and turned by a winch; when by their friction against one another and against the sides of the cylinder, they are rendered perfectly round and very smooth. The other patent shot is cast in moulds, in the same way as bullets are.

Shot Flaggon, a sort of flaggon somewhat bigger than ordinary, which in some counties, particularly Derbyshire, it is the custom for the host to serve his guests in, after they have drank above a shilling.

Small Shot, or that used for fowling, should be well sized, and of a moderate bigness: for should it be too great, then it flies thin, and scatters too much; or if too small, then it hath not weight and strength to penetrate far, and the bird is apt to fly away with it. In order, therefore, to have it suitable to the occasion, it not being always to be had in every place fit for the purpose, we shall set down the true method of making all sorts and sizes under the name of *mould-shot*. Its principal good properties are to be round and solid.

Take any quantity of lead you think fit, and melt it down in an iron vessel; and as it melts keep it stirring with an iron ladle, skimming off all impurities whatsoever that may arise at the top: when it begins to look of a greenish colour, strew on it as much auripigmentum or yellow orpiment, finely powdered, as will lie on a shilling, to every 12 or 14 pound of lead; then stirring them together, the orpiment will flame.

The ladle should have a notch on one side of the brim, for more easily pouring out the lead; the ladle must remain in the melted lead, that its heat may be the same with that of the lead, to prevent inconveniences which otherwise might happen by its being either too hot or too cold: then, to try your lead, drop a little of it into water, and if the drops prove round, then the lead is of a proper heat; if otherwise, and the shot have tails, then add more orpiment to increase the heat, till it be found sufficient.

Then take a plate of copper, about the bigness of a trencher, which must be made with a hollowness in the middle, about three inches compass, within which must be bored about 40 holes according to the size of the shot which you intend to cast: the hollow bottom should be thin; but the thicker the brim, the better it will retain the heat. Place this plate on a frame of iron, over a tub or vessel of water, about four inches from the water, and spread burning coals on the plate, to keep the lead melted upon it: then take some lead and pour it gently on the coals on the plate, and it will make its way through the holes into the water, and form itself into shot; do this till all your lead be run through the holes of the plate, taking care, by keeping your coals alive, that the lead do not cool, and so stop up the holes.

Shot, Shovel.

While you are casting in this manner, another person with another ladle may catch some of the shot, placing the ladle four or five inches underneath the plate in the water, by which means you will see if they are defective, and rectify them.

Your chief care is to keep the lead in a just degree of heat, that it be not so cold as to stop up the holes in your plate, nor so hot as to cause the shot to crack: to remedy the heat, you must refrain working till it is of a proper coolness; and to remedy the coolness of your lead and plate, you must blow your fire; observing, that the cooler your lead is, the larger will be your shot; as the hotter it is, the smaller they will be.

After you have done casting, take them out of the water, and dry them over the fire with a gentle heat, stirring them continually that they do not melt; when dry, you are to separate the great shot from the small, by the help of a sieve made for that purpose, according to their several sizes. But those who would have very large shot, make the lead trickle with a stick out of the ladle into the water, without the plate.

If it stop on the plate, and yet the plate be not too cool, give but the plate a little knock, and it will run again; care must be had that none of your implements be greasy, oily, or the like; and when the shot, being separated, are found too large or too small for your purpose, or otherwise imperfect, they will serve again at the next operation.

The sizes of common shot for fowling are from N° 1 to 6, and smaller, which is called mustard seed, or dust shot; but N° 5 is small enough for any shooting whatsoever. The N° 1 may be used for wild geese; the N° 2 for ducks, widgeons, and other water-fowl; the N° 3 for pheasants, partridges after the first month, and all the fen-fowl; the N° 4 for partridges, woodcocks, &c.; and the N° 5 for snipes and all the smaller birds.

Tin-Case Shot, in artillery, is formed by putting a great quantity of small iron shot into a cylindrical tin-box called a cannister, that just fits the bore of the gun. Leaden bullets are sometimes used in the same manner; and it must be observed, that whatever number or sizes of the shots are used, they must weigh with their cases nearly as much as the shot of the piece.

SHOVEL, Sir Cloudesly, a distinguished British admiral, was born about the year 1650, of parents in the lower rank of life. He was put apprentice to a shoemaker; but disliking this profession, he abandoned it a few years after, and went to sea. He was at first a cabin boy with Sir Christopher Mynns, but applying to the study of navigation with indefatigable industry, his skill as a seaman soon raised him above that station.

The corsairs of Tripoli having committed great outrages on the English in the Mediterranean, Sir John Narborough was sent in 1674 to reduce them to reason. As he had received orders to try the effects of negociation before he proceeded to hostilities, he sent Mr

Shovel,

Shovel, who was at that time a lieutenant in his fleet, to demand satisfaction. The Dey treated him with a great deal of disrespect, and sent him back without an answer. Sir John dispatched him a second time, with orders to remark particularly the situation of things on shore. The behaviour of the Dey was worse than ever. Upon Mr Shovel's return, he informed Sir John that it would be possible, notwithstanding their fortifications, to burn all the ships in the harbour. The boats were accordingly manned, and the command of them given to Lieut. Shovel, who seized the guardship, and burnt four others, without losing a man. This action so terrified the Tripolins, that they sued for peace.—Sir John Narborough gave so favourable an account of this exploit, that Mr Shovel was soon after made captain of the Sapphire, a fifth rate ship.

In the battle of Bantry-Bay, after the Revolution, he commanded the Edgar, and, for his gallant behaviour in that action, was soon after knighted by King William. Next year he was employed in transporting an army into Ireland; a service which he performed with so much diligence and dexterity, that the king raised him to the rank of rear-admiral of the blue, and delivered his commission with his own hands. Soon after he was made rear-admiral of the red, and shared the glory of the victory at La Hogue. In 1694, he bombarded Dunkirk. In 1703, he commanded the grand fleet in the Mediterranean, and did every thing in his power to assist the Protestants who were in arms in the Cevennes.

Soon after the battle off Malaga, he was presented by Prince George to Queen Anne, who received him graciously, and next year employed him as commander in chief.

In 1705 he commanded the fleet, together with the earl of Peterborough and Monmouth, which was sent into the Mediterranean; and it was owing to him chiefly that Barcelona was taken. After an unsuccessful attempt upon Toulon, he sailed for Gibraltar, and from thence homeward with a part of the fleet. On the 22d of October, at night, his ship, with three others, was cast away on the rocks of Scilly. All on board perished. His body was found by some fishermen on the island of Scilly, who stripped it of a valuable ring, and afterwards buried it. Mr Paxton, the purser of the Arundel, hearing of this, found out the fellows, and obliged them to discover where they had buried the body. He carried it on board his own ship to Portsmouth, from whence it was conveyed to London, and interred with great solemnity in Westminster Abbey. A monument was afterwards erected to his memory by the direction of the queen. He married the widow of his patron, Sir John Narborough, by whom he left two daughters, co-heiresses.

SHOVELER, a species of ANAS. See ANAS, ORNITHOLOGY *Index*.

SHOULDER-BLADE, a bone of the shoulder, of a triangular figure, covering the hind part of the ribs, called by anatomists the *scapula* and *omoplata*. See ANATOMY.

SHOUT, CLAMOUR, in antiquity, was frequently used on ecclesiastical, civil, and military occasions, as a sign of approbation, and sometimes of indignation.—Thus as Cicero, in an assembly of the people, was exposing the arrogance of L. Antony, who had had the impudence to cause himself to be inscribed the patron of the Romans, the people on hearing this raised a shout to show their indignation. In the ancient military discipline, shouts were used, 1. Upon occasion of the general's making a speech or harangue to the army from his tribunal. This they did in token of their approving what had been proposed. 2. Before an engagement, in order to encourage and spirit their own men, and fill the enemy with dread. This is a practice of great antiquity; besides which, it wants not the authority of reason to support it; for as mankind are endowed with two senses, hearing and seeing, by which fear is raised in the mind, it may be proper to make use of the ear as well as the eye for that purpose. Shouts were also raised in the ancient theatre, when what was acted pleased the spectators. It was usual for those present at the burning of the dead to raise a great shout, and call the dead person by his name before they set fire to the pile.

SHOWER, in *Meteorology*, a cloud condensed into RAIN.

SHREWMOUSE. See SOREX, MAMMALIA *Index*.

SHREWSBURY, the capital of Shropshire in England. This town, the metropolis of the county, grew up out of the ruins of Uriconium, anciently a city, now a village called *Wroxeter*, about four miles from it. The Saxons called it *Scrobbes Berig*, from the shrubs that grew about it; and from thence the present name of *Shrewsbury* is supposed to have been formed. It is pleasantly situated upon a hill near the Severn, over which there are two handsome bridges. It was a place of note in the Saxon times; after which it was granted by William the Conqueror, together with the title of *earl* and most of the county, to Roger de Montgomery, who built a castle upon the north side of it, where the Severn that encompasses it on all other sides, leaves an opening. His son Robert built also a wall across this neck of land, when he revolted from Henry I. We learn from Doomsday-book, that at that time, when a widow of this town married, she paid 20 shillings to the king, and a virgin 10. The above-mentioned Roger founded also, and endowed here, a Benedictine monastery and a collegiate church. When old age came upon him, he quitted the world, and spent the rest of his days as a monk in the abbey, and when he died was interred in its church. From the history of this church and monastery, it appears that ecclesiastical benefices about that time were hereditary. The abbey became so rich afterwards, that the abbot was mitred, and sat in parliament. Besides this abbey, in after times there were three others, viz. a Franciscan, Dominican, and Augustin; and likewise two collegiate churches, one dedicated to St Chad and the other to St Mary. In the contest between the empress Maud and Stephen, this town and its governor William Fitz-Allen sided with the empress. In Henry's III.'s time, a part of it was burnt down by the Welch; and in Richard II's reign a parliament was held in it. At a place called *Battlefield*, near this town, Henry Percy the younger, surnamed *Hotspur*, was killed in an engagement with Henry IV. against whom he had rebelled. The king afterwards built a chapel upon the spot, and endowed it for the support of two priests to pray for the souls of the slain. Two of Edward IV.'s sons were born here; namely,

namely, Richard, duke of York, whom Perkin Warbeck afterwards personated, and who was murdered in the Tower; and George Plantagenet, who died before his brothers. Here first broke out the sweating-sickness, which carried off great numbers so suddenly, that those who were seized with it either died or recovered in the space of 24 hours. In the beginning of the civil wars, King Charles I. came hither, and formed an army, with which he marched towards London; but was met by the parliament's forces at Edgehill. He continued here from the 20th of September to the 12th of October, during which time he was joined by Prince Rupert, and many of the gentry and nobility of these parts. This town anciently gave title of earl to the Montgomeries, and afterwards to the Talbots, by whom it is still retained. Here is a free grammar-school, with three masters and several ushers, well endowed by Edward VI. and Queen Elizabeth, and not inferior to many colleges in the universities. It has a good library and chapel, and there are several scholarships appropriated to it in the university of Cambridge. Here are also several hospitals, alms-houses, and charity-schools. This town is one of the most flourishing in England, having two great weekly markets for corn, cattle, and provisions; and another for Welch cottons and flannels, of which great quantities are sold. A great trade is carried on with the Welch, who bring their commodities hither, as to the common mart of both nations. The town is large and well-built, and the situation extremely pleasant. There is a very beautiful walk called the *quarry*, between the town walls and the Severn, delightfully shaded with rows of lime-trees, so that it is not inferior to the Mall in St James's Park. The town is also noted for its gallantry and politeness, being full of gentry, for whom there are always balls and assemblies once a-week all the year round.—Here is a fine house and gardens, which belonged to the earl of Bradford; and in the neighbourhood, at Wroxeter, the Roman highway, called Watling street, may be seen for several miles, where Roman coins are frequently found. In Shrewsbury are 12 incorporated trading companies; and the corporation has a power to try even capital causes of itself, except high treason. Shrewsbury contained 14,739 inhabitants in 1801, and, 16,606 in 1811.

SHRIKE. See LANIUS, ORNITHOLOGY *Index*.

SHRIMP. See CANCER, ENTOMOLOGY *Index*.

SHRINE, in *Ecclesiastical History*, a case or box to hold the relics of some saint.

SHROPSHIRE, a county of England, bounded on the south by Worcestershire, Herefordshire, and Radnorshire; on the north, by Cheshire; on the east, by Staffordshire; on the west, by Montgomeryshire and Denbighshire, in Wales. Its length is between 49 and 50 miles, its breadth about 38, and its circumference about 210. It is an inland county, containing 890,000 acres, and 15 hundreds, in which are 170 parishes, and 15 market towns; and the number of inhabitants in 1811 was 194,298. It makes a part of three bishoprics, viz. Hereford, Coventry and Litchfield, and St Asaph. Some part of it lies on the north, and some on the south side of the Severn. Besides the Severn, it is also watered by the *Temd* or *Tefidiauc*, which flows from the mountains of Radnorshire; and by the Tern, which has its rise and name from one of those pools called *tearnes*, in Staffordshire. All these abound with fish, especially trouts, pikes, lampreys, graylings, carp, and eels. The air, especially upon the hills, with which the county abounds, is very wholesome. There is as great a diversity of soil as in most other counties. On the hills, where it is poor, is very good pasture for sheep; and in the low grounds, where it is very rich, along the Severn in particular, there is plenty of grass for bay and black cattle, with all sorts of corn. This county is abundantly provided with fuel, having in it many extensive mines of coal; it has also mines of lead and iron. Over most of the coal pits in this county lies a stratum or layer of blackish porous rock, of which, by grinding and boiling, they make pitch and tar, which are rather better than the common sort for caulking ships, as they do not crack, but always continue close and smooth. Quarries of lime-stone and iron-stone are common in the county, and the soil in many places is a reddish clay. The abundance of coal and iron-stone in this county has given rise to numerous manufactories.

As it lies upon the borders of Wales, it was anciently full of castles and walled towns. On the side next that country there was an almost continued line of castles, to guard the county against the inroads and depredations of the Welch. The borders here, as those between England and Scotland, were called *marches*, and there were certain noblemen entitled *barones marchiæ*, *marchiones de marchia Walliæ*, "lords of the marches, or marquisses of the marches of Wales," who were vested with a sort of palatine jurisdiction, held courts of justice to determine controversies, and enjoyed many privileges and immunities, the better to enable and encourage them to protect the county against the incursions of the Welch, and to maintain order amongst the borderers; but they often abused their power, and were the greatest of tyrants.

As to the ecclesiastical government of the county, the far greater part, belonging to the bishoprics of Hereford, and of Litchfield and Coventry, is under the jurisdiction and visitation of the archdeacon of Shrewsbury, or Salop, and is divided into several deanries.

The Oxford circuit includes in it this county, which sends 12 members to parliament, viz. two for the shire, and two for each of the following towns, Shrewsbury, Ludlow, Wenlock, and Bishop's Castle. See SHROPSHIRE, SUPPLEMENT.

SHROVE-TUESDAY, is the Tuesday after the Quinquagesima Sunday, or the day immediately preceding the first of Lent; being so called from the Saxon word *shrive*, which signifies "to confess." Hence Shrove-Tuesday signfies Confession-Tuesday; on which day all the people in every parish throughout England (during the Romish times) were obliged to confess their sins, one by one, to their own parish priests, in their own parish-churches; and, that this might be done the more regularly, the great bell in every parish was rung at ten o'clock (or perhaps sooner), that it might be heard by all, and that they might attend, according to the custom then in use. And though the Romish religion has now given way to the Protestant religion, the custom of ringing the great bell in our ancient parish-churches, at least in some of them, still remains, and obtains in and about London the name of Pancake bell; perhaps, because after the confession it was customary for the several persons to dine on pancakes or fritters. Most churches,

churches, indeed, have rejected that custom of ringing the bell on Shrove-Tuesday; but the usage of dining on pancakes or fritters, and such like provision, still continues.

SHROUDS (*scrud* Sax.), a range of large ropes extending from the mast-heads to the right and left side of the ship, to support the masts, and enable them to carry sail, &c.

The shrouds as well as the sails are denominated from the masts to which they belong. Thus there are the main, fore, and mizen shrouds; the main-top-mast, fore-top-mast, or mizen-top-mast shrouds; and the main-top-gallant, fore-top-gallant, or mizen-top-gallant shrouds. The number of shrouds by which a mast is sustained, as well as the size of rope of which they are formed, is always in proportion to the size of the mast and the weight of the sail it is intended to carry.

Bowsprit shrouds are those which support the bowsprit. Bumkin shrouds are those which support the bumkins. Futtock shrouds are shrouds which connect the efforts of the topmast shrouds to the lower shrouds. Bentick shrouds are additional shrouds to support the masts in heavy gales. Preventer shrouds are similar to bentick shrouds, and are used in bad weather to ease the lower rigging. See Mast and Sail.

SHRUB, *frutex*, a little, low, dwarf tree, or a woody vegetable, of a size less than a tree; and which, instead of one single stem, frequently from the same root puts forth several sets or stems. See Plant and Tree. Such are privet, phillyrea, holly, box, honey-suckle, &c. Shrubs and trees put forth in autumn a kind of buttons, or gems, in the axis of the leaves; these buttons are as so many little ova, which, coming to expand by the warmth of the following spring, open into leaves and flowers. By this, together with the height, some distinguish shrubs from *suffrutices*, or under shrubs, which are low bushes, that do not put forth any of these buttons, as sage, thyme, &c.

The two hardiest shrubs we are possessed of are the ivy and box; these stand the severity of our sharpest winters unhurt, while other shrubs perish, and trees have their solid bodies split and torn to pieces. In the hard winter of the year 1683, these two shrubs suffered no injury any where; though the yews and hollies, which are generally supposed very hardy, were that winter in some places killed, and in others stripped of their leaves, and damaged in their bark. Furze-bushes were found to be somewhat hardier than these, but they sometimes perished, at least down to the root. The broom seemed to occupy the next step of hardiness beyond these. This lived where the others died, and where even this died, the juniper shrubs were sometimes found unhurt. This last is the only shrub that approaches to the hardiness of the box and ivy, but even it does not quite come up to them; for while they suffer nothing in whatever manner they are exposed, the juniper, though it bears cold well under the shelter of other trees, yet cannot bear the vicissitudes of heat and cold; insomuch that some juniper shrubs were found half dead and half vigorous; that side which faced the mid-day sun having perished by the successive thawings and freezings of its sap; while that which was not exposed to the vicissitudes of heat had borne the cold perfectly well. Such shrubs as are not hardy enough to defy the winter, but appear half dead in the spring, may often be recovered by Mr Evelyn's method of beating their branches with a slender hazel-wand, to strike off the withered leaves and buds, and give a free passage to the air to the internal parts. Where this fails, the method is to cut them down to the quick, and if no part of the trunk appears in a growing condition, they must be taken off down to the level of the ground. Philosophical Transactions, N° 165.

SHUTTLE, in the manufactures, an instrument used by the weavers, which guides the thread it contains, either of woollen, silk, flax, or other matter, so as to make it form the woofs of stuffs, cloths, linens, ribbands, &c. by throwing the shuttle alternately from left to right, and from right to left, across between the threads of the warp, which are stretched out lengthwise on the loom.

In the middle of the shuttle is a kind of cavity, called the *eye* or *chamber* of the shuttle; wherein is inclosed the spoul, which is a part of the thread destined for the woof; and this is wound on a little tube of paper, rush, or other matter.

The ribband-weaver's shuttle is very different from that of most other weavers, though it serves for the same purpose: it is of box, six or seven inches long, one broad, and as much deep; shod with iron at both ends, which terminate in points, and are a little crooked, the one towards the right, and the other towards the left, representing the figure of an ∽ horizontally placed. See Weaving.

SIALOGOGUES, medicines which promote the salivary discharge.

1 Boundaries and extent.

SIAM Proper, by some called *Upper*, (to distinguish it from the *Lower* Siam, under which are often included Laos, Cambodia, and Malacca), is bounded on the north by the kingdoms of Pegu and Laos; on the east by Cambodia and Cochin-China; on the south by Malacca and the bay of Siam; and on the west by the ocean. But as the opinions of geographers are extremely various concerning the situation and extent of most of the inland countries of Asia and Africa, neither the extent nor boundaries of Siam are yet accurately known. By some it is supposed to extend 550 miles in length, and 250 miles in breadth; in some places it is not above 50 miles broad.

2 Weather.

The winds blow here from the south upon the coast of Siam, in March, April, and May; in April the rains begin, in May and June they fall almost without ceasing. In July, August, and September, the winds blow from the west, and the rains continuing, the rivers overflow their banks nine or ten miles on each side, and for more than 150 miles up the stream. At this time, and more particularly in July, the tides are so strong as to come up the river Menan as far as the city of Siam, which is situated 60 miles from its mouth; and sometimes as far as Louvo, which is 50 miles higher. The winds blow from the west and north in October, when the rain ceases. In November and December the winds blow dry from the north, and the waters being in a few days reduced to their ancient channels, the tides become so insensible, that the water is fresh at the mouth of the river. At Siam there is never more than one flood and one ebb in the space of 24 hours. In January the wind blows from the east, and in February from the east and south. When the wind is at east, the

the current sets to the west; and, on the contrary, when the wind is at west, the currents run to the eastward.

As this country is situated near the tropic, it must necessarily be very hot; but yet, as in other places nearly of the same latitude, when the sun is vertical and shines with a most intense heat, the inhabitants are so skreened by the clouds, and the air is so refreshed by a deluge of rain that overflows the plains which the people chiefly inhabit, that the heat is very supportable. The coolest wind blows in December and January.

3 Vegetable productions. The vegetable produce of this country is chiefly rice and wheat, besides tropical and a few European fruits. The Siamese prepare the land for tillage as soon as the earth is sufficiently moistened by the floods. They plant their rice before the waters rise to any considerable height, and, as they rise slowly, the rice keeps pace with them, and the ear is always above the water. They reap their corn when the water retires, and sometimes go in boats to cut it while the waters are upon the ground. They also sow rice in several parts of the kingdom that are not overflowed, and this is thought better tasted, and will keep longer than the other; but they are forced to supply these fields constantly with water, while the rice is growing, from basins and ponds that lie about them.

They have no European fruits except oranges, lemons, citrons, and pomegranates. They have bananas, Indian figs, jaques, durions, mangoes, mangostans, tamarinds, ananas, and cocoa nuts; they have also abundance of pepper and sugar-canes. The mountains are covered with trees which make good masts. The vegetable of greatest use in the country is the bamboo, which grows chiefly in marshy soils, and is often found of a prodigious size. Cotton trees are found in great numbers; and others that yield *capoc*, a very fine cotton wool, but so short as to be unfit for spinning, though it answers very well for stuffing mattresses and pillows.

4 Animals. There is no country where elephants abound more than in Siam, or where they are held in greater veneration. They have a few horses, sheep, and goats, besides oxen and buffaloes; but they have no good animal food except the flesh of hogs, their beef and mutton being of a very indifferent quality.

5 Description of the inhabitants. The Siamese are of small stature, but well proportioned; their complexions are swarthy; the faces of both the men and women are broad, and their foreheads, suddenly contracting, terminate in a point, as well as their chins. They have small black eyes, hollow jaws, large mouths, and thick pale lips. Their teeth are dyed black, their noses are short and round at the end, and they have large ears, which they think very beautiful. Their hair is thick and lank, and both sexes cut it so short that it reaches no lower than their ears; the women make it stand up on their foreheads; and the men shave their beards.

6 Dress. People of distinction wear a piece of calico tied about their loins, that reaches down to their knees.—The men bring up this cloth between their legs, and tuck it into their girdles, which gives it the appearance of a pair of breeches. They have also a muslin shirt without a collar, with wide sleeves, no wristbands, and the bosom open. In winter they wear a piece of stuff or painted linen over their shoulders, like a mantle, and wind it about their arms.

The king of Siam is distinguished by wearing a vest of brocaded satin, with straight sleeves that reach down to the wrist, under such a shirt as we have just described, and it is unlawful for any subject to wear this dress unless he receives it from the king. They wear slippers with piked toes turned up, but no stockings. The king sometimes presents a military vest to the generals; this is buttoned before, and reaches to the knees; but the sleeves are wide, and come no lower than the elbows. All the retinue of the king, either in war or in hunting, are clothed in red. The king wears a cap in the form of a sugar-loaf, encompassed by a coronet or circle of precious stones, and those of his officers have a circle of gold, silver, or of vermilion gilt, to distinguish their quality; and these caps are fastened with a stay under the chin; they are only worn when they are in the king's presence, or when they preside in courts of justice, and on other extraordinary occasions. They have also hats for travelling; but, in general, few people cover their heads notwithstanding the scorching heat of the sun.

The women also wrap a cloth about their middle, which hangs down to the calf of their legs. They cover their breasts with another cloth, the ends of which hang over their shoulders. But they have no garment corresponding to a shift, nor any covering for their heads but their hair. The common people are almost naked, and wear neither shoes nor slippers. The women wear as many rings on the three last fingers of each hand as they can keep on, and bracelets upon their wrists and ancles, with pendants in their ears shaped like a pear.

For an inferior to stand before a superior is deemed insolent; and therefore slaves and people of inferior rank sit upon their heels, with their heads a little inclined, and their joined hands lifted up to their foreheads. In passing by a superior they bend their bodies, joining their hands, and lifting them towards their heads in proportion to the respect they would show. When an inferior pays a visit, he enters the room stooping, prostrates himself, and then remains upon his knees, sitting upon his heels without speaking a word till he is addressed by the person whom he visits; for he that is of the highest quality must always speak first. If a person of rank visits an inferior, he walks upright, and the master of the house receives him at the door, and waits on him so far when he goes away, but never farther. 7 Manners and customs.

The highest part of the house is esteemed the most honourable, and no person cares to lodge under another's feet. The Siamese indeed have but one story, but the rooms rise gradually, and the innermost, which are the highest, are always the most honourable. When the Siamese ambassador came to the French court, some of his retinue were lodged in a floor over the ambassador's head; but they no sooner knew it, than they were struck with the greatest consternation, and ran down tearing their hair at the thoughts of being guilty of what they considered as so unpardonable a crime.

The Siamese never permit such familiarities as are practised by gentlemen in Europe. Easiness of access,

and

Siam. and affability to inferiors, is in that part of the world thought a sign of weakness, and yet they take no notice of some things which may be looked upon as ill breeding among us; such as belching in company, which no man endeavours to prevent or so much as holds his hand before his mouth. They have an extraordinary respect for the head, and it is the greatest affront to stroke or touch that of another person; nay, their cap must not be used with too much familiarity; for when a servant carries it, it is put on a stick and held above his head; and when the master stands still the stick is set down, it having a foot to stand upon. They also show their respect by lifting their hands to the head; and therefore, when they receive a letter from any one for whom they have a great respect, they immediately hold it up to their heads, and sometimes lay it upon their heads.

8 Genius and dispositions. They are esteemed an ingenious people, and though rather indolent than active in disposition, they are not addicted to the voluptuous vices which often accompany a state of ease, being remarkably chaste and temperate, and even holding drunkenness in abhorrence.—They are, however, accounted insolent towards their inferiors, and equally obsequious to those above them; the latter of which qualities appears to be particularly inculcated from their earliest youth. In general, their behaviour is extremely modest, and they are averse to loquacity. Like the Chinese, they avoid speaking in the first person: and when they address a lady, it is always with some respectful epithet, insinuating personal accomplishments.

No man in this country learns any particular trade, but has a general knowledge of all that are commonly practised, and every one works six months for the king by rotation; at which time, if he should be found perfectly ignorant of the business he is set about, he is doomed to suffer the bastinado. The consequence of this burdensome service is, that no man endeavours to excel in his business, lest he should be obliged to practise it as long as he lives for the benefit of the crown.

9 Government. The government of this country is extremely oppressive, the king being not only sovereign but proprietor of all the lands, and chief merchant likewise; by which means he monopolizes almost the whole traffic, to the great prejudice of his subjects. The crown is said to be hereditary, but it is often transferred by revolutions, on account of the exorbitant abuse of power in those who exercise the royal office. In his palace, the king is attended by women, who not only prepare his food, and wait on him at table, but even perform the part of valets, and put on all his clothes, except his cap, which is considered as too sacred to be touched by any hand but his own. He shows himself to the people only twice a-year, when he distributes his alms to the talapoins or priests: and on those occasions he always appears in an elevated situation, or mounted on the back of an elephant. When he takes the diversion of hunting, he is as usual attended by his women on foot, preceded by a guard of 200 men, who drive all the people from the roads through which they are to pass; and when the king stops, all his attendants fall upon their faces on the ground.

10 Forms of process. All their proceedings in law are committed to writing, and none is suffered to exhibit a charge against another, without giving security to prosecute it, and answer the damages if he does not prove the fact against the person accused. When a person intends to prosecute another, he draws up a petition, in which he sets forth his complaint, and presents it to the *nai*, or head of the band to which he belongs, who transmits it to the governor; and if the complaint appears frivolous, the prosecutor, according to the laws of the country, should be punished; but the magistrates generally encourage prosecutions on account of the perquisites they bring to their office.

Every thing being prepared for hearing, the parties are several days called into court, and persuaded to agree; but this appears to be only a matter of form. At length the governor appoints a day for all parties to attend; and being come into court, the clerk reads the process and opinion of his associates, and then the governor examines upon what reasons their opinions are founded; which being explained to him, he proceeds to pass judgment.

When sufficient proofs are wanting, they have recourse to an ordeal trial, like that of our Saxon ancestors: both the plaintiff and the defendant walk upon burning coals, and he that escapes unhurt is adjudged to be in the right: sometimes the proof is made by puting their hands in boiling oil; and in both these trials, by some peculiar management, one or the other is said to remain unhurt. They have also a proof by water, in which he who remains longest under it is esteemed innocent. They have another proof, by swallowing pills, which their priests administer with severe imprecations; and the party who keeps them in his stomach without vomiting is thought to be innocent. 11 Trial by ordeal.

All these trials are made in the presence of the magistrates and people; and the king himself frequently directs them to be performed, when crimes come before him by way of appeal. Sometimes he orders both the informer and prisoner to be thrown to the tigers: and the person that escapes by his not being seized upon by those beasts, is sufficiently justified.

They maintain the docrine of transmigration, believing in a pre-existent state, and that they shall pass into other bodies till they are sufficiently purified to be received into paradise. They believe likewise that the soul is material, but not subject to the touch; that it retains the human figure after quitting a body of that species; and that when it appears to persons with whom it was acquainted, which they suppose it to do, the wounds of one that has been murdered will then be visible. They are of opinion that no man will be eternally punished; that the good, after several transmigrations, will enjoy perpetual happiness; but that those who are not reformed will be doomed to transmigration to all eternity. They believe in the existence of a Supreme Being; but the objects of their adoration are departed saints, whom they consider as mediators or intercessors for them; and to the honour of this numerous tribe both temples and images are erected. 12 Religious opinions.

The men of this country are allowed a plurality of women; but excepting one, who is a wife by contract, the others are only concubines, and their children deemed incapable of any legal inheritance. Previous to every nuptial contract, an astrologer must be consulted, who calculates the nativity of the parties, and determines whether their union is likely to prove fortunate or 13 Marriages.

Siam ‖ Sibenico.

or otherwise. When his prognostication is favourable, the lover is permitted to visit his mistress three times, at the last of which interviews the relations being present, the marriage portion is paid, when, without any religious ceremony performed, the nuptials are reckoned complete, and soon after consummated. A few days after the talapoin visits the married couple, sprinkles them with water, and repeats a prayer for their prosperity.

14 Funerals. The practice in Siam respecting funerals, is both to burn and bury the dead. The corpse being laid upon the pile, it is suffered to burn till a considerable part is consumed, when the remainder is interred in a burying-place contiguous to some temple. The reason which they give for not burning it entirely to ashes is, that they suppose the deceased to be happy when part of his remains escapes the fire. Instead of a tombstone, they erect a pyramid over the grave. It was formerly the custom to bury treasure with the corpse; but longer experience evincing, that the sacrilegious light in which robbing the graves was considered did not prevent the crime, they now discontinue the ancient practice, and instead of treasure bury only painted papers and other trifles.

15 Rivers. The two principal rivers are the Menan and the Mecon, which rise in the mountains of Tartary, and run to the south; the former passing by the city of Siam, falls into the bay of the same name, in the 13th degree of north latitude; and the latter running through Laos and Cambodia, discharges itself into the Indian ocean in the 9th degree of north latitude.

16 Description of the capital. The capital of the country is Siam, called by the natives *Sryothoya*, situated in the 101st degree of east longitude, and in the 14th degree of north latitude, being almost encompassed by the branches of the river Menan. It is about 10 miles in circumference within the walls, but not a sixth part of the ground is occupied by buildings. In the vacant spaces there are near 300 pagodas or temples, round which are scattered the convents of the priests and their burying-places. The streets of the city are spacious, and some have canals running through them, over which is a great number of bridges. The houses stand on pillars of the bamboo cane, and are built of the same materials: the communication between different families, during the winter season, being carried on as in other tropical countries by means of boats. The grounds belonging to the several tenements are separated by a palisado, within which the cattle are housed in barns, erected likewise upon pillars, to preserve them from the annual inundation.

SIBBALDIA, a genus of plants belonging to the class of pentandria, and to the order of pentagynia; and in the natural system arranged under the 35th order, *Senticosæ*. See BOTANY *Index*.

SIBENICO, or SEBENICO, the name of a city and province of Dalmatia. The province of Sibenico runs along the sea for more than 30 miles; reaches in some places above 20 miles within land, and comprehends above 70 islands. The city of Sibenico is situated near the mouth of the river Cherca, in the gulf of Venice, 55 miles north of Spalatto, and 25 south-east of Zara. E. Long. 16° 46′, N. Lat. 44° 17′. It belongs to the Venetians. It is defended on one side by a castle, which held out against repeated attacks of the Turks, and towards the sea by a fort.

Siberia.

1 Boundaries and extent. SIBERIA, a large country, comprehending the most northerly parts of the Russian empire in Asia. It is bounded on the east by the eastern ocean; on the south by Great Tartary; on the west by Russia; and on the north by the Frozen ocean. It is about 2000 miles in length from east to west, and 750 miles in breadth from north to south.

2 Conquered by the Russians. At what time this country was first inhabited, or by whom it was peopled, we are entirely ignorant; but writings have been found in it when it was discovered, which shows that it must have been early known to a civilized people *. The Russians, from whom we have received our knowledge, knew nothing of it before the middle of the 16th century. In the reign of John Basilowitz I. indeed, an incursion had been made into Siberia, and some Tartar tribes subdued: but these conquests were not permanent; and we hear of no further communication between Russia and Siberia till the time of John Basilowitz II. It was opened again at that time by means of one Anika Strogonoff, a Russian merchant, who had established some salt-works at a town in the government of Archangel. This man carried on a trade with the inhabitants of the north-west parts of Siberia, who brought every year to the town above-mentioned large quantities of the finest furs. Thus he acquired a very considerable fortune in a short time; when at last the czar, perceiving the advantages which would accrue to his subjects from having a regular intercourse with Siberia, determined to enlarge the communication which was already opened. With this view he sent into Siberia a body of troops, which crossed the Yugorian mountains, that form part of the north-eastern boundary of Europe. They seem, however, not to have passed the Irtish, or to have penetrated farther than the western branch of the river Oby. Some Tartar tribes were laid under contribution, and a chief named *Yediger* consented to pay an annual tribute of 1000 sables. But this produced no lasting advantage to Russia; for, soon after, Yediger was defeated and taken prisoner by Kutchum Khan, a descendant of the great Jenghiz Khan: and thus the allegiance of this country to Russia was dissolved.

* *Bell's Travels.*

For some time we hear of no further attempts made by the Russians on Siberia; but in 1577 the foundation of a permanent conquest was laid by one Yermac Temofeeff, a Cossack of the Don. This man was at first the head of a party of banditti who infested the Russians in the province of Casan; but being defeated by the troops of the czar, he retired with 6000 of his followers into the interior parts of that province. Continuing his course still eastward, he came to Orel, the most easterly of all the Russian settlements. Here he took up his winter-quarters: but his restless genius did not suffer him to continue for any length of time in a state of inactivity; and from the intelligence he procured concerning the situation of the neighbouring Tartars of Siberia, he turned his arms towards that quarter.

3 State of Siberia at the time of the Russian conquest. Siberia was at that time partly divided among a number of separate princes, and partly inhabited by the various tribes of independent Tartars. Of the former Kutchum Khan was the most powerful sovereign. His dominions consisted of that tract of country which now forms the south-western part of the province of Tobolsk; and stretched from the banks of the Irtish and Oby to those

Siberia. those of the Tobol and Tura. His principal residence was at Sibir, a small fortress upon the river Irtish, not far from the present town of Tobolsk, and of which some ruins are still to be seen. After a course of unremitted fatigue, and a series of victories which almost exceed belief, but of which we have not room to give the detail, our intrepid adventurer dispossessed this prince of his dominions, and seated himself on the throne of Sibir. The number of his followers, however, being greatly reduced, and perceiving he could not depend on the affection of his new subjects, he had recourse to the czar of Muscovy, and made a tender of his new acquisitions to that monarch, upon condition of receiving immediate and effectual support. This proposal was received with the greatest satisfaction by the czar, who granted him a pardon for all former offences, and sent him the required succours. Yermac, however, being soon after drowned in an unsucessful excursion, the Russians began to lose their footing in the country. But fresh reinforcements being seasonably sent, they not only recovered their ground, but pushed their conquests far and wide; wherever they appeared, the Tartars were either reduced or exterminated. New towns were built, and colonies were planted on all sides. Before a century had well elapsed, all that vast tract of country now called *Siberia*, which stretches from the confines of Europe to the Eastern ocean, and from the Frozen sea to the present frontiers of China, was annexed to the Russian dominions.

4 Climate. The air of Siberia is, in general, extremely piercing, the cold there being more severe than in any other part of the Russian dominions. The Siberian rivers are frozen very early, and it is late in the spring before the ice is thawed (A). If the corn does not ripen in August, there is little hope of a harvest in this country; and in the

(A) M. Gmelin, M. Muller, and two other philosophers, set out in the year 1733 to explore the dreary regions of Siberia, by desire of the empress Anne of Russia. After spending nine years and a half in observing every thing that was remarkable, they returned to Petersburgh; and an account of this journey was published by M. Gmelin. In order to examine how far the frost had penetrated into the ground, M. Gmelin, on the 18th of June, at a place called Jacutia, ordered the earth to be dug in high ground; they found mould to the depth of 11 inches, under which they met with loose sand to two feet and a half further, after which it grew harder, and at half a foot deeper so hard as scarcely to give way to the tools; so that the ground still remained unthawed at not less than the depth of four feet. He made the same experiment in a lower situation; the soil was 10 inches deep, after that a loose sand for two feet and ten inches, below which all was frozen and hard. At Jacutia the inhabitants preserve in cellars several sorts of berries, which they reckon among their dainties, perfectly good and fresh the whole year, though these cellars are scarcely a fathom deep. At the fortress of Argun, in little more than 50 degrees of latitude, the inhabitants relate that the earth in many places is never thawed above a yard and a half, and that the internal cold of the earth will scarcely permit a well to be dug, of which they bring an instance that happened not long before the author's arrival at that place. They designed to sink a well near a house at some distance from the river Argun, for which purpose they thawed the earth by degrees, and dug some fathoms till they had penetrated a fathom and half below the level of the river, but found no spring. Hence perhaps we may venture to assert, that besides the great elevation of the earth in these countries, there is another cause, perhaps latent in the earth itself, of this extraordinary cold, naturally suggested to us by considering the cavity of an old silver mine at Argun, which being exhausted of its ore, now serves the inhabitants in summer time for a cellar to keep their provisions: this place is so extremely cold as to preserve flesh meats from putrefaction in the hottest summers, and to sink the mercury in De Lisle's thermometer to 146 and 147. The author travelling from Nerschoi towards Argun, to visit the works of the silver mines in that place, August 1735, came to the river Orkija, near Solonischaia, on July the first, from whence he arrived a little before dark at the village of Seventua, distant from the river 27 leagues. In this journey he and his fellow travellers for more than four leagues felt it vastly cold; soon after they came into a warm air, which continued some leagues; after which the cold returned; and thus are travellers subjected to perpetual vicissitudes of warmth and cold. But it is observed in general, that the eastern parts are colder than the western, though situated in the same latitude; for as in those eastern regions some tracts of land are much colder than the rest, their effects must be felt by the neighbouring parts. And this conjecture is favoured by the thermometrical observations made with M. de L'Isle's instrument in all parts of Siberia, in which the mercury was depressed to the 226th degree, even in those parts that lie very much towards the south, as in the territory of Selinga, which said degree answers in Fahrenheit's thermometer to about 55.5 below 0, but the same thermometer sometimes indicated a much greater cold. At the fort of Kiringa, on February 10. 1738, at 8 in the morning, the mercury stood at 240, which answers nearly to 72 below 0 in Fahrenheit's. On the 23d of the same month it was a degree lower. At the same place, December 11. at three in the afternoon, it stood at 254 in De Lisle's thermometer, and very near 90 in Fahrenheit's; on December 29. at four in the afternoon, at 263; on November 27. at noon, at 270; January 9. at 275, which several depressions answer in Fahrenheit's to 99.44, 107.73, and 113.65; on January 5. at five in the morning, at 262; an hour after at 281, but at eight o'clock it returned to 250, and there remained till six in the afternoon, and then rose by degrees till an hour before midnight, when it stood at 202. So that the greatest depression of the mercury answers in Fahrenheit's thermometer to 120.76 degrees below 0, which is indeed very surprising, and what nobody ever imagined before. While this cold lasted at Jenisea, the sparrows and magpies fell to the ground, struck dead, as it were, with the frost, but revived if they were soon brought into a warm room. The author was told also that numbers of wild beasts were found in the woods dead and stiff with the frost, and several travellers had their blood and juices quite frozen in their vessels. The air itself at that time was so dismal, that you would think it changed to ice, as it was a thick fog, which was not dissipable by any exhalations, as in the spring and autumn, and the author could scarcely stand three minutes in the porch of his house for the cold.

Siberia. the province of Jeniseisk it is sometimes covered with snow before the peasants can reap it. To defend the inhabitants against this extreme severity of the climate, Providence seems more liberally to have dealt out to them wood for fuel and furs for clothing. As the winter days in the north parts of Siberia last but a few hours, and the storms and flakes of snow darken the air so much, that the inhabitants, even at noon, cannot see to do any thing without artificial lights, they sleep away the greatest part of that season.

These severe winters are rapidly succeeded by summers, in which the heat is so intense that the Tungusians, who live in the province of Jakutsk, go almost naked. Here is scarcely any night during that season; and towards the Frozen ocean the sun appears continually above the horizon. The vegetables and fruits of the earth are here extremely quick in their growth.

5 Soil and produce. The whole tract of land beyond the 60th degree of north latitude is a barren waste; for the north part of Siberia yields neither corn nor fruits; though barley is known frequently to come to perfection in Jakutsk.—For this reason, the inhabitants of the northern parts are obliged to live on fish and flesh, but the Russians are supplied with corn from the southern parts of Siberia, where the soil is surprisingly fertile. The countries beyond the lake of Baikal, especially towards the east, as far as the river Argun, are remarkably fruitful and pleasant; but such is the indolence of the inhabitants, that several fine tracts of land, which would make ample returns to the peasant for cultivating them, lie neglected. The pastures are excellent in this country, which abounds in fine horned cattle, horses, goats, &c. on which the Tartars chiefly depend for subsistence. However, there are several steppes, or barren wastes, and unimproved tracts in these parts; and not a single fruit tree is to be seen. There is great variety of vegetables, and in several places, particularly near Krasnoia Sloboda, the ground is in a manner overrun with asparagus of an extraordinary height and delicious flavour. The bulbs of the Turkish bundes, and other sorts of lilies, are much used by the Tartars instead of bread. This want of fruit and corn is richly compensated by the great quantities of wild and tame beasts and fowls, and the infinite variety of fine fish which the country affords (B).

In that part of Siberia which lies near the Icy sea, as well as in several other places, are woods of pine, larch, and other trees; besides which, a considerable quantity of wood is thrown ashore by the waves of the Icy sea; but whence it comes is not yet ascertained.

6 Wild beasts. Besides the wild fowl with which Siberia abounds, there is a prodigious number of quadrupeds, some of which are eatable, and others valuable for their skins or furs.

The animals most valued for their skins are the black fox, the sable, the hyena, the ermine, the squirrel, the beaver, and the lynx. The skin of a real black fox is more esteemed than even that of a sable. In the country near the Frozen ocean are also blue and white foxes. The finest sables come from Nertshinsk and Jakutsk, the inhabitants of which places catch them in the mountains of Stannowoi Krebet. The tributary nations were formerly obliged to pay their taxes in the skins of foxes and sables only. But now the skins of squirrels, bears, rein-deer, &c. and sometimes money, are received by way of tribute; and this not only from those who live near the Lena, but also in the governments of Ilinsk, Irkutzk, Selenginsk, and Nertshinsk. When the Tartars first became tributary to Russia, they brought their furs indiscriminately as they caught them, and among them were often sables of extraordinary value; and formerly, if any trader brought with him an iron kettle, they gave him in exchange for it as many sables as it would hold. But they are now better acquainted with their value. They sell their sables to smugglers at a very high price, and pay only a ruble instead of a skin to the revenue officers, who now receive more ready money than sables by way of tribute. The subjects plead the scarcity of furs, and indeed not without some appearance of truth.

Siberia has still other and more valuable treasures than those we have yet mentioned. The silver mines of Argun are extremely rich; the silver they produce yields some gold, and both of these are found among the copper ore of Koliwan. This country is also particularly rich in copper and iron ore. The former lies even upon the surface of the earth: and considerable mines of it are found in the mountains of Pietow, Koliwan, Ploskau, Woskeresensk, Kuswi, Alepaik, and several others, and in the government of Krasnoiarsk (C). Iron is still more plentiful in all these places, and very good; but that of Kamenski is reckoned the best. Several hundred thousand puds of these metals are annually exported from the smelting houses, which belong partly to the crown, and partly to private persons. Most of them lie in the government of Catharinenburg. The Tartars also extract a great quantity of iron from the ore. 7 Minerals.

The topazes of Siberia have a fine lustre; and in open sandy places, near the river Argun, as well as on the banks of other rivers and lakes, are found single small pieces of agate. Here are also cornelians and green jasper with red veins. The latter is chiefly met with in the deserts of Gobiskoi. 8 Precious stones.

The famous marienglas, or lapis specularis, great quantities 9 Marienglas.

(B) The oak, though frequent in Russia, it is said, is not to be found through this vast region nearer than the banks of the Argun and Amur, in the dominions of China. The white poplar, the aspen, the black poplar, the common sallow, and several species of the willow, are very common. The Norway and silver fir form great forests; but the former does not grow beyond the 60th degree of north latitude, and the latter not beyond 58 degrees. To this dreary region of Siberia, Europe is indebted for that excellent species of oats called *Avena Sibirica;* and our gardens are enlivened with the gay and brilliant flowers brought from the same country.

(C) The copper mines of Koliwan, from which gold and silver are extracted, employ above 40,000 people. The silver mines of Nertshinsk, beyond Lake Baikal, employ above 14,000. The whole revenue arising from these mines, according to Mr Coxe, is not less than 679,182l. 13s.

Siberia. quantities of which are dug up in Siberia, is by some called Muscovy or Russian glass. It is a particular species of transparent stone, lying in strata like so many sheets of paper. The matrix or stone in which it is found, is partly a light yellow quartz, or marcassia, and partly a brown indurated fluid; and this stone contains in it all the species of the marienglas. To render the marienglas fit for use, it is split with a thin two-edged knife; but care is taken that the laminæ be not too thin. It is used for windows and lanterns all over Siberia, and indeed in every part of the Russian empire, and looks very beautiful; its lustre and clearness surpassing that of the finest glass, to which it is particularly preferable for windows and lanterns of ships, as it will stand the explosion of cannon. It is found in the greatest plenty near the river Witim.

10 Magnets.

Siberia affords magnets of an extraordinary size, and even whole mountains of loadstone. Pit-coal is also dug up in the northern parts of this country. The kamennoe maslo, a yellowish kind of alum, unctuous and smooth to the touch, like tophus, is found in the mountains of Krasnoiarsk, Ural, Altaish, Jenisea, Baikal, Bargusik, Lena, and several others in Siberia.

11 Salt lakes and springs.

In this country are not only a great number of fresh water lakes, but likewise several whose waters are salt; and these reciprocally change their nature, the salt sometimes becoming fresh, and the fresh changing into saline. Some lakes also dry up, and others appear where none were ever seen before. The salt lake of Yamusha, in the province of Tobolsk, is the most remarkable of all, for it contains a salt as white as snow, consisting entirely of cubic crystals. One finds also in Siberia saline springs, salt water brooks, and a hill of salt.

12 Curiosities.

Siberia affords many other things which deserve notice. That useful root called rhubarb grows in vast quantities near the city of Seleginsk. The curious mammuth's bones and horns, as they are called, which are found along the banks of the Oby, Jenesei, Lena, and Irtish, are unquestionably the teeth and bones of elephants. But whether these elephants teeth and bones were conveyed to these northern regions by the general deluge, or by any other inundation, and were by degrees covered with earth, is a point which might lead us into long and very fruitless disquisitions; we shall therefore only observe, that such bones have likewise been found in Russia, and even in several parts of Germany. A kind of bones of a still larger size than these have also been dug up in Siberia, and seem to have belonged to an animal of the ox kind. The horn of the whale called *narwhal* has been found in the earth near the rivers Indigirka and Anadir; and the teeth of another species of whales, called *wolross*, about Anadirskoi. The latter are larger than the common sort, which are brought from Greenland, Archangel, and Kola.

13 Mountains.

The chain of Siberian mountains reaches from that of Werchoturie towards the south as far as the neighbourhood of the city of Orienburg, in a continued ridge, under the name of the Uralian mountains; but from thence it alters its direction westward. These mountains are a kind of boundary between Russia Proper and Siberia. Another chain of hills divides Siberia from the country of the Calmucks and Mongolians.—These mountains, between the rivers Irtish and Oby, are called the Altaic or Golden Mountains, which name they afterwards lose, particularly between the river Jenesei and the Baikal lake, where they are called the Sayanian mountains. Siberia || Sibyls.

14 Inhabitants.

The inhabitants of Siberia consist of the aborigines or ancient inhabitants, the Tartars, and Russians, and of state criminals.

Some of these nations have no other religion but that of nature; others are Pagans or Mahometans, and some of them have been converted to Christianity, or rather only baptised by the Russian missionaries.

SIBTHORPIA, a genus of plants belonging to the class of didynamia, and to the order of angiospermia; and in the natural system classed with those the order of which is doubtful. See Botany *Index*.

SIBYLS, in pagan antiquity, certain women said to have been endowed with a prophetic spirit, and to have delivered oracles, showing the fates and revolutions of kingdoms. Their number is unknown. Plato speaks of one, others of two, Pliny of three, Ælian of four, and Varro of ten; an opinion which is universally adopted by the learned. These ten Sibyls generally resided in the following places, Persia, Libya, Delphi, Cumæ in Italy, Erythræa, Samos, Cumæ in Æolia, Marpessa on the Hellespont, Ancyra in Phrygia, and Tiburtis. The most celebrated of the Sibyls is that of Cumæ in Italy, whom some have called by the different names of Amalthæa, Demiphile, Herophile, Daphne, Manto, Phemonoe, and Deiphobe. It is said, that Apollo became enamoured of her, and that to make her sensible of his passion he offered to give her whatever she should ask. The Sibyl demanded to live as many years as she had grains of sand in her hand, but unfortunately forgot to ask for the enjoyment of the health, vigour, and bloom, of which she was then in possession. The god granted her request, but she refused to gratify the passion of her lover though he offered her perpetual youth and beauty. Some time after she became old and decrepit, her form decayed, melancholy paleness and haggard looks succeeded to bloom and cheerfulness. She had already lived about 700 years when Æneas came to Italy, and as some have imagined, she had three centuries more to live before her years were as numerous as the grains of sand which she had in her hand. She gave Æneas instructions how to find his father in the infernal regions, and even conducted him to the entrance of hell. It was usual for the Sibyl to write her prophecies on leaves, which she placed at the entrance of her cave; and it required particular care in such as consulted her to take up these leaves before they were dispersed by the wind, as their meaning then became incomprehensible. According to the most authentic historians of the Roman republic, one of the Sibyls came to the palace of Tarquin the Second, with nine volumes, which she offered to sell for a very high price. The monarch disregarded her, and she immediately disappeared, and soon after returned, when she had burned three of the volumes. She asked the same price for the remaining six books; and when Tarquin refused to buy them, she burned three more, and still persisted in demanding the same sum of money for the three that were left.—This extraordinary behaviour astonished Tarquin; he bought the books, and the Sibyl instantly vanished, and never after appeared to the world. These books were preserved with great care by the monarch, and called the Sibylline verses. A college of priests was appointed to have the care of them; and such reverence did the Romans

Lempriere's Dictionary.

Sibyls | Sicily.

Romans entertain for these prophetic books, that they were consulted with the greatest solemnity, and only when the state seemed to be in danger. When the capitol was burnt in the troubles of Sylla, the Sibylline verses which were deposited there perished in the conflagration; and to repair the loss which the republic seemed to have sustained, commissioners were immediately sent to different parts of Greece to collect whatever verses could be found of the inspired writings of the Sibyls. The fate of these Sibylline verses which were collected after the conflagration of the capitol is unknown. There are now many Sibylline verses extant, but they are reckoned universally spurious; and it is evident that they were composed in the second century by some of the followers of Christianity, who wished to convince the heathens of their error, by assisting the cause of truth with the arms of pious artifice.

SICERA, a name given to any inebriating liquor by the Hellenistic Jews. St Chrysostom, Theodoret, and Theophilus of Antioch, who were Syrians, and who therefore ought to know the signification and nature of "sicera," assure us, that it properly signifies palm-wine. Pliny acknowledges, that the wine of the palm-tree was very well known through all the east, and that it was made by taking a bushel of the dates of the palm-tree, and throwing them into three gallons of water; then squeezing out the juice, it would intoxicate like wine. The wine of the palm tree is white: when it is drunk new, it has the taste of the cocoa, and is sweet as honey. When it is kept longer, it grows stronger, and intoxicates. After long keeping, it becomes vinegar.

SICILIAN, in *Music*, denotes a kind of gay sprightly air, or dance, probably invented in Sicily, somewhat of the nature of an English jig; usually marked with the characters $\frac{6}{8}$, or $\frac{12}{8}$. It consists of two strains; the first of four, and the second of eight, bars or measures.

1 Boundaries and extent.

SICILY, is a large island in the Mediterranean sea, adjoining to the southern extremity of Italy, and extends from latitude 36° 25′ to latitude 38° 25′, and from longitude 12° 50′ to longitude 16° 5′ east from London. Its greatest length 210 miles, breadth 133, circumference 600; its form triangular, the three angles being the promontories of Pelorum, Pachynum, and Lilybæum, or, as they are now called, the Faro, Capo Passaro, and Capo Boco. It is divided from Italy by the straits of Messina, reaching from the tower of Faro, which is the most northerly part of the island, to the *Capo dell' Armi*, or the Cape of Arms, the most southern part of Calabria. These straits, by the Latins called *Fretum Siculum*, by the Italians *Il Faro di Messina*, and by us the *Faro of Messina*, are between 12 and 15 miles over in the broadest places, and in the narrowest about a mile and a half; insomuch that when Messina was taken by the Carthaginians, many of the inhabitants are said to have saved themselves by swimming to the opposite coast of Italy. Hence has arisen an opinion that the island of Sicily was originally joined to the continent, but afterwards separated by an earthquake or some other natural cause. This separation, however, is reckoned by the most judicious among the ancients to be fabulous; and they content themselves with speaking of it as a thing said to have happened.

2 History during the fabulous ages.

Anciently this island was called *Sicania*, *Sicilia*, and *Trinacria* or *Triquetra*; the two former it had from the Sicani and Siculi, who peopled a considerable part of the country; the two latter from its triangular figure. Its first inhabitants, according to the most respectable ancient authors, were the Cyclopes and Læstrigones, who are said to have settled in the countries adjoining to Mount Etna; but of their origin we know nothing, except what is related by the poets. After them came the Sicani, who called themselves the original inhabitants of the country; but several ancient historians informs us that they came from a country in Spain watered by the river Siconus. Diodorus, however, is of opinion, that the Sicani were the most ancient inhabitants of this island. He tells us that they were in possession of the whole, and applied themselves to cultivate and improve the ground in the neighbourhood of Etna, which was the most fruitful part of the island: they built several small towns and villages on the hills to secure themselves against thieves and robbers; and were governed, not by one prince, but each city and district by its own king. Thus they lived till Etna began to throw out flames, and forced them to retire to the western parts of the island, which they continued to inhabit in the time of Thucydides. Some Trojans, after the destruction of their city, landed in the island, settled among the Sicani, and built the cities of Eryx and Egesta, uniting themselves with them, and taking the general name of Elymi or Elymæi. They were afterwards joined by some Phocenses, who settled here on their return from the siege of Troy.

After the Sicani had for many ages enjoyed an undisturbed possession of the whole of Sicily, or such parts of it as they chose to inhabit, they were visited by the Siculi, who were the ancient inhabitants of Ausonia properly so called; but being driven out from thence by the Opici, they took refuge in the island of Sicily. Not being contented with the narrow bounds allowed them by the Sicani, they began to encroach upon their neighbours; upon which a war ensuing, the Sicani were utterly defeated, and confined to a corner of the island, the name of which was now changed from *Sicania* into that of *Sicilia*.

About 300 years after the arrival of the Siculi, the island first began to be known to the Greeks, who established various colonies, and built many cities in different parts of the island; and it is only from the time of their arrival that we have any history of the island. The first of the Greeks that came into Sicily were the Chalcidians of Eubœa, under the conduct of Thucles, who built Naxus, and a famous altar of Apollo, which, as Thucydides tells us, was still standing in his time without the city. The year after, which was, according to Dionysius Halicarnassensis, the third of the 17th Olympiad, Archias the Corinthian, one of the Heraclidæ, laid the foundations of Syracuse. Seven years after, a new colony of Chalcidians founded Leontini and Catana, after having driven out the Siculi, who inhabited that tract. About the same time Lamis, with a colony from Megara, a city of Achaia, settled on the river Pantacius, at a place called *Trotilum*, where his adventurers lived some time in common with the Chalcidians of Leontini; but being driven from thence by the Leontines, he built the city of Thapsus, where he died. Upon his death, the colony left Thapsus; and under the conduct of Hyblon king of the Siculi, founded Megara Hyblæa, where they resided 245 years, till they

Sicily.

they were driven out by Gelon tyrant of Syracuse. During their abode at Megara, they sent one Pamilus, who was come from Megara in Achaia, their original city, to build Selinus. This city was founded about 100 years after the foundation of Megara. Antiphemus and Entimus, the former a Rhodian, the other a Cretan, led each a colony of their countrymen, and jointly built the city of Gela on a river of the same name, establishing in their new settlement the Doric customs, about 45 years after the founding of Syracuse. The inhabitants of Gela founded Agrigentum 108 years after their arrival in Sicily, and introduced the same customs there. A few years after, Zancle was built by the pirates of Cumæ in Italy; but chiefly peopled by the Chalcidians, Samians, and Ionians, who chose rather to seek new settlements than live under the Persian yoke. Some time after, Anaxales, tyrant of Rheginm, drove out the ancient proprietors; and, dividing his lands amongst his followers, called the city *Messana* or *Messene*, which was the name of his native city in Peloponnesus. The city of Himera was founded by the Zancleans under the direction of Eucleides, Simus, and Sacon; but peopled by the Chalcidians and some Syracusan exiles, who had been driven out by the contrary faction.

The Syracusans built Acræ, Chasmenæ, and Camarina; the first 70 years, the second 90, and the third 135, after the foundation of their own city. This is the account which Thucydides, a most judicious and exact writer, gives us of the various nations, whether Greeks or Barbarians, who settled in Sicily. Strabo counts among the ancient inhabitants of Sicily the Morgetes, who being driven out of Italy by the Oenotrians, settled in that part of the island where the ancient city of Morgantium stood. The Campani, who assumed the name of *Mamertini*, that is, *invincible warriors*, and the Carthaginians, who settled very early in Sicily, ought likewise to be counted among the ancient inhabitants of the island.

Before this period the history of Sicily is blended with fables, like the early history of almost every other country. After the settlement of the Greeks in the island, its various revolutions have been traced from their several sources by many writers; but by none with greater accuracy than Mr Swinburne. From his account of his Travels in the Two Sicilies, we have therefore taken the following concise history of this kingdom, which will at once gratify such of our readers as interest themselves in the fate of a generous people who long struggled in vain for freedom; and at the same time afford them a specimen of the entertainment they may receive from the very elegant work of the author.

Swinburne's Travels in the Two Sicilies, vol. ii. p. 176.

3 Grecian colonies in Sicily.

" Aristocracy prevailed at first in the Greek settlements, but soon made way for tyranny; which in its turn was expelled by democracy. One of the earliest destroyers of common liberty was Phalaris of Agrigentum, who reigned 600 years before Christ: his example was contagious; a legion of tyrants sprung up, and not a commonwealth in the island escaped the lash of an usurper. Syracuse was most oppressed and torn to pieces by dissension; as its wealth and preponderance in the general scale held out a greater temptation than other cities to the ambition of wicked men. It requires the combined testimony of historians to enforce our belief of its wonderful prosperity, and the no less extraordinary tyranny of some of its sovereigns. These Grecian colonies attained to such excellence in arts and sciences as emboldened them frequently to vie with the learned and ingenious in the mother country; nay, often enabled them to bear away the palm of victory: there needs no stronger proof of their literary merits than a bare recital of the names of Archimedes, Theocritus, Gorgias, and Charondas.

4 Carthaginians conquer great part of it.

" But the Sicilian Greeks were not destined to enjoy the sweets of their situation without molestation. Very soon after their arrival, the inhabitants of the neighbouring coast of Africa began to aspire to a share of Sicily. Carthage sent large bodies of forces at different times to establish their power in the island, and about 500 years before the Christian era had made themselves masters of all the western parts of it. The Siculi retained possession of the midland country, and the southern and eastern coasts were inhabited by the Greeks.

5 Gelo chosen king.

" About that time Gelo was chosen prince of Syracuse on account of his virtues, which grew still more conspicuous after his exaltation: had the example he set been followed by his successors, the advantages of freedom would never have been known or wished for by the Syracusans. The Carthaginians found in him a vigorous opponent to their project of enslaving Sicily, a project invariably pursued but never accomplished.

6 Is succeeded by Hiero.

" Hiero succeeded his brother Gelo, and, contrary to the usual progression, began his reign by a display of bad qualities. Sensible of his error, and improved by experience, he afterwards adopted more equitable measures. At his death the Syracusans threw off the yoke, and for sixty years revelled in all the joys of freedom. Their peace was, however, disturbed by the Athenians and the Carthaginians. The latter plundered Agrigentum, and threatened ruin to the rest of the Grecian states; but a treaty of peace averted that storm. The Athenians, under pretence of supporting their allies the people of Segesta, but in reality from a thirst of dominion, invested Syracuse with a formidable land and naval armament under the command of Nicias; in consequence of a rash indigested plan, ill conducted attacks, and inadequate supplies, their whole host was cut to pieces or led away into captivity.

7 Dionysius the elder and younger.

" Syracuse had scarcely time to breathe after her victory ere intestine wars broke out, and raised Dionysius to supreme command. Avarice, despotism, and cruelty, marked every day of his reign; but his military enterprises were crowned with constant success. He died in peace, and bequeathed a powerful sovereignty to a son of his name tainted with the same and worse vices, but not endowed with equal capacity and martial ability: in such hands the rod of tyranny ceased to be formidable, and the tyrant was driven out of Sicily by the patriotic party; but matters were not sufficiently settled for popular government, and Dionysius resumed the sceptre for a while, till Timoleon forced him into perpetual exile."

8 Agathocles the tyrant.

Liberty seemed now to be established on a permanent basis; but in Syracuse such prospects always proved illusory. Agathocles, a tyrant more inhuman than any preceding usurper, seized the throne, and deluged the country with blood. He was involved in a perilous contest with the Carthaginians, who obtained many advantages

Sicily.

vantages over him, drove his troops from post to post, and at last blocked up his capital. In this desperate situation, when all foreign helps were precluded, and hardly a resource remained at home, the genius of Agathocles compassed his deliverance by a plan that was imitated among the ancients by Hannibal, and among the moderns by the famous Cortes. He embarked with the flower of his army; forced his way through innumerable obstacles; landed in Africa; and, having burnt his fleet, routed the Carthaginians in a pitched battle, and laid their territory waste. Carthage seemed to be on the brink of ruin, and that hour might have marked her downfal had the Sicilian host been composed of patriotic soldiers, and not of ungovernable assassins; discord pervaded the victorious camp, murder and riot ensued; and the tyrant, after beholding his children and friends butchered before his face, escaped to Sicily, to meet a death as tragical as his crimes deserved.

9 Pyrrhus king of Epirus deceives the Sicilians.

Anarchy now raged throughout the island, and every faction was reduced to the necessity of calling in the assistance of foreign powers; among whom Pyrrhus king of Epirus took the lead, and reduced all parties to some degree of order and obedience. But ambition soon prompted him to invade those rights which he came to defend; he cast off the mask, and made Sicily feel under his sway as heavy a hand as that of its former oppressors; but the Sicilians soon assumed courage and strength enough to drive him out of the island.

10 The Mamertini surprise Messina and are assisted by the Romans;

About this period the Mamertini, whom Mr Swinburne indignantly styles a crew of miscreants, surprised Messina, and, after a general massacre of the citizens, established a republican form of government. Their commonwealth became so troublesome a neighbour to the Greeks, that Hiero II. who had been raised to the chief command at Syracuse in consideration of his superior wisdom and warlike talents, found himself necessitated to form a league with Carthage, in order to destroy this nest of villains. In their distress the Mamertini implored the assistance of Rome, though the senate had recently punished with exemplary severity one of their own legions for a similar outrage committed at Rhegium. The virtue of the Romans gave way to the temptation, and the desire of extending their empire beyond the limits of Italy cast a veil over every odious circumstance attending this alliance. A Roman army crossed the Faro, relieved Messina, defeated the Carthaginians, and humbled Hiero into an ally of the republic.

11 which gives rise to the first Punic war.

Thus begun the first Punic war, which was carried on for many years in Sicily with various success. The genius of Hamilcar Barcas supported the African cause under numberless disappointments and the repeated overthrows of his colleagues; at last, finding his exertions ineffectual, he advised the Carthaginian rulers to purchase peace at the price of Sicily. Such a treaty was not likely to be observed longer than want of strength should curb the animosity of the vanquished party: when their vigour was recruited, Hannibal son of Hamilcar easily persuaded them to resume the contest, and for 16 years waged war in the heart of the Roman territories. Meanwhile Hiero conducted himself with so much prudence, that he retained the friendship of both parties, and preserved his portion of Sicily in perfect tranquillity. He died in extreme old age, beloved and respected both at home and abroad.

12 The second Punic war raised by Hannibal.

His grandson Hieronymus, forsaking this happy line of politics, and contracting an alliance with Carthage, fell an early victim to the troubles which his own folly had excited. Once more, and for the last time, the Syracusans found themselves in possession of their independence: but the times were no longer suited to such a system; dissensions gained head, and distracted the public councils. Carthage could not support them, or prevent Marcellus from undertaking the siege of Syracuse, immortalized by the mechanical efforts of Archimedes, and the immensity of the plunder. See SYRACUSE.

13 Sicily conquered by the Saracens, and afterwards by the Normans.

The Sicilians after this relinquished all martial ideas, and during a long series of generations turned their attention solely to the arts of peace and the labours of agriculture. Their position in the centre of the Roman empire preserved them both from civil and foreign foes, except in two instances of a servile war. The rapacity of their governors was a more constant and insupportable evil. In this state of apathy and opulence Sicily remained down to the 7th century of our era, when the Saracens began to disturb its tranquillity. The barbarous nations of the north had before invaded and ravaged its coasts, but had not long kept possession. The Saracens were more fortunate. In 827 they availed themselves of quarrels among the Sicilians to subdue the country. Palermo was chosen for their capital, and the standard of Mahomet triumphed about 200 years. In 1038 George Maniaces was sent by the Greek emperor with a great army to attack Sicily. He made good his landing, and pushed his conquests with vigour: his success arose from the valour of some Norman troops, which were at that time unemployed and ready to sell their services to the best bidder. Maniaces repaid them with ingratitude; and by his absurd conduct gave the Mussulmans time to breathe, and the Normans a pretext and opportunity of invading the Imperial dominions in Italy. Robert and Roger of Hauteville afterwards conquered Sicily on their own account, not as mercenaries; for having substantially settled their power on the continent, they turned their arms against this island in obedience to the dictates of zeal and ambition. After ten years struggle, the Saracens yielded up the rich prize, and Robert ceded it to his brother Roger, who assumed the title of Great Earl of Sicily, ruled the state with wisdom, and ranks deservedly among the greatest characters in history. He raised himself from the humble station of a poor younger son of a private gentleman, to the exalted dignity of a powerful monarch, by the sole force of his own genius and courage; he governed a nation of strangers with vigour and justice, and transmitted his possessions undisputed to his posterity. Such an assemblage of great qualities is well intitled to our admiration.

14 Under the dominion of different monarchs.

He was succeeded by his son Simon, whose reign was short, and made way for a second son called Roger. In 1127 this prince joined to his Sicilian possessions the whole inheritance of Robert Guiscard (see NAPLES, N° 23.), and assumed the regal style. The greatest part of his reign was taken up in quelling revolts in Italy, but Sicily enjoyed profound peace. In 1154 his son William ascended the throne, and passed his life in war and confusion. William II. succeeded his father, and died without issue. Tancred, though basely born, was elected his successor, and after him his son William III. who was vanquished by Henry of Swabia. During the

Sicily. the troubles that agitated the reign of his son the emperor Frederic, peace appears to have been the lot of Sicily. A short-lived sedition, and a revolt of the Saracens, are the only commotions of which we read. For greater security, the Saracens were removed to Puglia 400 years after the conquest of Sicily by their ancestors. Under Conrad and Manfred Sicily remained quiet; and from that time the history of Sicily is related under the article NAPLES, N° 20, &c.

15 Is at length conquered by the Spaniards.

At the death of Charles II. of Spain, his spoils became an object of furious contention; and at the peace of Utrecht, Sicily was ceded to Victor duke of Savoy, who, not many years after, was forced by the emperor Charles VI. to relinquish that fine island, and take Sardinia as an equivalent. But as the Spaniards had no concern in these bargains, they made a sudden attempt to recover Sicily, in which they failed through the vigilance of the English admiral Byng. He destroyed their fleet in 1718, and compelled them to drop their scheme for a time. In 1734 the Spanish court resumed their design with success. The infant Don Carlos drove the Germans out, and was crowned king of the two Sicilies at Palermo. When he passed into Spain to take possession of that crown, he transferred the Sicilian diadem to his son Ferdinand III. of Sicily, and IV. of Naples, and it has ever since remained in the possession of the same family.

16 Account of the straits of Messina.

Sicily is separated, as we have already observed, from Italy by a narrow strait called the *Faro of Messina*. This strait is still remarkable for the rapidity of its currents and the irregular ebbing and flowing of the sea, which sometimes rushes in with such violence as to endanger ships riding at anchor. Anciently it was much more remarkable for Scylla and Charybdis, the one a rock, and the other a whirlpool, between which it was very dangerous to steer, and concerning which so many fables have been related by the ancients. Scylla is a rock on the Italian side, opposite to Cape Pylorus, which runs out into the sea on the Sicilian side. Mr Brydone informs us, that the navigation of the straits is not even yet performed without danger. He also informs us, that the noise of the current which sets through the straits may be heard for several miles, like the roaring of some large impetuous river confined between narrow banks. In many places the water rose into whirlpools and eddies, which are dangerous to shipping. The current set exactly for the rock of Scylla, and would certainly have carried any thing thrown into it against that point. Our author, however, is by no means of opinion that the strait is so dangerous as the ancients have represented it; though he thinks that the strait is now probably much wider than formerly, which may have diminished the danger. There are many small rocks, which show their heads near the base of the large ones. These are probably the dogs described by the ancient poets as howling round Scylla. The rock is near 200 feet high, and has a kind of a castle or fort built on its summit with a town called *Scylla* or *Sciglio*, containing 300 or 400 inhabitants on its south side, which gives the title of prince to a Calabrese family.

The following account of these rocks and whirlpools is given by the celebrated naturalist Spallanzani. He informs us, that Scylla is a lofty rock, 12 miles from Messina, rising almost perpendicular from the sea on the shore of Calabria, beyond which is the small city of the same name. Though there was scarcely any wind, Spallanzani heard, about two miles distant from the rock, a noise like a confused barking of dogs, and on a nearer approach he discovered the cause. This rock contains a number of caverns, one of the largest of which is called by the people *Dragara*. The waves, when in the least agitated, rushing into these caverns, break, dash, throw up frothy bubbles, and thus occasion these various and multiplied sounds. He then perceived with how much truth and resemblance of nature Homer and Virgil, in their personifications of Scylla, had pourtrayed this scene, by describing the monster they drew as lurking in the darkness of a vast cavern, surrounded by ravenous barking mastiffs, together with wolves, to increase the horror.

Though the tide is almost imperceptible in the open parts of the Mediterranean, it is very strong in the strait of Messina, owing to the narrowness of the channel, and regulated by the periodical elevations and depressions of the water. Where the current is accompanied by a wind blowing the same way, vessels have nothing to fear, since they either do not enter the strait, both the wind and stream opposing them; or, if both are favourable, enter on full sail, and pass with such rapidity that they seem to fly over the water. When the current runs from south to north, and the north wind blows hard at the same time, the ship is resisted by the opposite current, and impelled by two forces in contrary directions, is dashed on the rock of Scylla, or driven on the neighbouring sands. The current, where it is strongest, does not extend over the whole strait, but winds through it in intricate meanders, with the course of which the sailors stationed to give strangers assistance are well acquainted, and thus able to guide the ship in such a manner as to avoid it. Should the pilot, however, confiding in his own skill, neglect such assistance, he would run the most imminent risk of being shipwrecked. In this conflict of the waters, it is useless to throw the line to discover the depth of the bottom, the violence of the current frequently carrying the lead almost on the surface of the water. The strongest cables, though some feet in circumference, break like small cords. Every expedient afforded by the art of navigation, is useless here. The only means of avoiding being dashed against the rocks, or driven upon the sands in the midst of this perilous contest of the winds and waves, is to have recourse to the skill and courage of the Messinese seamen.

Charybdis is distant from the shore of Messina about 750 feet, and is called by the people of the country *Calofaro*, not from the agitation of the waves, but from καλος and φαρος, *beautiful tower*, from the lighthouse erected near it for the guidance of vessels. When the current sets in from the north, the pilots call it the *descending rema*, or current; and when it runs from the south, the *ascending rema*. The current ascends or descends at the rising or setting of the moon, and continues for six hours. In the interval between each ascent or descent, there is a calm which lasts at least 15 minutes, but not longer than an hour. Afterwards, at the rising or setting of the moon, the current enters from the north, making various angles of incidence with the shore, and at last reaches the Calofaro. This delay sometimes continues

Sicily. continues two hours; sometimes it immediately falls into the Calofaro; and then experience regards it as a certain indication of bad weather.

When Spallanzani observed Charybdis from the shore, it appeared like a group of tumultuous waters, which group as he approached became more extensive and more agitated. He was carried to the edge, where he stopped some time to make the requisite observations; and was then convinced beyond the shadow of a doubt, that what he saw was by no means a vortex or whirlpool.

Though he was convinced that there was no gulf under the Calofaro, as otherwise there would have been a whirlpool, which would have carried down into it the floating substances; he determined to sound the bottom with a plummet, and found its greatest depth did not exceed 500 feet. He was also informed, to his great surprise, that beyond the Calofaro, towards the middle of the straight, the depth was double.

When the wind and current are contrary to each other, and both in their greatest violence, the swelling and dashing of the waves within the Calofaro is much stronger, more impetuous, and more extensive. It then contains three or four small whirlpools, or even more, according to the greatness of its extent and violence. If at this time small vessels are driven into the Calofaro by the current or the wind, they are seen to whirl round, rock, and plunge, but are never drawn down into the vortex. They only sink when filled with water, by the waves beating over them. When vessels of a larger size are forced into it, whatever wind they have they cannot extricate themselves; their sails are useless; and after having been for some time tossed about by the waves, if they are not assisted by the pilots of the country, who know how to bring them out of the course of the current, they are furiously driven upon the neighbouring shore of the Lanterna, where they are wrecked, and the greater part of their crews perish in the waves.

If a ship be extricated from the fury of Charybdis, and carried by a strong southerly wind along the strait towards the northern entrance, it will indeed pass out safely; but should it meet with a wind in a nearly opposite direction, it would become the sport of both these winds, and unable to advance or recede, be driven in a middle course between their two directions, that is to say, full upon the rock of Scylla, if it be not immediately assisted by the pilots. It is likewise observed, that in these hurricanes a land wind frequently rises, which descends from a narrow pass in Calabria, and increases the force with which the ship is impelled towards the rock. Thus, the saying which became proverbial among the ancients;—that "he who endeavours to avoid Charybdis, dashes upon Scylla," is, in a great measure, true.

In the straits, Mr Brydone informs us, a most surprising phenomenon is to be observed. In the heat of summer, after the sea and air have been much agitated, there appears in the heavens over the straits a great variety of singular forms, some at rest and others moving with great velocity. These forms, in proportion as the light increases, seem to become more aerial, till at last, some time before sunrise, they totally disappear. The Sicilians represent this as the most beautiful sight in nature. Leonti, one of the best Sicilian writers, says, that the heavens appear crowded with a variety of objects, such as palaces, woods, gardens, &c. besides the figures of men and other animals that are seen in motion among them. Some treatises have been written concerning this phenomenon; but nothing satisfactory has been delivered concerning its cause. Sicily.

17 Climate and produce.

Though Sicily lies in a warm climate, the air is healthful, being refreshed with sea-breezes on every side. It has at all times been remarkably fertile; but the era of its greatest prosperity was from the siege of Syracuse by the Athenians to the Carthaginian conquests. Then and long after it supplied with grain, in years of scarcity, all the countries upon the Mediterranean except Egypt and the coasts of Asia, and Rome and Carthage continually. Even now, under all the impediments of superstition and bad government, its productions are, in quantity and quality, the best in Europe. Of the vegetable are grain, wines, oil, fruits, tobacco, mulberry trees for the silkworm, cotton, medicinal roots, and sugar canes. The last of these flourish near Avola and Merilli. They are of an inferior quality to those of the West Indies, but their sugar is sweeter than any other. The animal production is similar to that of Italy, but the horned cattle are a smaller breed. The coasts abound with fish, particularly with tunney and anchovies; the export of which forms a very lucrative branch of commerce. There are mines of silver, copper, and lead, but none are worked. Near Palma are beds of the best sulphur; at the mouth of the river Giaretta is found a yellow amber, preferable to that of the Baltic: and in every part of the island quarries of marbles, that have furnished materials for all the noble edifices of Sicily. The most beautiful are in the neighbourhood of Palermo, particularly the yellow, and those that resemble the verde antique, porphyry, and lapis lazuli. The population of the island in 1815, amounted to 1,655,000 souls; not as much again as the single city of Syracuse formerly contained.

Watkin's Travels through Switzerland, Italy, Sicily, &c.

18 Rivers and mountains.

Here are several rivers and good springs; but few of the rivers are navigable, having but a short course, and descending precipitately from the mountains. The chief are the Bantera, the Jaretta, and the Salso; of which, the two former run from west to east, and the third from north to south.

Of the mountains in this island the most noted is Mount Etna, now called *Monte Gibello*, or *Mongibello*, a volcano whose eruptions have often proved fatal to the neighbouring country. See ETNA.

19 Constitution and government.

Were the Sicilians a cultivated people, among whom those arts were encouraged which not only promote the wealth and comfort of a nation, but also exercise the nobler faculties and extend the views of mankind, the circumstances of their government are such, that it might gradually be improved into a free constitution: but to this the ignorance, superstition, and poverty, of the people seem to be invincible obstacles. The monarchical power in Sicily is far from being absolute; and the parliament claims a share of public authority independently of the will of the king, deduced from a compact made between Roger and the Norman barons after the expulsion of the Saracens. This claim is denied by the king, who wishes the nobles to consider their privileges as derived solely from his favour. Hence the government is in a situation which greatly resembles that of our own and the other kingdoms of Europe in the feudal times; there are continual jealousies and oppositions between the king and the barons, of which an enlightened people might easily take advantage, and obtain that share in the constitution which might secure them

Munter's Memoirs relative to Naples and Sicily.

Sicily.

them from future oppression. In these disputes, the king has the advantage at least of power, if not of right; and several works, in which the claims of the Sicilian barons have been asserted, were publicly burned not many years ago.

As the sovereign holds his court at Naples, Sicily is governed by a viceroy, who is appointed only for three years, though at the end of that term his commission is sometimes renewed. He lives in great state, and, as the representative of the king, his power is very considerable. He presides in all the courts and departments of government, and is commander in chief of all the forces: he calls or dissolves the parliament when he pleases; and by him all orders, laws, and sentences, must be signed; and his office is far from being desirable, as it generally renders him the object either of the jealousy of the court of Naples, or of the hatred of the Sicilians.

The parliament consists of the nobles, the bishops, and abbots, and the representatives of 43 cities, which are immediately subject to the crown. Those cities which are subject to any of the nobles send no members to the parliament; in these the king has not much authority, and derives little advantage from them. According to the laws, the parliament ought to be assembled at the end of every three years: but the government pays little attention to this rule. The common people are in general very much attached to the nobles, and are inclined to take their part in all their differences with the court: but the magistrates and principal inhabitants of the cities which belong to these feudal lords, wish to get rid of their authority, and imagine that they should be less oppressed, if immediately subject to the king: these inclinations are not disagreeable to the court, and are encouraged by most of the lawyers, who are of great service to government in contesting the privileges of the nobles. Many of these privileges are now abridged; and the power of the barons, with respect to the administration of justice in their domains, was very properly limited by the viceroy Caraccioli, in the year 1785. The government of this nobleman was very beneficial to Sicily, as he, in a great measure, cleared the island of the banditti that used to infest it, and made several excellent regulations for the establishment of social order and personal security. He deserves the thanks of every well-wisher to mankind for having abolished the court of inquisition, which had been established in this country by Ferdinand the Catholic, and made dependent on the authority of the grand inquisitor of Spain. Its last *auto da fe* was held in the year 1724, when two persons were burned. At length Charles III. rendered it independent of the Spanish inquisitor, and abridged its power, by forbidding it to make use of the torture, and to inflict public punishments. The Marchese Squillace, and his successor the Marchese Tanucci, were both enemies to the hierarchy; and, during their viceroyalties, took care to appoint sensible and liberal men to the office of inquisitor: the last of whom was Ventimiglia, a man of a most humane and amiable character, who heartily wished for the abolition of this diabolical court, and readily contributed toward it. While he held the office of inquisitor, he always endeavoured to procure the acquittal of the accused; and when he could succeed no other way, would pretend some informality in the trial, The total annihilation of this instrument of the worst of tyranny was reserved for

20 Inquisition.

Sicily, Sida.

Caraccioli. A priest being accused to the inquisition, was dragged out of his house and thrown into the dungeon. He was condemned; but, on account of informality, and a violation of justice in the trial, he appealed to the viceroy, who appointed a committee of jurists to examine the process. The inquisitor refused to acknowledge the authority of this commission; pretending that to expose the secrets of the holy office, and to submit its decisions to the examination of lay judges, would be so inconsistent with his duty, that he would see the inquisition abolished rather than consent to it. Caraccioli took him at his word, and procured a royal mandate by which the holy office was at once annihilated. He assembled all the nobility, judges, and bishops, on the 27th of March 1782, in the palace of the inquisition, and commanded the king's order to be read; after which he took possession of the archives, and caused all the prisons to be set open: in these were at that time only two prisoners, who had been condemned to perpetual confinement for witchcraft. The papers relating to the finances were preserved; but all the rest were publicly burned. The possessions of the holy office were assigned to the use of churches and charitable institutions: but the officers then belonging to it retained their salaries during their lives. The palace itself is converted into a customhouse, and the place where heretics were formerly roasted alive for the honour of the Catholic faith, is now changed into a public garden. The cognizance of offences against orthodoxy is committed to the bishops: but they cannot cite any one to appear before them without permission from the viceroy; neither can they confine any person to a solitary prison, nor deny him the privilege of writing to his friends, and conversing freely with his advocate. The nobility are so numerous in this island, that Labat says it is paved with noblemen. The general assembly of parliament is composed of 66 archbishops, bishops, abbots, and priors, which form the Bracchio ecclesiastico. Fifty-eight princes, 27 dukes, 37 marquisses, 27 counts, one viscount, and 79 barons, form the militaire; and the demaniale consists of 43 representatives of free towns. Out of each bracchio four deputies are chosen to conduct public business. The government was new-modelled while the British forces occupied the island; but the alterations introduced have since fallen to the ground. The government has resumed its old course, and the noblemen who supported the reform have been banished. See Russell's Tour, 1817.

21 abolished by Caraccioli.

SICINIUS Dentatus, a tribune of the people, lived a little after the expulsion of the kings from Rome. He was in 120 battles and skirmishes, besides single combats, in all of which he came off conqueror. He served under nine generals, all of whom triumphed by his means. In these battles he received 45 wounds in the forepart of his body, and not one in his back. The senate made him great presents, and he was honoured with the name of the Roman Achilles.

SICYOS, a genus of plants belonging to the class of monœcia, and to the order of syngenesia; and in the natural system arranged under the 34th order, *Cucurbitaceæ*. See Botany *Index*.

SIDA, *Yellow* or *Indian Mallow*, a genus of plants belonging to the class of monadelphia, and to the order of polyandria; and in the natural system ranging under the 37th order, *Columniferæ*. See Botany *Index*.

SIDDEE,

SIDDEE, or SEDEE, an Arabic title, by which the Abyssinians or Habashys are always distinguished in the courts of Hindostan; where, being in great repute for firmness and fidelity, they are generally employed as commanders of forts or in posts of great trust.

SIDEREAL YEAR. See ASTRONOMY *Index*.

SIDERIA, in *Natural History*, the old name of a genus of crystals, used to express those altered in their figure by particles of iron. These are of a rhomboidal figure, and composed only of six planes. Of this genus there are four known species. 1. A colourless, pellucid, and thin one; found in considerable quantities among the iron ores of the forest of Dean in Gloucestershire, and in several other places. 2. A dull, thick, and brown one; not uncommon in the same places with the former. And, 3. A black and very glossy kind, a fossil of great beauty; found in the same place with the others, as also in Leicestershire and Sussex.

SIDERITE, a substance supposed by Meyer to be a new metal; but according to Bergman and Kirwan it is nothing else than a natural combination of phosphoric acid with iron.

SIDERITIS, IRON-WORT; a genus of plants belonging to the class of didynamia, and to the order of gymnospermia; and in the natural system ranging under the 42d order, *Verticillatæ*. See BOTANY *Index*.

SIDEROXYLON, IRON-WOOD; a genus of plants belonging to the class of pentandria, and to the order of monogynia; and in the natural system ranging under the 53d order, *Dumosæ*. See BOTANY *Index*.

SIDNEY, SIR PHILIP, was born, as is supposed, at Penshurst in Kent in the year 1554: His father was Sir Henry Sidney, an Irish gentleman, and his mother Mary the eldest daughter of John Dudley duke of Northumberland. He was sent when very young to Christchurch college at Oxford, but left the university at 17 to set out on his travels. After visiting France, Germany, Hungary, and Italy, he returned to England in 1575, and was next year sent by Queen Elizabeth as her ambassador to Rodolph emperor of Germany. On his return he visited Don John of Austria, governor of the Netherlands by whom he was received with great respect. In 1579, when Queen Elizabeth seemed on the point of concluding her long projected marriage with the duke of Anjou, Sir Philip wrote her a letter, in which he dissuaded her from the match with unusual elegance of expression, as well as force of reasoning. About this time a quarrel with the earl of Oxford occasioned his withdrawing from court; during which retirement he is supposed to have written his celebrated romance called *Arcadia*.

In 1585, after the queen's treaty with the United States, he was made governor of Flushing and master of the horse. Here he distinguished himself so much both by his courage and conduct, that his reputation rose to the highest pitch. He was named, it is pretended, by the republic of Poland as one of the competitors for that crown, and might even have been elected had it not been for the interference of the queen. But his illustrious career was soon terminated; for in 1586 he was wounded at the battle of Zutphen, and carried to Arnheim, where he soon after died. His body was brought to London, and buried in St Paul's cathedral. He is described by the writers of that age as the most perfect model of an accomplished gentleman that could be formed even by the wanton imagination of poetry or fiction. Virtuous conduct, polite conversation, heroic valour, and elegant erudition, all concurred to render him the ornament and delight of the English court: and as the credit which he enjoyed with the queen and the earl of Leicester was wholly employed in the encouragement of genius and literature, his praises have been transmitted with advantage to posterity. No person was so low as not to become an object of his humanity. After the battle of Zutphen, while he was lying on the field mangled with wounds, a bottle of water was brought him to relieve his thirst; but observing a soldier near him in a like miserable condition, he said, *This man's necessity is still greater than mine*; and resigned to him the bottle of water. Besides his *Arcadia*, he wrote several smaller pieces both in prose and verse, which have been published.

SIDNEY, *Algernon*, was the second son of Robert earl of Leicester, and of Dorothy eldest daughter of the earl of Northumberland. He was born about the year 1617. During the civil wars he took part against the king, and distinguished himself as a colonel in the army of the parliament. He was afterwards appointed one of King Charles's judges, but declined appearing in that court. During the usurpation of Cromwell, Sidney, who was a violent republican, retired to the country, and spent his time in writing those discourses on government which have been so deservedly celebrated. After the death of the Protector, he again took part in the public transactions of his country, and was abroad on an embassy to Denmark when King Charles was restored. Upon this he retired to Hamburgh, and afterwards to Francfort, where he resided till 1677, when he returned to England and obtained from the king a pardon. It has been affirmed, but the story deserves no credit, that during his residence abroad King Charles hired ruffians to assassinate him. After his return he made repeated attempts to procure a seat in parliament, but all of them proved unsuccessful. After the intention of the commons to seclude the duke of York from the throne had been defeated by the sudden dissolution of parliament, Sidney joined with eagerness the councils of Russel, Essex, and Monmouth, who had resolved to oppose the duke's succession by force of arms. Frequent meetings were held at London; while, at the same time, a set of subordinate conspirators, who were not, however, admitted into their confidence, met and embraced the most desperate resolutions. Keiling, one of these men, discovered the whole conspiracy; and Algernon Sidney, together with his noble associates, was immediately thrown into prison, and no art was left unattempted in order to involve them in the guilt of the meaner conspirators.

Howard, an abandoned nobleman, without a single spark of virtue or honour, was the only witness against Sidney; but as the law required two, his discourses on government, found unpublished in his closet, were construed into treason, and declared equivalent to another witness. It was in vain for Sidney to plead that papers were no legal evidence; that it could not be proved they were written by him; and that if they were, they contained nothing treasonable. The defence was overruled; he was declared guilty, condemned, and executed! His attainder was reversed in the first year of King William.

He was a man of extraordinary courage; steady even to obstinacy; of a sincere but rough and boisterous temper. Though he professed his belief in the Christian religion, he was an enemy to an established church, and even, according to Burnet, to every kind of public worship. In his principles he was a zealous republican: government was always his favourite study; and his essays on that subject are a proof of the progress which he made.

SIDON, in *Ancient Geography*, a city of Phœnicia in Asia, famous in Scripture for its riches, arising from the extensive commerce carried on by its inhabitants. Heavy judgments were denounced against the Sidonians on account of their wickedness, which were accomplished in the time of Ochus king of Persia: for that monarch having come against them with an army on account of their rebellion, the city was betrayed by its king; upon which the wretched inhabitants were seized with despair; they set fire to their houses, and 40,000 with their wives and children, perished in the flames.

This city is now called *Saide*, and, according to Mr Bruce's account, not only its harbour is filled up with sand, but the pavement of the ancient city stood 7½ feet lower than the ground on which the present city stands. Volney describes it as an ill-built dirty city. Its length along the sea-shore is about 600 paces, and its breadth 150. At the north-west side of the town is the castle, which is built in the sea itself, 80 paces from the main land, to which it is joined by arches. To the west of this castle is a shoal 15 feet high above the sea, and about 200 paces long. The space between this shoal and the castle forms the road, but vessels are not safe there in bad weather. The shoal, which extends along the town, has a bason inclosed by a decayed pier. This was the ancient port; but it is so choked up by sand, that boats alone can enter its mouth near the castle. Fakr-el-din, emir of the Druses, destroyed all these little ports from Bairout to Acre, by sinking boats and stones to prevent the Turkish ships from entering them. The bason of Saide, if it were emptied, might contain 20 or 25 small vessels. On the side of the sea, the town is absolutely without any wall; and that which encloses it on the land side is no better than a prison-wall. The whole artillery does not exceed six cannons, and these are without carriages and gunners. The garrison scarcely amounts to 100 men. The water comes from the river Aoula, through open canals, from which it is fetched by the women. These canals serve also to water the orchards of mulberry and lemon trees.

Saide is a considerable trading town, and is the chief emporium of Damascus and the interior country. The French, who are the only Europeans to be found there, have a consul, and five or six commercial houses. Their exports consist in silks, and particularly in raw and spun cottons. The manufacture of this cotton is the principal art of the inhabitants, the number of whom may be estimated at about 5000. It is 45 miles west from Damascus. E. Long. 36. 5. N. Lat. 37.

SIDUS GEORGIUM, in *Astronomy*, a new primary planet, discovered by Dr Herschel in the year 1781. By most foreign, and even by some British philosophers, it is known by the name of *Herschel*, in honour of the discoverer. As the other planets are distinguished by marks or characters, the planet Herschel is distinguished by an H, the initial letter of the discoverer's name, and a cross to show that it is a Christian planet. See ASTRONOMY *Index*.

SIEGE, in the art of war, is to surround a fortified place with an army, and approach it by passages made in the ground, so as to be covered against the fire of the place.

SIEGEN, a town of Germany in Wetteravia, with a castle and the title of a principality, which it gives to a branch of the house of Nassau. It is seated on a river of the same name, in E. Long. 8. 5. N. Lat. 50. 53.

SIENNA, a large, ancient, and celebrated city of Tuscany in Italy; capital of the Siennese, with an archbishop's see, a famous university, and a citadel. It is about four miles in circumference, and surrounded with an old wall. The metropolitan church is much esteemed by travellers; and though it is a Gothic structure, the architecture is admirable. It is built with black and white marble, and the pavement is of mosaic work. The town is adorned with a great number of palaces, fountains, and superb churches, as also a magnificent hospital. The great area is round, and the houses about it are of the same height, supported by piazzas, under which people may walk in hot or rainy weather; in the middle is a bason, which can be filled with water at any time, to represent a sea fight with small vessels. The Italian language is taught here with such purity, that a great many foreigners frequent it on that account. It is seated on three eminences, in a fertile soil, in E. Long. 11. 11. N. Lat. 43. 10.

SIENNESE, a duchy in Italy; bounded on the north by the Florentino, on the south by the Mediterranean sea and the duchy of Castro, on the east by the Perugino and Orvietano, and on the west by the Florentino and the Tuscan sea; being about 55 miles in length, and as much in breadth. The soil is pretty fertile, especially in mulberry trees, which feed a great number of silk-worms; and there are several mineral springs. Sienna is the capital town.

SIERRA LEONA, a large country on the west coast of Africa, which some extend from the Grain Coast on the south-east to Cape Verga or Vega on the north-west, i. e. between 7° and 10° N. Lat. Others, however, confine the country between Cape Verga and Cape Tagrin. There runs through it a great river of the same name, of which the source is unknown but the mouth is in longitude 12. 30. west, lat. 8. 5. north, and is nine miles wide. The climate and soil of this tract of country appear to be, on both sides of the river, among the best in Africa, or at least the most favourable to European constitutions. The heat is much the same as that of the West Indies; but on the higher grounds there is a cool sea breeze, and in the mountainous parts the air is very temperate. According to Lieutenant Matthew, "Sierra Leona, if properly cleared and cultivated, would be equal in salubrity and superior in produce to any of the islands in the West Indies;" and others have affirmed, that "the air is better for a man's health than in many places of Europe." These advantages of climate induced the English to establish a factory at Sierra Leona; but they chose not the most healthful situation. For the benefit of a spring of good water they fixed their residence in a low valley, which is often overspread with mists and noisome vapours, while the air

Sierra.

air is clear and serene on the summits of the hills, to which water from the well might easily be carried.

Within the district occupied by this colony are the Foulahs, who are in general of a tawney complexion, though many of them are entirely black. They lead a wandering life, and roam about the country with large droves of cows, sheep, goats, and horses. They are much praised by travellers for their hospitality; nor is their humanity in other respects, less commendable; for, if one of their countrymen have the misfortune to fall into slavery, the rest join stock to redeem him. Elephants are so numerous in the country of the Foulahs, that they are frequently seen in droves of 200 together. The people are very dexterous at hunting them, and other wild beasts; from which they derive their principal articles of trade.

The animal productions of Sierra Leona are lions, from which it has its name; leopards, hyænas, musk cats, and many kinds of weasels; the japanzee or chimpanzee, a species of simia, which has a still more striking resemblance to the human figure than even the ouran outang; porcupines, wild hogs, squirrels, and antelopes. Besides these, which are natives of the country, oxen thrive in it, and even grow fat; asses too are employed in labour, and do not suffer by the climate; but sheep suffer much from the heat, change their wool into hair, grow lean and increase very little: while the hardy goat is here as prolific and large as in any other country. Of the birds which frequent the woods of Sierra Leona we can give no perfect account. A species of crane is mentioned as easily tamed; common poultry multiply fast; ducks thrive well, but geese and turkeys seem not to agree with the climate. Turtles of all kinds are very common, and sometimes of a large size. Crocodiles or alligators of a non-descript species have been found ten or twelve feet in length, and lizards of six different species. Snakes, which are almost innumerable, haunt the houses in the night in search of poultry; and one was observed which measured 18 feet, but was happily found not to be venomous. Fishes are in great variety both in the sea and in the rivers. Besides the whale, the shark, stinging ray, and porpoise, there are eels, horse-mackarel, tarpoons, cavillos, mullets, snappers, yellow-tails, old-maids, ten-pounders, and some other fishes; all of which, except the eels and ten-pounders, are esteemed fine eating. Oysters are found in great abundance, and another shell-fish, which the natives eat. Among the zoophytes, none is more worthy of notice than the common sponge, which covers all the sandy beaches of the river, particularly on the Bullom shore, and would fetch a high price in Great Britain.

Of the numerous vegetable productions of Sierra Leona, our limits will permit us only to mention the following. Rice, which is the plant chiefly cultivated, as the natives subsist almost entirely upon it, grows both in the high and low grounds. It prospers indeed best in swamps, though the grain is better in a drier soil. Next to rice the cassada constitutes the chief food of the inhabitants, and is cultivated with great care. The country likewise produces yams, various kinds of potatoes, eddoes, or the *arum esculentum*. Oil-palm, plantains, and bananas; papaw, guava, oranges and limes; pompions, melons, and cucumbers; pine-apples, pigeon-peas, which dressed like English peas are a good pulse; maize or Indian corn; millet, cocoa-nut trees; ockra; the tallow-tree; a great variety of tamarinds; different kinds of fig-trees and plums; a kind of fruit resembling grapes, but more acid and acrid; cherries resembling a fine nectarine in taste; a species of the bread fruit-tree; the cream fruit, so called because when wounded it yields a fine white juice resembling sugar or the best milk, of which the natives are very fond; the malaguetta pepper, or grains of paradise; a new species of nutmeg, but whether so good as the common sort has not yet been ascertained; a new species of the Peruvian bark, which it is hoped will prove as useful as the other; and cola, a fruit highly esteemed by the natives for the same virtues with that bark; the ricinus, cassia, dye-stuffs, and gums, of great value; cotton, tobacco, and sugar-canes, which, it is thought, would thrive exceedingly well under proper cultivation.

Sierra.

Considering the ardour of the maritime nations of Europe for settling colonies in distant regions of the globe, it is somewhat surprising that a climate so temperate and a soil so productive as that of Sierra Leona did not long ago attract their notice. But it was left to be colonized for a better purpose than that which first drew the natives of Europe to the West Indies and the American continent. Being thinly inhabited, Sierra Leona appeared to some benevolent gentlemen in England a place where, without incommoding the natives, a sufficient quantity of ground might be bought on which to settle a great number of free negroes, who in 1786 swarmed in London in idleness and want. About 400 of these wretches, together with 60 whites, mostly women of bad character and in ill health, were accordingly sent out, at the charge of government, to Sierra Leona. Necessity, it was hoped, would make them industrious and orderly; and Captain Thomson of the navy, who conducted them, obtained, for their use, a grant of land to his majesty from King Tom, the neighbouring chief, and afterwards from Naimbanna, the king of the country. The colony, however, soon went to ruin; but the land which they occupied, being about 20 miles square, his majesty was enabled to grant by act of parliament to another colony founded on better principles and for a still nobler purpose.

The most intelligent members of that society, which laboured so strenuously to procure an abolition of the slave-trade, justly concluded that the natives of Guinea would reap very little benefit from the attainment of their object, unless they should be taught the principles of religion and the arts of civil life, which alone can render them really free, conceived the plan of a colony at Sierra Leona to be settled for the truly generous purpose of civilizing the Africans, by maintaining with them a friendly intercourse, and a commerce in every thing but men. This plan could not be carried into effect but at a very great expence. Subscriptions were therefore opened upon rational and equitable terms, and a sum deemed sufficient was speedily raised. An act of parliament was passed in favour of the subscribers, by which they were incorporated by the denomination of the *Sierra Leona Company;* and in pursuance of that act they held their first meeting at London in October 1791.

The directors having stated the natural advantages of Sierra Leona, and its present miserable condition, observed, that they had not merely to establish a commercial

mercial

Sierra.

mercial factory, but that, to introduce civilization, cultivation, and a safe trade, the company must provide for the security of the persons and property of the colonists. The directors therefore resolved, that three or four vessels should sail at once, with such a number of people as would be able to protect and assist each other; with goods both for trade and for the supply of the colony. Accordingly several vessels sailed, having on board a council for the government of the colony and the management of the company's affairs; a number of artificers and other servants of the company; some soldiers, and a very few English settlers. The directors were laudably cautious in the choice of colonists. They admitted into the society no white man of bad character, or who was not a declared enemy to the slave-trade; and as the chief object of their enterprise was the civilization of the natives, it was with great propriety that they chose more than three-fourths of their settlers from the free negroes in Nova Scotia, who had borne arms for the British government during the American war. The superintendant and council were particularly instructed to secure to all blacks and people of colour, at Sierra Leona, equal rights and equal treatment, in all respects, with whites. They were to be tried by jury, as well as others; and the council was desired to allot to the blacks employments suited to their present abilities, and to afford them every opportunity of cultivating their talents. All practicable means of maintaining subordination were directed to be used; and the council was especially instructed to promote religion and morals, by supporting public worship and the due observance of the Sabbath, and by the instruction of the people, and the education of children. But no person was to be prevented from performing or attending religious worship in whatever place, time, or manner, he might think fit, or from peaceably inculcating his own religious opinions. Orders were given in choosing the scite of a town, to consider health as the first object; and the first town was directed to be called *Free Town*. Articles for building and cultivation were sent out, besides the cargoes for prosecuting the company's commerce; and schools for reading, writing, and accounts, were ordered to be set up for the purpose of instructing the children of such natives as should be willing to put them under the company's care.

The leading object of the company was to substitute, for that disgraceful traffic which has too long subsisted, a fair commerce with Africa, and all the blessings which might be expected to attend it. Considerable advantages appeared hereby likely to result to Great Britain, not only from our obtaining several commodities cheaper, but also for opening a market for British manufactures, to the increasing demands of which it is difficult to assign a limit. From this connection, Africa was likely to derive the still more important benefits of religion, morality, and civilization. To accomplish these purposes, it was necessary for the company to possess a tract of land, as a repository for their goods, and which the Africans might cultivate in peace, secure from the ravages of the slave-trade. It had been ascertained, beyond a doubt, that the climate and soil of Africa were admirably suited to the growth of sugar, spices, coffee, cotton, indigo, rice, and every other species of tropical produce. The company proposed to instruct the natives to raise these articles, and to set them the example, by a spirited cultivation, on its own account. Directions were given to the company's commercial agent to push forward a trade, in a mode prescribed, in the present produce of Africa. Measures were taken for cultivating, on the company's account, the most profitable tropical produce; and in particular, a person of long experience in the West Indies was ordered to begin a sugar plantation. A mineralogist and botanist were likewise engaged to go out and explore the country for new articles of commerce.

Every thing being thus settled upon the most equitable and benevolent principles, the ships sailed with the British colonists, to whom, in March 1792, were added 1131 Blacks from Nova Scotia. The native chiefs being reconciled to the plan, and made to understand its beneficent tendency towards their people, the colony proceeded to build *Free-Town*, on a dry and rather elevated spot on the south side of the river. It occupied between 70 and 80 acres, its length being about one-third of a mile, and its breadth nearly the same; and it contained near 400 houses, each having one-twelfth of an acre annexed, on which a few vegetables were raised. There were nine streets running from north-west to south-east, and three cross streets, all 80 feet wide, except one of 160 feet, in the middle of which were all the public buildings. These consisted of a governor's house and offices; a large store-house; a large hospital; six or eight other houses, offices, and shops, occupied by the company's servants; and a church capable of containing 800 people. The colonists at first suffered much from the rainy season, against which it was not in their power to provide sufficient protection; but at the end of it they recovered in a great measure their health and spirits, and proceeded with alacrity to execute the various purposes of their settlement. To excite emulation in culture, the government gave premiums to those colonists who raised the greatest quantities of rice, yams, eddoes, cabbages, Indian corn, and cotton, respectively. To limit the excesses of the slave-trade, and gain the favour of the neighbouring chiefs, the directors instructed the governor and council to redeem any native from the neighbourhood, who should be unjustly sold either to or by a British subject. The servants of the company conducted themselves with the utmost propriety, being sober, moral, and exemplary; and from the labours of the clergymen were derived services highly important in every point of view. Before the end of two years from the institution of the colony, order and industry had begun to show their effects in an increasing prosperity. The woods had been cut down to the distance of about three English miles all round the town. By these means the climate had become healthier, and sickness had diminished. The fame of the colony spread not only along the whole western coast of Africa, but also to parts far distant from the coast; embassies had been received of the most friendly nature from kings and princes several hundred miles distant; and the native chiefs had begun to send their children to the colony, with full confidence, to be taught reading, writing, and accounts, and to be brought up in the Christian religion. In a word, it was not without grounds that the directors looked forward to that joyful period when, by the influence of the company's measures, the continent of Africa should be rescued from her present state of darkness and misery, and exhibit a delightful scene of light and

Sierra.

and knowledge of civilization and order, of peaceful industry and domestic comfort. On their beneficent exertions they hoped with confidence for the blessing of Providence; they were countenanced and supported by the British government; and upon the breaking out of the present war, the French Convention authorised one of their agents to write to the directors, requesting a full account of the design of the institution, and the names of the ships employed in their service, and assuring them of the good wishes of the French government to so noble an undertaking. How completely that government fulfilled its promise is very generally known. Having vindicated the rights of man in Europe by the violation of every principle of truth and justice, they determined by the same means to give light and liberty to the Africans; and that they have fully carried their determination into effect will be seen by the following extract of a letter from Mr Afzelius, the company's botanist, dated Sierra Leona, 15th November 1794. "The French have been here and have ruined us. They arrived on the 28th of September last, early in the morning, with a fleet consisting of one large ship, two frigates, two armed brigs, and one cutter, together with two large armed merchant ships, taken by them at the Isles de Loss, an English slave factory to the north of our colony, and which they have also destroyed and burnt. So well had they concealed their nation, that we took them at first for English. They had English-built vessels, which were rigged in the English way. They showed the English flag, and had their sailors, at least those we saw on deck, dressed like English. In short, we did not perceive our mistake till we observed them pointing their guns. We had not strength sufficient to resist, and therefore our governor gave orders, that as soon as they should begin to fire, the British flag should be struck, and a flag of truce hoisted. Accordingly this was done, but still they continued firing, and did much damage, both within and without the town. They killed two people and wounded three or four. But as we did not understand the meaning of this proceeding, we asked them for an explanation; and they answered us, that we should display the flag of liberty, as a proof of our submission. We assured them that it should already have been done, if we had had any, which terminated the hostilities from the ships. In the mean time, most of the inhabitants had fled from the town, having taken with them as much of their property as they conveniently could in such a hurry. I was with the governor, together with a number of others; but as soon as I was certain they were enemies, I went towards my own house with a view to save as much as possible of my property and natural collections; but was received in such a manner, that I could not venture to proceed. My house was situated near the shore, and unfortunately just opposite the frigate which fired. I saw the balls passing through the house, and heard them whizzing about my ears. I saw that I should lose all my property; but life was dearer to me, and I hastened to the woods.

Wadstrom, part 2. p. 28.

"In the afternoon the enemy landed, finding the town almost destitute of people, but rich in provisions, clothing and other stores. They began immediately to break open the houses and to plunder. What they did not want, they destroyed, burnt, or threw into the river. They killed all the cattle and animals they found in the fields or streets, yards or elsewhere, not sparing even asses, dogs, and cats. These proceedings they continued the whole succeeding week, till they had entirely ruined our beautiful and prospering colony; and when they found nothing more worth plundering, they set fire to the public buildings and all the houses belonging to the Europeans; and burnt, as they said, by mistake nine or ten houses of the colonists. In the mean time, they were not less active on the water. They sent three of their vessels to Bance island, an English slave factory higher up the river, which they plundered and burnt, together with some slave ships lying there. They took besides about 10 or 12 prizes, including the company's vessels. Most of these they unloaded and burnt. They took along with them also two of our armed vessels, one of which was a large ship, laden with provisions, and which had been long expected; but she unfortunately arrived a few days too soon, and was taken with her whole cargo. We expected at least, to receive our private letters, but even this was refused, and they were thrown overboard. At last, after inflicting on us every hardship we could suffer, only sparing our lives and the houses of the colonists, they sailed on the 13th of October last, at noon, proceeding downwards to the Gold Coast, and left us in the most dreadful situation, without provisions, medicines, clothes, houses, or furniture, &c. &c. and I fear much, that most of us should have perished, had not our friends in the neighbourhood, both native and Europeans, who were so happy as to escape the enemy, been so kind as to send us what they could spare. In the mean time, most of us have either been, or still are, very sick, and many have died for want of proper food and medicine. The worst, however, is now past. At least we are not in any want of provision, although of the coarsest kind, but are destitute of the most necessary articles and utensils for the house, the table, and the kitchen.

It was thus that the Convention executed their purpose of *spreading light and liberty through the world.* The Sierra Leona colony was established for no other end than to abolish the slave-trade, to enlighten the Africans, and to render them virtuous, rational, free, and happy; and those powerful patrons of the rights of man destroyed that colony with many circumstances of the most wanton cruelty. Though Mr Afzelius is a Swede, and ought therefore to have been protected by the laws of neutrality, they burnt his house with the rest; deprived him of his trunks, his clothes, and his bed; destroyed the natural curiosities which he had collected at the hazard of his life; and carried away the instruments by means of which only he could collect more.

In 1798, Free-Town consisted of about 300 houses, and a number of public buildings, together with three wharfs. The government-house, so situated as to command the town and harbour, was protected by a palisade, and six pieces of cannon. The inhabitants of this colony were then computed at 1200, of whom 15 were shopkeepers, 25 fishermen, 10 trading shipmasters, owners of small vessels, 15 seamen, 20 labourers employed by the company, 4 schoolmasters; about one half of the whole population petty farmers, and the rest mechanics. The number of Europeans resident at that time in the colony was

Sierra.

was about 30, and nearly 400 free natives wrought as labourers for wages, on the farms in the colony.

A charter of justice was obtained in 1800, to controul the turbulence of the blacks from Nova Scotia, and a small military force from Goree was stationed at Sierra Leona. Parliament allowed the company 7000l. for the purpose of erecting a fort, with a promise of 8000l. more for the same undertaking. The company also received 10,000l. for their expence in settling the blacks from Nova Scotia, and a vote of parliament agreed to pay 4000l. for supporting the civil government of the colony.

The Maroons arrived in Sierra Leona in the month of October 1800, and greatly assisted in suppressing an insurrection of the Nova Scotia blacks, who had attempted to seize on the government of the colony. A body of natives of the Timmaney, headed by two of the fugitive blacks, made an attack on the unfinished fort on the 18th of November, about day-break, but they were repulsed with loss. A truce was concluded; but it was supposed that the Timmanee chiefs would make use of this interval to form alliances with the natives against the British, in order to exterminate them from this part of Africa. Soldiers to the amount of 65 were brought from Goree, and a ship of war was stationed in the river, to defend the settlement.

In 1802, parliament again voted 10,000l. to the company, for the annual expence of the settlement; and in February 1803, the directors were informed by Lord Hobart, that it would be for the interest of the colony to transfer the civil and military power from the company to the British government.

When Captain Hallowell arrived at Sierra Leona on the 12th of January 1803, he found the colony in a wretched condition, reporting to government on his return, that the Maroons were not satisfied with their condition, regarding it as one in which they could not find subsistence; that provisions of every description were both scarce and dear; that its inhabitants lived in hourly danger from the natives; and that the whole colonists lived in a state of despondency. Government, however, was afterwards satisfied, from the explanations of the directors and their servants, that the account of Captain Hallowell was by much too unfavourable. Expectations are indulged that, since the entire abolition of the slave-trade, the colony will soon obtain a flourishing trade with the natives, in the exchange of British manufactures for the raw produce of the interior parts of Africa.

A committee of the house of commons has had a most satisfactory proof of the progressive improvement of the internal administration of the colony, arising from the additional powers conferred on the company by the charter of justice, and the increased vigilance and exertion of the Company's servants. The Maroons have, in a great measure, abandoned some pernicious habits they had long indulged, and by their attachment to the colony, and peaceable demeanour, have merited the approbation of government. The progress made in the erection of works has been considerable, and the colony may be regarded in a state of sufficient security against the attack of any native power. A body of volunteers has been raised within the colony, whose fidelity and attachment have been tried by experience. The sickness and mortality which for some time existed, have in a great degree subsided; and there is reason to believe, that it rather originated with the troops when they entered the colony, and their habits of intemperance, than from any disorder connected with their residence in that situation. The number of births, which has for some time exceeded that of the deaths in the colony, is a satisfactory proof that it is not unfriendly to population.

Sierra || Si-Fans.

Sierra Leona is already rendered secure against the only enemies whose hostilities it has immediately to apprehend; its resources are increased; its cultivation reviving; and it is in the possession of every advantage that can arise from the enjoyment of internal tranquillity and order. It is sufficiently manifest, from the inconveniences already experienced in the colony, that during its continuance, it will be essentially necessary to support a local government capable of maintaining order among its inhabitants, and affording them protection. The expence of the civil establishment for some years to come cannot be estimated at less than 10,000l. per annum *; that of completing the proposed works has been estimated at 8000l. It also appears that the defence of the colony will require the present volunteer force to be permanently kept up, the expence of which has been estimated at 4000l. per annum; or if that establishment should be discontinued, a regular garrison must be maintained at the constant establishment of 100 effective men, exclusive of about 20 artillery men, which, considering the numerous casualties in that climate, and great expence of supporting them, would exceed the sum already mentioned.

* The expence of the civil establishment for 1809 exceeded 17,000l.

SIERRA MORENA, a considerable ridge of mountains of Andalusia in Spain. See SPAIN.

SIEUR, a title of respect among the French, like that of *master* among us. It is much used by lawyers, as also by superiors in their letters to inferiors.

SIFANTO, or SIPHANTO, an island of the Archipelago, to the west of Paros, to the north-east of Milo, and to the south-west of Serphanto. The air is so good here, that many of the inhabitants live to the age of 120; and their water, fruits, wild fowl, and poultry, are excellent, but more especially the grapes. It abounds with marble and granite, and is one of the most fertile and best cultivated of these islands. The inhabitants employ themselves in cultivating olive-trees and capers; and they have very good silk. They trade in figs, onions, wax, honey, and straw-hats; and may be about 8000 in all. E. Long. 25. 15. N. Lat. 37. 9.

SI-FANS, or TOU-FANS, a people inhabiting the country on the west of China. Their country is only a continued ridge of mountains, inclosed by the rivers Hoang-ho on the north, Ya-long on the west, and Yang-tse-kiang on the east, between the 30th and 35th degrees of north latitude.

Grosier's General Description of China, vol. i. p. 203.

The Si-fans are divided into two kinds of people; the one are called by the Chinese *Black Si-fans*, the other *Yellow*; names which are given them from the different colours of their tents. The black are the most clownish and wretched; they live in small bodies, and are governed by petty chiefs, who all depend upon a greater.

The yellow Si-fans are subject to families, the oldest of which becomes a lama, and assumes the yellow dress. These lama princes, who command in their respective districts, have the power of trying causes, and punishing

ing criminals; but their government is by no means burdensome; provided certain honours are paid them, and they receive punctually the dues of the god Fo, which amount to very little, they molest none of their subjects. The greater part of the Si-fans live in tents; but some of them have houses built of earth, and even brick. Their habitations are not contiguous; they form at most but some small hamlets, consisting of five or six families. They feed a great number of flocks, and are in no want of any of the necessaries of life. The principal article of their trade is rhubarb, which their country produces in great abundance. Their horses are small; but they are well shaped, lively and robust.

These people are of a proud and independent spirit, and acknowledge with reluctancy the superiority of the Chinese government, to which they have been subjected: when they are summoned by the mandarins, they rarely appear; but the government, for political reasons, winks at this contempt, and endeavours to keep these intractable subjects under by mildness and moderation: it would, besides, be difficult to employ rigorous means in order to reduce them to perfect obedience; their wild and frightful mountains (the tops of which are always covered with snow, even in the month of July) would afford them places of shelter, from which they could never be driven by force.

The customs of these mountaineers are totally different from those of the Chinese. It is, for example, an act of great politeness among them to present a white handkerchief of taffety or linen, when they accost any person whom they are desirous of honouring. All their religion consists in their adoration of the god Fo, to whom they have a singular attachment; their superstitious veneration extends even to his ministers, on whom they have considered it as their duty to confer supreme power and the government of the nation.

SIGAULTIAN OPERATION, a method of delivery in cases of difficult labour, first practised by M. Sigault. It consists in enlarging the dimensions of the pelvis, in order to procure a safe passage to the child without injuring the mother.

SIGESBECKIA, a genus of plants belonging to the class of syngenesia, and to the order of polygamia superflua; and in the natural system ranging under the 49th order, *Compositæ*. See BOTANY *Index*.

SIGETH, a town of Lower Hungary, and capital of a county of the same name. It is seated in a morass, and has a triple wall, with ditches full of water; and is defended by a citadel, being one of the strongest places in Hungary. It now belongs to the house of Austria, and was retaken from the Turks in 1669, after it had been blocked up two years. In some maps it is called *Zigat*. E. Long. 18. 58. N. Lat. 46. 17.

SIGHING, an effort of nature, by which the lungs are put into greater motion, and more dilated, so that the blood passes more freely, and in greater quantity, to the left auricle, and thence to the ventricle. Hence we learn, says Dr Hales, how sighing increases the force of the blood, and consequently proportionably cheers and relieves nature, when oppressed by its too slow motion, which is the case of those who are dejected and sad.

SIGHT, or VISION. See ANATOMY, N° 142. and *Index* subjoined to OPTICS.

Imperfection of SIGHT *with regard to Colours*. Under the article COLOURS, is given an instance of a strange deficiency of sight in some people, who could not distinguish between the different colours. In the Phil. Trans. vol. lxviii. p. 611. we have an account of a gentleman who could not distinguish a claret colour from black. These imperfections are totally unaccountable from any thing we yet know concerning the nature of this sense.

Second SIGHT. See SECOND *Sight*.

SIGN, in general, the mark or character of something absent or invisible. See CHARACTER.

Among physicians, the term *sign* denotes some appearance in the human body which serves to indicate or point out the condition of the patient with regard to health or disease.

SIGN, in *Algebra*. See ALGEBRA.

SIGN, in *Astronomy*, a constellation containing a 12th part of the zodiac. See ASTRONOMY *Index*.

NAVAL SIGNALS. When we read at our fireside the account of an engagement, or other interesting operation of an army, our attention is generally so much engaged by the results, that we give but little to the movements which led to them, and produced them; and we seldom form to ourselves any distinct notion of the conduct of the day. But a professional man, or one accustomed to reflection, and who is not satisfied with the mere indulgence of eager curiosity, follows every regiment in its movements, endeavours to see their connection, and the influence which they have had on the fate of the day, and even to form to himself a general notion of the whole scene of action, at its different interesting periods. He looks with the eye of the general, and sees his orders succeed or fail.

But few trouble themselves farther about the narration. The movement is ordered; it is performed; and the fortune of the day is determined. Few think how all this is brought about; and when they are told that during the whole of the battle of Custrin, Frederic the Great was in the upper room of a country inn, from whence he could view the whole field, while his aids de camp, on horseback, waited his orders in the yard below, they are struck with wonder, and can hardly conceive how it can be done: but, on reflection, they see the possibility of the thing. Their imagination accompanies the messenger from the inn yard to the scene of action; they hear the general's orders delivered, and they expect its execution.

But when we think for a moment on the situation of the commander of a fleet, confined on board one ship, and this ship as much, or more closely, engaged, than any other of the fleet; and when we reflect that here are no messengers ready to carry his orders to ships of the squadron at the distance of miles from him, and to deliver them with precision and distinctness, and that even if this were possible by sending small ships or boats, the vicissitudes of wind and weather may render the communication so tedious that the favourable moment may be irretrievably lost before the order can be conveyed.—When we think of all these circumstances, our thoughts are bewildered, and we are ready to imagine that a sea battle is nothing but the unconnected struggle of individual ships; and that when the admiral has once "cried havoc, and let slip the dogs of war," he

Naval Signals.

he has done all that his situation empowers him to do, and he must leave the fate of the day to the bravery and skill of his captains and sailors.

1 Signals a language to the eye.

Yet it is in this situation, apparently the most unfavourable, that the orders of the commander can be conveyed, with a dispatch that is not attainable in the operations of a land army. The scene of action is unincumbered, so that the eye of the general can behold the whole without interruption. The movements which it is possible to execute are few, and they are precise. A few words are sufficient to order them, and then the mere fighting the ships must always be left to their respective commanders. This simplicity in the duty to be performed has enabled us to frame a language fully adequate to the business in hand, by which a correspondence can be kept up as far as the eye can see. This is the language of SIGNALS, a language by writing, addressed to the eye, and which he that runneth may read. As in common writing certain arbitrary marks are agreed on to express certain sounds used in speech, or rather, as in hieroglyphics certain arbitrary marks are agreed on to express certain thoughts, or the subjects of these thoughts; so here certain exhibitions are made, which are agreed on to express certain movements to be executed by the commander to whom they are addressed, and all are enjoined to keep their eyes fixed on the ship of the conductor of the fleet, that they may learn his will.

2 Used in ancient times,

It is scarcely possible for any number of ships to act in concert, without some such mode of communication between the general and the commanders of private ships. We have no direct information of this circumstance in the naval tactics of the ancient nations, the Greeks and Romans; yet the necessity of the thing is so apparent, that we cannot suppose it to have been omitted by the most ingenious and the most cultivated people who have appeared on the great theatre of the world: and we are persuaded that Themistocles, Conon, and other renowned sea commanders of Athens, had signals by which they directed the movements of their fleets. We read, that when Ægeus sent his son Theseus to Crete, it was agreed on, that if the ship should bring the young prince back in safety, a white flag should be displayed. But those on board, in their joy for revisiting their country after their perilous voyage, forgot to hoist the concerted signal. The anxious father was every day expecting the ship which should bring back his darling son, and had gone to the shore to look out for her. He saw her, but without the signal agreed on. On which the old man threw himself into the sea. We find, too, in the history of the Punic wars by Polybius, frequent allusions to such a mode of communication; and Ammianus Marcellinus speaks of the *speculatores* and *vexillarii*, who were on board the ships in the Adriatic. The coins both of Greece and Rome exhibit both flags and streamers. In short, we cannot doubt of the ancients having practised this hieroglyphical language. It is somewhat surprising that Lord Dudley, in his *Arcano del Mare*, in which he makes an ostentations display of his knowledge of every thing connected with the sea service, makes no express mention of this very essential piece of knowledge, although he must, by his long residence in Italy, have known the marine discipline of the Venetians and Genoese, the greatest maritime powers then in Europe.

3 as well as in modern

In the naval occurrences of modern Europe, mention is frequently made of signals. Indeed, as we have already observed, it seems impossible for a number of ships to act in any kind of concert, without some method of communication. Numberless situations must occur, when it would be impossible to convey orders or information by messengers from one ship to another, and coast and alarm signals had long been practised by every nation. The idea, therefore, was familiar. We find, in particular, that Queen Elizabeth, on occasion of the expedition to Cadiz, ordered her secretaries to draw up instructions, which were to be communicated to the admiral, the general, and the five counsellors of war, and by them to be copied and transmitted to the several ships of the navy, not to be opened till they should arrive in a certain latitude. It was on this occasion (says our historian Guthrie), "that we meet with the first regular sets of signals and orders to the commanders of the English fleet." But till the movements of a fleet have attained some sort of uniformity, regulated and connected by some principles of propriety, and agreed on by persons in the habit of directing a number of ships, we may with confidence affirm that signals would be nothing but a parcel of arbitrary marks, appropriated to particular pieces of naval service, such as attacking the enemy, landing the soldiers, &c.; and that they would be considered merely as referring to the final result, but by no means pointing out the mode of execution, or directing the movements which were necessary for performing it.

4 but first formed into a system by James II. when duke of York.

It was James II. when duke of York, who first considered this practice as capable of being reduced into a system, and who saw the importance of such a composition. He, as well as the king his brother, had always showed a great predilection for the sea service; and when appointed admiral of England, he turned his whole attention to its improvement. He had studied the art of war under Turenne, not as a pastime, but as a science, and was a favourite pupil of that most accomplished general. Turenne one day pointed him out, saying, "Behold one who will be one of the first princes and greatest generals of Europe." When admiral of England, he endeavoured to introduce into the maritime service all those principles of concert and arrangement which made a number of individual regiments and squadrons compose a great army. When he commanded in the Dutch war, he found a fleet to be little better than a collection of ships, on board of each of which the commander and his ship's company did their best to annoy the enemy, but with very little dependence on each other, or on the orders of the general: and in the different actions which the English fleet had with the Dutch, every thing was confusion as soon as the battle began. It is remarkable that the famous pensionary De Witt, who from a statesman became a navigator and a great sea commander in a few weeks, made the same representation to the States General on his return from his first campaign.

In the memoirs of James II. written by himself, we have the following passage: "1665. On the 15th of March, the duke of York went to Gunfleet, the general rendezvous of the fleet, and hastened their equipment. He ordered all the flag officers on board with him every morning, to agree on the order of battle and rank. In former battles, no order was kept, and this

under

Naval Signals.

under the duke of York, was the first in which fighting in a line and regular form of a battle was observed."

This must be considered as full authority for giving the duke of York the honour of the invention. For whatever faults may be laid to the charge of this unfortunate prince, his word and honour stand unimpeached. And we are anxious to vindicate his claim to it, because our neighbours the French, as usual, would take the merit of this invention, and of the whole of naval tactics, to themselves. True it is, that Colbert, the great and justly celebrated minister of Louis XIV. created a navy for his ambitious and vain-glorious master, and gave it a constitution which may be a model for other nations to copy. By his encouragement, men of the greatest scientific eminence were engaged to contribute to its improvement; and they gave us the first treatises of naval evolutions. But it must ever be remembered, that our accomplished, though misguided sovereign, was then residing at the court of Louis; that he had formerly acted in concert with the French as a commander and flag officer, and was at this very time aiding them with his knowledge of sea affairs. In the memorable day at La Hogue, the gallant Russel, observing one of Tourville's movements, exclaimed, "There! they have got Pepys * among them." This anecdote we give on the authority of a friend, who heard an old and respectable officer (Admiral Clinton) say, that he had it from a gentleman who was in the action, and heard the words spoken; and we trust that our readers will not be displeased at having this matter of general opinion established on some good grounds.

* Pepys was secretary to the duke of York.

5 Wonderful simplicity of his system.

It was on this occasion, then, that the duke of York made the movements and evolutions of a fleet the object of his particular study, reduced them to a system, and composed that "System of Sailing and Fighting Instructions," which has ever since been considered as the code of discipline for the British navy, and which has been adopted by our rivals and neighbours as the foundation of their naval tactics. It does great honour to its author, although its merit will not appear very eminent to a careless surveyor, on account of that very simplicity which constitutes its chief excellence. It is unquestionably the result of much sagacious reflection and painful combination of innumerable circumstances, all of which have their influence; and it is remarkable, that although succeeding commanders have improved the subject by several subordinate additions, no change has to this day been made in its general principles or maxims of evolution.

Till some such code be established, it is evident that signals can be nothing but arbitrary and unconnected hieroglyphics, to be learned by rote, and retained by memory, without any exercise of the judgment; and the acquisition of this branch of nautical skill must be a more irksome task than that of learning the Chinese writing. But such a code being once settled, the character in which it may be expressed becomes a matter of rational discussion.

Accordingly, the sailing and fighting instructions of the duke of York were accompanied by a set of signals for directing the chief or most frequent movements of the fleet. These also were contrived with so much judgment, and such attention to distinctness, simplicity, and propriety, that there has hardly been any change found necessary; and they are still retained in the British navy as the usual signals in all cases when we are not anxious to conceal our movements from an enemy.

6 yet as an art has since his time received considerable improvements.

Notwithstanding this acknowledged merit of the duke of York's signals, it must be admitted that great improvements have been made on this subject, considered as an art. The art military has, in the course of a century past, become almost an appropriate calling, and has therefore been made the peculiar study of its professors. Our rivals the French were sooner and more formally placed in this situation; and the ministers of Louis XIV. took infinite and most judicious pains to make their military men superior to all others by their academical education. A more scientific turn was given to their education, and the assistance of scientific men was liberally given them; and all the nations of Europe must acknowledge some obligations to them for information on every thing connected with the art of war. They have attended very much to this subject, have greatly improved it, and have even introduced a new principle into the art; and by this means have reduced it to the most simple form of reference to the code of sailing and fighting instructions, by making the signals immediately expressive, not of orders, but of simple numbers. These numbers being prefixed to the various articles of the code of instructions, the officer who sees a signal thrown out by the admiral reads the number, and reports it to his captain, perhaps without knowing to what it relates. Thus simplicity and secrecy, with an unlimited power of variation, are combined. We believe that M. de la Bourdonnais, a brave and intelligent officer, during the war 1758, was the author of this ingenious thought.

We do not propose to give a system of British signals. This would evidently be improper. But we shall show our readers the practicability of this curious language, the extent to which it may be carried, and the methods which may be practised in accomplishing this purpose. This may make it an object of attention to scientific men, who can improve it; and the young officer will not only be able to read the orders of the commander in chief, but will not be at a loss, should circumstances place him in a situation where he must issue orders to others.

Signals may be divided into,

I. Day Signals.

II. Night Signals; and,

III. Signals in a Fog.

They must also be distinguished into, 1. Signals of Evolution, addressed to the whole Fleet, or to Squadrons of the fleet, or to Divisions of these squadrons. 2. Signals of Movements to be made by particular ships; and, 3. Signals of Service, which may be either general or particular.

7 During an engagement the signals of the admiral are repeated by frigates stationed out of the line.

The great extent of a large fleet, the smoke in time of battle, and the situation of the commander in chief, who is commonly in the midst of the greatest confusion and hottest fire, frequently makes it very difficult for the officers of distant ships to perceive his signals with distinctness. Frigates, therefore, are stationed out of the line, to windward or to leeward, whose sole office it is to observe the admiral's signals, and instantly to repeat them. The eyes of all the signal officers in the private ships of war are directed to the repeating frigates, as well as to the admiral; and the officers of the repeating frigate, having no other duty, observe the admiral incessantly,

Naval Signals.

santly, and, being unembarrassed by the action, can display the signal with deliberation, so that it may be very distinctly seen. Being minutely acquainted with the substitutions which must be made on board the admiral when his masts and rigging are in disorder, his (perhaps imperfect) signal is exhibited by the repeating frigate in its proper form, so as to be easily understood. And to facilitate this communication, the commanders of the different squadrons repeat the signals of the commander in chief, and the commanders of division repeat the signals of the commanders of their squadron.

8 Evolution signals are preceded by a signal of advertisement, and accompanied with a directive signal.

Every evolution signal is preceded by a signal of ADVERTISEMENT and PREPARATION, which is general, and frequently by a gun, to call attention; and when all the signals have been made which direct the different parts of that evolution, another signal is made, which marks the close of the complex signal, and divides it from others which may immediately follow it: and as the orders of the commander in chief may relate either to the movements of the whole fleet, those of a single division, or those of certain private ships, the EXECUTIVE SIGNAL, which dictates the particular movement, is accompanied by a DIRECTIVE SIGNAL, by which these ships are pointed out, to which the order is addressed.

9 Answered by the commander to whom they are addressed.

The commander of the ship to which any signal is addressed, is generally required to signify by a signal (which is general) that he has observed it. And if he does not thoroughly understand its meaning, he intimates this by another general signal. And here it is to be observed, that as soon as the signal is answered by the ships to which it is addressed, it is usual to haul it down, to avoid the confusion which might arise from others being hoisted in the same place. The order remains till executed, notwithstanding that the signal is hauled down.

10 Annulling signal.

It may happen that the commander who throws out the signal for any piece of service, sees reasons for altering his plan. He intimates this by a general ANNULLING signal, accompanying the signal already given. This will frequently be more simple than to make the signals for the movements which would be required for re-establishing the ships in their former situation.

All these things are of very easy comprehension, and require little thought for their contrivance. But when we come to the particular evolutions and movements, and to combine these with the circumstances of situation in which the fleet may be at the time, it is evident, that much reflection is necessary for framing a body of signals which may be easily exhibited, distinctly perceived, and well understood, with little risk of being mistaken one for another. We shall take notice of the circumstances which chiefly contribute to give them these qualities as we proceed in describing their different classes.

I. *Of* Day Signals.

These are made by means of the ship's sails, or by colours of various kinds.

Those made with sails are but few in number, and are almost necessarily limited to the situation of a fleet at anchor. Thus,

The following Signals	*usually signify*
Main topgallant staysail hoisted	Officers and men belonging to the ship to come on board.
Fore topsail loose	To prepare for sailing.
Main topsail loose	To unmoor.
Main topsail sheets hauled home	To weigh.
Main topsail sheets clewed up, and the yard hoisted	Annul the former signal, and the ship to come to an anchor.
Topgallant sails loose, and the sheets flying	Discovering strange sails.
Main-topgallant sail loose and hoisted. Topsail-yard down	Recal ships in chase.
Mizen topsail hoisted, and the sheets clewed up	Moor.

Before we proceed to the description of the signals by means of colours, such as FLAGS, BANNERS (or triangular flags), PENDANTS or VANES, we must take notice of the ostensible distinctions of the various divisions and subdivisions of a fleet, so that we may understand how the same signal may be addressed to a squadron, division, or single ship or ships. We suppose it known that a fleet of ships of war is distributed into three grand divisions (which we shall term *squadrons*), called the *van*, *centre*, and *rear*. These denominations have not always a relation to the one being more advanced than the other, either towards the enemy, or in the direction of their course.

11 Meaning of the terms van, centre, and rear, in the line of battle at sea.

In a land army, the position of every part is conceived from its reference to the enemy; and the reader, conceiving himself as facing the enemy, easily understands the terms *van*, *centre*, and *rear*, the *right* and *left wing*, &c. But the movements of a sea army having a necessary dependence on the wind, they cannot be comprehended unless expressed in a language which keeps this circumstance continually in view. The simplest and most easily conceived disposition of a fleet, is that in which it is almost indispensably obliged to form in order to engage an enemy. This is a straight line, each ship directly ahead of its neighbour, and close hauled. This is therefore called the *line of battle*. In this position, the two extremities of the fleet correspond to the right and left wings of an army. Suppose this line to be in the direction east and west, the wind blowing from the north-north-west, and therefore the fleet on the starboard tack; the ships heads are to the west, and the westermost division is undoubtedly the van of the fleet, and the eastermost division is the rear. And it is in conformity to this arrangement and situation that the LIST OF THE FLEET is drawn up. But the ships may be on the same east and west line, close hauled, with their heads to the west, but the wind blowing from the south-south-west. They must therefore be on the larboard tack. The same ships, and the same division, are still, in fact, the van of the fleet. But suppose the ships heads to be to the eastward, and that they are close hauled,

Naval Signals.

hauled, having the wind from the south-south-east or the north-north-east, the ships which were the real van on both tacks in the former situation are now, in fact, the rear on both tacks; yet they retain the denomination of the *van squadron* of this fleet, and are under the immediate direction of the officer of the second rank, while the other extremity is under the direction of the third officer. This subordination therefore is rather an arrangement of rank and precedence than of evolution. It is, however, considered as the NATURAL ORDER to which the general signals must be accommodated. For this reason, the division which is denominated *van* in the list of this fleet, is *generally* made to lead the fleet when in the line of battle on the starboard tack, and to form the *weathermost* column in *the order of sailing in columns;* and, in general, it occupies that station from which it can most easily pass into the place of the leading division on the starboard line of battle ahead. Although this is a technical nicety of language, and may frequently puzzle a landsman in reading an account of naval operations, the reflecting and intelligent reader will see the propriety of retaining this mode of conceiving the subordinate arrangement of a fleet, and will comprehend the employment of the signals which are necessary for re-establishing this arrangement, or directing the movements while another arrangement is retained.

12 The signals are addressed to each of the divisions.

This being understood, it is easy to contrive various methods of distinguishing every ship by the place which she occupies in the fleet, both with respect to the whole line, with respect to the particular squadron, the particular division of that squadron, and the particular place in that division. This may be done by a combination of the position and colour of the pendants and vanes of each ship. Thus the colour of the pendants may indicate the squadron, their position or mast on which they are hoisted may mark the division of that squadron, and a distinguishing vane may mark the place of the private ship in her own division. The advantages attending this method are many. In a large fleet it would hardly be possible for the commander in chief to find a sufficient variety of single signals to mark the ship to which an order is addressed, by hoisting it along with the signal appropriated to the intended movement. But by this contrivance one-third part of these signals of address is sufficient. It also enables the commander in chief to order a general change of position by a single signal, which otherwise would require several. Thus, suppose that the fore, main, and mizen masts, are appropriated (with the proper modifications) for exhibiting the signals addressed to the van, the centre, and the rear squadrons of the fleet, and that a red, a white, and a blue flag, are chosen for the distingnishing flags of the officers commanding these squadrons; then, if the commander in chief shall hoist a red flag at his mizen topgallant mast head, it must direct the van squadron to take the position then occupied by the rear squadron, the evolution necessary for accomplishing this end being supposed known by the commander of the squadron, who will immediately make the necessary signals to the squadron under his particular direction. In the same manner, the distinguishing signal for the leading ship of a squadron being hoisted along with the signal of address to the whole fleet, and the signal for any particular service, will cause the three or the nine leading ships to execute that order, &c, &c.

All that has been said hitherto may be considered as so many preparations for the real issuing of orders by the commander in chief. The most difficult part of the language remains, viz. to invent a number of signals which shall correspond to that almost infinite variety of movements and services which must be performed.

13 Essential qualities of signals are distinctness.

Distinctness, simplicity, and propriety, are the three essential qualities of all signals. A signal must be some object easily seen, strongly marked, so that it may be readily understood, with little risk of its being mistaken for another. When made by flags, banners, or pendants, they must be of the fullest colours, and strongest contrasts. The ships are frequently at a very great distance, so that the intervening air occasions a great degradation of colour. They are seen between the eye and a very variable sky; and in this situation, especially in the morning or evening, or a dark day, it is not easy to distinguish one full colour from another, all of them approaching to the appearance of a black. At the distance of a very few miles hardly any full colours can be distinguished but a scarlet and a blue. Red, blue, yellow, and white, are the colours which can be distinguished at greater distances than any others, and are therefore the only colours admitted as signals. Even these are sometimes distinguished with difficulty. A yellow is often confounded with a dirty white, and a blue with a red. All other dark colours are found totally unfit. But as these afford but a small variety, we must combine them in one flag, by making it striped, spotted, or chequered, taking care that the opposition of colour may be as great as possible, and that the pieces of which the flags are made up may not be too minute. Red must never be striped nor spotted with blue; and the stripes, spots, or chequers, should never be less than one third of the breadth of the flag. Pl. CCCCXCVI. is a selection by an officer of experience, as a set very easily recognised, and little liable to be confounded. Their colours are represented by hatching, in the same manner as in heraldry (see HERALDRY).

Difference of shape, as flags, banners, or pendants, is another distinction by which the expression may be varied. And in doing this, we must recollect, that in light winds it may be difficult to distinguish a flag from a banner, as neither are fully displayed for want of wind to detach the fly from the staff.

And, lastly, signals may be varied by their position, which may be on any lofty and well detached part of the masts, yards, or rigging.

14 Simplicity.

Simplicity is an eminent property in all signals. They are addressed to persons not much accustomed to combinations, and who are probably much occupied by other pressing duties. It were to be wished that every piece of service could be indicated by a single flag. This is peculiarly desirable with respect to the signals used in time of battle. The rapid succession of events on this occasion call for a multitude of orders from the commander in chief, and his ship is frequently clad over with flags and pendants, so that it is exceedingly difficult for the signal officer of a private ship to distinguish the different groups, each of which make a particular signal.

These

15 and propriety.

These considerations are the foundation of a certain *propriety* in signals, which directs us to a choice among marks which appear altogether arbitrary. Signals which run any risk of being confounded, on account of some resemblance, or because their position hinders us from immediately perceiving their difference, should be appropriated to pieces of service which are hardly possible to be executed, or can hardly be wanted, in the same situation. No bad consequence could easily result though the signal for *coming to closer action* should resemble that for *unmooring*, because the present situation of the ships makes the last operation impossible or absurd. Such considerations direct us to select for battle signals, those which are of easiest exhibition, are the most simple, and have the least dependence on the circumstance of position; so that their signification may not be affected by the damages sustained in the masts or rigging of the flag ship. Such signals as are less easily seen at a distance, should be appropriated to orders which can occur only in the middle of the fleet, &c. &c. Signals which are made to the admiral by private ships may be the same with signals of command from the flag ship, which will considerably diminish the number of signals perfectly different from each other.

16 By what means signals are distinctly conveyed,

With all these attentions and precautions a system of signals is at last made up, fitted to the code of sailing and fighting instructions. It is accompanied by another small set for the duty of convoys. It must be engrossed in two books; one for the officer of the flag-ship, who is to make the signals, and the other is delivered to every private ship. In the first, the evolutions, movements, and other operations of service, are set down in one column, and their corresponding signals in another. The first column is arranged, either alphabetically, by the distinguishing phrase, or systematically, according to the arrangement of the sailing and fighting instructions. The officer whose duty it is to make the signals turns to this column for the order which he is to communicate, and in the other column he finds the appropriated signal.

17 and understood.

In the other book, which is consulted for the interpretation of the signals, they are arranged in the leading column, either by the flags, or by the places of their exhibition. The first is the best method, because the derangement of the flag-ship's masts and rigging in time of action may occasion a change in the place of the signal.

18 The art of signals much improved since the publication of the *Tactique Navale.*

The *Tactique Navale* of the Chevalier de Morogues contains a very full and elaborate treatise on signals. We recommend this work to every sea-officer, as full of instruction. The art of signals has been greatly simplified since the publication of this work, but we cannot but ascribe much of the improvements to it. We believe that the author is the inventor of that systematic manner of addressing the order or *effective signal* to the different squadrons and divisions of the fleet, by which the art of signals is made more concise, the execution of orders is rendered more systematic, and the commanders of private ships are accustomed to consider themselves as parts of an army, with a mutual dependence and connection. We are ready enough to acknowledge the superiority of the French in manœuvring, but we affect to consider this as an imputation on their courage. Nothing can be more unjust; and dear-bought experience should long ere now have taught us the value of this superiority. What avails that courage which we would willingly arrogate to ourselves, if we cannot come to action with our enemy, or must do it in a situation in which it is almost impossible to succeed, and which needlessly throws away the lives of our gallant crews? Yet this must happen, if our admirals do not make evolutions their careful study, and our captains do not habituate themselves, from the first hoisting a pendant, to consider their own ship as connected with the most remote ship in the line. We cannot think that this view of their situation would in the least lessen the character which they have so justly acquired, of fighting their ship with a courage and firmness unequalled by those of any other nation. And we may add, that it is only by such a rational study of their profession, that the gentleman can be distinguished from the mercenary commander of a privateer.

II. Night Signals.

It is evident, that the communication of orders by night must be more difficult and more imperfect than by day. We must, in general, content ourselves with such orders as are necessary for keeping the fleet together, by directing the more general movements and evolutions which any change of circumstances may render necessary. And here the division and subordinate arrangement of the fleet is of indispensable necessity, it being hardly possible to particularise every ship by a signal of address, or to see her situation. The orders are therefore addressed to the commanders of the different divisions, each of whom is distinguished by his poop and top-lights, and is in the midst of, and not very remote from, the ships under his more particular charge. Yet even in this unfavourable situation, it is frequently necessary to order the movements of particular ships. Actions during the night are not uncommon. Pursuits and rallyings are still oftener carried on at this time. The common dangers of the sea are as frequent and more disastrous. The system of signals therefore is very incomplete till this part be accomplished.

Night signals must be made by guns, or by lights, or by both combined.

19 How gun-signals may be varied.

Gun-signals are susceptible of variety both in number and in disposition. The only distinct variation which can be made in this disposition, is by means of the time elapsed between the discharges. This will easily admit of three varieties, slow, moderate, and quick.—Half-minute guns are as slow as can easily be listened to as appertaining to one signal. Quarter-minute guns are much better, and admit of two very distinct subdivisions. When the gunners, therefore, are well trained to this service (especially since the employment of firelocks for cannon), intervals of 15 or 12 seconds may be taken for slow firing, 8 or 10 seconds for moderate, and 4 or 5 seconds for quick firing. If these could be reduced one half, and made with certainty and precision, the expression would be incomparably more distinct. A very small number of firings varied in this way will give a considerable number of signals. Thus five guns, with the variety of only quick and moderate, will give 20 very distinguishable signals. The same principle must be attended to here as in the flag signals. The most simple must be appropriated to the most important orders, such as occur in the worst weather, or such as are most

Naval Signals.

most liable to be mistaken. Quick firing should not make part of a signal to a very distant ship, because the noise of a gun at a great distance is a lengthened sound, and two of them, with a very short interval, are apt to coalesce into one long-continued sound. This mode of varying gun-signals by the time must therefore be employed with great caution, and we must be very certain of the steady performance of the gunners.

Note, that a preparatory signal or advertisement that an effective signal is to be made, is a very necessary circumstance. It is usual (at least in hard weather) to make this by a double discharge, with an interval of half a second, or at most a second.

Gun-signals are seldom made alone, except in ordinary situations and moderate weather; because accident may derange them, and inattention may cause them to escape notice, and, once made, they are over, and their repetition would change their meaning. They are also improper on an enemy's coast, or where an enemy's cruisers or fleets may be expected.

20 Signals by lights.

Signals by lights are either made with LIGHTS simply so called, i. e. lanthorns shown in different parts of the ship, or by rockets. Lights may differ by number, and by position, and also by figure. For the flag ship always carrying poop or top-lights, or both, presents an object in the darkest night, so that we can tell whether the additional lights are exhibited about the mainmast, the foremast, the mizenmast, &c. And if the lights shown from any of these situations are arranged in certain distinguishable situations in respect to each other, the number of signals may be greatly increased. Thus three lights may be in a vertical line, or in a horizontal line, or in a triangle; and the point of this triangle may be up, or down, or forward, or aft, and thus may have many significations.

Lights are also exhibited by false fires or rockets: These can be varied by number, and by such differences of appearance as to make them very distinguishable. Rockets may be with stars, with rain fire, or simple squibs.

21 The two species of signals may be combined.

By varying and combining these, a very great number of signals may be produced, fully sufficient to direct every general movement or evolution, or any ordinary and important service. The Chevalier de Morogues has given a specimen of such a system of night signals, into which he has even introduced signals of address or direction to every ship of a large fleet; and has also given signals of number, by which depths of soundings, points of the compass, and other things of this kind, may be expressed both easily and distinctly. He has made the signals by rockets perfectly similar in point of number to those by lanthorns, so that the commander can take either; a choice which may have its use, because the signals by rockets may cause the presence of a fleet to be more extensively known than may be convenient.

22 General observations concerning night signals.

The commander in chief will inform the fleet by signal, that guns, or perhaps rockets, are not to be used that night. This signal, at the same time, directs the fleet to close the line or columns, that the light signals may be better observed.

It is indeed a general rule to show as few lights as possible; and the commander frequently puts out his own poop and top-lights, only showing them from time to time, that his ships may keep around him.

The signal lanthorns on board the flag ship, and a lanthorn kept in readiness on board of every private ship, to answer or acknowledge signals from the commander in chief, are all kept in bags, to conceal their lights till the moment they are fixed in their places, and the preparatory or advertising signal has been made.

The commander in chief sometimes orders by signal every ship to show a light for a minute or two, that he may judge of the position of the fleet; and the admiral's signal must always be acknowledged by those to whom it is addressed.

It is of particular importance that the fleet be kept together. Therefore the leading ships of the fleet, on either tack, are enjoined to acknowledge the signals of the commander in chief by a signal peculiar to their station. Thus the commander in chief learns the position of the extremities of his fleet.

In framing a set of night signals, great attention must be given to their position, that they be not obscured by the sails. The nature of the order to be given will frequently determine this. Thus, an order for the rear ships to make more sail, will naturally direct us to exhibit the signal at the mizen peek; and so of other pieces of service. Lanthorns exposed in groups, such as triangles, lozenges, &c. are commonly suspended at the corners of large frames of laths, at the distance of a fathom at least from each other. Attempts have been made to show lights of different colours; but the risk of mistake or failure in the composition at the laboratory, makes this rather hazardous. Coloured lanthorns are more certain; but when the glasses are made of a colour sufficiently intense, the vivacity of the light (which at no time is very great) is too much diminished. Besides, the very distance changes the colour exceedingly and unaccountably.

III. *Of* Signals *in a* Fog.

These can be made only by noises, such as the firing of cannon and muskets, the beating of drums and ringing of bells, &c. Fog signals are the most difficult to contrive of any, and are susceptible of the least variety. The commander in chief is principally concerned to keep his fleet together; and unless something very urgent requires it, he will make no change in his course or rate of sailing. But a shift of wind or other causes may make this necessary. The changes which he will order, it will be prudent to regulate by some fixed rule, which is in general convenient. Thus, when a fleet is in the order of sailing upon a wind, and a fog comes on, the fleet will hold on the same course. If the wind should come a little more on the beam, the fleet will still keep close to the wind. Certain general rules of this kind being agreed on, no signals are necessary for keeping the fleet together; and the ships can separate or run foul of each other only by difference in their rate of sailing, or by inaccurate steerage. To prevent this, the commander in chief fires a gun from time to time, and the ships of the fleet judge of his situation and distance by the sound. The commanders of divisions fire guns, with some distinction from those of the commander in chief. This both informs the commander in chief of the position of his squadrons, and enables the private ships of each division to keep in the neighbourhood of their own flag ship. On board of every private ship the drum is beaten, or the bell is chimed, every quarter

23 By observing certain general rules signals during a fog are in many cases unnecessary.

Naval Signals.

quarter of an hour, according as the ship is on the starboard or larboard tack. By such contrivances, it is never difficult to keep a fleet in very good order when sailing on a wind. The wind is almost always moderate, and the ships keep under a very easy sail. It is much more difficult when going large, and separation can be prevented only by the most unwearied attention. The greatest risk is the falling in with strange ships steering another course.

But evolutions and other movements are frequently indispensable. The course must be changed by tacking or wearing, and other services must be performed. None, however, are admitted but the most probable, the most simple, and the most necessary.

24 How they are given when necessary.

The commander in chief first informs the fleet by the *preparatory fog signal*, that he is about order an evolution, and that he is to direct it by *fog signals*. This precaution is indispensable to prevent mistakes. Along with this advertising signal he makes the signal of the movement intended. This not only calls the attention of the fleet, but makes the ships prepare for the precise execution of that movement. The commanders of divisions repeat the advertising signal, which informs their ships of their situation, and the private ships beat their drums or chime their bells. Thus the whole ships of the fleet close a little, and become a little better acquainted with their mutual position. It is now understood that a movement is to be made precisely a quarter of an hour after the advertisement. At the expiration of this time, the effective signal for this movement is made by the commander in chief, and must be instantly repeated by the commanders of divisions, and then the movement must be made by each ship, according to the sailing and fighting instructions. This must be done with the utmost attention and precision, because it produces a prodigious change in the relative position of the ships; and even although the good sense of the commander in chief will select such movements for accomplishing his purpose as produce the smallest alterations, and the least risk of separation or running foul of each other; it is still extremely difficult to avoid these misfortunes. To prevent this as much as possible, each ship which has executed the movement, or which has come on a course thwarting that of the fleet, intimates this by a signal properly adapted, often adding the signal of the tack on which it is now standing, and even its particular signal of recognizance. This is particularly incumbent on the flag ships and the leading ships of each division.

After a reasonable interval, the commander in chief will make proper signals for bringing the fleet to a knowledge of their reunion in this new position.

25 Improper to publish a particular account of signals.

This must serve for a general account of the circumstances which must be attended to in framing a code of signals. The arbitrary characters in which the language is written must be left to the sagacity of the gentlemen of the profession. It must be observed, that the stratagems of war make secrecy very necessary. It may be of immense hazard if the enemy should understand our signals. In time of battle it might frequently frustrate our attempts to destroy them, and at all times would enable them to escape, or to throw us into disorder. Every commander of a squadron, therefore, issues private signals, suited to his particular destination; and therefore it is necessary that our code of signals be susceptible of endless variations. This is exceedingly easy, without any increase of their number. The commander needs only intimate that such and such a signal is so and so changed in its meaning during his command.

26 Signals may be made the immediate expressions of numbers.

We cannot leave this article without returning to an observation which we made almost in the beginning, viz. that the system of signals, or, to speak more properly, the manner of framing this system, has received much improvement from the gentlemen of the French navy, and particularly from the most ingenious thought of M. de la Bourdonnais, of making the signals the immediate expressions of *numbers* only, which numbers may be afterwards used to indicate any order whatever. We shall present our readers with a scheme or two of the manner in which this may be done for all signals, both day, night, and fog. This alone may be considered as a system of signals, and is equally applicable to every kind of information at a distance. Without detracting in the smallest degree from the praise due to M. de la Bourdonnais, we must observe, that this principle of *notation* is of much older date. Bishop Wilkins, in his Secret and Swift Messenger, expressly recommends it, and gives specimens of the manner of execution; so does Dr Hooke in some of his proposals to the Royal Society. Gaspar Schottus also mentions it in his *Technica Curiosa;* and Kircher, among others of his Curious Projects.

27 M. de la Bourdonnais's method for doing this.

M. de la Bourdonnais's method is as follows:

He chooses pendants for his effective signals, because they are the most easily displayed in the proper order. Several pendants, making part of one signal, may be hoisted by one hallyard, being stopped on it at the distance of four or six feet from each other. If it be found proper to throw out another signal at the same time and place, they are separated by a red pendant without a point. His colours are chosen with judgement, being very distinctly recognised, and not liable to be confounded with the addressing signals appropriated to the different ships of the fleet. They are,

For N° 1.	Red.	For N° 6.	Red, with blue tail.
2.	White.	7.	White, with blue tail.
3.	Blue.	8.	White, with red tail.
4.	Yellow.	9.	Blue, with yellow tail.
5.	Red, with white tail.	10.	Yellow, with blue tail.

Three sets of such pendants will express every number under a thousand, by hoisting one above the other, and reckoning the uppermost hundreds, the next below it tens, and the lowest units. Thus the number 643 will be expressed by a pendant red with blue tail, a yellow pendant below it, and a blue one below the last.

This method has great advantages. The signals may be hoisted in any place where best seen, and therefore the signification is not affected by the derangement of the flag-ship's masts and rigging. And by appropriating the smaller numbers to the battle signals, they are more simple, requiring fewer pendants.

28 might be rendered much simpler by using fewer colours

As this method requires a particular set of colours, it has its inconveniences. An admiral is often obliged to shift his flag, even in time of action. He cannot easily take the colours along with him. It is therefore better to make use of such colours as every private ship is provided with. One set of 11 will do, with the addition

Naval Signals.

dition of three, at most of four pendants, of singular make, to mark 100, 200, 300, 400. Two of these flags, one above the other, will express any number under 100, by using the 11th as a substitute for any flag that should be repeated. Thus the 11th flag, along with the flag for eight or for six, will express the number 88 or 66, &c. Thus we are able to express every number below 500, and this is sufficient for a very large code of signals.

And in order to diminish as much as possible the number of these compound signals, it will be proper that a number of single flag signals be preserved, and even varied by circumstances of position, for orders which are of very frequent occurrence, and which can hardly occur in situations where any obstructions are occasioned by loss of masts, &c. And farther, to avoid all chance of mistake, a particular signal can be added, intimating that the signals now exhibited are numerary signals; or, which is still better, all signals may be considered as numerary signals; and those which we have just now called *single flag signals* may be set down opposite to, or as expressing, the largest numbers of the code.

This method requires the signal of advertisement, the annulling signal, the signal of address to the particular ship or division, the signal of acknowledgment, the signal of indistinctness, of distress, of danger, and one or two more which, in every method must be employed.

Another method of expressing numbers with fewer colours.

Another method of expressing numbers with fewer colours is as follows: Let the flags be A, B, C, D, E, F, and arrange them as follows:

	A	B	C	D	E	F
	1	2	3	4	5	6
A	7	8	9	10	11	12
B	13	14	15	16	17	18
C	19	20	21	22	23	24
D	25	26	27	28	29	30
E	31	32	33	34	35	36
F	37	38	39	40	41	42

The number expressed by any pair of flags is found in the intersection of the horizontal and perpendicular columns. Thus the flag D, hoisted along with and above the flag F, expresses the number 40, &c. In order to express a greater number (but not exceeding 84) suppose 75, hoist the flag $\substack{C\\E}$, which expresses 33, or 75 wanting 42, and above them a flag or signal G, which alone expresses 42.

3[?] which may be also improved.

This method may be still farther improved by arranging the flags thus:

	A	B	C	D	E	F
	1	2	3	4	5	6
A	7	8	9	10	11	12
B	—	13	14	15	16	17
C	—	—	18	19	20	21
D	—	—	—	22	23	24
E	—	—	—	—	25	26
F	—	—	—	—	—	27

In this last method the signification of the signal is totally independent of the position of the flags. In whatever parts of the ship the flags D and E are seen, they express the number 23. This would suit battle signals.

31 A third method.

Another method still may be taken. Flags hoisted anywhere on the foremast may be accounted units, those on the mainmast tens, and those on the mizenmast hundreds. Thus numeral signals may be made by a ship dismasted, or having only poles in their place.

Many other ways may be contrived for expressing numbers by colours, and there is great room for exercising the judgment of the contriver. For it must always be remembered, that these signals must be accompanied with a signal by which it is addressed to some particular ship or division of the fleet, and it may be difficult to connect the one with the other, which is perhaps shown in another place, and along with other executive signals.

32 Advantages of numeral signals.

One great advantage of these numeral signals is, that they may be changed in their signification at pleasure. Thus, in the first method, it can be settled, that on Sundays the colours A, B, C, D, &c. express the cyphers 1, 2, 3, 4, &c. but that on Mondays they express the cyphers 0, 1, 2, 3, &c. and on Tuesdays the cyphers 9, 0, 1, 2, &c.; and so on through all the days of the week. This mean of secrecy is mentioned by Dr Hooke for the coast and alarm signals, where, by the by, he shews a method for conveying intelligence over land very similar to what is now practised by the French with their telegraph.

33 Numbers may be also expressed by night signals.

It is equally easy to express numbers by night signals. Thus M. de la Bourdonnais proposes that one discharge of a great gun shall express 7, and that 1, 2, 3, 4, 5, 6, shall be expressed by lights. Therefore to express 24, we must fire three guns, and show three lights. This is the most perfect of all forms of night and fog signals. For both the manner of firing guns and of exhibiting lights may be varied to a sufficient extent with very few guns or lights, and with great distinctness.

Thus, for guns. Let F mark the firing of a single gun at moderate intervals, and *ff* a double gun, that is, two discharged at the interval of a second. We may express numbers thus:

1	F.
2	F, F.
3	F, F, F.
4	F, F, F, F.
5	F, *ff*.
6	F, F, *ff*.
7	F, *ff*, F.
8	F, *ff*, F, F.
9	F, *ff*, F, *ff*.
10	*ff*.
100, &c.	*ff*, *ff*, or *fff*.

It might be done with fewer guns if the *ff* were admitted as the first firing. But it seems better to begin always with the single gun, and thus the double gun beginning a signal distinguishes the tens, &c.

In like manner, a small number of lights will admit of a great variety of very distinct positions, which may serve for all signals to ships not very remote from the commander in chief. For orders to be understood at a very great distance, it will be proper to appropriate the numbers which are indicated by signals made with rockets.

rockets. These can be varied in number and kind to a sufficient extent, so as to be very easily distinguished and understood. It is sufficient to have shown how the whole, or nearly the whole, notation of signals may be limited to the expression of numbers.

34 Concluding remarks.

We have taken little notice of the signals made by private ships to the commander in chief. This is a very easy business, because there is little risk of confounding them with other signals. Nor have we spoken of signals from the flag ships whose ultimate interpretation is number, as when ships are directed to change their course so many points. Those also are easily contrived in any of the methods already described: also when a private ship wishes to inform the commander in chief that soundings are found at so many fathoms. In like manner, by numbering the points of the compass, the admiral can direct to chace to any one of them, or may be informed of strange ships being seen in any quarter, and what is their number.

Signals by the Drum, made use of, in the exercise of the army, instead of the word of command, viz.

Signals.	*Operations.*
A short roll. -	To caution.
A flam, - -	To perform any distinct thing.
To arms, -	To form the line or battalion.
The march,	To advance, except when intended for a salute.
The quick march,	To advance quick.
The point of war,	To march and charge.
The retreat, -	To retreat.
Drum ceasing, -	To halt.
Two short rolls, -	To perform the flank firing.
The dragoon march,	To open the battalion.
The grenadier march,	To form the column.
The troop, - -	To double divisions.
The long roll, -	To form the square.
The grenadier march,	To reduce the square to the column.
The preparative,	To make ready and fire.
The general, -	To cease firing.
Two long rolls, -	To bring or lodge the colours.

SIGNATURE, a sign or mark impressed upon any thing, whether by nature or art. Such is the general signification of the word; but in the plural number it has been used, in a particular sense, to denote those external marks by which physiognomists and other dabblers in the occult sciences pretend to discover the nature and internal qualities of every thing on which they are found. According to Lavater, every corporeal object is characterised by signatures peculiar to itself.

The doctrine of signatures, like alchemy and astrology, was very prevalent during the 15th and 16th centuries; and was considered as one of the occult sciences which conferred no small degree of honour on their respective professors. Some of these philosophers, as they thought fit to style themselves, maintained that plants, minerals, and animals, but particularly plants, had signatures impressed on them by the hand of nature, indicating to the adept the *therapeutic* uses to which they might be applied. Others, such as the mystic theosophists and chemists of that day, proceeded much farther in absurdity, maintaining that every substance in nature had either *external* signatures immediately discernible, or *internal* signatures, which, when brought into view by fire or menstrua, denoted its connection with some sidereal or celestial archetype. Of the doctrine of signatures, as it relates merely to the therapeutic uses of plants and minerals, traces are to be found in the works of some of the greatest authors of antiquity; but the celestial signatures, we believe, were discovered only by the moonlight of the monkish ages. Pliny informs us *, that the marble called *ophites*, from its being spotted like a serpent, was discovered by those spots to be a sovereign remedy for the bite of that animal; and that the colour of the *hæmatites* or blood-stone intimated that it was fit to be employed to stop an hemorrhagy; but we do not recollect his attributing the virtues of these minerals to a sidereal or celestial influence.

* Hist. Nat. lib. 34.

Signature, a signing of a person's name at the bottom of an act or deed written by his own hand.

Signature, in *Printing*, is a letter put at the bottom of the first page at least, in each sheet, as a direction to the binder in folding, gathering, and collating them. The signatures consist of the capital letters of the alphabet, which change in every sheet; if there be more sheets than letters in the alphabet, to the capital letter is added a small one of the same sort, as A a, B b; which are repeated as often as necessary. In large volumes it is easy to distinguish the number of alphabets, after the first three or four, by placing a figure before the signature, as 5 B, 6 B, &c.

SIGNET, one of the king's seals, made use of in sealing his private letters, and all grants that pass by bill signed under his majesty's hand: it is always in the custody of the secretaries of state.

Signet, in *Scots Law*. See Law, Part III. § 17.

SILENE, Catchfly, or *Viscous Campion*, a genus of plants belonging to the class *decandria*, and order *trigynia*; and in the natural system arranged under the 22d order, *Caryophylleæ*. See Botany *Index*.

SILESIA, a duchy of Germany, bounded on the east by Poland; on the west, by Bohemia and Lower Lusatia; on the south, by a chain of mountains, and a thicket of considerable extent which separates it from Hungary; and to the north by the marquisate of Brandenburg and Poland. From north-west to south-east it is about 274 miles, and about 100 where broadest: but it is much contracted at both ends. Upon the frontiers of this country, to the west and south, are very high mountains, and some likewise in other parts of it. One of the ridges upon the frontiers is styled the *Riphæan Mountains*, another the *Moravian*, another the *Bohemian*, and another the *Hungarian*, *Crapack*, or *Carpathian*. A branch of the Bohemian is called the *Giant Mountains*. The winter on these hilly tracts is more severe, sets in sooner, and lasts longer than in the low lands. The inhabitants use a kind of skates when the snow is deep, as they do in Carniola. Little or no grain is raised in the mountains and some sandy tracts; but the rest of the country is abundantly fruitful, not only in grain, but fruits, roots, pasture, flax, hops, madder, tobacco, and hemp, yielding also some wine, with considerable quantities of silk and honey. In many places are great woods of pines, fir, beech, larch, and other trees, affording tar, pitch, rosin, turpentine, lamp-black, and timber for all uses. In this country also is found marble of several sorts, some precious stones, limestone, millstone, pitcoal, turf, vitriol, some silver ore, copper, lead, iron, and mineral springs. Great numbers

bers of black cattle and horses are brought hither from Poland and Hungary for sale, those bred in the country not being sufficient; but of sheep, goats, game, and venison, they have great plenty. As for wild beasts, here are lynxes, foxes, weasels, otters, and beavers. The rivers, lakes, and ponds, yield fish of several sorts, particularly sturgeons several ells in length, and salmon. Besides a number of smaller streams to water this country, there is the Oder, which traverses it almost from one end to the other; and the Vistula, which after a pretty long course through it enters Poland. The inhabitants are a mixture of Germans, Poles, and Moravians. The language generally spoken is German; but in some places the vulgar tongue is a dialect of the Sclavonic. The states consist of the princes and dukes, and those called *state-lords*, with the nobility, who are immediately subject to the sovereign, and the representatives of the chief cities; but since the country fell under the dominion of the king of Prussia, no diets have been held. The king, however, when he took possession of the country, confirmed all the other privileges of the inhabitants. With respect to religion, not only Protestants, but Papists, Jews, and Greeks, enjoy full liberty of conscience. The greatest part of Silesia lies in the diocese of Breslaw, but some part of it in the Polish dioceses of Posen and Cracow. The bishop of Breslaw stands immediately under the pope with regard to spirituals; but all ecclesiastical benefices, not excepting the see of Breslaw, are in the king's gift. Besides Latin schools, colleges, and seminaries, at Breslaw is an university, and at Lignitz an academy for martial exercises. The principal manufactures here are woollens, linens, and cottons of several sorts, with hats, glass-ware, gunpowder, and iron manufactures. Of these there is a considerable exportation. Accounts are generally kept in rix-dollars, silver groschens, and ducats. With respect to its revolutions and present government, it was long a part of the kingdom of Poland; afterwards it had several dukes and petty princes for its sovereigns, who by degrees became subject to the kings of Bohemia, until at last King Charles IV. incorporated the whole duchy with Bohemia; and thus it continued in the possession of the house of Austria, until the king of Prussia in 1742, taking advantage of the troubles that ensued upon the death of the emperor Charles VI. and pretending a kind of claim, wrested a great part of it, together with the county of Glatz, from his daughter and heiress Maria Theresa, the late empress dowager; so that now only a small part of it is possessed by the house of Austria, and connected with the empire, the rest being governed by the king of Prussia, without acknowledging any sort of dependence on the crown of Bohemia or the empire. For the administration of justice in all civil, criminal, and feudal cases, and such as relate to the revenue, the king of Prussia has established three supreme judicatories, to which an appeal lies from all the inferior ones, and from which, when the sum exceeds 500 rix-dollars, causes may be moved to Berlin. The Lutheran churches and schools are under the inspection of the upper consistories, and those of the Papists under that of the bishop's court at Breslaw; but from both an appeal lies to the tribunal at Berlin. As to the revenue, the excise here is levied only in the walled towns, being on the same footing as in the marquisate of Brandenburg; but in the rest of the country the contributions are fixed, and the same both in peace and war. The several branches of the revenue are under the management of the war and domain offices of Breslaw and Glogau. The whole revenue arising to the king of Prussia from Silesia and the county of Glatz amounts to about $13\frac{1}{2}$ millions of florins per annum.

Silesia is divided into Upper and Lower, and each of these again into principalities and lordships; of some of which both the property and jurisdiction belong immediately to the sovereign, but of others to his subjects and vassals. Silesia is the most industrious province in the Prussian dominions, and the seat of the principal manufactures. Its exports in 1804 amounted to 21 millions of florins. It is rich in mines, and furnishes annually 405,000 centners of iron. Its population in 1818 amounted to 2,017,058, and has doubled itself since the year 1746. In short, Silesia may now be considered as the most valuable province belonging to the Prussian monarchy.

SILESIAN EARTH, in the *Materia Medica*, a fine astringent bole. It is very heavy, of a firm compact texture, and in colour of a brownish yellow. It breaks easily between the fingers, and does not stain the hands; is naturally of a smooth surface, is readily diffusible in water, and melts freely into a butter-like substance in the mouth. It leaves no grittiness between the teeth, and does not ferment with acids. It is found in the perpendicular fissures of rocks near the gold mines in Hungary.

SILICERNIUM, among the Romans, was a feast of a private nature, provided for the dead some time after the funeral. It consisted of beans, lettuces, bread, eggs, &c. These were laid upon the tomb, and they foolishly believed that the dead would come out for the repast. What was left was generally burnt on the stone. The word *silicernium* is derived from *silex* and *cœna*, i. e. "a supper upon a stone." Eating what had thus been provided for the dead, was esteemed a mark of the most miserable poverty. A similar entertainment was made by the Greeks at the tombs of the deceased; but it was usual among them to treat the ghosts with the fragments from the feast of the living. See FUNERAL and INFERIÆ.

SILEX. See FLINT.

SILICEOUS EARTHS. See SILICA, CHEMISTRY *Index*.

SILIUS ITALICUS, CAIUS, an ancient Roman poet, and author of an epic poem in 17 books, which contains an history of the second Punic war, so famous for having decided the empire of the world in favour of the Romans. He was born in the reign of Tiberius, and is supposed to have derived the name of *Italicus* from the place of his birth; but whether he was born at Italica in Spain, or at Corfinium in Italy, which, according to Strabo, had the name of *Italica* given it during the Social war, is a point which cannot be known: though, if his birth had happened at either of these places, the grammarians would tell us, that he should have been called *Italicensis*, and not *Italicus*. When he came to Rome, he applied himself to the bar; and, by a close imitation of Cicero, succeeded so well, that he became a celebrated advocate and most accomplished orator. His merit and character recommended him to the highest offices in the republic, even to the consulship, of which

Silius, Silk.

which he was possessed when Nero died. He is said to have been aiding and assisting in accusing persons of high rank and fortune, whom that wicked emperor had devoted to destruction: but he retrieved his character afterwards by a long and uniform course of virtuous behaviour. Vespasian sent him as proconsul into Asia, where he behaved with clean hands and unblemished reputation. After having thus spent the best part of his life in the service of his country, he bade adieu to public affairs, resolving to consecrate the remainder to polite retirement and the muses. He had several fine villas in the country: one at Tusculum, celebrated for having been Cicero's; and a farm near Naples, said to have been Virgil's, at which was his tomb, which Silius often visited. Thus Martial compliments him on both these accounts:

Silius hæc magni celebrat monumenta Maronis,
Jugera facundi qui Ciceronis habet.
Hæredem Dominumque sui tumulique larisque
Non alium mallet nec Maro nec Cicero.
Epigr. 49. lib. xi.

Of Tully's seat my Silius is possess'd,
And his the tomb where Virgil's ashes rest.
Could those great shades return to choose their heir,
The present owner they would both prefer.

In these retirements he applied himself to poetry: led not so much by any great force of genius, which would certainly not have suffered him to stay till life was in the wane and his imagination growing cold, as by his exceeding great love of Virgil, to whose memory he paid the highest veneration. He has imitated him in his poem; and though he falls infinitely short of him, yet he has discovered a great and universal genius, which would have enabled him to succeed in some degree in whatever he undertook.

Having been for some time afflicted with an imposthume, which was deemed incurable, he grew weary of life, to which, in the language of Pliny, he put an end with determined courage.

There have been many editions of Silius Italicus. A neat and correct one was published at Leipsic in 1696, in 8vo, with short and useful notes by Cellarius: but the best is that *cum notis integris variorum et Arnoldi Drakenborch.* Traject. ad Rhen. 1717, in 4to.

SILK, a very soft, fine, bright thread, the work of an insect called *bombyx*, or the silk worm.

As the silk worm is a native of China, the culture of silk in ancient times was entirely confined to that country. We are told, that the empresses, surrounded by their women, spent their leisure hours in hatching and rearing silk worms, and in weaving tissues and silk veils. That this example was soon imitated by persons of all ranks, we have reason to conclude; for we are informed that the Chinese, who were formerly clothed in skins, in a short time after were dressed in vestments of silk. Till the reign of Justinian, the silk worm was unknown beyond the territories of China, but silk was introduced into Persia long before that period. After the conquest of the Persian empire by Alexander the Great, this valuable commodity was brought into Greece, and thence conveyed to Rome. The first of the Roman writers extant by whom silk is mentioned, are Virgil and Horace; but it is probable that neither of them knew from what country it was obtained, nor how it was produced. By some of the ancients it was supposed to be a fine down adhering to the leaves of certain trees or flowers. Others imagined it to be a delicate species of wool or cotton; and even those who had learned that it was the work of an insect, show by their descriptions that they had no idea of the manner in which it was formed. Among the Romans, silk was deemed a dress too expensive and too delicate for men, and was appropriated wholly to women of eminent rank and opulence. Elagabulus is said to have been the first man among the Romans who wore a garment of fine silk: Aurelian complained that a pound of silk was sold at Rome for 12 ounces of gold, and it is said he refused to give his wife permission to wear it on account of its exorbitant price.

1 Opinions of the ancients concerning the nature of silk.

2 Brought from China by the Persians till the time of Justinian.

For several centuries the Persians supplied the Roman empire with the silks of China. Caravans traversed the whole latitude of Asia, in 243 days, from the Chinese ocean to the sea-coast of Syria, carrying this commodity. Sometimes it was conveyed to the ports of Guzerat and Malabar, and thence transported by sea to the Persian gulf. The Persians, with the usual rapacity of monopolists, raised the price of silk to such an exorbitant height, that Justinian eager not only to obtain a full and certain supply of a commodity which was become of indispensable use, but solicitous to deliver the commerce of his subjects from the exactions of his enemies, endeavoured, by means of his ally, the Christian monarch of Abyssinia, to wrest some portion of the silk trade from the Persians. In this attempt he failed; but when he least expected it, he, by an unforeseen event, attained, in some measure, the object which he had in view. Two Persian monks having been employed as missionaries in some of the Christian churches, which were established (as we are informed by Cosmas) in different parts of India, had penetrated into the country of the Seres, or China. There they observed the labours of the silk worm, and became acquainted with all the arts of man in working up its productions into such a variety of elegant fabrics. The prospect of gain, or perhaps an indignant zeal, excited by seeing this lucrative branch of commerce engrossed by unbelieving nations, prompted them to repair to Constantinople. There they explained to the emperor the origin of silk, as well as the various modes of preparing and manufacturing it, mysteries hitherto unknown, or very imperfectly understood in Europe; and encouraged by his liberal promises, they undertook to bring to the capital a sufficient number of those wonderful insects, to whose labours man is so much indebted. This they accomplished, by conveying the eggs of the silk worm in a hollow cane. They were hatched by the heat of a dunghill, fed with the leaves of a wild mulberry tree, and they multiplied and worked in the same manner as in those climates where they first became objects of human attention and care. Vast numbers of these insects were soon reared in different parts of Greece, particularly in the Peloponnesus. Sicily afterwards undertook to breed silk worms with equal success, and was imitated, from time to time, in several towns of Italy. In all these places extensive manufactures were established and carried on with silk of domestic production. The demand for silk from the east diminished of course, the subjects of the Greek emperors were no longer obliged to have recourse to the Persians for a supply of it, and a considerable change took place in

Robertson's Disquisition concerning India, p. 88.

3 Silk worms introduced into Europe by two monks.

in the nature of the commercial intercourse between Europe and India.

As silk is the production of a worm, it will be first necessary to give a description of its nature and mode of manufacturing. But before we give any account of the most approved methods of managing silk worms in Europe, it will be proper to present a short description of the methods practised in China, the original country of the silk worm. These are two: they either permit them to remain at liberty on mulberry trees, or keep them in rooms. As the finest silk is produced by worms confined in rooms, and as the first method is very simple, it will suffice to describe the second.

4
Method of rearing silk worms in China.

To begin with the eggs, which are laid on large sheets of paper, to which they firmly adhere. The sheets are hung up on a beam of the room, with the eggs inward, and the windows are opened in the front to admit the wind; but no hempen ropes must ever come near the worms or their eggs. After some days the sheets are taken down, rolled up loosely with the eggs inward, and then hung up again, during the summer and autumn. At the end of December, or the beginning of January, the eggs are put into cold water, with a little salt dissolved in it. Two days after they take them out, hang them up again, and when dry roll them a little tighter, and enclose each separately, standing on one end in an earthen vessel. Some put them into a lye made of mulberry tree ashes, and then lay them some moments in snow-water, or else hang them up three nights on a mulberry tree to receive the snow or rain, if not too violent. The time of hatching them is when the leaves of the mulberry trees begin to open, for they are hastened or impeded according to the different degrees of heat or cold to which they are exposed. When they are ready to come forth, the eggs swell, and become a little pointed.

The third day before they are hatched, the rolls of paper are taken out of the vessel, stretched out, and hung up with their backs toward the sun, till they receive a kindly warmth; and then being rolled up close, they are set upright in a vessel in a warm place. This is repeated the next day, and the eggs change to an ash-gray. They then put two sheets together, and rolling them close tie the ends.

The third day, towards night, the sheets are unrolled and stretched on a fine mat, when the eggs appear blackish. They then roll three sheets together, and carry them into a pretty warm place, sheltered from the south wind. The next day the people taking out the rolls, and opening them, find them full of worms like small black ants.

The apartment chosen for silk worms is on a dry ground, in a pure air, and free from noise. The rooms are square, and very close, for the sake of warmth; the door faces the south, and is covered with a double mat, to keep out the cold; yet there should be a window on every side, that when it is thought necessary the air may have a free passage. In opening a window to let in a refreshing breeze, care must be taken to keep out the gnats and flies. The room must be furnished with nine or ten rows of frames, about nine inches one above the other. On these they place rush hurdles, upon which the worms are fed till they are ready to spin; and, to preserve a regular heat, stove fires are placed at the corners of the room, or else a warming pan is carried up and down it; but it must not have the least flame or smoke. Cow-dung dried in the sun is esteemed the most proper fuel.

The worms eat equally day and night. The Chinese give them on the first day forty-eight meals, that is, one every half hour; the next thirty; the third day they have still less. As cloudy and rainy weather takes away their stomach, just before their repast a wisp of very dry straw, the flame of which must be all alike, is held over the worms to free them from the cold and moisture that benumbs them, or else the blinds are taken from the windows to let in the full day-light.

Eating so often hastens their growth, on which the chief profit of the silk worm depends. If they come to maturity in 23 or 25 days, a large sheet of paper covered with worms, which at their first coming from the eggs weigh little more than a drachm, will produce 25 ounces of silk; but if not till 28 days, they then yield only 20 ounces; and if they are a month or 40 days in growing, they then produce but ten.

They are kept extremely clean, and are often removed; and when they are pretty well grown, the worms belonging to one hurdle are divided into three, afterwards they are placed on six, and so on to the number of 20 or more; for being full of humours, they must be kept at a due distance from each other. The critical moment for removing them is when they are of a bright yellow and ready to spin; they must be surrounded with mats at a small distance, which must cover the top of the place to keep off the outward air; and because they love to work in the dark. However, after the third day's labour, the mats are taken away from one o'clock till three, but the rays of the sun must not shine upon them. They are at this time covered with the sheets of paper that were used on the hurdles.

The cocoons are completed in seven days, after which the worm is metamorphosed into a chrysalis; the cocoons are then gathered, and laid in heaps, having first set apart those designed for propagation upon a hurdle, in a cool airy place. The next care is to kill the moths in those cones which are not to be bored. The best way of doing it is to fill large earthen vessels with cones in layers of ten pounds each, throwing in four ounces of salt with every layer, and covering it with large dry leaves like those of the water-lily, and closely stopping the mouth of the vessels. But in laying the cones into the vessels, they separate the long, white, and glittering ones, which yield a very fine silk, from those that are thick, dark, and of the colour of the skin of an onion, which produce a coarser silk.

5
Description and history of the silk worm.

The silk worm is a species of caterpillar, which, like all others of the same class, undergoes a variety of changes, that, to persons who are not acquainted with objects of this kind, will appear to be not a little surprising.

It is produced from a yellowish-coloured egg, about the size of a small pin-head, which has been laid by a kind of grayish-coloured moth, which the vulgar confound with the butterfly. *The Bee, No. 72.*

These eggs, in the temperature of this climate, if kept beyond the reach of the fire and sunshine, may be preserved during the whole of the winter and spring months without danger of hatching: and even in summer they may easily be prevented from hatching if they be kept in a cool place; but in warmer climates it is

scarcely

Silk.

scarcely possible to preserve them from hatching, even for a few days, or from drying so much as to destroy them. Hence it is easy for a native of Britain to keep the eggs till the food on which the worm is to feed be ready for that purpose. When this food is in perfection, the eggs need only be exposed to the sun for a day or two, when they will be hatched with great facility.

When the animal is first protruded from the egg, it is a small black worm, which is active, and naturally ascends to the top of the heap in search of food. At this stage of his growth the silk worm requires to be fed with the youngest and most tender leaves. On these leaves, if good, he will feed very freely for about eight days, during which period he increases in size to about a quarter of an inch in length. He is then attacked with his first sickness, which consists in a kind of lethargic sleep for about three days continuance; during which time he refuses to eat, and changes his skin, preserving the same bulk. This sleep being over, he begins to eat again, during five days, at which term he is grown to the size of full half an inch in length; after which follows a second sickness, in every respect like the former.

He then feeds for other five days; during which time he will have increased to about three quarters of an inch in length, when he is attacked with his third sickness. This being over, he begins to eat again, and continues to do so for five days more, when he is attacked by his fourth sickness, at which time he is arrived at his full growth. When he recovers this sickness, he feeds once more during five days with a most voracious appetite; after which he disdains his food, becomes transparent, a little on the yellowish cast, and leaves his silky traces on the leaves where he passes. These signs denote that he is ready to begin his cocoon, and will eat no more.

Thus it appears that the whole duration of the life of the worm, in this state of its existence, in our climate, is usually about 46 days; 28 of which days he takes food, and remains in his sick or torpid state 18; but it is to be observed, that during warm weather the periods of sickness are shortened, and in cold weather lengthened, above the terms here specified. In very hot climates it may be said to live faster, and sooner to attain maturity, than in those that are colder. Dr Anderson informs us, that at Madras the worm undergoes its whole evolutions in the space of 22 days. It appears, however, that it feeds fully as many days in India as in Europe, the difference being entirely occasioned by shortening the period of sickness. The longest sickness he had seen them experience there did not exceed two days; and during summer it only lasts a few hours.

When the worm has attained its full growth, it searches about for a convenient place for forming its cocoon, and mounts upon any branches or twigs that are put in its way for that purpose. After about two days spent in this manner, it settles in its place, and forms the cocoon, by winding the silk which it draws from its bowls round itself into an oblong roundish ball.

During this operation it gradually loses the appearance of a worm; its length is much contracted, and its thickness augmented. By the time the web is finished, it is found to be transformed into an oblong roundish ball, covered with a smooth shelly skin, and appears to be perfectly dead. In this state of existence it is called an *aurelia*. Many animals in this state may be often seen sticking on the walls of out-houses, somewhat resembling a small bean.

In this state it remains for several days entirely motionless in the heart of the cocoon, after which it bursts like an egg hatching, and from that comes forth a heavy dull-looking moth with wings; but these wings it never uses for flying; it only crawls slowly about in the place it has been hatched. This creature forces its way through the silk covering which the worm had woven, goes immediately in quest of its mate, after which the female lays her eggs; and both male and female, without tasting food in this stage of their existence, die in a very short time.

The silk worm, when at its full size, is from an inch and a quarter to an inch and a half in length, and about half an inch in circumference. He is either of a milk or pearl colour, or blackish; these last are esteemed the best. His body is divided into seven rings, to each of which are joined two very short feet. He has a small point like a thorn exactly above the anus. The substance which forms the silk is in his stomach, which is very long, wound up, as it were, upon two spindles, as some say, and surrounded with a gum, commonly yellowish, sometimes white, but seldom greenish. When the worm spins his cocoon, he winds off a thread from each of his spindles, and joins them afterwards by means of two hooks which are placed in his mouth, so that the cocoon is formed of a double thread. Having opened a silk worm, you may take out the spindles, which are folded up in three plaits, and, on stretching them out, and drawing each extremity, you may extend them to near two ells in length. If you then scrape the thread so stretched out with your nail, you scrape off the gum, which is very like bees wax, and performs the same office to the silk it covers as gold leaf does to the ingot of silver it surrounds, when drawn out by the wire drawer. This thread which is extremely strong and even, is about the thickness of a middling pin.

6 Particular attention ought to be paid to the breed of silk worms.

Of silk worms, as of most other animals, there is a considerable variety of breeds, some of which are much more hardy, and possess qualities considerably different from others. This is a particular of much importance to be adverted to at the time of beginning to breed these creatures in any place; for it will make a great difference in the profit on the whole to the undertaker if he rears a good or a bad sort (A). This is a department in respect to the economy of animals that has been in every

(A) As the success of the silk manufacture must depend on the breed of worms, it is of great consequence to bring them from those countries where they are reckoned best.

Mr Andrew Wright, an ingenious silk manufacturer of Paisley, has given the following directions for conveying the eggs of the silk worm from distant countries by sea: As soon as the moth has laid her eggs, dry them immediately, and put them into glass phials; seal them so close that damp air or water will not penetrate into them. Put these phials that contain the eggs into earthen pots filled with cold water; and as often as the water becomes warm

Silk.

every case much less adverted to than it deserves; and in particular with regard to the silk worm it has been almost entirely overlooked. A few eggs of the silk worm can be easily transported by post in a letter from any part of Europe to another, especially during the winter season. It would therefore be an easy matter for any patriotic society, such as the Society of Arts in London, to obtain a specimen of the eggs from every country in which silk is now reared, to put these under the care of a person who could be depended upon, and who understood the management of them, with orders to keep each kind distinct from another, and advert to every particular that occurred in their management, so as to make a fair estimate of their respective merits. By these means the best might be selected, and those of inferior value rejected. Forty or fifty of each sort might be enough for the experiment; but it ought to be repeated several times before conclusions could be drawn from it that might be altogether relied upon; for it is well known that a variation of circumstances will make a change in the result; and it is by no means certain that the same particular would affect those of one breed exactly in the same manner as it would do those of a different breed. One may be more hardy with regard to cold, another more delicate in respect to food, and so on. It is experience alone that can ascertain the circumstances here inquired for.

The management of silk worms must be different in different climates;

From the above-mentioned particulars, it is evident, that the management of silk worms must be very different in hot climates from what is required in those that are colder. At Madras, it appears from Dr Anderson's experiments that it is very difficult to prevent the eggs from hatching for a very few days, so that many generations of them must be propagated in one year. "In this hottest season," says he, in a letter to Sir Joseph Banks, dated July 6. 1791, "the shortest time I have been able to remark for the whole evolutions of the silk worm is 40 days; that is to say, six days an egg, 22 a worm, 11 a grub in the cocoon, and one a moth or butterfly." Fortunately, where the climate forces forward their production so rapidly, nature hath been equally provident of food for their subsistence; for in these regions the mulberry continues to grow and push out leaves throughout the whole year.

8 but may be easily reared in temperate climes.

Though the silk worm be a native of China, there is no doubt but it might easily be progagated perhaps in most parts of the temperate zones. The eggs of this insect, indeed, require a considerable degree of warmth to hatch them, but they can also endure a severe frost. No less than 5400lbs. of silk were raised in 1789 in the cold, sandy territories of Prussia. In the province of Pekin, in China, where great quantities of silk are fabricated, the winter is much colder than even in Scotland. From the information of some Russians who were sent thither to learn the Chinese language, we find that Reaumur's thermometer was observed from 10 to 15, and even 20 degrees below the freezing point. Nor is it difficult to rear the food of the silk worm in a temperate clime. The mulberry-tree is a hardy vegetable, which bears, without injury, the winters of Sweden, and even of Siberia. Of the seven species of the mulberry (see Morus) enumerated by Linnæus, four of these (viz. the white, red, black, and Tartarian), there is every reason to believe could be reared both in Britain and Ireland. The *white* grows in Sweden; the *red* is abundant round Quebec; the *black* delights in bleak situations, exposed to wind, on the sea shore; and the *Tartarian* mulberry is represented as growing in the chilly regions of Siberia.

Bee, M. 156.

9 Whether any species of mulberry tree be superior to others.

As to the superior qualities of the different species, probably there is very little to be pointed out amongst the four just mentioned with regard to nourishment, except what may be drawn from the following fact: that if the first three are laid down together, the silk worm will first eat the white, then the red, and next the black, in the order of the tenderness of the leaves. The Tartarian seems to hold as high a place in its esteem as either the red or black; but all must yield to the white, which seems to be its natural food.

In Calabria the red mulberry is used; in Valencia the white; and in Granada, where excellent silk is produced, the mulberries are all black. The white seems to prosper very well in a moist stiff soil: the black agrees well with a dry, sandy, or gravelly soil; and the white is most luxuriant in a moist rich loam.

10 Britain possesses some advantages over warmer countries for raising silk.

It may justly be asserted, that Britain possesses some advantages in the raising of raw silk which are not enjoyed by warmer countries. Even in the south of France, Mr Arthur Young informs us, the mulberry leaves are often nipped by frost in the bud; and this is scarcely ever the case with us. It is well known that thunder and lightning are hurtful to the silk worm. Now our climate can boast that it is almost wholly exempted from those dreadful storms of thunder and lightning which prevail so much in hot climates. Nature has then furnished us with every thing requisite for the silk manufacture; it remains only for us to improve the advantages which we possess. Let mulberry trees be planted by proprietors of lands, and let a few persons of skill and attention devote their time to the raising of silk worms. This is an employment that will not interfere with any manufacture already established; on the contrary, it would afford a respectable, a lucrative, and agreeable employment to ladies, or to females in general, who have at present too few professions to which they can apply. The society instituted at London for the encouragement of arts, manufactures, and commerce, much to their honour, have offered premiums to those who shall plant a certain number of mulberry trees.

11 Method of raising mulberry trees in the south of France.

The following method of raising mulberry trees from seed is practised in the south of France, and has been repeated with success in the East Indies by Dr Anderson of Madras. "Take the ripe berries of the mulberry when it is full of juice and of seeds. Next take a rough horse-hair line or rope, such as we dry linen on, and with a good handful of ripe mulberries run your hand along the line, bruising the berries and mashing them

Letters on the Culture of Raw Silk on the Coast of Coromandel.

---

warm renew it. Place the earthen vessels in the coldest place of the ship, and let them remain until the end of the voyage. It must be observed, that the ship chosen for this purpose ought to be one that would arrive in Britain in the months of June or July.

them as much as possible as your hand runs along, so that the pulp and seeds of the berries may adhere in great abundance to the rope or hair line. Next dig a trench in the ground where you wish to plant them, much like what is practised in kitchen gardens in England for crops of various kinds. Next cut the rope or hair line into lengths according to the length of the trench you think fit to make, and plunge the line full of mashed berries into the trench, and then cover it over well with earth, always remembering afterwards to water it well, which is essential to the success. The seeds of the berries thus sown will grow, and soon shoot out young suckers, which will bear young leaves, which are the best food for the silk worm.

"The facility and rapidity with which young leaves may by this means be produced is evident, for as many rows of trenches may thus be filled as can be wished; and it can never be necessary to have mulberry trees higher than our raspberries, currants, or gooseberry bushes. Whenever they get beyond that, they lose their value; and if these trenches succeed, you may have a supply coming fresh up day after day, or any quantity you please." Thus abundance of these trees might be reared. But as mulberry trees are not yet found in abundance in this country, it were to be wished that some other food could be substituted in their place: attempts have accordingly been made by those who have reared silk worms, and it has been found possible to support the silk worm upon lettuce (B).

Bee, N° 70.

12 Miss Rhodes fed silk worms on lettuce for some time.

Miss Henrietta Rhodes, a lady who has made some successful experiments on raising silk worms in England, had found that the silk worm could with safety be kept on lettuce for some time. This is pretty generally known by ladies who have turned their attention to this subject; but she found that in general they could not with safety be kept upon that food above three weeks. If longer fed upon that plant, the worms for the most part die without spinning a web at all. She found, however, that they did not always die, but that in some cases they produced very good cocoons, even when fed entirely on lettuce. She therefore with reason suspected that the death of the animal must be occasioned by some extraneous circumstance, and not from the poisonous quality of the food itself: the circumstance she suspected, from some incidental observations, was the coldness of that food; and therefore she thought it was not impossible, but if they were kept in a very warm place, while fed on lettuce, they might attain, in all cases, a due perfection.

13 General Mordaunt still more successful.

General Mordaunt having been informed of this conjecture, resolved to try the experiment. He got some silk worm eggs, had them hatched in his hot-house, and caused them to be all fed upon lettuce and nothing else. They prospered as well as any worms could do, few or none of them died; and they afforded as fine cocoons as if they had been fed upon mulberry leaves. As far as one experiment can go, this affords a very exhilarating prospect in many points of view. If one kind of food has been noxious, merely on account of an improper temperature, others may be found which have been hurtful only from a similar cause; so that it is not impossible but we may at last find that this delicate creature may be supported by a variety of kinds of food. Few, however, could be more easily obtained than lettuce; and this plant, when cabbaged (the coss or ice lettuce especially), would possess one quality that the mulberry leaf never can possess, from the want of which many millions of worms die in those countries where silk is now reared; for it is observed, that when the leaves are gathered wet, it is scarcely possible to preserve the worms alive for any length of time; so that during a continuance of rainy weather many of them are unavoidably cut off; but a lettuce, when cabbaged, resists moisture. If gathered, even during rain, the heart of it is dry; so that if the outer leaves be thrown aside at that time, the worms would be continued in perfect health. The expence, too, of cultivating and gathering lettuce, would be so much less than that of gathering mulberry leaves, as to occasion a saving that would be much more than sufficient to counterbalance the expence of heating the conservatory, as a little reflection will show.

But the great point to be now ascertained is, whether it is a fact that worms fed on lettuce, if kept in a due temperature, will continue in good health, in general, till they shall have perfected their cocoon? One experiment is too little to establish this fact with perfect certainty. It would therefore be necessary that more experiments should be made on this subject.

It is said that Dr Lodovico Bellardi, a learned and ingenious botanist of Turin, has, after a number of experiments, discovered a new method of feeding silk worms, when they are hatched before the mulberry trees have produced leaves, or when it happens that the frost destroys the tender branches. This new method consists in giving the worms dried leaves of the mulberry-tree. One would think that this dry nourishment would not be much relished by these insects; but repeated experiments made by our author, prove that they prefer it to any other, and eat it with the greatest avidity. The mulberry leaves must be gathered about the end of autumn, before the frosts commence, in dry weather, and at times when the heat is greatest. They must be dried afterwards in the sun, by spreading them upon large cloths, and laid up in a dry place after they have been reduced to powder. When it is necessary to give this powder to the worms, it should be gently moistened with a little water, and a thin coat of it must be placed around the young worms, which will immediately begin to feed upon it. 14 Silk worms said to be fed on dried mulberry leaves.

We have mentioned all the different kinds of food, which, as far as we have heard, have been tried with any success to nourish the silk worm; not, however, with great confidence, but as experiments which it might be worth while carefully to consider and perform. We must not omit to mention that one person, who has had much 15 Proper experiments ought to be made on various vegetables.

(B) It is not improbable, says Dr Anderson, to whose valuable work entitled the *Bee*, we have been much indebted in drawing up this article, that other kinds of food may be found which will answer the same purpose. The cichorium intybus and common endive might be tried, as they have the same lactescent quality with the lettuce.

Silk.

much experience in the managing of silk worms, assures us, that the silk produced from any other food than mulberry leaves is of an inferior quality, and that the worms are sickly. We think, however, that there is reason to suspect that the experiment has not been skilfully performed; and therefore, before every other food except mulberry leaves is discarded, the experiment ought to be performed with more attention and care. We know that many animals in a domestic state can live upon food very different from that which supported them when running wild in the fields. Certain it is, however, that every animal, in its state of nature, partakes of a food peculiar to itself, which is rejected by other animals as if it were of a poisonous quality; and it may be mentioned as a curious fact, as well as an admirable instance of the care of that Being who feeds the fowls of heaven, that notwithstanding the numberless insects that prey upon animals and vegetables, the mulberry tree is left untouched by them all, as the exclusive property of the silk worm, the chief of the insect tribe, which toils and spins for the use of man.

16 What situation and apartments proper for the insects.

Having now considered the food proper for the silk worm, we shall next consider what situation is most favourable to them. In the opinion of some persons in this country who have been in the practice of rearing silk worms, they ought always to be kept in a dry place, well sheltered, and possessing a considerable degree of warmth, and which is not exposed to sudden transitions from heat to cold. If the weather be too cold, a small fire must be made; this is of most importance when the worms are ready for spinning. A southern exposure is therefore preferable. Some think light is of great utility to silk worms, others think that they thrive better in the dark. As to what apartments are best accommodated for promoting the health of silk worms, and most convenient for those who have the care of them, they may be various according to the extent of the manufacture or the wealth of the proprietors. Silk worms may be kept in boxes or in shelves. When shelves are to be used, they may be constructed in the following manner: The shelves may be of wicker, ranged at the distance of a foot and a half, and fixed in the middle of the room: their breadth ought to be such, that any person can easily reach to the middle from either side. This is perhaps the simplest and cheapest apparatus for rearing silk worms; but there is another apparatus which may be recommended to those who are anxious to unite some degree of elegance with convenience. This apparatus is the invention of the Rev. George Swayne of Puckle-church, a gentleman who has studied this subject much, in order to find out the way for promoting the culture of silk among the poor. This apparatus, with the description of it, may be found in the Transactions of the Society for encouraging Arts, Manufactures, and Commerce, vol. vii. p. 148. The apparatus consists of a wooden frame four feet two inches high, each side 16 inches and a half wide, divided into eight partitions by small pieces of wood which form grooves, into which the slides run, and are thus easily thrust into or drawn out of the frame. The upper slide in the model sent to the Society by Mr Swayne is of paper only, and designed to receive the worms as soon as hatched; the two next are of catgut, the threads about one-tenth of an inch distant from each other: these are for the

17 Mr Swayne's apparatus described.

insects when a little advanced in size: the five lower ones are of wicker work; but, as Mr Swayne afterwards found, netting may be substituted with advantage instead of wicker bottoms. Under each of these, as well as under those of catgut, are sliders made of paper, to prevent the dung of the worms from falling on those feeding below them.

18 Proper time for hatching silk worms.

The management of silk worms is next to be attended to. The proper time for hatching them is when the leaves of the mulberry are full grown, or nearly so; that as soon as these insects are capable of receiving food they may obtain it in abundance. To attempt to hatch them sooner would be hurtful, as the weather would not be sufficiently warm. Besides, as leaves are necessary to the life of a vegetable, if the young leaves of the mulberry tree are cropped as soon as they are unfolded, the tree will be so much weakened as to be incapable of producing so many leaves as it would otherwise have done; and if this practice be frequently repeated, will inevitably be destroyed.

19 How they ought to be hatched and fed.

When the proper season is arrived, the eggs may be hatched either by the heat of the sun, when it happens to be strong enough, or by placing them in a small room moderately heated by a stove or fire; and after being exposed for six or seven days to a gentle heat, the silk worm issues from the egg in the form of a small black hairy caterpillar. When Mr Swayne's apparatus is used, the worms are to be kept on the drawers with paper bottoms till they are grown so large as not readily to creep through the gauze-bottomed drawers: they are then to be placed on those drawers, where they are to remain till their excrements are so large as not readily to fall through; when this is the case they must be removed to the drawers with the wicker or netting bottoms, and fed thereon, till they show symptoms of being about to spin. It is scarcely necessary to mention, that the paper slides beneath the gauze and wicker drawers are intended to receive the dung, which should be emptied as often as the worms are fed, at least once a-day; or to direct, that when the worms are fed, the slides are to be first drawn out a considerable way, and the drawers to rest upon them.

20 Wet or damp food produces contagious diseases.

It has been already mentioned, that wet or damp food is exceedingly prejudicial to those insects. It produces contagious and fatal diseases. To prevent the necessity of giving them wet or damp food, attention ought to be paid to the weather, so that when there is an immediate prospect of rain, a sufficient quantity of leaves may be gathered to serve the worms two or three days. In this country, the leaves of the black or red mulberry tree may be preserved good for food, although kept four or five days, by the following method: When new gathered, lay them loosely in glazed earthen vessels, place these in a cold place, well aired, not exposed to drought.

21 Ought to be kept as clean as possible.

The utmost attention must be paid to preserve the place where silk worms are kept as clean as possible: the house or room must be well ventilated, that no noxious vapours be accumulated. By some experiments of M. Faujas de St Fond, which are recorded in his history of Languedoc, it appears that the silk worm is much injured by foul air. All decayed leaves must be removed from them, as it is now well known that they emit bad air in great abundance.

Silk.

Bee, N° 95. One of the most difficult branches of the management of silk worms has hitherto been the cleaning without bruising them. To avoid this inconvenience, the peasants in France and Italy frequently allow the whole litter to remain without ever cleaning them, which is the cause of that unwholesome stench that has been so often remarked by those who visit the places for rearing silk worms in these countries. This difficulty may be effectually removed by providing a net, or, what would be still better, a wire-bottomed frame, wrought into large meshes like a riddle. Have that made of a size exactly sufficient to cover the wooden box in which the worms are kept. When you mean to shift them, spread fresh leaves into the wire basket; and let it down gently over the worms till it comes within their reach. They no sooner perceive the fresh food than they abandon the rubbish below, and creep through the meshes, so as to fix themselves upon the leaves; then by gently raising the fresh basket, and drawing out the board below (which ought to be made to slip out like the slip-bottom of a bird's cage), you get off all the excrements and decayed leaves, without incommoding the worms in the smallest degree; and along with the litter you will draw off an inch or two in depth of the foulest mephitic vapours. To get entirely rid of these, the board, when thus taken out, should be carried without doors, and there cleaned; and the slip-board immediately replaced to receive all the excrements and offals. After it is replaced, the wire frame that had been elevated a little, may be allowed to descend to a convenient distance above the board without touching it. Thus will there be left a vacant space for the mephitic air to fall below the worms, so as to allow them to inhabit a wholesome region of the atmosphere.

22 How they may be cleaned without bruising them.

When a fresh supply of food is to be given before cleaning, the wire frame ought to be let down as close to the board as can be safely done, and another wire-bottomed frame put over it, with fresh leaves, as before described. When the worms have abandoned that in their turn, let the slip-board, together with the lower wire frame, be drawn out and removed, and so on as often as necessary. To admit of this alternate change, every table, consisting of one slip-board, ought to have two sets of wire-bottomed frames of the same size; the slip-board to be always put into its place immediately after it is cleaned, and the wire frames reserved to be afterwards placed over the other. By this mode of management, it is probable that the worms would be saved from the diseases engendered by the mephitic air, and the numerous deaths that are the consequence of it avoided.

23 Quicklime would absorb all the bad air which surrounds them.

Dr Anderson, to whom we have already acknowledged our obligations, and to whom this country has been much indebted for valuable works on agriculture, the fisheries, &c. advises those who have the management of silk worms to strew a thin stratum of fresh slaked quicklime upon the slip-board each time it is cleaned immediately before it is put into its place. This would absorb the mephitic gas, for as soon as it is generated it would descend upon the surface of the quicklime. Thus would the worms be kept continually in an atmosphere of pure air (c). Were the walls of the apartments to be frequently washed with quicklime and water, it would tend much to promote cleanliness at a small expence, and augment the healthiness of the worms as well as that of the persons who attend them.

24 Mr Swayne's receptacle for the worms, when going to spin. *Transactions of the Society for the Encouragement of Arts*, vol. vii. p. 123.

When the silk worm refuses its food, and leaves silky traces on the leaves over which it passes, it is a proof that it is ready to begin its cocoon. It is now necessary to form a new receptacle, which is commonly done by pinning together papers in the shape of inverted cones with broad bases. "This method (says Mr Swayne), where there are many worms, is exceedingly tedious, wastes much paper, and uses a large number of pins; besides, as the silk worm always weaves an outer covering or defensive web before it begins the cocoon or oval ball, I apprehended that it caused a needless waste of silk in forming the broad web at the top. The method I make use of is, to roll a small piece of paper (an uncut octavo leaf, such as that of an old magazine, is sufficient for three), round my fore-finger, and to give it a twist at the bottom; which is done with the utmost expedition, and gives no occasion for the use of pins. These rolled paper-cases being likewise of a form more nearly resembling that of a cocoon, with a much narrower opening on the top than the others, takes away the necessity of wasting much silk in the outer web, and consequently leaves more to be employed in forming the ball. The silk is readily taken out of these cases by untwisting the bottom; and if this be done with moderate care, and the papers are preserved, they will serve several times for the like purpose."

25 Others recommend bushes of heath.

Others advise, that when the silk worms are preparing to spin, little bushes of heath, broom, or twigs, should be

(c) To put this question beyond a doubt, Mr Blancard made the following comparative experiments, which were several times repeated. "I procured (says he) four glass jars nine inches high and five in diameter, closing the mouth with cork stoppers. After which I placed in each of them, in their second life (so *mue* may be translated, which means the stage between the different sicknesses), twelve silk worms, which were fed four times a-day; and which I confined in this kind of prison all their life, without taking away either their dead companions or their ordure or litter. I sprinkled with chalk the worms of only two of these jars, and kept the two others to compare with them.

"In those without lime, I never obtained either more or less than three small and imperfect cocoons (*chiques ou bouffard*), and in the two that were sprinkled with lime, I had very often twelve, and never less than nine fine full-sized firm cocoons."

This experiment affords the most satisfactory proof of the utility of this process. From a number of trials he found, that even when the worms were covered with a large proportion of lime, they never were in any way incommoded by it.

Silk.

be stuck upright neat the shelf or box in which they are inclosed: the worms mount these, and attach their web to them.

26 [How silk worms may be revived when affected by thunder. *Transactions of the American Philosophical Society*, vol. ii.]

When the worms are ready to mount, in order to spin, if the weather be hot, attended with thunder, you will see them in a languishing condition; your care must then be to revive them, which is effected thus: Take a few eggs and onions, and fry them in a pan with some stale hog's lard, the ranker the better, and make pancake; which done, carry it smoaking hot into the room where they are kept, and go round the chamber with it. You will be surprised to see how the smell revives them, excites those to eat who have not done feeding, and makes the others that are ready to spin climb up the twigs.

27 [Different kinds of cocoons.]

In about ten or twelve days, according to the accounts which we have received from Mr Andrew Wright of Paisley, it may be safely concluded, that if the worms have finished their work, the cocoons may be collected.

We shall now distinguish the cocoons from one another according to their value or their use, and consider the method of managing each. They may be distinguished into the good and bad. The good cocoons may be known by these marks: they are little, strong, and firm; have a fine grain, both ends are round, and they are free from spots. Among the good cocoons also may be arranged those which are called *calcined* cocoons, in which the worm, in consequence of sickness, is petrified or reduced to a fine powder. These cocoons produce more silk than others, and are sold in Piedmont at half as much again. They may be distingnished by the noise which the worm makes when the cocoon is shaken. Of the bad cocoons there are six species: 1. The *pointed cocoons*, one extremity of which ends in a point; the silk which covers the point is weak, and soon breaks or tears. 2. The *cocalons*, which are bigger, but the contexture is weak. 3. The *dupions*, or double cocoons, which have been formed by the joint labour of two and sometimes of three worms. 4. The *soufflons*, which have a loose contexture, sometimes so loose that they are transparent. 5. The *perforated cocoons*, which have a hole at one end. 6. The *bad choquette*, which is composed of defective cocoons, spotted or rotten. Besides these there is the *good choquette*, which does not properly belong to either of these two classes: it is formed of those cocoons in which the worm dies before the silk is brought to perfection. The worms adhere to one side of the cocoon, and therefore when the cocoon is shaken will not rattle: the silk is as fine, but is not of so bright a colour, nor is so strong and nervous, as that which is obtained from good cocoons.

[Mr Wright's instructions for selecting and preserving the royal cocoons.]

The cocoons which are kept for breeding are called *royal* cocoons. For selecting and preserving these, we have been favoured with some valuable instructions by Mr Wright of Paisley, which we shall present to our readers.—The largest and best cocoons ought to be kept for breed, about an equal number of males and females; the cocoons that contain the former are sharper pointed at the ends than those that contain the latter. Although it should happen that there are more females than males, little inconvenience or ill consequences can arise from it, as one male will serve two or three females, if the time of their coming out of the cocoons answer. About 12 or 15 days after they begin to spin, the cocoons for breed may be laid on sheets of white paper; about this time the moth opens for itself a passage through the end of its cocoon, and issues out. When the female has laid her eggs, which on an average may amount to 250, they are spread upon sheets of paper, and hung up to dry in some place where they may not be exposed to the heat of the sun: after being dried they must be kept in a cool well-aired place, where neither vapours nor moisture can reach them. That they may be preserved from external accidents, as insects of different kinds will destroy them, and mice is their enemy in all the stages of their existence, they should be kept in stone pots or glass bottles with their mouths stopped, and there remain until brought out next season to be hatched.

29 [How to prepare the cocoons for being wound.]

The cocoons from which the silk is to be immediately wound must be exposed to the heat of an oven, in order to kill the chrysalis or aurelia, which would otherwise eat its way through the cocoon, and render it useless. The following directions are given for managing this process by one of the first silk manufacturers in Italy.

[*Transactions of the American Philosophical Society*, vol. ii.]

Put your cocoons in long shallow baskets, and fill them within an inch of the top. You then cover them up with paper, and put a wrapper over that. These baskets are to be disposed in an oven, whose heat is as near as can be that of an oven from which the bread is just drawn after being baked. When your cocoons have remained therein near an hour, you must draw them out; and to see whether all the worms are dead, draw out a dupion from the middle of your basket and open it: if the worm be dead, you may conclude all the rest are so; because the contexture of the dupion being stronger than that of the other cocoons, it is consequently less easy to be penetrated by the heat. You must observe to take it from the middle of the basket, because in that part the heat is least perceptible. After you have drawn your baskets from the oven, you must first cover each of them with a woollen blanket or rug, leaving the wrapper besides, and then you pile them above one another. If your baking has succeeded, your woollen cover will be all over wet with a kind of dew, the thickness of your little finger. If there be less, it is a sign your cocoons have been too much or too little baked. If too much baked, the worm, being over-dried, cannot transpire a humour he no longer contains, and your cocoon is then burnt. If not enough baked, the worm has not been sufficiently penetrated by the heat to distil the liquor he contains, and in that case is not dead.

You must let your baskets stand thus covered five or six hours if possible, in order to keep in the heat, as this makes an end of stifling those worms which might have avoided the first impression of the fire. You are likewise to take great care to let your cocoons stand in the oven the time that is necessary; for if they do not stand long enough, your worms are only stunned for a time, and will afterwards be revived. If, on the other hand, you leave them too long in the oven, you burn them: many instances of these two cases are frequently to be met with. It is a good sign when you see some of the butterflies spring out from the cocoons which have been baked, because you may be certain they are not burnt. For if you would kill them all to the last worm, you would burn many cocoons which might be more exposed to the heat than that particular worm.

The next operation is the winding of the silk. Before

Silk.

fore you begin to wind, you must prepare your cocoons as follows:

30 How the silk is to be wound from the cocoons.

1. In stripping them of that waste silk that surrounds them, and which served to fasten them to the twigs. This burr is proper to stuff quilts, or other such uses; you may likewise spin it to make stockings, but they will be coarse and ordinary.

2. You must sort your cocoons, separating them into different classes in order to wind them apart. These classes are, the good white cocoons; the good cocoons of all the other colours; the dupions; the cocalons, among which are included the weak cocoons; the good choquette; and, lastly, the bad choquette. In sorting the cocoons, you will always find some perforated cocoons amongst them, whose worm is already born; those you must set apart for fleuret. You will likewise find some soufflons, but very few; for which reason you may put them among the bad choquette, and they run up into waste.

The good cocoons, as well white as yellow, are the easiest to wind; those which require the greatest care and pains are the cocalons; you must wind them in cooler water than the others, and if you take care to give them to a good windster, you will have as good silk from them as the rest. You must likewise have careful windsters for the dupions and choquettes. These two species require hotter water than the common cocoons.

The good cocoons are to be wound in the following manner: First, choose an open convenient place for your filature, the longer the better, if you intend to have many furnaces and coppers. The building should be high and open on one side, and walled on the other, as well to screen you from the cold winds and receive the sun, as to give a free passage to the steam of your basons or coppers.

These coppers or basons are to be disposed (when the building will admit of it) in a row on each side of the filature, as being the most convenient method of placing them, for by that means in walking up and down you see what every one is about. And these basons should be two and two together, with a chimney between every couple.

Having prepared your reels (which are turned by hand, and require a quick eye), and your fire being a light one under every bason, your windster must stay till the water is as hot as it can be without boiling. When every thing is ready, you throw into your basons two or three handfuls of cocoons, which you gently brush over with a wisk about six inches long, cut stumpy like a broom worn out: by these means the threads of the cocoons stick to the wisk. You must disengage these threads from the wisk, and purge them by drawing these ends with your fingers till they come off entirely clean. This operation is called *la Battue.*

When the threads are quite clear, you must pass four of them (if you will wind fine silk) through each of the holes in a thin iron bar, that is placed horizontally at the edge of your bason; afterwards you twist the two ends (which consist of four cocoons each) twenty or twenty-five times, that the four ends in each thread may the better join together in crossing each other, and that your silk may be plump, which otherwise would be flat.

Your windster must always have a bowl of cold water by her, to dip her fingers in, and to sprinkle very often the said bar, that the heat may not burn the thread.

Your threads, when thus twisted, go upon two iron hooks called rampins, which are placed higher, and from thence they go upon the reel. At one end of the axis of the reel is a cog-wheel, which catching in the teeth of the post-rampin, moves it from the right to the left, and consequently the thread that is upon it; so that your silk is wound on the reel crossways, and your threads form two hanks of about four fingers broad.

As often as the cocoons you wind are done, or break or diminish only, you must join fresh ones to keep up the number requisite, or the proportion; because, as the cocoons wind off, the thread being finer, you must join two cocoons half wound to replace a new one: Thus you may wind three new ones and two half wound, and your silk is from four to five cocoons.

When you would join a fresh thread, you must lay one end on your finger, which you throw lightly on the other threads that are winding, and it joins them immediately, and continues to go up with the rest. You must not wind off your cocoons too bare or to the last, because when they are near at an end, the *bairré*, that is, the husk, joins in with the other threads, and makes the silk foul and gouty.

When you have finished your first parcel, you must clean your basons, taking out all the striped worms, as well as the cocoons, on which there is a little silk, which you first open and take out the worm, and then throw them into a basket by you, into which you likewise cast the loose silk that comes off in making the battue.

You then proceed as before with other two or three handfuls of cocoons; you make a new battue; you purge them, and continue to wind the same number of cocoons or their equivalent, and so to the end.

As was already mentioned, the windster must always have a bowl of cold water by her, to sprinkle the bar, to cool her fingers every time she dips them in the hot water, and to pour into her bason when necessary, that is, when her water begins to boil. You must be very careful to twist your threads a sufficient number of times, about 25, otherwise your silk remains flat, instead of being round and full; besides, when the silk is not well crossed, it never can be clean, because a gout or nub that comes from a cocoon will pass through a small number of these twists, though a greater will stop it. Your thread then breaks, and you pass what foulness there may be in the middle of your reel between the two hanks, which serves for a head-band to tie them.

You must observe that your water be just in a proper degree of heat. When it is too cold, the thread is dead, and has no body; when it is too hot, the ends which form the thread do not join well, and form a harsh ill-qualified silk.

You must change the water in your bason four times a day for your dupions and choquette, and twice only for good cocoons when you wind fine silk; but if you wind coarse silk, it is necessary to change it three or four times. For if you were not to change the water, the silk would not be so bright and glossy, because the worm contained

contained in the cocoons foul it very considerably. You must endeavour to wind as much as possible with clear water, for if there are too many worms in it, your silk is covered with a kind of dust which attracts the moth, and destroys your silk.

You may wind your silk of what size you please, from one cocoon to 1000; but it is difficult to wind more than 30 in a thread. The nicety, and that in which consists the greatest difficulty, is to wind even; because as the cocoon winds off the end is finer, and you must then join other cocoons to keep up the same size. This difficulty of keeping the silk always even is so great, that (excepting a thread of two cocoons, which we call such) we do not say a silk of three, of four, or six cocoons; but a silk of three to four, of four to five, of six to seven cocoons. If you proceed to a coarser silk, you cannot calculate so nicely as to one cocoon more or less. We say, for example, from 12 to 15, from 15 to 20, and so on.

51 What number of worms produce a certain quantity of silk.

What number of worms are necessary to produce a certain quantity of silk has not been ascertained. And as different persons who wished to determine this point have had different results, the truth seems to be, that from various circumstances the same number of worms may produce more silk at one time than at another. It is related in the second volume of the Transactions of the Society for encouraging Arts, &c. that Mrs Williams obtained nearly an ounce and a half of silk from 244 cocoons. Mr Swayne from 50 cocoons procured 100 grains. Miss Rhodes obtained from 250 of the largest cocoons, three quarters of an ounce and a dram. From a paper in the second volume of the American Transactions, which we have before referred to in the course of this article, we are informed that 150 ounces of good cocoons yield about 11 ounces of silk from five to six cocoons: if you wind coarser, something more. But what appears astonishing, Mr Salvatore Bertezen, an Italian, to whom the Society for encouraging Arts, &c. adjudged their gold medal, raised five pounds of excellent silk from 12,000 worms.

52 Length of the threads.

The cocoons produce a thread of very unequal length; you may meet with some that yield 1200 ells, whilst others will scarcely afford 200 ells. In general, you may calculate the production of a cocoon from 500 to 600 ells in length.

Silk-Loom. See Weaving.

Silk-Worm. See Silk.

SILLA, a large town on the Niger, by which the travels of Mr Park were bounded towards the east. He gives no particular description of the place, which his health and spirits permitted him not to survey, but assigns the reasons by which he was induced to proceed no farther. On his arrival, he was allowed to remain under a tree, till it was quite dark, surrounded by hundreds of people. But their language was extremely different from the other parts of Bambarra; and he was given to understand, that in his progress eastward, the Bambarra tongue was very little understood; and that, on his reaching Jenné, he would find the greater part of the inhabitants accustomed to speak a different language. He had now become the prey of sickness, exhausted with hunger and fatigue, half naked, and without any article of value, to procure for himself provisions, clothes, or lodging, on which account he resolved to return, finding that to prosecute his journey further in that direction was wholly impracticable. Silla, according to the latest map of Africa, is in 14° 48′ N. Lat and 1° 24′ W. Long.

SILPHA, Carrion-Beetle, a genus of insects belonging to the order *coleopteræ*. See Entomology *Index*.

SILPHIUM, a genus of plants belonging to the class of syngenesia, and to the order of polygamia necessaria; and in the natural system arranged under the 49th order, *Compositæ*. See Botany *Index*.

SILVER, a well known metallic substance. For an account of its properties, see Chemistry *Index*.

Silver, Ores of. See Mineralogy *Index*.

Shell-Silver, is prepared of the shreds of silver leaf, or of the leaves themselves, for the use of painters, after the same manner as shell-gold. See *Shell-Gold*.

SILVERING, the covering of any thing with silver. It is usual to silver metals, wood, paper, &c. which is performed either with fire, oil, or size. Metal-gilders silver by the fire; painter gilders all the other ways. See Gilding.

To silver copper or brass. 1. Cleanse the metal with aquafortis, by washing it lightly, and immediately throwing it into pure water; or by heating it red hot, and scouring it with salt and tartar, and pure water, with a small wire brush 2. Dissolve some silver in aquafortis, in a broad-bottomed glass vessel, or of glazed earth; then evaporate away the aquafortis over a chaffing dish of coals. 3. Put five or six times its quantity of water, or as much as will be necessary to dissolve it perfectly, on the remaining dry calx; evaporate this water with the like heat; then put more fresh water, and evaporate again; and, if need be, the third time, making the fire towards the latter end so strong as to leave the calx perfectly dry, which, if your silver is good, will be of a pure white. 4. Take of this calx, common salt, crystals of tartar, of each a like quantity or bulk, and mixing well the whole composition, put the metal into pure water, and take of the said powder with your wet fingers, and rub it well on, till you find every little cavity of the metal sufficiently silvered over. 5. If you would have it richly done, you must rub on more of the powder; and, in the last place, wash the silvered metal in pure water, and rub it hard with a dry cloth.

Silvering of Glasses. See *Foliating of Looking-glasses*.

SILURIS, a genus of fishes belonging to the order abdominales. See Ichthyology *Index*.

SIMANCAS, a village on the eastern boundary of the kingdom of Leon in Spain, six miles below Valladolid, on the river Gisnerga. Dr Robertson, in the introduction to his History of America, makes mention of it, and it is remarkable for the archives of the kingdoms of Leon and Castile, kept in the castle. This collection was begun when the kings often resided at Valladolid, in which city is still the civil and military tribunal for almost the whole of Spain to the north of the Tagus. It was thought proper to have those papers kept in the vicinity of that court, for which purpose this castle was peculiarly fitted, being entirely erected of stone. At one period there were two large halls in this office filled with papers respecting the first settlement of the Spaniards in South America. There was likewise in the room called the *ancient royal patronage*, a box containing

containing treatises with England, in which are many letters and treaties between the kings of England and Spain, from the year 1400 to 1600. There was also a strong box in the same archives, with five locks, which, we are told, has not been opened since the time of Philip II. and it is supposed that it contains the process against Philip's son Prince Charles. But it appears that some of the state papers have been removed to Madrid.

SIMEON *of Durham*, the cotemporary of William of Malmsbury, took great pains in collecting the monuments of our history, especially in the north of England, after they had been scattered by the Danes. From these he composed a history of the kings of England, from A. D. 616 to 1130; with some smaller historical pieces. Simeon both studied and taught the sciences, and particularly the mathematics at Oxford; and became precentor of the church at Durham, where he died, probably soon after the conclusion of his history, which was continued by John, prior of Hexham, to A. D. 1156.

SIMIA, the Monkey, a genus of quadrupeds belonging to the class of mammalia, and order of primates, in the Linnæan system, but by Mr Pennant arranged under the digitated quadrupeds. See Mammalia *Index*.

SIMILE, or Similitude, in *Rhetoric*, a comparison of two things, which though different in other respects, yet agree in some one. The difference between a simile and comparison is said to consist in this, that the simile properly belongs to whatever we call the quality of a thing, and the comparison to the quantity. See Comparison; and Oratory, N° 118.

SIMILOR, a name given to an alloy of red copper and zinc, made in the best proportions, to imitate silver and gold.

SIMON Maccabeus, a celebrated leader and high-priest of the Jews, who, after rendering the most important services to his country, was at last treacherously slain by his son-in-law. See *the History of the Jews*, N° 15.

Simon Magus, or the Sorcerer, was a native of Gitton, a village of Samaria. According to the usual practice of the Asiatics of that age, he visited Egypt, and there probably became acquainted with the sublime mysteries taught in the Alexandrian school, and learned those theurgic or magical operations, by means of which it was believed that men might be delivered from the power of evil demons. Upon his return into his own country, the author of the Clementine Recognitions relates, that he imposed upon his countrymen by high pretensions to supernatural powers. And St Luke attests, that this artful fanatic, using sorcery, had bewitched the people of Samaria, giving out that he was *some great one;* and that he obtained such general attention and reverence in Samaria, that the people all gave heed to him from the least to the greatest, saying "This man is the great power of God."

Enfield's History of Philosophy, vol. ii. p. 161.

By the preaching of Philip the Deacon, he was with other Samaritans converted to the Christian faith, and admitted into the infant church by the ordinance of baptism. His conversion, however, seems not to have been real; for, upon seeing the miraculous effects of the laying on of the apostle's hands, he offered them money, saying, "Give me also this power, that on whomsoever I lay hands he may receive the Holy Ghost." He probably thought Peter and John magicians like himself, but better skilled in the art of deceiving the multitude.

Being sharply reproved for this impiety, he seems by his answer to have been made sensible of his sin; but his repentance, if sincere, was of short duration. Returning to his former practices of imposture, he travelled through various provinces of the empire, opposing the progress of the gospel; and arriving at Rome, he led astray vast numbers of people by his pretended miracles. How long he lived in that metropolis of the world, or in what manner he died, we have no accounts that can be fully depended on. The Christian writers tell us, that being raised in the air by two dæmons, he was deprived of their support by the prayers of St Peter and St Paul, and falling, broke his legs. By some he is thought to have been the person mentioned by Suetonius, who, undertaking to fly in the presence of Nero, fell to the ground with such violence, that his blood spurted up to the gallery where the emperor was sitting.

The sum of this impostor's doctrine, divested of allegory, was, that from the Divine Being, as a fountain of light, flow various orders of æons, or eternal natures, subsisting within the plenitude of the divine essence; that beyond these, in the order of emanation, are different classes of intelligences, among the lowest of which are human souls; that matter is the most remote production of the emanative power, which, on account of its infinite distance from the Fountain of Light, possesses sluggish and malignant qualities, which oppose the divine operations, and are the cause of evil; that it is the great design of philosophy to deliver the soul from its imprisonment in matter, and restore it to that divine light from which it was derived: and that for this purpose God had sent him one of the first æons among men. To his wife Helena he also ascribed a similar kind of divine nature, pretending that a female æon inhabited the body of this woman, to whom he gave the name of Εννοια, *Wisdom;* whence some Christian fathers have said, that he called her the *Holy Spirit.* He also taught the transmigration of souls, and denied the resurrection of the body.

Simon, *Richard*, was born at Dieppe the 15th May 1638. He began his studies among the priests of the Oratory in that city, but quitted their society in a short time. From Dieppe he went to Paris, where he made great progress in the study of the oriental languages. Some time afterwards he joined the society of the Oratory again, and became a priest of it in 1660. In 1670 he published some pieces of a smaller kind. In 1678 his Critical History of the Old Testament appeared, but was immediately suppressed by the intrigues of Messieurs du Port Royal. It was reprinted the year after, and its excellence soon drew the attention of foreigners; an edition of it was accordingly published at Amsterdam in Latin, and at London in English.

He died at Dieppe in 1712, at the age of 74.

He certainly possessed a vast deal of learning: his criticism is exact, but not always moderate; and there reigns in his writings a spirit of novelty and singularity which raised him a great many adversaries. The most celebrated of these were Le Clerc, Vossius, Jurieu, Du Pin, and Bossuet. Simon wrote an answer to most of the

Simon
Simonides.

the books that were published against him, and displays a pride and obstinacy in his controversial writings which do him little honour.

He was the author of a great many books. The following are the principal: 1. The Ceremonies of the Jews, translated from the Italian of Leo of Modena, with a supplement concerning the sects of the Carraites and Samaritans. 2. *L'Histoire Critique du Vieux Testament*, "The Critical History of the Old Testament." This is a very important work, and deserves the attention of every clergyman. He sometimes, however, deviates from the road of integrity, to serve the cause of the church of Rome, particularly in his endeavours to prove the uncertainty of the Hebrew language. These passages have been very justly exposed and confuted by Dr Campbell, in his ingenious Preliminary Dissertations to his new Translation of the Gospels. 3. Critical History of the Text of the New Testament. 4. Critical History of the Versions of the New Testament. 5. Critical History of the principal Commentators on the New Testament. 6. Inspiration of the Sacred Books. 7. A translation of the New Testament. This book was censured by Cardinal Noailles and Bossuet. 8. The History of the rise and progress of Ecclesiastical Revenues, which is commended by Voltaire, as is his Critical History of the Old Testament. It resulted from a quarrel with a community of Benedictines. 9. A new select Library, which points out the good books in various kinds of literatnre, and the use to be made of them. 10. Critical History of the Belief and Customs of the Nations on the Levant. 11. Critical Letters, &c.

SIMONICAL, is applied to any person guilty of simony. See SIMONY.

SIMONIDES, the name of several poets celebrated in antiquity; but by the Marbles it appears that the eldest and most illustrious of them was born in the 55th Olympiad, 538 years B. C. and that he died in his 90th year; which nearly agrees with the chronology of Eusebius. He was a native of Ceos, one of the Cyclades, in the neighbourhood of Attica, and the preceptor of Pindar. Both Plato and Cicero give him the character not only of a good poet and musician, but speak of him as a person of great virtue and wisdom. Such longevity gave him an opportunity of knowing a great number of the first characters in antiquity with whom he was in some measure connected. It appears in Fabricius, from ancient authority, that Simonides was cotemporary and in friendship with Pittacus of Mitylene, Hipparchus tyrant of Athens, Pausanias king of Sparta, Hiero tyrant of Syracuse, with Themistocles, and with Alevades king of Thessaly. He is mentioned by Herodotus; and Xenophon, in his Dialogue upon Tyranny, makes him one of the interlocutors with Hiero king of Syracuse. Cicero alleges, what has often been quoted in proof of the modesty and wisdom of Simonides, that when Hiero asked him for a definition of God, the poet required a whole day to meditate on so important a question: at the end of which, upon the prince putting the same question to him a second time, he asked two days respite; and in this manner always doubled the delay each time he was required to answer it; till at length, to avoiding offending his patron by more disappointments, he frankly confessed that he found the question so difficult, that the more he meditated upon it, the less was his hope of being able to solve it.

In his old age, perhaps from seeing the respect which money procured to such as had lost the charms of youth and the power of attaching mankind by other means, he became somewhat mercenary and avaricious. He was frequently employed by the victors at the games to write panegyrics and odes in their praise, before his pupil Pindar had exercised his talents in their behalf: but Simonides would never gratify their vanity in this particular, till he had first tied them down to a stipulated sum for his trouble; and upon being upbraided for his meanness, he said, that he had two coffers, in one of which he had for many years put his pecuniary rewards; the other was for honours, verbal thanks, and promises; that the first was pretty well filled, but the last remained always empty. And he made no scruple to confess in his old age, that of all the enjoyments of life, the love of money was the only one of which time had not deprived him.

He was frequently reproached for his vice; however, he always defended himself with good humour. Upon being asked by Hiero's queen, Whether it was most desirable to be learned or rich? he answered, that it was far better to be rich; for the learned were always dependent on the rich, and waiting at their doors; whereas, he never saw rich men at the doors of the learned. When he was accused of being so sordid as to sell part of the provisions with which his table was furnished by Hiero, he said he had done it in order "to display to the world the magnificence of that prince and his own frugality." To others he said, that his reason for accumulating wealth was, that "he would rather leave money to his enemies after death, than be troublesome to his friends while living."

He obtained the prize in poetry at the public games when he was fourscore years of age. According to Suidas, he added four letters to the Greek alphabet; and Pliny assigns to him the eighth string of the lyre; but these claims are disputed by the learned.

His poetry was so tender and plaintive, that he acquired the cognomen of *Melicertes*, "sweet as honey;" and the tearful eye of his muse was proverbial. Dionysins places him among those polished writers who excel in a smooth volubility, and flow on like plenteous and perennial rivers, in a course of even and uninterrupted harmony.

It is to Dionysius that we are indebted for the preservation of the following fragment of this poet. Danae being by her merciless father inclosed in a chest, and thrown into the sea with her child, when night comes on, and a storm arises which threatens to overset the chest, she, weeping and embracing the young Perseus, cries out:

Sweet child! what anguish does thy mother know,
Ere cruel grief has taught thy tears to flow!
Amidst the roaring wind's tremendous sound,
Which threats destruction as it howls around;
In balmy sleep thou liest, as at the breast,
Without one bitter thought to break thy rest.——
The glimm'ring moon in pity hides her light,
And shrinks with horror at the ghastly sight.
Didst thou but know, sweet innocent! our woes,
Not opiate's pow'r thy eyelids now could close.

Sleep

Simonides || Simoom.

Sleep on, sweet babe! ye waves in silence roll;
And lull, O lull, to rest my tortur'd soul!

There is a second great poet of the name of Simonides recorded on the Marbles, supposed to have been his grandson, and who gained, in 478 B. C. the prize in the games at Athens.

SIMONY, is the corrupt presentation of any one to an ecclesiastical benefice for money, gift, or reward. It is so called from the resemblance it is said to bear to the sin of Simon Magus, though the purchasing of holy orders seems to approach nearer to his offence. It was by the canon law a very grievous crime: and is so much the more odious, because, as Sir Edward Coke observes, it is ever accompanied with perjury; for the presentee is sworn to have committed no simony. However, it was not an offence punishable in a criminal way at the common law: it being thought sufficient to leave the clerk to ecclesiastical censures. But as these did not affect the simoniacal patron, nor were efficacious enough to repel the notorious practice of the thing, divers acts of parliament have been made to restrain it by means of civil forfeitures; which the modern prevailing usage, with regard to spiritual preferments, calls aloud to be put in execution. The statute 31 Eliz. c. 6. enacts, that if any patron, for money or any other corrupt consideration or promise, directly or indirectly given, shall present, admit, institute, induct, install, or collate any person to an ecclesiastical benefice or dignity, both the giver and taker shall forfeit two years value of the benefice or dignity; one moiety to the king, and the other to any one who will sue for the same. If persons also corruptly resign or exchange their benefices, both the giver and taker shall in like manner forfeit double the value of the money or other corrupt consideration. And persons who shall corruptly ordain or license any minister, or procure him to be ordained or licensed (which is the true idea of simony), shall incur a like forfeiture of forty pounds; and the minister himself of ten pounds, besides an incapacity to hold any ecclesiastical preferment for seven years afterwards. Corrupt elections and resignations in colleges, hospitals, and other eleemosynary corporations, are also punished, by the same statute, with forfeiture of the double value, vacating the place or office, and a devolution of the right of election, for that turn, to the crown.

SIMOOM, a hot wind which blows occasionally in the deserts of Africa, and probably in other widely extended countries parched in the same manner by a vertical sun. Its effects on the human body are dreadful. If inhaled in any quantity, it produces instant suffocation, or at least leaves the unhappy sufferer oppressed with asthma and lowness of spirits. The approach of this awful scourge of God is indicated by a redness in the air, well understood by those who are accustomed to journey through the desert; and the only refuge which they have from it, is to fall down with their faces close to the ground, and to continue as long as possible without drawing in their breath.

Bruce's Travels. vol. iv. p. 559.

Mr Bruce, who, in his journey through the desert, suffered from the simoom, gives of it the following graphical description: "At eleven o'clock, while we contemplated with great pleasure the rugged top of Chiggre, to which we were fast approaching, and where we were to solace ourselves with plenty of good water, Idris our guide cried out, with a loud voice, Fall upon your faces, for here is the simoom. I saw from the south-east a haze come, in colour like the purple part of the rainbow, but not so compressed or thick. It did not occupy twenty yards in breadth, and was about twelve feet high from the ground. It was a kind of blush upon the air, and it moved very rapidly; for I scarce could turn to fall upon the ground with my head to the northward, when I felt the heat of its current plainly upon my face. We all lay flat on the ground as if dead, till Idris told us it was blown over. The meteor or purple haze which I saw was indeed passed, but the light air that still blew was of heat to threaten suffocation. For my part, I found distinctly in my breast that I had imbibed a part of it, nor was I free of an asthmatic sensation till I had been some months in Italy, at the baths of Poretta, near two years afterwards." Though the severity of this blast seems to have passed over them almost instantaneously, it continued to blow so as to exhaust them till twenty minutes before five in the afternoon, lasting through all its stages very near six hours, and leaving them in a state of the utmost despondency.

Simoom || Simplicity.

SIMPLE, something not mixed or compounded; in which sense it stands opposed to *compound*.

SIMPLE, in the *Materia Medica*, a general name for all herbs or plants, as having each its particular virtue, whereby it becomes a simple remedy.

SIMPLICITY IN WRITING. If we examine the writers whose compositions have stood the test of ages, and obtained that highest honour, "the concurrent approbation of distant times and nations," we shall find that the character of simplicity is the unvarying circumstance which alone hath been able to gain this universal homage from mankind. Among the Greeks, whose writers in general are of the simple kind, the divinest poet, the most commanding orator, the finest historian, and deepest philosopher, are, above the rest, conspicuously eminent in this great quality. The Roman writers rise towards perfection according to that measure of simplicity which they mingle in their works; indeed they are all inferior to the Greek models. But who will deny that Lucretius, Horace, Virgil, Livy, Terence, Tully, are at once the simplest and best of Roman writers? unless we add the noble annalist who appeared in after-times; who, notwithstanding the political turn of his genius, which sometimes interferes, is admirable in this great quality, and by it far superior to his contemporaries. It is this one circumstance that hath raised the venerable Dante, the father of modern poetry, above the succeeding poets of his country, who could never long maintain the local and temporary honours bestowed upon them; but have fallen under that just neglect which time will ever decree to those who desert a just simplicity for the florid colourings of style, contrasted phrases, affected conceits, the mere trappings of composition and Gothic minutiæ. It is this which has given to Boileau the most lasting wreath in France, and to Shakespeare and Milton in England; especially to the former, whose writings contain specimens of perhaps the purest and simplest English that is anywhere to be found, except in the Bible or Book of Common Prayer. As it appears from these instances, that simplicity is the only universal characteristic of just writing, so the superior eminence of the sacred Scriptures in in this quality hath been generally acknowledged. One of the greatest critics in antiquity, himself conspicuous in the sublime and simple manner, hath borne this testimony to the writings of Moses and St Paul; and by parity of reason we must conclude, that had he been conversant with the other sacred writers, his taste and candour would have allowed them the same encomium.

It hath been often observed, even by writers of no mean rank, that the "Scriptures suffer in their credit by the disadvantage of a literal version, while other ancient writings enjoy the advantage of a free and embellished translation." But in reality these gentlemen's concern is ill placed and groundless: for the truth is, "that most other writings are impaired by a literal translation; whereas giving only a due regard to the idiom of different languages, the sacred writings, when literally translated, are then in their full perfection."

Now this is an internal proof, that in all other writings there is a mixture of local, relative, exterior ornament, which is often lost in the transfusion from one language to another. But the internal beauties, which depend not on the particular construction of tongues, no change of tongue can destroy. Hence the Bible preserves its native beauty and strength alike in every language, by the sole energy of unadorned phrase, natural images, weight of sentiment, and great simplicity.

It is in this respect like a rich vein of gold, which, under the severest trials of heat, cold, and moisture, retains its original weight and splendour, without either loss or alloy; while baser metals are corrupted by earth, air, water, fire, and assimilated to the various elements through which they pass.

This circumstance, then, may be justly regarded as sufficient to vindicate the composition of the sacred Scriptures, as it is at once their chief excellence and greatest security. It is their excellence, as it renders them intelligible and useful to all; it is their security, as it prevents their being disguised by the false and capricious ornaments of vain or weak translators. We may safely appeal to experience and fact for the confirmation of these remarks on the superior simplicity, utility, and excellence, of the style of the Holy Scripture. Is there any book in the world so perfectly adapted to all capacities? that contains such sublime and exalted precepts, conveyed in such an artless and intelligible strain, that can be read with such pleasure and advantage by the lettered sage and the unlettered peasant?

SIMPLOCE. See ORATORY, N° 72.

SIMPSON, THOMAS, professor of mathematics at the royal academy at Woolwich, fellow of the Royal Society, and member of the Royal Academy at Stockholm, was born at Market Bosworth in Leicestershire in 1710. His father, a stuff-weaver, taught him only to read English, and brought him up to his own business; but meeting with a scientific pedlar, who likewise practised fortune-telling, young Simpson by his assistance and advice left off weaving, and professed astrology. As he improved in knowledge, however, he grew disgusted with this pretended art; and renouncing it, was driven to such difficulties for the subsistence of his family, that he came up to London, where he worked as a weaver, and taught mathematics at his spare hours.

As his scholars increased, his abilities became better known, and he published his Treatise on Fluxions, by subscription, in 1737: in 1740, he published his Treatise on the Nature and Laws of Chance; and Essays in Speculative and Mixed Mathematics. After these appeared his Doctrine of Annuities and Reversions; Mathematical Dissertations; Treatise on Algebra; Elements of Geometry; Trigonometry, Plane and Spherical; Select Exercises; and his Doctrine and Application of Fluxions, which he professes to be rather a new work, than a second edition of his former publication on fluxions. In 1743, he obtained the mathematical professorship at Woolwich academy; and soon after was chosen a member of the Royal Society, when the president and council, in consideration of his moderate circumstancs, were pleased to excuse his admission-fees, and his giving bonds for the settled future payments. At the academy he exerted all his abilities in instructing the pupils who were the immediate objects of his duty, as well as others whom the superior officers of the ordnance permitted to be boarded and lodged in his house. In his manner of teaching he had a peculiar and happy address, a certain dignity and perspicuity, tempered with such a degree of mildness, as engaged the attention, esteem, and friendship of his scholars. He therefore acquired great applause from his superiors in the discharge of his duty. His application and close confinement, however, injured his health. Exercise and a proper regimen were prescribed to him, but to little purpose: for his spirits sunk gradually, till he became incapable of performing his duty, or even of reading the letters of his friends. The effects of this decay of nature were greatly increased by vexation of mind, owing to the haughty and insulting behaviour of his superior the first professor of mathematics. This person, greatly his inferior in mathematical accomplishments, did what he could to make his situation uneasy, and even to depreciate him in the public opinion: but it was a vain endeavour, and only served to depress himself. At length his physicians advised his native air for his recovery, and he set out in February 1761; but was so fatigued by his journey, that upon his arrival at Bosworth, he betook himself to his chamber, and grew continually worse till the day of his death, which happened on the 14th of May in the 51st year of his age.

SIMSON, DR ROBERT, professor of mathematics in the university of Glasgow, was born in the year 1687 of a respectable family, which had held a small estate in the county of Lanark for some generations. He was, we think, the second son of the family. A younger brother was professor of medicine in the university of St Andrew's, and is known by some works of reputation, particularly a Dissertation on the Nervous System, occasioned by the Dissection of a Brain completely Ossified.

Dr Simson was educated in the university of Glasgow under the eye of some of his relations who were professors. Eager after knowledge, he made great progress in all his studies; and, as his mind did not, at the very first openings of science, strike into that path which afterwards so strongly attracted him, and in which he proceeded so far almost without a companion, he acquired in every walk of science a stock of information, which, though it had never been much augmented afterwards, would have done credit to a professional man in

Simson.

in any of his studies. He became, at a very early period, an adept in the philosophy and theology of the schools, was able to supply the place of a sick relation in the class of oriental languages, was noted for historical knowledge, and one of the most knowing botanists of his time.

It was during his theological studies, as preparatory for his entering into orders, that mathematics took hold of his fancy. He used to tell in his convivial moments how he amused himself when preparing his exercises for the divinity hall. When tired with vague speculation, in which he did not meet with certainty to reward his labours, he turned up a book of oriental philology, in which he found something which he could discover to be true or to be false, without going out of the line of study which was to be of ultimate use to him. Sometimes even this could not relieve his fatigue. He then had recourse to mathematics, which never failed to satisfy and refresh him. For a long while he restricted himself to a very moderate use of the cordial, fearing that he would soon exhaust the small stock which so limited and abstract a science could yield; till at last he found, that the more he learned, a wider field opened to his view, and scenes that were inexhaustible. Becoming acquainted with subjects far beyond the elements of the science, and with numbers of names celebrated during that period of ardent research all over Europe, he found it to be a manly and important study, by which he was as likely to acquire reputation as by any other. About this time, too, a prospect began to open of making mathematics his profession for life. He then gave himself up to it without reserve.

His original incitement to this study as a treat, as something to please and refresh his mind in the midst of severer tasks, gave a particular turn to his mathematical studies, from which he never could afterwards deviate. Perspicuity and elegance are more attainable, and more discernible, in pure geometry, than in any other parts of the science of measure. To this therefore he chiefly devoted himself. For the same reason he preferred the ancient method of studying pure geometry, and even felt a dislike to the Cartesian method of substituting symbols for operations of the mind, and still more was he disgusted with the substitution of symbols for the very objects of discussion, for lines, surfaces, solids, and their affections. He was rather disposed in the solution of an algebraical problem, where quantity alone was considered, to substitute figure and its affections for the algebraical symbols, and to convert the algebraic formula into an analogous geometrical theorem. And he came at last to consider algebraic analysis as little better than a kind of mechanical knack, in which we proceed without ideas of any kind, and obtain a result without meaning, and without being conscious of any process of reasoning, and therefore without any conviction of its truth. And there is no denying, that if genuine unsophisticated taste alone is to be consulted, Dr Simson was in the right: for though it must also be acknowledged, that the reasoning in algebra is as strict as in the purest geometry of Euclid or Apollonius, the *expert* analyst has little perception of it as he goes on, and his final equation is not felt by himself as the result of ratiocination, any more than if he had obtained it by Pascal's arithmetical mill. This does not in the least diminish our admiration of the algebraic analysis; for its almost boundless grasp, its rapid and certain procedure, and the delicate metaphysics and great address which may be displayed in conducting it. Such, however, was the gronnd of the strong bias of Dr Simson's mind to the analysis of the ancient geometers. It increased as he went forward; and his veneration (we may call it his *love* or *affection*) for the ancient geometry was carried to a degree of idolatry. His chief labours were exerted in efforts to restore the works of the ancient geometers; and he has nowhere bestowed much pains in advancing the modern discoveries in mathematics. The noble inventions, for example, of fluxions and of logarithms, by which our progress in mathematical knowledge, and in the useful application of this knowledge, is so much promoted, attracted the notice of Dr Simson; but he has contented himself with demonstrating their truth on the genuine principles of the ancient geometry. Yet was he very thoroughly acquainted with all the modern discoveries; and there are to be seen among his papers discussions and investigations in the Cartesian method, which show him thoroughly acquainted with all the principles, and even expert in the *tours de main*, of the most refined symbolical analysis (A).

About the age of 25 Dr Simson was chosen professor of mathematics in the university of Glasgow. He went to London immediately after his appointment, and there formed an acquaintance with the most eminent men of that bright era of British science. Among these he always mentioned Captain Halley (the celebrated Dr Edmund Halley) with particular respect; saying, that he had the most acute penetration, and the most just taste in that science, of any man he had ever known. And, indeed, Dr Halley has strongly exemplified both of these in his divination of the work of *Apollonius de Sectione Spatii*, and the 8th book of his *Conics*, and in some of the most beautiful theorems in Sir Isaac Newton's *Principia*. Dr Simson also admired the wide and masterly steps which Newton was accustomed to take in his investigations, and his manner of substituting geometrical figures for the quantities which are observed in the phenomena of nature. It was from Dr Simson that the writer of this article had the remark which has been oftener than once repeated in the course of this Work, "That the 39th proposition of the first book of the *Principia* was the most important proposition

(A) In 1752 the writer of this article being then his scholar, requested him to examine an account which he gave him of what he thought a new curve (a conchoid having a circle for its base). Dr Simson returned it next day with a regular list of its leading properties, and the investigation of such as he thought his scholar would not so easily trace. In this hasty scrawl the lines related to the circle were familiarly considered as arithmetical fractions of the radius considered as unity. This was before Euler published his Arithmetic of the Sines and Tangents, now in universal use.

position that had ever been exhibited to the physico-mathematical philosopher;" and he used always to illustrate to his more advanced scholars the superiority of the geometrical over the algebraic analysis, by comparing the solution given by Newton of the inverse problem of centripetal forces, in the 42d proposition of that book, with the one given by John Bernoulli in the Memoirs of the Academy of Sciences at Paris for 1713. We have heard him say, that to his own knowledge Newton frequently investigated his propositions in the symbolical way, and that it was owing chiefly to Dr Halley that they did not finally appear in that dress. But if Dr Simson was well informed, we think it a great argument in favour of the symbolic analysis, when this most successful *practical artist* (for so we must call Newton when engaged in a task of discovery) found it conducive either to dispatch or perhaps to his very progress.

Returning to his academical chair, Dr Simson discharged the duties of a professor for more than 50 years with great honour to the university and to himself.

It is almost needless to say, that in his prelections he followed strictly the Euclidian method in elementary geometry. He made use of Theodosius as an introduction to spherical trigonometry. In the higher geometry he prelected from his own Conics; and he gave a small specimen of the *linear problems* of the ancients, by explaining the properties, sometimes of the conchoid, sometimes of the cissoid, with their application to the solution of such problems. In the more advanced class he was accustomed to give Napier's mode of conceiving logarithms, i. e. quantities as generated by motion; and Mr Cotes's view of them, as the sums of ratiunculæ; and to demonstrate Newton's lemmas concerning the limits of ratios; and then to give the elements of the fluxionary calculus; and to finish his course with a select set of propositions in optics, gnomonics, and central forces. His method of teaching was simple and perspicuous, his elocution clear, and his manner easy and impressive. He had the respect, and still more the affection, of his scholars.

With respect to his studies, we have already informed the reader that they got an early bias to pure geometry, and to the elegant but scrupulous methods of the ancients.

We have heard Dr Simson say, that it was in a great measure owing to Dr Halley that he so early directed his efforts to the restoration of the ancient geometers. He had recommended this to him, as the most certain way for him, then a very young man, both to acquire reputation, and to improve his own knowledge and taste; and he presented him with a copy of Pappus's Mathematical Collections, enriched with some of his own notes. The perspicuity of the ancient geometrical analysis, and a certain elegance in the nature of the solutions which it affords, especially by means of the local theorems, soon took firm hold of his fancy, and made him, with the sanguine expectation of a young man, direct his very first efforts to the recovery of this *in toto*; and the restoration of Euclid's Porisms was the first task which he set himself. The accomplished geometer knows what a desperate task this was, from the scanty and mutilated account which we have of this work in a single passage of Pappus. It was an ambition which nothing but success could justify in so young an adventurer. He succeeded; and so early as 1718 seemed to have been in complete possession of this method of investigation, which was considered by the eminent geometers of antiquity as their surest guide through the labyrinths of the higher geometry. Dr Simson gave a specimen of his discovery in 1723 in the Philosophical Transactions. And after this time he ceased not from his endeavours to recover that choice collection of Porisms which Euclid had collected, as of the most general use in the solution of difficult questions. What some of these must have been was pointed out to Dr Simson by the very nature of the general proposition of Pappus, which he has restored. Others were pointed out by the lemmas which Pappus has given as helps to the young mathematician towards their demonstration. And, being thus in possession of a considerable number, their mutual relations pointed out a sort of system, of which these made a part, and of which the blanks now remained to be filled up.

Dr Simson, having thus gained his favourite point, had leisure to turn his attention to the other works of the ancient geometers; and the porisms of Euclid now had only an occasional share. The *loci plani* of Apollonius was another task which he very early engaged in, and completed about the year 1738. But, after it was printed, he imagined that he had not given the *ipsissimæ propositiones* of Apollonius, and in the precise spirit and order of that author. The impression lay by him for some years; and it was with great reluctance that he yielded to the intreaties of his mathematical friends, and published the work, in 1746, with some emendations, where he thought he had deviated farthest from his author. He quickly repented of this scanty concession, and recalled what he could of the small number of copies which he had given to the booksellers, and the impression again lay by him for years. He afterwards recorrected the work, and still with some reluctance allowed it to come abroad as the Restitution of Apollonius. The public, however, had not been so fastidious as Dr Simson, and the work had acquired great celebrity, and he was now considered as one of the first and the most elegant geometers of the age: for, in the mean time, he had published his Conic Sections, a work of uncommon merit, whether we consider it as equivalent to a complete restitution of the celebrated work of Apollonius Pergæus, or as an excellent system of this important part of mathematics. It is marked with the same features as the *loci plani*, the most anxious solicitude to exhibit the very text of Apollonius, even in the propositions belonging to the books which had been completely lost. These could be recovered in no other way but by a thorough knowledge of the precise plan proposed by the author, and by taking it for granted that the author had accurately accomplished this plan. In this manner did Viviani proceed in the first attempt which was made to restore the conics of Apollonius; and he has given us a detail of the process of his conjectures, by which we may form an opinion of its justness, and of the probability how far he has attained the desired object. Dr Simson's view in his performance was something different, deviating a little in this one case from his general track. He was not altogether pleased with the work of Viviani, even as augmented by the eighth book added by Halley, and his wish was to restore the ancient original. But, in the mean time, an

Simson.

academical text book for conic sections was much wanted. He was much dissatisfied with those in common use; and he was not insensible of the advantage resulting from the consideration of these sections, independent of the cone first introduced by Dr Wallis. He therefore composed this excellent treatise as an elementary book, not to supersede, but to prepare for the study of Apollonius; and accordingly accommodates it to this purpose, and gives several important propositions in their proper places, *expressly as restitutions of Apollonius*, whom he keeps constantly in view through the whole work.

Much about this time Dr Simson seriously began to prepare a perfect edition of Euclid's Elements. The intimate acquaintance which he had by this time acquired with all the original works of the ancient geometers, and their ancient commentators and critics, encouraged him to hope that he could restore to his original lustre this leader in mathematical science; and the errors which had crept into this celebrated work, and which still remained in it, appeared of magnitude sufficient to merit the most careful efforts for their removal. The DATA also, which were in like manner the introduction to the whole art of geometrical investigation, seemed to call more loudly for his amending hand. For it appears that the Saracens, who have preserved to us the writings of the ancients, have contented themselves with admiring these celebrated works, and have availed themselves of the knowledge which they contain; but they have shown no inclination to add to the stock, or to promote the sciences which they had received. They could not do any thing without the synthetical books of the geometers; but, not meaning to go beyond the discoveries which they had made, they neglected all the books which related to the analytic art alone, and the greatest part of them (about 25 out of 30) have irrecoverably perished. The data of Euclid have fortunately been preserved, but the book was neglected, and the only ancient copies, which are but three or four, are miserably erroneous and mutilated. Fortunately, it is no very arduous matter to reinstate this work in its original perfection. The plan is precise, both in its extent and its method. It had been restored, therefore, with success by more than one author. But Dr Simson's comprehensive view of the whole analytical system pointed out to him many occasions for amendment. He therefore made its restitution a joint task with that of the elements. All the lovers of true geometry will acknowledge their obligations to him for the edition of the Elements and Data which he published about 1758. The text is corrected with the most judicious and scrupulous care, and the notes are inestimable, both for their information, and for the tendency which they must have to form the mind of the student to a true judgment and taste in mathematical subjects. The more accomplished reader will perhaps be sometimes disposed to smile at the axiom which seems to pervade the notes, "that a work of Euclid must be supposed without error or defect." If this was not the case, Euclid has been obliged to his editor in more instances than one. Nor should his greatest admirers think it impossible that in the progress of human improvement, a geometrical truth should occur to one of these latter days, which escaped the notice of even the Lincean Euclid. Such merit, however, Dr Simson nowhere claims, but lays every blame of error, omission, or obscurity, to the charge of Proclus, Theon, and other editors and commentators of the renowned Grecian.

There is another work of Apollonius on which Dr Simson has bestowed great pains, and has restored, as we imagine, *omnibus numeris perfectum*, viz. the SECTIO DETERMINATA; one of those performances which are of indispensable use in the application of the ancient analysis. This also seems to have been an early task, though we do not know the date of his labours on it. It did not appear till after his death, being then published along with the great work, the Porisms of Euclid, at the expence of the late Earl Stanhope, a nobleman intimately conversant with the ancient geometry, and zealous for its reception among the mathematicians of the present age. He had kept up a constant correspondence with Dr Simson on mathematical subjects; and at his death in 1768, engaged Mr Clow professor of logic in the university of Glasgow, to whose care the Doctor had left all his valuable papers, to make a selection of such as would serve to support and increase his well-earned reputation as THE RESTORER of ANCIENT GEOMETRY.

We have been thus particular in our account of Dr Simson's labours in these works, because his manner of execution, while it does honour to his inventive powers, and shows his just taste in mathematical composition, also confirms our former assertion, that he carried his respect for the ancient geometers to a degree of superstitious idolatry, and that his fancy, unchecked, viewed them as incapable of error or imperfection. This is distinctly to be seen in the emendations which he has given of the texts, particularly in his editions of Euclid. Not only every imperfection of the reading is ascribed to the ignorance of copyists, and every indistinctness in the conception, inconclusiveness in the reasoning, and defect in the method, is ascribed to the ignorance or mistake of the commentators; but it is all along assumed that the work was perfect in its kind; and that by exhibiting a perfect work, we restore the genuine original. This is surely gratuitous; and it is very possible that it has, in some instances, made Dr Simson fail of his anxious purpose, and give us even a better than the original. It has undoubtedly made him fail in what *should have been* his great purpose, viz. to give the world a connected system of the ancient geometrical analysis; such as would, in the first place, exhibit it in its most engaging form, elegant, perspicuous, and comprehensive; and, in the next place, such as should engage the mathematicians of the present age to adopt it as the most certain and successful conductor in those laborious and difficult researches in which the demands of modern science continually engage them. And this might have been expected, in the province of speculative geometry at least, from a person of such extensive knowledge of the properties of figure, and who had so eminently succeeded in the many trials which he had made of its powers. We might have expected that he would at least have exhibited in one systematic point of view, what the ancients had done in several detached branches of the science, and how far they had proceeded in the solution of the several successive classes of problems; and we might have hoped, that he would have instructed us in what manner we should apply that method to the solution of problems of a more elevated kind, daily presented

Simson.

sented to us in the questions of physico-mathematical science. By this he would have acquired distinguished honour, and science would have received the most valuable improvement. But Dr Simson has done little of all this; and we cannot say that great helps have been derived from his labours by the eminent mathematicians of this age, who are successfully occupied in advancing our knowledge of nature, or in improving the arts of life. He has indeed contributed greatly to the entertainment of the speculative mathematician, who is more delighted with the conscious exercise of his own reasoning powers, than with the final result of his researches. Yet we are not even certain that Dr Simson has done this to the extent he wished and hoped. He has not engaged the liking of mathematicians to this analysis, by presenting it in the most agreeable form. His own extreme anxiety to tread in the very footsteps of the original authors, has, in a thousand instances, precluded him from using his own extensive knowledge, that he might not employ principles which were not of a class inferior to that of the question in hand. Thus, of necessity, did the method appear trammelled. We are deterred from employing a process which appears to restrain us in the application of the knowledge which we have already acquired, and, disgusted with the tedious, and perhaps indirect path, by which we must arrive at an object which we see clearly over the hedge, and which we could reach by a few steps, of the security of which we are otherwise perfectly assured. These prepossessions are indeed founded on mistake; but the mistake is such, that all fall into it, till experience has enlarged their views. This circumstance alone has hitherto prevented mathematicians from acquiring that knowledge of the ancient analysis which would enable them to proceed in their researches with certainty, dispatch, and delight. It is therefore deeply to be regretted, that this eminent genius has occupied, in this superstitious palæology, a long and busy life, which might have been employed in original works of infinite advantage to the world, and honour to himself.

Our readers will, it is hoped, consider these observations as of general scientific importance, and as intimately connected with the history of mathematics; and therefore as not improperly introduced in the biographical account of one of the most eminent writers on this science. Dr Simson claimed our notice as a mathematician; and his affectionate admiration of the ancient analysis is the prominent feature of his literary character. By this he is known all over Europe; and his name is never mentioned by any foreign author without some very honourable allusion to his distinguished geometrical elegance and skill. Dr James Moor, professor of Greek in the university of Glasgow, no less eminent for his knowledge in ancient geometry than for his professional talents, put the following apposite inscription below a portrait of Dr Simson:

GEOMETRIAM, SUB TYRANNO BARBARO SÆVA
SERVITUTE DIU SQUALENTEM, IN LIBERTATEM
ET DECUS ANTIQUUM VINDICAVIT
UNUS.

Yet it must not be understood that Dr Simson's predilection for the geometrical analysis of the ancients did so far mislead him as to make him neglect the symbolical analysis of the present times; on the contrary, he was completely master of it, as has been already observed, and frequently employed it. In his academical lectures to the students of his upper classes, he used to point out its proper province (which he by no means limited by a scanty boundary), and in what cases it might be applied with safety and advantage even to questions of pure geometry. He once honoured the writer of this article with the sight of a very short dissertation on this subject (perhaps the one referred to in the preface to his Conic Sections). In this piece he was perhaps more liberal than the most zealous partizans of the symbolical analysis could desire, admitting as a sufficient equation of the Conic Sections $L=\frac{p^2 c}{x^2}$, where L is the *latus rectum*, x is the distance of any point of the curve from the focus, p is the perpendicular drawn from the focus to the tangent in the given point, and c is the chord of the equicurve circle drawn through the focus. Unfortunately this dissertation was not found among his papers. He spoke in high terms of the Analytical Works of Mr Cotes, and of the two Bernoullis. He was consulted by Mr M'Laurin during the progress of his inestimable Treatise of Fluxions, and contributed not a little to the reputation of that work. The spirit of that most ingenious algebraic demonstration of the fluxions of a rectangle, and the very process of the argument, is the same with Dr Simson's in his dissertation on the limits of quantities. It was therefore from a thorough acquaintance with the subject, and by a just taste, that he was induced to prefer his favourite analysis, or, to speak more properly, to exhort mathematicians to employ it in its own sphere, and not to become ignorant of geometry, while he successfully employed the symbolical analysis in cases which did not require it, and which suffered by its admission. It must be acknowledged, however, that in his later years, the disgust which he felt at the artificial and slovenly employment on subjects of pure geometry, sometimes hindered him from even looking at the most refined and ingenious improvements of the algebraic analysis which occur in the writings of Euler, D'Alembert, and other eminent masters. But, when properly informed of them, he never failed to give them their due praise; and we remember him speaking, in terms of great satisfaction, of an improvement of the infinitesimal calculus, by D'Alembert and De la Grange, in their researches concerning the propagation of sound, and the vibration of musical cords.

And that Dr Simson not only was master of this calculus and the symbolical calculus in general, but held them in proper esteem, appears from two valuable dissertations to be found in his posthumous works; the one on logarithms, and the other on the limits of ratios. The last, in particular, shows how completely he was satisfied with respect to the solid foundation of the method of fluxions; and it contains an elegant and strict demonstration of all the applications which have been made of the method by its illustrious author to the objects of pure geometry.

We hoped to have given a much more complete and instructive account of this eminent geometer and his works, by the aid of a person fully acquainted with both, and able to appreciate their value; but an accident has deprived us of this assistance, when it was too late to procure an equivalent: and we must request our readers to accept of this very imperfect account, since we cannot do justice to Dr Simson's merit, unless almost equally

Simson.

equally conversant in all the geometry of the ancient Greeks.

The life of a literary man rarely teems with anecdote; and a mathematician, devoted to his studies, is perhaps more abstracted than any other person from the ordinary occurrences of life, and even the ordinary topics of conversation. Dr Simson was of this class; and, having never married, lived entirely a college life. Having no occasion for the commodious house to which his place in the university entitled him, he contented himself with chambers, good indeed, and spacious enough for his sober accommodation, and for receiving his choice collection of mathematical writers, but without any decoration or commodious furniture. His official servant sufficed for valet, footman, and chambermaid. As this retirement was entirely devoted to study, he entertained no company in his chambers, but in a neighbouring house, where his apartment was sacred to him and his guests.

Having in early life devoted himself to the restoration of the works of the ancient geometers, he studied them with unremitting attention; and, retiring from the promiscuous intercourse of the world, he contented himself with a small society of intimate friends, with whom he could lay aside every restraint of ceremony or reserve, and indulge in all the innocent frivolities of life. Every Friday evening was spent in a party at whist, in which he excelled, and took delight in instructing others, till increasing years made him less patient with the dulness of a scholar. The card-party was followed by an hour or two dedicated solely to playful conversation. In like manner, every Saturday he had a less select party to dinner at a house about a mile from town. The Doctor's long life gave him occasion to see the *dramatis personæ* of this little theatre several times completely changed, while he continued to give it a personal identity: so that, without any design or wish of his own, it became, as it were, his own house and his own family, and went by his name. In this state did the present writer first see it, with Dr Simson as its father and head, respected and beloved by every branch; for, as it was for relaxation, and not for the enjoyment of his acknowledged superiority, that he continued this habit of his early youth; and as his notions "of a fine talk" did not consist in the pleasure of having "tossed and gored a good many to-day," his companions were as much at their ease as he wished to be himself; and it was no small part of their entertainment (and of his too), to smile at those innocent deviations from common forms, and those mistakes with respect to life and manners, which an almost total retirement from the world, and incessant occupation in an abstract science, caused this venerable president frequently to exhibit. These are remembered with a more affecting regret, that they are now "with the days that are past," than the most pithy apophthegms, ushered in with an emphatical "Why, Sir!" or "No, Sir!" which precludes all reply. Dr Simson never exerted his presidial authority, unless it were to check some infringment of good breeding, or any thing that appeared unfriendly to religion or purity of manners; for these he had the highest reverence. We have twice heard him sing (he had a fine voice and most accurate ear) some lines of a Latin hymn to the Divine Geometer, and each time the rapturous tear stood in his eye.

Simson ‖ Sinai.

But we ask the reader's pardon for this digression; it is not however useless, since it paints the man as much as any recital of his studies; and to his acquaintances we are certain that it will be an acceptable memorandum. To them it was often matter of regret, that a person of such eminent talents, which should have made him shine equally in any line of life, should have allowed himself to be so completely devoted to a study which abstracted him from the ordinary pursuits of men, unfitted him for the active enjoyment of life, and kept him out of those walks which they frequented, and where they would have rejoiced to meet him.

Dr Simson was of an advantageous stature, with a fine countenance; and even in his old age had a graceful carriage and manner, and always, except when in mourning, dressed in white cloth. He was of a cheerful disposition; and though he did not make the first advances to acquaintance, had the most affable manner, and strangers were at perfect ease in his company. He enjoyed a long course of uninterrupted health; but towards the close of life suffered from an acute disease, and was obliged to employ an assistant in his professional labours for a few years preceding his death, which happened in 1768, at the age of 81. He left to the university his valuable library, which is now arranged apart from the rest of the books, and the public use of it is limited by particular rules. It is considered as the most choice collection of mathematical books and manuscripts in the kingdom, and many of them are rendered doubly valuable by Dr Simson's notes.

SIN, a breach or transgression of some divine law or command.

SINAI, or SINA, a famous mountain of Arabia Petræa, upon which God gave the law to Moses. It stands in a kind of peninsula, formed by the two arms of the Red sea, one of which stretches out towards the north, and is called the *gulf of Kolsum*; the other extends towards the east, and is called the *gulf of Elan*, or the *Elanitish sea*. At this day the Arabians call Mount Sinai by the name of *Tor*, that is, the "mountain," by way of excellence; or *Gibel* or *Jibel Mousa*, "the mountain of Moses." It is 260 miles from Cairo, and generally it requires a journey of ten days to travel thither. The wilderness of Sinai, where the Israelites continued encamped for almost a year, and where Moses erected the tabernacle of the covenant, is considerably elevated above the rest of the country; and the ascent to it is by a very craggy way, the greatest part of which is cut out of the rock; then one comes to a large space of ground, which is a plain surrounded on all sides by rocks and eminences, whose length is nearly 12 miles. Towards the extremity of this plain, on the north side, two high mountains show themselves, the highest of which is called *Sinai* and the other *Horeb*. The tops of Horeb and Sinai have a very steep ascent, and do not stand upon much ground, in comparison to their extraordinary height: that of Sinai is at least one-third part higher than the other, and its ascent is more upright and difficult.

Two German miles and a half up the mountain stands the convent of St Catharine. The body of this monastery is a building 120 feet in length and almost as many in breadth. Before it stands another small building, in which is the only gate of the convent, which remains always shut, except when the bishop is here.

Niebuhr's Travels, vol. i. p. 191.

here. At other times, whatever is introduced within the convent, whether men or provisions, is drawn up by the roof in a basket, and with a cord and a pulley. The whole building is of hewn stone; which, in such a desert, must have cost prodigious expense and pains. Near this chapel issues a fountain of very good fresh water; it is looked upon as miraculous by some who cannot conceive how water can flow from the brow of so high and barren a mountain. Five or six paces from it they show a stone, the height of which is four or five feet, and breadth about three, which, they say, is the very stone whence Moses caused the water to gush out. Its colour is of a spotted gray, and it is, as it were, set in a kind of earth where no other rock appears. This stone has twelve holes or channels, which are about a foot wide, whence it is thought the water came forth for the Israelites to drink.

Much has been said of the writings to be seen at Sinai and in the plain about it; and such were the hopes of discoveries respecting the wanderings of the Israelites from these writings, that Dr Clayton, bishop of Clogher, offered 500l. sterling to defray the expences of journey to any man of letters who would undertake to copy them. No man, we believe, undertook this task: and the accurate Danish traveller Niebuhr found no writings there, but the names of persons who had visited the place from curiosity, and of Egyptians who had chosen to be buried in that region.

SINAPIS, Mustard, a genus of plants belonging to the class tetradynamia, and to the order siliquosa; and in the natural system ranged under the 39th order, *Siliquosæ*. See Botany *Index*.

SINAPISM, in *Pharmacy*, an external medicine, in form of a cataplasm, composed chiefly of mustard seed pulverised, and other ingredients mentioned in the preceding article.

SINCERITY, honesty of intention, freedom from hypocrisy. See Moral Philosophy, N° 157.

SINCIPUT, in *Anatomy*, the forepart of the head, reaching from the forehead to the coronal suture.

SINDY, a province of Hindostan Proper, bounded on the west by Makran, a province of Persia; on the north by the territories of the king of Candahar; on the north-east by those of the Seiks; on the east by a sandy desert; and on the south-east by Cutch. It extends along the course of the river Sinde or Indus from its mouth to Behker or Bhakor, on the frontiers of Moultan. Reckoned that way, it is 300 miles long; and its breadth, in its widest part, is about 160. In many particulars of soil and climate, and in the general appearance of the surface, Sindy resembles Egypt; the lower part of it being composed of rich vegetable mould, and extended into a wide dell; while the upper part of it is a narrow slip of country, confined on one side by a ridge of mountains, and on the other by a sandy desert, the river Indus, equal at least to the Nile, winding through the midst of this level valley, and annually overflowing it. During great part of the south-west monsoon, or at least in the months of July, August, and part of September, which is the rainy season in most other parts of India, the atmosphere is here generally clouded; but no rain falls except very near the sea. Indeed, very few showers fall during the whole year; owing to which, and the neighbourhood of the sandy deserts, which bound it on the east and on the north-west, the heats are so violent, and the winds from those quarters so pernicious, that the houses are contrived so as to be occasionally ventilated by means of apertures on the tops of them, resembling the funnels of small chimneys. When the hot winds prevail, the windows are closely shut; and the lower part of the current of air, which is always the hottest, being thus excluded, a cooler, because more elevated part, descends into the house through the funnels. By this contrivance also vast clouds of dust are excluded: the entrance of which would alone be sufficient to render the houses uninhabitable. The roofs are composed of thick layers of earth instead of terraces. Few countries are more unwholesome to European constitutions, particularly the lower part of the Delta. The prince of this province is a Mahometan, tributary to the king of Candahar. He resides at Hydrabad, although Tatta is the capital. The Hindoos, who were the original inhabitants of Sindy, are by their Mahometan governors treated with great rigour, and denied the public exercise of their religion; and this severity drives vast numbers of them into other countries. The inland parts of Sindy produce saltpetre, sal-ammoniac, borax, bezoar, lapis lazuli, and raw silk. They have also manufactories of cotton and silk of various kinds; and they make fine cabinets, inlaid with ivory, and finely lackered. They also export great quantities of butter, clarified and wrapt up in duppas, made of the hides of cattle. The ladies wear hoops of ivory on both their arms and legs, which when they die are burnt with them. They have large black cattle, excellent mutton, and small hardy horses. Their wild game are deer, hares, antelopes, and foxes, which they hunt with dogs, leopards, and a small fierce creature called a shiahgush.

SINE, or *Right Sine of an Arch*, in *Trigonometry*, is a right line drawn from one end of that arch, perpendicular to the radius drawn to the other end of the arch; being always equal to half the cord of twice the arch. See Trigonometry and Geometry.

SINECURE, a nominal office, which has a revenue without any employment.

SINEW, a tendon, that which unites the muscles to the bones.

SINGING, the action of making divers inflections of the voice, agreeable to the ear, and correspondent to the notes of a song or piece of melody. See Melody.

The first thing to be done in learning to sing, is to raise a scale of notes by tones and semitones to an octave, and descend by the same notes; and then to rise and fall by greater intervals, as a third, fourth, fifth, &c. and to do all this by notes of different pitch. Then these notes are represented by lines and spaces, to which the syllables *fa*, *sol*, *la*, *mi*, are applied, and the pupil taught to name each line and space thereby; whence this practise is called *sol-faing*, the nature, reason, effects, &c. whereof, see under the article Solfaing.

Singing of Birds. It is worthy of observation, that the female of no species of birds ever sings: with birds it is the reverse of what occurs in human kind. Among the feathered tribe, all the cares of life fall to the lot of the tender sex; theirs is the fatigue of incubation; and the principal share in nursing the helpless brood: to alleviate these fatigues, and to support her under them, nature hath given to the male the song, with all the little

little blandishments and soothing arts; these he fondly exerts (even after courtship) on some spray contiguous to the nest, during the time his mate is performing her parental duties. But that she should be silent is also another wise provision of nature, for her song would discover her nest; as would a gaudiness of plumage, which, for the same reason, seems to have been denied her.

On the song of birds several curious experiments and observations have been made by the Hon. Daines Barrington See *Phil. Trans.* vol. lxiii.

SINGULAR NUMBER, in *Grammar*, that number of nouns and verbs which stands opposed to plural. See GRAMMAR, N° 14.

SINISTER, something on or towards the left hand. Hence some derive the word *sinister à sinendo;* because the gods, by such auguries, permit us to proceed in our designs.

SINISTER, is ordinarily used among us for unlucky; though, in the sacred rites of divination, the Romans used it in an opposite sense. Thus *avis sinistra*, or a bird on the left hand, was esteemed a happy omen: whence, in the law of the 12 tables, *Ave sinistra populi magister esto.*

SINISTER, in *Heraldry*. The sinister side of an escutcheon is the left-hand side; the sinister chief, the left angle of the chief; the sinister base, the left-hand part of the base.

SINISTER Aspect, among astrologers, is an appearance of two planets happening according to the succession of the signs; as Saturn in Aries, and Mars in the same degree of Gemini.

SINISTRI, a set of ancient heretics, thus called because they held the left hand in abhorrence, and made it a point of religion not to receive any thing therewith.

SINKING FUND, a provision made by parliament, consisting of the surplusage of other funds, intended to be appropriated to the payment of the national debt; on the credit of which very large sums have been borrowed for public uses.

As the funding system had been adopted in other countries long before it was resorted to in Great Britain, a provision of this kind had appeared necessary at a much earlier period, and had been established in Holland in 1655, and in the Ecclesiastical States in 1685. These funds were both formed by the reduction of the interest on the public debts, and by appropriating the annual sum thus saved to the gradual discharge of the principal.

In the reign of King William, when the mode of providing for extraordinary expences was first adopted in this country, the particular tax on which money was borrowed, generally produced much more than was sufficient to pay the annual interest, and the surplus was applied in sinking the principal, which was generally effected in a few years. Had this plan been pursued, there never could have been any great accumulation of public debts; but, as the expenditure increased, and the necessity of loans of still greater amount became more frequent, it was found difficult to provide for the annual interest of the sums thus borrowed; and the repayment of the principal was either put off to a distant period, or left without any provision to the chance of more flourishing times.

Some of the effects of an accumulating public debt soon became evident in the discount at which all government securities sold, and in the difficulties experienced in providing for the annual expenditure; the propriety of reducing, and even of wholly discharging, the debt, was generally acknowledged; and the plan of a sinking fund was recommended in a pamphlet published in 1701. In 1713 Mr Archibald Hutchison presented to George I. a plan for payment of the public debts. In 1715 different projects for this purpose were published by Edward Leigh, Mr Asgill, and others. And in 1717 a plan for the gradual discharge of the debt was actually adopted, which was afterwards generally known by the name of the sinking fund.

For a few years the fund was strictly applied to the purposes for which it was established; and so well were its nature and importance then understood, that money was at the same time borrowed for extraordinary expences. In 1724, the sum of 15,144l. 19s. was taken from the fund, to make good the loss to the treasury from the reduction of the value of gold coin; and within 12 years from its establishment it was charged with the interest of new loans. In 1733, the gross sum of half a million was taken from it towards the supplies, at which time the medium annual produce of the fund for five years had been 1,212,000l. This amount would have fully discharged the debt which then existed, but the alienation of it was continued.

This was succeeded by the consolidated fund, one object of which was, to lay the foundation of a new sinking fund, and consisting, like the old one, in the application of the principle of compound interest. On this occasion Mr Pitt consulted the late Dr Price, who communicated three plans, one of which was afterwards adopted, but with such alterations as greatly affected its efficacy, and which it had been since found necessary to correct. By the act passed for carrying this scheme into execution, the annual sum of 1,000,000l. was placed in the hands of commissioners, to be issued in four equal quarterly payments, and to be applied either in paying off such redeemable annuities as were at or above par, or in the purchase of annuities below par, at the market-price.

On the 17th of February, 1792, Mr Pitt proposed that the sum of 400,000l. should be issued in addition to the million, for the purpose of accelerating the operation of the fund: and stated that it might be expected that 25 millions of 3 per cents would be paid off by the year 1800; and that in the year 1808, the fund would amount to 4,000,000l. per annum, the sum to which it was then restricted. The injudicious restriction of the fund to 4,000,000l. per annum, was done away by an act passed in 1802, which directed that the produce of the two funds should continue to accumulate, without any limitation as to its amount, and be from time to time applied, according to the former provisions, in the redemption or purchase of stock, until the whole of the perpetual redeemable annuities, existing at the time of passing the act, shall have been completely paid off. At the same time, the annual grant of 200,000l. in aid of the fund, was made a permanent charge, to be issued in quarterly payments from the consolidated fund, in the same manner as the original million per annum. In consequence of these improvements, the increase of the fund has been much greater than it was originally

Sinking Sinus.

originally estimated; and on the 1st of February, 1806, was as follows:

Annual charge by act of 26 Geo. III.	L. 1,000,000	0	0
Ditto 42 Geo. III.	200,000	0	0
Annuities for 99 and 96 years, expired 1792	54,880	14	6
Short annuities, expired 1787	25,000	0	0
Life annuities, unclaimed and expired	50,308	5	7
Dividend on 98,386,402l. at 3 per cent.	2,951,592	1	2
Ditto on 2,617,400l. at 4 per cent.	104,696	0	0
Ditto on 142,000l. at 5 per cent.	7,100	0	0
One per cent. on capitals erected since 1723	3,202,672	1	10
Total,	L. 7,596,249	3	1

This sum is exclusive of the fund for the reduction of the public debt of Ireland, which at the above period amounted to 479,537l. 8s. and of the fund for reduction of the imperial debt, which amounted to 56,960l. 9s. 4d.

The progress of the fund from the commencement of its operation on 1st August 1786, to the 1st February 1806, will appear from the following statement of the total amount of the stock redeemed by the commissioners up to the latter period.

Consolidated 3 per cent. annuities	L. 39,922,421
Reduced 3 per cent. annuities	51,493,981
Old South sea annuities	3,492,000
New South sea annuities	2,783,000
Three per cents 1751	695,000
Consolidated 4 per cent. annuities	2,617,400
Navy 5 per cent. annuities	142,000
Total,	L. 101,145,802

The total sum which had been paid for this amount of stock was, 62,842,782l. 7s. 10d. the consolidated 3 per cents having been bought up on an average at 61l. per cent. and the reduced at somewhat less.

The progress already made by the fund, and the important effect it has had in supporting the value of the government securities at a time when it has been necessary to borrow unprecedented sums in almost every year, sufficiently demonstrate the great utility of this measure. As its increase will be continually augmenting, it will, if steadily persevered in, and faithfully applied, become ultimately capable of discharging a debt of any amount with which it is possible to suppose the country will ever be encumbered.

SINOPLE, in *Heraldry*, denotes vert, or green colour in armories.—Sinople is used to signify love, youth, beauty, rejoicing, and liberty; whence it is that letters of grace, ambition, legitimation, &c. are always sealed with green wax.

SINUOSITY, a series of bends and turns in arches or other irregular figures, sometimes jutting out and sometimes falling in.

SINUS, in *Anatomy*, denotes a cavity in certain bones and other parts, the entrance whereof is very narrow, and the bottom wider and more spacious.

Sinus Sirens.

Sinus, in *Surgery*, a little cavity or sacculus, frequently formed by a wound or ulcer, wherein pus is collected.

SIPHON. See Hydrodyamics.

SIPHONANTHUS, a genus of plants belonging to the class of tetrandria and order of monogynia. See Botany *Index*.

SIPONTUM, Sepuntum, or *Sipus*, in *Ancient Geography*, a town of Apulia, so denominated (according to Strabo) from the great quantity of *sepiæ* or cuttlefish that are thrown upon the coast. Diomede is supposed by the same author to have been the founder of this place; which appears from Livy to have become a colony of Roman citizens. In the early ages of Christian hierarchy, a bishop was fixed in this church; but, under the Lombards, his see was united to that of Beneventum. Being again separated, Sipontum became an archiepiscopal diocese in 1094, about which time it was so ill treated by the Barbarians, that it never recovered its splendour, but sunk into such misery, that in 1260 it was a mere desert, from the want of inhabitants, the decay of commerce, and the insalubrity of the air. Manfred having taken these circumstances into consideration, began in 1261 to build a new city on the sea-shore, to which he removed the few remaining Sipontines. (See the article Manfredonia). Sipontum was situated at the distance of a mile from the shore. Excepting a part of its Gothic cathedral, scarce one stone of the ancient city now remains upon another.

SIPUNCULUS, in *Natural History*, a genus of the class of vermes, and order intestina. See Helminthology *Index*,

SIR, the title of a knight or baronet, which, for distinction's sake, as it is now given indiscriminately to all men, is always prefixed to the knight's Christian name, either in speaking or writing to them.

SIRCAR, any office under the government in Hindostan. It is sometimes used for the state of government itself. Likewise a province, or any number of pergunnahs placed under one head in the government books, for conveniency in keeping accounts. In common usage in Bengal, the under banyans of European gentlemen are called *sircars*.

SIRE, a title of honour formerly given to the king of France as a mark of sovereignty.

Sire, was likewise anciently used in the same sense with *sieur* and *seigneur*, and applied to barons, gentlemen, and citizens.

SIRENS, in fabulous history, certain celebrated songstresses who were ranked among the demigods of antiquity. Hyginus places their birth among the consequences of the rape of Proserpine. Others make them daughters of the river Acheloüs and one of the muses*. The number of the Sirens was three, and their names were *Parthenope*, *Lygea*, and *Leucosia*. Some make them half women and half fish; others half women and half birds. There are antique representations of them still subsisting under both these forms. Pausanias tells us, that the Sirens, by the persuasion of Juno, challenged the Muses to a trial of skill in singing; and these having vanquished them, plucked the golden feathers from the wings of the Sirens, and formed them into crowns,

*Ovid Met. lib. iv.

crowns, with which they adorned their own heads. The Argonauts are said to have been diverted from the enchantment of their songs by the superior strains of Orpheus: Ulysses, however, had great difficulty in securing himself from seduction. See *Odys.* lib. xii.

Pope, in his notes to the twelfth book of the Odyssey, observes, the critics have greatly laboured to explain what was the foundation of this fiction of the Sirens. We are told by some, that the Sirens were queens of certain small islands named *Sirenusæ*, that lie near Capræa in Italy, and chiefly inhabited the promontory of Minerva, upon the top of which that goddess had a temple, as some affirm, built by Ulysses. Here there was a renowned academy, in the reign of the Sirens, famous for eloquence and the liberal sciences, which gave occasion to the invention of this fable of the sweetness of the voice and attracting songs of the Sirens. But why then are they fabled to be destroyers, and painted in such dreadful colours? We are told, that at last the students abused their knowledge, to the colouring of wrong, the corruption of manners, and the subversion of government: that is, in the language of poetry, they were feigned to be transformed into monsters, and with their music to have enticed passengers to their ruin, who there consumed their patrimonies, and poisoned their virtues with riot and effeminacy. The place is now called *Massa*. Some writers tell us of a certain bay, contracted within winding straits and broken cliffs, which, by the singing of the winds and beating of the waters, returns a delightful harmony, that allures the passenger to approach, who is immediately thrown against the rocks, and swallowed up by the violent eddies. Thus Horace, moralising, calls idleness a *Siren*.

——Vitanda est improba Siren
Desidia.——

But the fable may be applied to all pleasures in general, which, if too eagerly pursued, betray the incautious into ruin; while wise men, like Ulysses, making use of their reason, stop their ears against their insinuations.

The learned Mr Bryant says, that the Sirens were Cuthite and Canaanitish priests, who had founded temples in Sicily, which were rendered infamous on account of the women who officiated. They were much addicted to cruel rites, so that the shores upon which they resided are described as covered with the bones of men destroyed by their artifice. *Virgil. Æneid.* lib. v. ver. 864.

All ancient authors agree in telling us, that Sirens inhabited the coast of Sicily. The name, according to Bochart, who derives it from the Phœnician language, implies a songstress. Hence it is probable, says Dr Burney, that in ancient times there may have been excellent singers, but of corrupt morals, on the coast of Sicily, who, by seducing voyagers, gave rise to this fable. And if this conjecture be well founded, he observes, the Muses are not the only pagan divinities who preserved their influence over mankind in modern times; for every age has its Sirens, and every Siren her votaries; when beauty and talents, both powerful in themselves, are united, they become still more attractive.

Siren, in *Zoology*, a genus of animals belonging to the class of *amphibia* and the order of *meantes*. It is a biped, naked, and furnished with a tail; the feet are brachiated with claws. This animal was discovered by Dr Garden in Carolina; it is found in swampy and muddy places, by the sides of pools, under the trunks of old trees that hang over the water. The natives call it by the name of *mud-iguana*. Linnæus first apprehended, that it was the larva of a kind of lizard; but as its fingers are furnished with claws, and it makes a croaking noise, he concluded from these properties, as well as from the situation of the anus, that it could not be the larva of the lizard, and therefore formed of it a new genus under the name of *siren*. He was also obliged to establish for this uncommon animal a new order called *meantes* or *gliders*; the animals of which are amphibious, breathing by means of gills and lungs, and furnished with arms and claws.

Phil. Trans. vol. lvi. p. 189.

SIREX, a genus of insects belonging to the order of *hymenopteræ*. See Entomology *Index*.

SIRIUM, a genus of plants belonging to the class of tetrandria and order of monogynia. See Botany *Index*.

SIRIUS, in *Astronomy*, a bright star in the constellation Canis. See Astronomy, N° 403, &c.

SIRLET, Flavius, an eminent Roman engraver on precious stones: his Laocoon, and representations in miniature of antique statues at Rome, are very valuable and scarce. He died in 1737.

SIROCCO, a periodical wind which generally blows in Italy and Dalmatia every year about Easter. It blows from the south-east by south: it is attended with heat, but not rain; its ordinary period is twenty days, and it usually ceases at sunset. When the sirocco does not blow in this manner, the summer is almost free from westerly winds, whirlwinds, and storms. This wind is prejudicial to plants, drying and burning up the buds; though it hurts not men any otherwise than by causing an extraordinary weakness and lassitude; inconveniencies that are fully compensated by a plentiful fishing, and a good crop of corn on the mountains. In the summer time, when the westerly wind ceases for a day, it is a sign that the sirocco will blow the day following, which usually begins with a sort of whirlwind.

Fortis's Travels into Dalmatia, p. 277.

SISKIN. See Fringilla, Ornithology *Index*.

SISON, Bastard Stone Parsley, a genus of plants belonging to the class of pentandria, and to the order of digynia; and in the natural system arranged under the 45th order, *Umbellatæ*. See Botany *Index*.

SISTRUM, or Cistrum, a kind of ancient musical instrument used by the priests of Isis and Osiris. It is described by Spon as of an oval form, in manner of a racket, with three sticks traversing it breadthwise; which playing freely by the agitation of the whole instrument, yielded a kind of sound which to them seemed melodious. Mr Malcom takes the sistrum to be no better than a kind of rattle. Oiselius observes, that the sistrum is found represented on several medals, and on talismans.

SISYMBRIUM, Water-cresses, a genus of plants belonging to the class of *tetradynamia*, and to the order of *siliquosa*; and in the natural system ranged under the 39th order, *Siliquosæ*. See Botany *Index*.

SISYPHUS, in fabulous history, one of the descendants of Eolus, married Merope, one of the Pleiades, who bore him Glaucus. He resided at Epyra in Peloponnesus, and was a very crafty man. Others say, that he was a Trojan secretary, who was punished for dicovering

Sisyphus ‖ Sium.

vering secrets of state; and others again, that he was a notorious robber, killed by Theseus. However, all the poets agree that he was punished in Tartarus for his crimes, by rolling a great stone to the top of a hill, which constantly recoiled, and rolling down incessantly, renewed his labour.

SISYRINCHIUM, a genus of plants belonging to the class of *gynandria*, and order of *triandria*; and in the natural system ranged under the 5th order *Ensatæ*. See BOTANY *Index*.

SITE, denotes the situation of an house, &c. and sometimes the ground-plot or spot of earth on which it stands.

SITTA, NUTHATCH, a genus of birds belonging to the order of *picæ*. See ORNITHOLOGY *Index*.

SITOPHYLAX, Σιτοφυλαξ, formed from σιτος, "corn," and φυλαξ, "keeper," in antiquity, an Athenian magistrate, who had the superintendence of the corn, and was to take care that nobody bought more than was necessary for the provision of his family. By the Attic laws, particular persons were prohibited from buying more than fifty measures of wheat a man; and that such persons might not purchase more, the sitophylax was appointed to see the laws properly executed. It was a capital crime to prevaricate in it. There were 15 of these *sitophylaces*, ten for the city, and five for the Piræus.

SITUS, in *Algebra* and *Geometry*, denotes the situation of lines, surfaces, &c. Worfius delivers some things in geometry, which are not deduced from common analysis, particularly matters depending on the *situs* of lines and figures. Leibnitz has even founded a particular kind of analysis upon it, called *calculus situs*.

SIVA, a name given by the Hindoos to the Supreme Being, when considered as the avenger or destroyer. Sir William Jones has shown that in several respects the character of Jupiter and Siva are the same. As Jupiter overthrew the Titans and giants, so did Siva overthrow the Daityas, or children of Diti, who frequently rebelled against Heaven; and as during the contest the god of Olympus was furnished with lightning and thunderbolts by an eagle, so Brahma, who is sometimes represented riding on the Garuda, or eagle, presented the god of destruction with fiery shafts. Siva also corresponds with the Stygian Jove, or Pluto; for, if we can rely on the Persian translation of the Bhágavat, the sovereign of Pátála, or the infernal regions, is the king of serpents, named *Seshanaga*, who is exhibited in painting and sculpture, with a diadem and sceptre, in the same manner as Pluto. There is yet another attribute of Siva, or Mahádéva, by which he is visibly distinguished in the drawings and temples of Bengal. To destroy, according to the Vedantis of India, the Sufis of Persia, and many philosophers of our European schools, is only to generate and reproduce in another form. Hence the god of destruction is holden in this country to preside over generation, as a symbol of which he rides on a white bull. Can we doubt that the loves and feats of Jupiter Genitor (not forgetting the white bull of Europa), and his extraordinary title of Lapis, for which no satisfactory reason is commonly given, have a connection with the Indian philosophy and mythology?

Asiatic Researches.

SIUM, WATER PARSNEP, a genus of plants belonging to the class of *pentandria*, and order of *digynia*, and in the natural system ranging under the 44th order, *Umbellatæ*. See BOTANY *Index*.

Siwa.

SIWA, or SIWAH, a town in Egypt to the westward of Alexandria, built on a small fertile spot, surrounded on all sides by desert land. A considerable portion of this space is filled with date trees, but there are also plantains, pomegranates, figs, apricots, and olives; and the gardens are in a very flourishing condition. The people cultivate rice, which is of a reddish colour, and different from that of the Delta. The rest of the land furnishes abundance of wheat for the consumption of the inhabitants.

The greatest curiosity about Siwa is a ruin of undoubted antiquity, measuring 32 feet in length, 18 in height, and 15 in breadth, which does not appear ever to have been much larger. Mr Horneman estimates the dimensions of it at 36 feet long, 24 feet wide, and 27 high, which agrees with no other traveller whatever; and indeed Mr Horneman himself allows that the jealousy of the natives prevented him from pursuing any plan of accurate examination or admeasurement. The people of Siwa have no tradition respecting this edifice, nor attribute any quality to it, but that of concealing treasures, and as the haunt of demons. It has, however, been supposed, that Siwa is the *Siropum* of Pliny, and that this building was coeval with the temple of Jupiter Ammon, and a dependency on it; yet neither the natives of Siwa, nor the various tribes of Arabs who frequent that place, know any thing of the ruins of that temple, about which Mr Browne made every possible enquiry.

The complexion of the people of Siwa is generally darker than that of the Egyptians, and their dialect is also different. They do not habitually make use of snuff or tobacco. Their sect is that of Malik. The dress of the lower class is very simple, as they are almost naked; among those whose costume was discernible, it approaches nearer to that of the Arabs of the desert than the Egyptians or Moors. Their clothing consists of a shirt of white cotton, with large sleeves reaching to the feet, a red cap without a turban, and shoes of the same colour. Some earthen ware made by themselves, and a few mats, form the chief part of their household furniture, none but the higher ranks being possessed of copper utensils. They sometimes purchase a few slaves from the Mourzouk caravan. The rest of their wants are supplied from Cairo or Alexandria, whither their dates are transported, both in a dry state, and beaten into mash, which, when good, greatly resembles a sweet meat. They do not eat large quantities of animal food, and bread known to us is uncommon. They drink plentifully of the liquor extracted from the date tree, which they call *date-tree water*, though it has frequently the power of inebriating in the state in which they drink it. Their animals are the hairy sheep and goat of Egypt, the ass, and a very small number of oxen and camels. The women wear veils as in Egypt. After the rains, the ground in the vicinity of Siwa is covered with salt for many weeks.

Siwa has sometimes been compared to a bee hive, which it very much resembles, whether in respect to the general appearance of the eminence covered with buildings, the swarm of its people crowded together, or the confused noise, or hum and buz from its narrow passages and streets, and which reach the ear at a considerable distance. North-west of the town there is a stratum of salt extending a full mile, and near it salt is found on

 the

the surface. There are numerous springs, and frequently a spring of water perfectly sweet is found within a few paces of one that is salt. The people, according to Horneman, are obtrusive and thievish. Siwa is situated in 29° 12′ N. Lat. and 44° 54′ E. Long.

SIX-CLERKS, officers in chancery of great account, next in degree below the twelve masters, whose business it is to enrol commissions, pardons, patents, warrants, &c. which pass the great seal, and to transact and file all proceedings by bill, answer, &c. They were anciently *clerici*, and forfeited their places, if they married; but when the constitution of the court began to alter, a law was made to permit them to marry, Stat. 14 and 15 Hen. VIII. cap. 8. They are also solicitors for parties in suits depending in the court of chancery. Under them are six deputies and 60 clerks, who, with the under clerks, do the business of the office.

SIX NATIONS. See NIAGARA.

SIXTH, in *Music*, one of the simple original concords, or harmonical intervals. See INTERVAL.

SIXTUS V. POPE, was born the 13th December, 1521, in La Marca, a village in the seigniory of Montalto. His father, Francis Peretti, was a gardener, and his mother a servant maid. He was their eldest child, and was called Felix. At the age of nine he was hired out to an inhabitant of the village to keep sheep; but disobliging his master, he was soon after degraded to be keeper of the hogs. He was engaged in this employment when Father Michael Angelo Selleri, a Franciscan friar, asked the road to Ascoli, where he was going to preach. Young Felix conducted him thither, and struck the father so much with his conversation and eagerness for knowledge, that he recommended him to the fraternity to which he had come. Accordingly he was received among them, invested with the habit of a lay brother, and placed under the sacristan, to assist in sweeping the church, lighting the candles, and other offices of that nature; for which he was to be taught the responses, and the rudiments of grammar. His progress in learning was so surprising, that at the age of 14 he was thought qualified to begin his noviciate, and was admitted the year following to make his profession.

He pursued his studies with such unwearied assiduity, that he was soon reckoned equal to the best disputants. He was ordained priest in 1545, when he assumed the name of Father Montalto; soon after he took his doctor's degree, and was appointed professor of theology at Sienna. It was then that he so effectually recommended himself to Cardinal di Carpi, and his secretary Bossius, that they ever remained his steady friends. Meanwhile the severity and obstinacy of his temper incessantly engaged him in disputes with his monastic brethren. His reputation for eloquence, which was now spread over Italy, about this time gained him some new friends. Among these were the Colonna family, and Father Ghisilieri, by whose recommendation he was appointed inquisitor-general at Venice: but he exercised that office with so much severity, that he was obliged to flee precipitately from that city. Upon this he went to Rome, where he was made procurator-general of his order, and soon after accompanied Cardinal Buon Compagnon into Spain, as a chaplain and consultor to the inquisition. There he was treated with great respect, and liberal offers were made him to induce him to continue in Spain, which, however, he could not be prevailed on to accept.

In the mean time, news were brought to Madrid that Pius IV. was dead, and that Father Ghisilieri, who had been made Cardinal Alexandrino by Paul IV. had succeeded him under the name of Pius V. These tidings filled Montalto with joy, and not without reason, for he was immediately invested by the pontiff with new dignities. He was made general of his order, bishop of St Agatha, was soon after raised to the dignity of cardinal, and received a pension. About this time he was employed by the pope to draw up the bill of excommunication against Queen Elizabeth.

He began now to cast his eyes upon the papacy; and, in order to obtain it, formed and executed a plan of hypocrisy with unparalleled constancy and success. He became humble, patient, and affable. He changed his dress, his air, his words, and his actions, so completely, that his most intimate friends declared him a new man. Never was there such an absolute victory gained over the passions; never was a fictitious character so long maintained, nor the foibles of human nature so artfully concealed. He courted the ambassadors of every foreign power, but attached himself to the interests of none; nor did he accept a single favour that would have laid him under any peculiar obligation. He had formerly treated his relations with the greatest tenderness, but he now changed his behaviour altogether. When his brother Anthony came to visit him, he lodged him in an inn, and sent him home next day, charging him to inform his family that he was now dead to his relations and the world.

When Pius V. died in 1572, he entered the conclave with the other cardinals, but seemed altogether indifferent about the election, and never left his apartment except to his devotion. When solicited to join any party, he declined it, declaring that he was of no consequence, and that he would leave the choice of a pope entirely to persons of greater knowledge and experience. When Cardinal Buon Compagnon, who assumed the name of Gregory XIII. was elected, Montalto assured him that he never wished for any thing so much in his life, and that he would always remember his goodness, and the favours he had conferred on him in Spain. But the new pope treated him with the greatest contempt, and deprived him of his pension. The cardinals also, deceived by his artifices, paid him no greater respect, and used to call him, by way of ridicule, the Roman beast; the ass of La Marca.

He now assumed all the infirmities of old age; his head hung down upon his shoulders; he tottered as he walked, and supported himself on a staff. His voice became feeble, and was often interrupted by a cough so exceedingly severe, that it seemed every moment to threaten his dissolution. He interfered in no public transactions, but spent his whole time in acts of devotion and benevolence. Mean time he constantly employed the ablest spies, who brought him intelligence of every particular.

When Gregory XIII. died in 1585, he entered the conclave with the greatest reluctance, and immediately shut himself up in his chamber, and was no more thought of than if he had not existed. When he went to

Sixtus.

to mass, for which purpose alone he left his apartment, he appeared perfectly indifferent about the event of the election. He joined no party, yet flattered all.

He knew early that there would be great divisions in the conclave, and he was aware that when the leaders of the different parties were disappointed in their own views, they all frequently agreed in the election of some old and infirm cardinal, the length of whose life would merely enable them to prepare themselves sufficiently for the next vacancy. These views directed his conduct, nor was he mistaken in his hopes of success.

Three cardinals, the leaders of opposite factions, being unable to procure the election which each of them wished, unanimously agreed to make choice of Montalto. When they came to acquaint him with their intention, he fell into such a violent fit of coughing that every person thought he would expire on the spot. He told them that his reign would last but a few days; that, besides a continual difficulty of breathing, he wanted strength to support such a weight, and that his small experience rendered him very unfit for so important a charge. He conjured them all three not to abandon him, but to take the whole weight of affairs upon their own shoulders; and declared that he would never accept the mitre upon any other terms: "If you are resolved," added he, "to make me pope, it will only be placing yourselves on the throne. For my part, I shall be satisfied with the bare title. Let the world call me pope, and I make you heartily welcome to the power and authority." The cardinals swallowed the bait, and exerted themselves so effectually that Montalto was elected. He now pulled off the mask which he had worn for 14 years. No sooner was his election secured, than he started from his seat, flung down his staff in the middle of the hall, and appeared almost a foot taller than he had done for several years.

When he was asked, according to custom, if he would accept of the papacy, he replied, "It is trifling to ask whether I will accept what I have already accepted.—However, to satisfy any scruple that may arise, I tell you that I accept it with great pleasure, and would accept another if I could get it; for I find myself able, by the Divine assistance, to manage two papacies." His former complaisance and humility disappeared, together with his infirmities, and he now treated all around him with reserve and haughtiness. The first care of Sixtus V. the name which Montalto assumed, was to correct the abuses, and put a stop to the enormities, which were daily committed in every part of the ecclesiastical state. The lenity of Gregory's government had introduced a general licentiousness of manners, which burst forth with great violence, after that pontiff's death. It had been usual with former popes to release delinquents on the day of their coronation, who were therefore accustomed to surrender themselves voluntary prisoners immediately after the election of the pope. At present, however, they were fatally disappointed.—When the governor of Rome and the keeper of St Angelo waited on his Holiness, to know his intention in this particular, he replied, "What have you to do with pardons, and releasing of prisoners? Is it not sufficient that our predecessor has suffered the judges to remain unemployed these 13 years? Shall we also stain our pontificate with the same neglect of justice? We have too long seen, with inexpressible concern, the prodigious degree of wickedness that reigns in the state, to think of granting pardons. Let the prisoners be brought to a speedy trial, and punished as they deserve, to show the world that Divine Providence has called us to the chair of St Peter, to reward the good, and chastise the wicked: that we bear not the sword in vain, but are the ministers of God, and a revenger to execute wrath on them that do evil."

He appointed commissioners to inspect the conduct of the judges, displaced those who were inclined to lenity, and put others of severe dispositions in their room. He offered rewards to any person who could convict them of corruption or partiality. He ordered the syndics of all the towns and signiories to make out a complete list of the disorderly persons within their districts, and threatened the strapado for the smallest omission. In consequence of this edict, the syndic of Albino was scourged in the market-place, because he had left his nephew, an incorrigible libertine, out of his list.

He made very severe laws against robbers and assassins. Adulterers, when discovered, suffered death; and they who willingly submitted to the prostitution of their wives, a custom then common in Rome, received the same punishment. He was particularly careful of the purity of the female sex, and never forgave those who attempted to debauch them.

His execution of justice was as prompt as his edicts were rigorous. A Swiss happening to give a Spanish gentleman a blow with his halberd, was struck by him so rudely with a pilgrim's staff that he expired on the spot. Sixtus informed the governor of Rome that he was to dine early, and that justice must be executed on the criminal before he sat down to table. The Spanish ambassador and four cardinals intreated him not to disgrace the gentleman by suffering him to die on a gibbet, but to order him to be beheaded. "He shall be hanged (replied Sixtus), but I will alleviate his disgrace by doing him the honour to assist personally at his death." He ordered a gibbet to be erected before his own windows, where he continued sitting during the whole execution. He then called to his servants to bring in dinner, declaring that the act of justice which he had just seen had increased his appetite. When he rose from table, he exclaimed, "God be praised for the good appetite with which I have dined!"

When Sixtus ascended the throne, the whole ecclesiastical state was infested with bands of robbers, who, from their numbers and outrages, were exceedingly formidable; by his prudent and vigorous conduct, however, he in a short time extirpated the whole of these banditti.

Nor was the vigour of his conduct less conspicuous in his transactions with foreign nations. Before he had been pope two months he quarrelled with Philip II. of Spain, Henry III. of France, and Henry king of Navarre. His intrigues indeed in some measure influenced all the councils of Europe.

After his accession to the pontificate he sent for his family to Rome, with express orders that they should appear in a decent and modest manner. Accordingly, his sister Camilla came thither, accompanied by her daughter and two grandchildren. Some cardinals, in order to pay court to the pope, went out to meet her, and introduced her in a very magnificent dress. Sixtus pretended not to know her, and asked two or three times

Sixtus.

time who she was: Upon this one of the cardinals said, "It is your sister, holy father." "I have but one sister (replied Sixtus with a frown), and she is a poor woman at Le Grotte; if you have introduced her in this disguise, I declare I do not know her; yet I think I would know her again, if I saw her in the clothes she used to wear."

Her conductors at last found it necessary to carry her to an inn, and strip her of her finery. When Camilla was introduced a second time, Sixtus embraced her tenderly, and said, "Now we know indeed that it is our sister; nobody shall make a princess of you but ourselves." He stipulated with his sister, that she should neither ask any favour in matters of government, nor intercede for criminals, nor interfere in the administration of justice; declaring that every request of that kind would meet with a certain refusal. These terms being agreed to, and punctually observed, he made the most ample provision not only for Camilla but for his whole relations.

This great man was also an encourager of learning. He caused an Italian translation of the Bible to be published, which raised a good deal of discontent among the Catholics. When some cardinals reproached him for his conduct in this respect, he replied, "It was published for the benefit of you cardinals who cannot read Latin."

Sixtus died in 1590, after having reigned little more than five years. His death was ascribed to poison, said to have been administered by the Spaniards; but the story seems rather improbable.

It was to the indulgence of a disposition naturally formed for severity, that all the defects of this wonderful man are to be ascribed. Clemency was a stranger to his bosom; his punishments were often too cruel, and seemed sometimes to border on revenge. Pasquin was dressed one morning in a very nasty shirt, and being asked by Marforio why he wore such dirty linen? replied, that he could get no other, for the pope had made his washerwoman a princess, alluding to Camilla, who had formerly been a laundress. The pope ordered strict search to be made for the author of this lampoon, and offered him his life and a thousand pistoles if he would discover himself. The author was simple enough to make his appearance and claim the reward. "It is true (said the pope) we made such a promise, and we shall keep it; your life shall be spared, and you shall receive the money presently: but we have reserved to ourselves the power of cutting off your hands and boring your tongue through, to prevent your being so witty for the future." It is needless to add, that the sentence was immediately executed. This, however, is the only instance of his resenting the many severe satires that were published against him.

But though the conduct of Sixtus seldom excites love, it generally commands our esteem, and sometimes our admiration. He strenuously defended the cause of the poor, the widow, and the orphan: he never refused audience to the injured, however wretched or forlorn their appearance was. He never forgave those magistrates who were capable of partiality or corruption; nor suffered crimes to pass unpunished, whether committed by the rich or the poor. He was frugal, temperate, sober, and never neglected to reward the smallest favour which had been conferred on him before his exaltation.

Sixtus ‖ Sizar.

When he mounted the throne, the treasury was not only exhausted, but in debt: at his death it contained five millions of gold.

Rome was indebted to him for several of her greatest embellishments, particularly the Vatican library; it was by him, too, that trade was first introduced into the Ecclesiastical State.

SIYA-GHUSH, the caracal of Buffon, an animal of the cat kind. See FELIS, MAMMALIA *Index*.

SIZAR, or SIZER, in Latin *Sizator*, an appellation by which the lowest order of students in the universities of Cambridge and Dublin are distinguished, is derived from the word *size*, which in Cambridge, and probably in Dublin likewise, has a peculiar meaning. To *size*, in the language of the university, is to get any sort of victuals from the kitchens, which the students may want in their own rooms, or in addition to their commons in the hall, and for which they pay the cooks or butchers at the end of each quarter. A size of any thing is the smallest quantity of that thing which can be thus bought; two sizes, or a part of beef, being nearly equal to what a young person will eat of that dish to his dinner; and a size of ale or beer being equal to half an English pint.

The sizars are divided into two classes, viz. subsizatores or sizars, and sizatores or proper sizars. The former of these are supplied with commons from the table of the fellows and fellow commoners; and in former times, when these were more scanty than they are now, they were obliged to supply the deficiency by sizing, as is sometimes the case still. The proper sizars had formerly no commons at all, and were therefore obliged to size the whole. In St John's college they have now some commons allowed them for dinner, from a benefaction, but they are still obliged to size their suppers: in the other colleges they are allowed a part of the fellow-commons, but must size the rest; and from being thus obliged to size the whole or part of their victuals, the whole order derived the name of *sizars*.

In Oxford, the order similar to that of sizar is denominated *servitor*, a name evidently derived from the menial duties which they perform. In both universities these orders were formerly distinguished by round caps and gowns of different materials from those of the pensioners or commoners, the order immediately above them. But about 30 years ago the round cap was entirely abolished in both seminaries. There is still, however, in Oxford, we believe, a distinction in the gowns, and there is also a trifling difference in some of the small colleges in Cambridge; but in the largest colleges the dress of the pensioners and sizars is entirely the same.

In Oxford, the servitors are still obliged to wait at table on the fellows and gentlemen-commoners; but much to the credit of the university of Cambridge, this most degrading and disgraceful custom was entirely abolished about 10 or 12 years ago, and of course the sizars of Cambridge are now on a much more respectable footing than the servitors of Oxford.

The sizars are not upon the foundation, and therefore while they continue sizars are not capable of being elected

elected fellows; but they may at any time, if they choose, become pensioners; and they generally sit for scholarships immediately before they take their first degrees. If successful, they are then on the foundation, and are entitled to become candidates for fellowships when they have got that degree. In the mean time, while they continue sizars, besides free commons they enjoy many benefactions, which have been made at different times, under the name of *sizar's prætor*, *exhibitions*, &c. and the rate of tuition, the rent of rooms, and other things of that sort within their respective colleges, is less than to the other orders. But though their education is thus obtained at a less expence, they are not now considered as a menial order; for sizars, pensioner-scholars, and even sometimes fellow commoners, mix together with the utmost cordiality. It is worthy of remark, that at every period this order has supplied the university with its most distinguished officers; and that many of the most illustrious members of the church, many of the most distinguished men in the other liberal professions, have, when under-graduates, been sizars, when that order was on a less respectable footing than it is now.

SIZE, the name of an instrument used for finding the bigness of fine round pearls. It consists of thin pieces or leaves, about two inches long, and half an inch broad, fastened together at one end by a rivet. In each of these are round holes drilled of different diameters. Those in the first leaf serve for measuring pearls from half a grain to seven grains; those of the second, for pearls from eight grains or two carats to five carats, &c.; and those of the third, for pearls from six carats and a half to eight carats and a half.

SIZE, is also a sort of paint, varnish, or glue, used by painters, &c.

The shreds and parings of leather, parchment, or vellum, being boiled in water and strained, make size. This substance is much used in many trades.—The manner of using size is to melt some of it over a gentle fire; and scraping as much whiting into it as will just colour it, let them be well incorporated together; after which you may whiten frames, &c. with it. After it dries, melt the size again, and put more whiting and whiten the frames, &c. seven or eight times, letting it dry between each time: but before it is quite dry, between each washing with size, you must smooth and wet it over with a clean brush-pencil in fair water.

To make gold-size. Take gum-anime and asphaltum, of each one ounce; minium, litharge of gold, and amber, of each half an ounce: reduce all into a very fine powder, and add to them four ounces of linseed oil, and eight ounces of drying oil: digest them over a gentle fire that does not flame, so that the mixture may only simmer, but not boil; lest it should run over and set the house on fire, stir it constantly with a stick till all the ingredients are dissolved and incorporated, and do not leave off stirring till it becomes thick and ropy; after being sufficiently boiled, let it stand till it is almost cold, and then strain it through a coarse linen cloth, and keep it for use.—To prepare it for working, put what quantity you please in a horse-muscle shell, adding as much oil of turpentine as will dissolve it; and making it as thin as the bottom of your seed-lac varnish, hold it over a candle, and then strain it through a linen-rag into another shell; add to these as much vermilion as will make it of a darkish red; if it is too thick for drawing, you may thin it with some oil of turpentine. The chief use of this size is for laying on metals.

The best gold size for burnishing is made as follows: Take fine bole, what quantity you please; grind it finely on a piece of marble, then scrape into it a little beef suet; grind all well together; after which mix in a small proportion of parchment size, with a double proportion of water, and it is done.

To make silver-size. Take tobacco-pipe clay in fine powder, into which scrape some black-lead and a little Genoa soap, and grind them all together with parchment size as already directed.

SKATING, an exercise on ice, both graceful and healthy. Although the ancients were remarkable for their dexterity in most of the athletic sports, yet skating seems to have been unknown to them. It may therefore be considered as a modern invention; and probably it derived its origin in Holland, where it was practised, not only as a graceful and elegant amusement, but as an expeditious mode of travelling when the lakes and canals were frozen up during winter. In Holland long journeys are made upon skates with ease and expedition; but in general less attention is there paid to graceful and elegant movements, than to the expedition and celerity of what is called *journey skating*. It is only in those countries where it is considered as an amusement, that its graceful attitudes and movements can be studied; and there is no exercise whatever better calculated to set off the human figure to advantage. The acquirement of most exercises may be attained at an advanced period of life; but to become an expert skater, it is necessary to begin the practice of the art at a very early age. It is difficult to reduce the art of skating to a system. It is principally by the imitation of a good skater that a young practitioner can form his own practice. The English, though often remarkable for feats of agility upon skates, are very deficient in gracefulness; which is partly owing to the construction of the skates. They are too much curved in the surface which embraces the ice, consequently they involuntarily bring the users of them round on the outside upon a quick and small circle; whereas the skater, by using skates of a different construction, less curved, has the command of his stroke, and can enlarge or diminish the circle according to his own wish and desire. The metropolis of Scotland has produced more instances of elegant skaters than perhaps any other country whatever; and the institution of a skating club about 50 years ago, has contributed not a little to the improvement of this elegant amusement. We are indebted for this article to a gentleman of that club, who has made the practice and improvement of skating his particular study; and as the nature of our work will not permit the insertion of a full treatise on skating, we shall present our readers with a few instructions.

Those who wish to be proficients should begin at an early period of life; and should first endeavour to throw off the fear which always attends the commencement of an apparently hazardous amusement. They will soon acquire a facility of moving on the inside: when they have done this, they must endeavour to acquire the movement on the outside of the skates; which is nothing more than throwing themselves upon the outer edge of the skate, and making the balance of their body tend towards

towards that side which will necessarily enable them to form a semicircle. In this, much assistance may be derived from placing a bag of lead-shot in the pocket next to the foot employed in making the outside stroke, which will produce an artificial poise of the body, which afterwards will become natural by practice. At the commencement of the outside stroke, the knee of the employed limb should be a little bended, and gradually brought to a rectilineal position when the stroke is completed. When the practitioner becomes expert in forming the semicircle with both feet, he is then to join them together, and proceed progressively and alternately with both feet, which will carry him forward with a graceful movement. Care should be taken to use very little muscular exertion, for the impelling motion should proceed from the mechanical impulse of the body thrown into such a position as to regulate the stroke. At taking the outside stroke, the body ought to be thrown forward easily, the unemployed limb kept in a direct line with the body, and the face and eyes directly looking forward: the unemployed foot ought to be stretched towards the ice, with the toes in a direct line with the leg. In the time of making the curve, the body must be gradually, and almost imperceptibly, raised, and the unemployed limb brought in the same manner forward; so that, at finishing the curve, the body will bend a small degree backward, and the unemployed foot will be about two inches before the other, ready to embrace the ice and form a correspondent curve. The muscular movement of the whole body must correspond with the movement of the skate, and should be regulated so as to be almost imperceptible to the spectators. Particular attention should be paid in carrying round the head and eyes with a regular and imperceptible motion; for nothing so much diminishes the grace and elegance of skating as sudden jerks and exertions, which are too frequently used by the generality of skaters. The management of the arms likewise deserves attention. There is no mode of disposing of them more gracefully in skating outside, than folding the hands into each other, or using a muff.

There are various feats of activity and manœuvres used upon skates; but they are so various that we cannot pretend to detail them. Moving on the outside is the primary object for a skater to attain; and when he becomes an adept in that, he will easily acquire a facility in executing other branches of the art. There are few exercises but will afford him hints of elegant and graceful attitudes. For example, nothing can be more beautiful than the attitude of drawing the bow and arrow whilst the skater is making a large circle on the outside: the manual exercise and military salutes have likewise a pretty effect when used by an expert skater.

SKELETON, in *Anatomy*, the dried bones of any animal joined together by wires, or by the natural ligament dried, in such a manner as to show their position when the creature was alive.

We have, in the Philosophical Transactions, an account of a human skeleton, all the bones of which were so united, as to make but one articulation from the back to the os sacrum, and downwards a little way. On sawing some of them, where they were unnaturally joined, they were found not to cohere throughout their whole substance, but only about a sixth of an inch deep all round. The figure of the trunk was crooked, the spinæ making the convex, and the inside of the vertebræ the concave part of the segment. The whole had been found in a charnel-house, and was of the size of a full grown person.

SKIDS, or SKEEDS, in sea-language, are long compassing pieces of timber, notched below so as to fit closely upon the wales, extending from the main-wale to the top of the side, and retained in this position by bolts or spike-nails. They are intended for preserving the planks of the side, when any heavy body is hoisted or lowered.

SKIE, ISLE OF. See SKYE.

SKIFF, a small boat resembling a yawl, usually employed for passing rivers.

SKIMMER, BLACK. See RHYNCHOPS, ORNITHOLOGY *Index*.

SKIMMIA, a genus of plants belonging to the tetrandria class; and in the natural method ranking under the 40th order, *Personatæ*. See BOTANY *Index*.

SKIN, in *Anatomy*, the general covering of the body of any animal. See ANATOMY, N° 74.

SKIN, in *Commerce*, is particularly used for the membrane stripped off the animal to be prepared by the tanner, skinner, parchment-maker, &c. and converted into leather, &c. See TANNING.

SKINNER, STEPHEN, an English antiquarian, was born in 1622. He travelled, and studied in several foreign universities during the civil wars; and in 1654, returned and settled at Lincoln, where he practised physic with success until the year 1667, when he died of a malignant fever. His works were collected in folio in 1671, by Mr Henshaw, under the title of *Etymologicon Linguæ Anglicanæ*, &c.

SKIPPER, or SAURY, a species of fish. See ESOX, ICHTHYOLOGY *Index*.

SKIRMISH, in *War*, a slight engagement between small parties, without any regular order; and is therefore easily distinguished from a *battle*, which is a general engagement between two armies continued for some time.

SKIRMISH Bay, the name given by Lieutenant Broughton to a bay in an island which was discovered by him in latitude 43° 48′ south, and in longitude 183° east. The Chatham armed tender worked up into the bay, and came to anchor about a mile from the shore. When the captain and some of the people landed, they found the natives so extremely inhospitable, that self-preservation made it necessary to fire upon them. The land is of considerable magnitude, whether island or continent, and what they saw of it extended nearly 40 miles from east to west, and the appearance of the country they regarded as very promising. The natives resemble those of New Zealand, from which they are distant about 100 leagues; but their skins were destitute of any marks, and they seemed to be cleanly in their persons. Their dresses were of seal skin, while some had fine mats fastened round the waist. Mr Broughton says, "on our first landing, their surprise and exclamations can hardly be imagined; they pointed to the sun, and then to us, as if to ask whether we had come from thence?" The arms they made use of were clubs, spears, and a small weapon resembling the patoo of New Zealand.

SKULL, in *Anatomy*, the bony case in which the brain is enclosed. See ANATOMY, N° 11, &c.

SKULL-

Skull | Skye.

Skull-Cap. See Scutellaria, Botany *Index.*

SKY, the blue expanse of air or atmosphere. For the reason of its blue colour and concave figure, see Optics, N° 223.

SKYE, one of the greatest of the Western islands of Scotland, so called from *Skianach*, which in the Erse dialect signifies *winged*, because the two promontories of Valerness and Toternish, by which it is bounded on the north-west and north-east, are supposed to resemble wings. The island lies between the shire of Ross and the western part of Lewis. According to the computation of Mr Pennant, Dr Johnson, and Dr Campbell, it is 60 miles in length, and nearly the same in width where broadest; according to others it is 50 miles in length, and in some places 30 broad. The island of Skye was formerly divided between two proprietors; the southern part belonged to the laird of Macleod, said to be lineally descended from Leod son to the black prince of Man, but part of this division has fallen into other hands; the northern district is the property of Lord Macdonald, whose ancestor was Donald, king or lord of the isles, and chief of the numerous clan of Macdonalds, who are counted the most warlike of all the Highlanders. Skye is part of the shire of Inverness, and formerly belonged to the diocese of the Isles: on the south it is parted from the main land by a channel three leagues in breadth; though, at the ferry of Glenelg, it is so narrow that a man may be heard calling for the boat from one side to the other. Skye is well provided with a variety of excellent bays and harbours.

The face of the country is roughened with mountains, some of which are so high as to be covered with snow on the top at midsummer; in general, their sides are clothed with heath and grass, which afford good pasturage for sheep and black cattle. Between the mountains there are some fertile valleys, and the greater part of the land towards the sea-coast is plain and arable. The island is well watered with a great number of rivers, above 30 of which afford salmon; and some of them produce black muscles in which pearls are bred, particularly the rivers Kilmartin and Ord: Martin was assured by the proprietor of the former, that a pearl hath been found in it valued at 20l. sterling. Here is also a considerable number of fresh-water lakes well stored with trout and eels. The largest of these lakes takes its denomination from St Columba, to whom is dedicated a chapel that stands upon a small isle in the middle of the lake. Skye likewise affords several cataracts, that roar down the rocks with great impetuosity. That the island has been formerly covered with woods, appears from the large trunks of fir and other trees daily dug out of the bogs and peat-marshes in every part of the country.

Statistical Account of Scotland, vol. xx p. 140.

From the height of the hills, and proximity of the sea, the air seldom continues long of the same temperature; sometimes it is dry, oftener moist, and in the latter end of winter and beginning of spring cold and piercing; at an average, three days in twelve throughout the year scarcely free from rain, far less from clouds. These, attracted by the hills, sometimes break in useful and refreshing showers; at other times suddenly bursting, pour down their contents with tremendous noise, in impetuous torrents that deluge the plains below, and render the smallest rivulet impassable; which, together with the stormy winds so common in this country in the months of August and September, frequently blast the hopes, and disappoint the expectations, of the husbandman. Snow has been often known to lie on the ground for three or seven weeks; and on the highest hills, even in the middle of June, some spots of it are to be seen. To this various temperature of the air, and uncertainty of weather, the fevers and agues, head-achs, rheumatisms, colds, and dysenteries, which are the prevailing distempers, may be ascribed. That it is far, however, from being unwholesome, is sufficiently evinced by experience; for the inhabitants are, in general, as strong and healthy, and arrive at as advanced an age, as those who live in milder climates, and under a serener sky. The gout is scarcely known in this island.

Skye.

The soil is generally black, though it likewise affords clay of different colours; such as white, red, and blue, and in some places fuller's earth. It is, however, much less adapted for agriculture than for pasture, and seldom, unless, in very good years, supplies itself with a sufficiency of provisions. Yet, though the soil is not very fertile or rich, it might with proper management be made to produce more plentiful crops. But the generality of the farmers are so prejudiced in favour of old customs, and indeed so little inclined to industry, that they will not easily be prevailed on to change them for better; especially if the alteration or amendment proposed be attended with expence. Therefore, with respect to improvements in agriculture, they are still much in the same state as they were 20 or 30 years ago. Ploughs, on a new and improved model, that in comparison to the advantages derived from them might be had at a moderate expence, have lately been introduced into several districts around, where their good effects are manifest in improving the crops and diminishing the labour of man and beast; but the laird of Raasay and one other gentleman are the only persons in Portree that have used them. The *cascroim*, a crooked kind of spade, is almost the only instrument for labouring the ground used among the ordinary class of tenants. The average crops of corn are 8000 bolls.

When Mr Knox visited this island in 1786, the number of inhabitants amounted to 15,000; but between 1790-98, according to the Statistical History of Scotland, the population is only 14,470.

Various minerals are found in Skye, but none have been wrought to any advantage. Near the village of Sartle, the natives find black and white marcasites, and variegated pebbles. The Applesglen, in the neighbourhood of Lochfallart, produces beautiful agates of different colours: stones of a purple hue are, after great rains, found in the rivulets: crystal, of different colours and forms, abounds in several part of the island, as well as black and white marble, free-stone, lime-stone, and talc: small red and white coral is found on the southern and western coasts in great abundance. The fuel consists chiefly of peat and turf, which are impregnated with iron ore; and coal has been discovered in several districts; but it does not appear to be worth working.

The wild birds of all sorts most common in the country, are, solan geese, gulls, cormorants, cranes, wild geese, and wild ducks; eagles, crows, ravens, rooks, cuckoos, rails, woodcocks, moor-fowl, partridges, plover, wild pigeons, and blackbirds, owls, hawks, snipes, and

Skye.

a variety of small birds. In mild seasons, the cuckoo and rail appear in the latter end of April; the former disappears always before the end of June; the latter sometimes not till September. The woodcock comes in October, and frequently remains till March. The tame sorts of fowl are geese, ducks, turkeys, cocks, pullets, and tame pigeons.

The black cattle are here exposed to all the rigours of the severe winter, without any other provender than the tops of the heath and the alga marina; so that they appear like mere skeletons in the spring; though, as the grass grows up, they soon become plump and juicy, the beef being sweet, tender, and finely interlarded.—The amphibious animals are seals and otters. Among the reptiles may be reckoned vipers, asps, frogs, toads, and three different kinds of serpents; the first spotted black and white, and very poisonous; the second yellow, with brown spots; and the third of a brown colour, the smallest and least poisonous.

Whales, and cairbans or sun-fish, come in sometimes to the sounds after their prey, but are rarely pursued with any success. The fishes commonly caught on the coast are herrings, ling, cod, skate, haddock, mackerel, lythe, sye, and dog-fish. The average price of ling at home is 13l. 13s. per ton; when sold, one by one, if fresh, the price is from 3d. to 5d.; if cured, from 5d. to 7d. The barrel of herrings seldom sells under 19s. which is owing to the great difficulty of procuring salt, even sometimes at any price; and the same cause prevents many from taking more than are sufficient for their own use.

The kyle of Scalpe teems with oysters, in such a manner, that after some spring-tides, 20 horse-loads of them are left upon the sands. Near the village of Bernstill, the beach yields muscles sufficient to maintain 60 persons per day; this providential supply helps to support many poor families in times of scarcity.

The people are strong, robust, healthy, and prolific. They generally profess the Protestant religion; are honest, brave, innocent, and hospitable. They speak the language, wear the habit, and observe the customs that are common to all the Hebrides. The meconium in new-born infants is purged away with fresh butter: the children are bathed every morning and evening in water, and grow up so strong, that a child of 10 months is able to walk alone: they never wear shoes or stockings before the age of eight or ten, and night-caps are hardly known; they keep their feet always wet; they lie on beds of straw or heath, which last is an excellent restorative: they are quick of apprehension, ingenious, and very much addicted to music and poetry. They eat heartily of fish; but seldom regale themselves with flesh-meat: their ordinary food consists of butter, cheese, milk, potatoes, colewort, brochan, and a dish called *oon*, which indeed is no other than the froth of boiled milk or whey raised with a stick like that used in making chocolate.

A sort of coarse woollen cloth called *cloa*, or *caddoes*, the manufacture of their wives, made into short jackets and trousers is the common dress of the men. The philibeg is rarely worn, except in summer and on Sundays; on which days, and some other occasions, those in better circumstances appear in tartans, a bonnet, and short hose, and some in a hat, short coat, waistcoat, and breeches, of Scotch or English manufacture. The women are in general very cleanly, and so excessively fond of dress, that many maid-servants are often known to lay out their whole wages that way.

Skye ‖ Slavery.

There are two fairs held annually at Portree, to which almost every part of Skye sends cattle. The first is held in the end of May, and the second in the end of July. The fair commonly continues from Wednesday till the Saturday following. The commodities which are sold in these are horses, cows, sheep, goats, hides, butter, cheese, fish, and wool. The cattle sold in these fairs swim over to the main land through a mile or half a mile of sea. Thousands of these are yearly exported, at from 2l. to 3l. each. Many of them are driven to England, where they are fatted for the market, and counted delicious eating.

In Skye appear many ruins of Danish forts, watch-towers, beacons, temples, and sepulchral monuments. All the forts are known by the term *Dun*; such as Dun-Skudborg, Dun-Derig, Dun-Skeriness, Dun-David, &c.

Sky-Colour. To give this colour to glass, set in the furnace a pot of pure metal of fritt from rochetta or barilla, but the rochetta fritt does best; as soon as the metal is well purified, take for a pot of twenty pounds of metal six ounces of brass calcined by itself; put it by degrees at two or three times into the metal, stirring and mixing it well every time, and diligently skimming the metal with a ladle: at the end of two hours the whole will be well mixed, and a proof may be taken: if the colour be found right, let the whole stand 24 hours longer in the furnace, and it will then be fit to work, and will prove of a most beautiful sky colour.

SLAB, an outside sappy plank or board, sawed off from the sides of a timber tree. The word is also used for a flat piece of marble.

Slab-Line, in sea-language, a small cord passing up behind a ship's main-sail, or fore-sail, and being reeved through a block attached to the lower part of the yard, is thence transmitted in two branches to the foot of the sail, to which it is fastened. It is used to truss up the sail as occasion requires, and more particularly for the convenience of the pilot or steersman, that they may look forward beneath it as the ship advances.

SLACK-WATER, in sea-language, denotes the interval between the flux and reflux of the tide, or between the last of the ebb and the first of the flood, during which the current is interrupted, and the water apparently remains in a state of rest.

SLACKEN, in *Metallurgy*, a term used by miners to express a spongy and semivitrified substance which is mixed with the ores of metals, to prevent their fusion. It is the scoria or scum separated from the surface of the former fusions of metals. To this is frequently added limestone, and sometimes a kind of coarse iron ore, in the running of the poorer gold ores.

SLATE, a stone of a compact texture and laminated structure, splitting into fine plates, some varieties of which are employed for covering houses. See *Clay-Slate*, under MINERALOGY, p. 185. See also GEOLOGY.

SLAVE. See SLAVERY.

SLAVERY is a word, of which, though generally understood, it is not easy to give a proper definition. An excellent moral writer has defined it to be "an obligation to labour for the benefit of the master, without the contract or consent of the servant." But may not he be 1 Slavery defined.

Slavery.

be properly called a slave who has given up his freedom to discharge a debt which he could not otherwise pay, or who has thrown it away at a game of hazard? in many nations, debts have been legally discharged in this manner; and in some savage tribes, such is the universal ardour for gaming, that it is no uncommon thing for a man, after having lost at play all his other property, to stake, on a single throw of dice, himself, his wife, and his children (A). That persons who have thus lost their liberty are slaves, will hardly be denied; and surely the infatuated gamester is a slave by his own contract. The debtor, too, if he was aware of the law, and contracted debts larger than he could reasonably expect to be able to pay, may justly be considered as having come under an obligation to labour for the benefit of a master *with his own consent;* for every man is answerable for all the known consequences of his voluntary actions.

This definition of slavery seems to be defective as well as inaccurate. A man may be under an obligation to labour through life for the benefit of a master, and yet that master have no right to dispose of him by sale, or in any other way to make him the property of a third person; but the word *slave*, as used among us, always denotes a person who may be bought, and sold like a beast in the market (B). In its original sense, indeed, it was of the same import with *noble, illustrious;* but vast numbers of the people among whom it had that signification being, in the decline of the Roman empire, sold by their countrymen to the Venetians, and by them dispersed over all Europe, the word *slave* came to denote a person in the lowest state of servitude, who was considered as the absolute property of his master. See PHILOLOGY, N° 220.

Inequalities of rank inevitable.

As nothing can be more evident than that all men have, by the law of nature, an equal right to life, liberty, and the produce of their own labour (see RIGHT, N° 5.), it is not easy to conceive what can have first led one part of them to imagine that they had a right to enslave another. Inequalities of rank are indeed inevitable in civil society; and from them results that servitude which is founded in contract, and is of temporary duration. (See MORAL PHILOSOPHY, N° 141.). He who has much property has many things to attend to, and must be disposed to hire persons to assist and serve him; while those who have little or no property must be equally willing to be hired for that purpose. And if the master be kind, and the servant faithful, they will both be happier in this connection than they could have been out of it. But from a state of servitude, where the slave is at the absolute disposal of his master in all things, and may be transferred without his own consent from one proprietor to another, like an ox or an ass, happiness must be for ever banished. How then came a traffic so unnatural and unjust as that of slaves to be originally introduced into the world?

The common answer to this question is, that it took its rise among savages, who, in their frequent wars with each other, either massacred their captives in cold blood, or condemned them to perpetual slavery. In support of this opinion we have heard it observed, that the Latin word *servus*, which signifies not a *hired* servant, but a *slave*, is derived from *servare*, "to preserve;" and that such men were called *servi*, because they were captives, whose lives were preserved on the condition of their becoming the property of the victor.

3 Origin of slavery.

That slavery had its origin from war, we think extremely probable (C), nor are we inclined to controvert this etymology of the word *servus;* but the traffic in men prevailed almost universally long before the Latin language or Roman name was heard of; and there is no good evidence that it began among savages. The word עכד, in the Old Testament, which in our version is rendered *servant*, signifies literally a *slave*, either born in the family or bought with money, in contradistinction to שביר, which denotes a hired servant: and as Noah makes use of the word עבר in the curse which he denounces upon Ham and Canaan immediately after the deluge, it would appear that slavery had its origin before that event. If so, there can be little doubt but that it began among those violent persons whom our translators have called *giants* *, though the original word נפלים literally signifies *assaulters of others.* Those wretches seem first to have seized upon women, whom they forcibly compelled to minister to their pleasures; and from this kind of violence the progress was natural to that by which they enslaved their weaker brethren among the men, obliging them to labour for their benefit, without allowing them fee or reward.

4 Prior to the deluge.

* Gen. vi. 4.

5 Nimrod enslaved his captives.

After the deluge the first dealer in slaves seems to have been Nimrod. "He began," we are told, "to be a mighty one in the earth, and was a mighty hunter before the Lord." He could not, however, be the first hunter of wild beasts; for that species of hunting must have been practised from the beginning; nor is it probable that his dexterity in the chase, which was then the universal employment, could have been so far superior to that of all his contemporaries, as to entitle him to the appellation of "the mighty hunter before the Lord." Hence most commentators have concluded, that he was a hunter of men; an opinion which they think receives some countenance from the import of his name, the word *Nimrod* signifying a rebel. Whatever

3 C 2 be

(A) Aleam (quod mirere) sobrii inter seria exercent, tanta lucrandi perpendive temeritate, ut cum omnia defecerunt, extremo ac novissimo jactu de libertate et corpore contendant. Victus voluntariam servitutem adit; quamvis junior, quamvis robustior, alligari se ac venire patitur.—*Tacitus de Mor. Germ.*

The savages of North America are equally addicted to gaming with the ancient Germans, and the negroes on the Slave Coast of Guinea perhaps still more.

(B) The Roman orator's definition of *slavery*, Parad. V. is as accurate as any that we have seen. "Servitus est obedientia fracti animi et abjecti et arbitrio carentis suo;" whether the unhappy person fell into that state with or without his own contract or consent.

(C) In the article SOCIETY, the reader will find another account of the origin of slavery, which we think likewise probable, though we have transferred it to this place; as it would, in our opinion, be wrong to give to one writer what we know to belong to another. It may be proper, however, to observe here, that between the two articles there is no contradiction, as barbarous wars were certainly *one* source of slavery.

Slavery. be in this, there can be little doubt but that he became a mighty one by violence; for being the sixth son of his father, and apparently much younger than the other five, it is not likely that his inheritance exceeded theirs either in extent or in population. He enlarged it, however, by conquest; for it appears from Scripture, that he invaded the territories of Ashur the son of Shem, who had settled in Shinar; and obliging him to remove into Assyria, he seized upon Babylon, and made it the capital of the first kingdom in the world. As he had great projects in view, it seems to be in a high degree probable that he made bond-servants of the captives whom he took in his wars, and employed them in building or repairing the metropolis of his kingdom; and hence we think is to be dated the origin of postdiluvian slavery.

6 Slavery in the days of Abraham.

That it began thus early can hardly be questioned; for we know that it prevailed universally in the age of Abraham, who was born within seventy years after the death of Nimrod. That patriarch had three hundred and eighteen servants or slaves, born in his own house, and trained to arms, with whom he pursued and conquered the four kings who had taken captive his brother's son †. And it appears from the conversation which took place between him and the king of Sodom after the battle, that both believed the conqueror had a right to consider his prisoners as part of his spoil. "Give me (says the king) the *persons*, and take the *goods* to thyself." It is indeed evident from numberless passages of scripture, that the domestics whom our translators call *servants* were in those days universally considered as the most valuable part of their master's property, and classed with his flocks and herds. Thus when the sacred historian describes the wealth of Abraham, he says, that "he had sheep and oxen, and he-asses, and men-servants, and maid-servants, and she-asses, and camels." And when Abimelech wished to make some reparation to the patriarch for the unintended injury that he had done him, "he took sheep and oxen, and men-servants, and women-servants, and gave them unto Abraham, and restored to him Sarah his wife." The riches and power of Isaac and Jacob are estimated in the very same manner. Of the former it is said, that "the man waxed great, and went forward and grew, until he became very great: for he had possession of flocks, and possession of herds, and great store of servants, ועבדה of slaves; and the Philistines envied him." The latter, we are told, "increased exceedingly, and had much cattle, and maid-servants, and men-servants, and camels, and asses ‡."

That the practice of buying and selling servants thus early began among the patriarchs descended to their posterity, is known to every attentive reader of the Bible. It was expressly authorised by the Jewish law, in which are many directions how such servants were to be treated. They were to be bought only of the heathen; for if an Israelite grew poor and sold himself either to discharge a debt, or to procure the means of subsistence, he was to be treated uot as a slave עבד, but as a hired servant שכיר, and restored to freedom at the year of Jubilee. "Both thy bond-men and thy bond-maids (says Moses) shall be of the heathen that are round about you: of them shall ye buy bond-men and bond-maids. And ye shall take them as an inheritance for your children after you, to inherit them for a possession; they shall be your bond-men for ever ||." Unlimited as the power thus given to the Hebrews over their bond-servants of heathen extraction appears to have been, they were strictly prohibited from acquiring such property by any other means than fair purchase: "he that *stealeth* a man and selleth him," said their great lawgiver, "shall surely be put to death §."

7 Authorised by the Mosaic law.

|| Lev. xxv. 39, 40, 44, 46.

§ Lev xxi. 16.

Whilst slavery, in a mild form, was permitted among the people of God, a much worse kind of it prevailed among the heathen nations of antiquity. With other abominable customs, the traffic in men quickly spread from Chaldea into Egypt, Arabia, and over all the east, and by degrees found its way into every known region under heaven (D).

8 Spread over the whole world.

Of this hateful commerce we shall not attempt to trace the progress through every age and country, but shall content ourselves with taking a transient view of it among the Greeks and Romans, and a few other nations, in whose customs and manners our readers must be interested.

9 Slavery among the Greeks and

One can hardly read a book of the Iliad or Odyssey, without perceiving that in the age of Homer, all prisoners of war were liable to be treated as slaves, and compelled, without regard to their rank, sex, or years, to labour for their masters in offices of the vilest drudgery. So universally was this cruel treatment of captives admitted to be the right of the victor, that the poet introduces Hector in the very act of taking a tender and perhaps last farewell of his wife, when it was surely his business to afford her every consolation in his power, telling her, as a thing of course which could not be concealed, that, on the conquest of Troy, she would be compelled

> To bear the victor's hard commands, or bring
> The weight of water from Hyperia's spring (E).
> Pope.

At that early period, the Phœnicians, and probably the Greeks themselves, had such an established commerce in slaves, that, not satisfied with reducing to bondage their prisoners of war, they scrupled not to kidnap in cold blood

---

(D) If credit be due to a late account of China, the people of that vast empire have never made merchandise of men or women. The exception, however, is so singular, that we should be glad to see it better anthenticated; for it is apparent from works of the most undoubted credit, that over all the other eastern countries with which we are acquainted, slavery has prevailed from time immemorial, and that some of the Indian nations make long journeys into Africa for the sole purpose of buying slaves.

(E) In those early times drawing water was the office of the meanest slaves. This appears from Joshua's curse upon the Gibeonites who had deceived him.—"Now therefore ye are cursed, and there shall none of you be freed from being bond-men, and hewers of wood, and drawers of water, for the house of my God." To this state of bondage Homer makes Hector say, that Andromache would *necessarily* be brought upon the destruction of Troy; κρατερη δ' επικεισετ' αναγκη.—*Iliad.* lib. vi.

Slavery.

blood persons who had never kindled their resentment, in order to supply their foreign markets. In the 14th book of the Odyssey, Ulysses represents himself as having narrowly escaped a snare of this kind laid for him by a false Phœnician, who had doomed the hero to Libyan slavery: and as the whole narrative, in which this circumstance is told, is an artful fiction, intended to have the appearance of truth to an Ithacan peasant, the practice of kidnapping slaves could not then have appeared incredible to any inhabitant of that island.

Such were the manners of the Greeks in the heroic age; nor were they much improved in this respect at periods of greater refinement. Philip of Macedon having conquered the Thebans, not only sold his captives, but even took money for permitting the dead to be buried*; and Alexander, who had more generosity than Philip, afterwards razed the city of Thebes, and sold the inhabitants, men, women, and children, for slaves†. This cruel treatment of a brave people may indeed be supposed to have proceeded, in the first instance, from the avarice of the conqueror; and in the second, from the momentary resentment of a man who was savage and generous by turns, and who had no command of his passions. We shall not positively assign it to other causes; but from the manner in which the Spartans behaved to their slaves, there is little reason to imagine that had they received from the Thebans the same provocation with Alexander, they would have treated their captives with greater lenity. "At Sparta (says a humane and elegant writer) slaves were treated with a degree of rigour that is hardly conceivable; although to them, as their husbandmen and artificers, their proud and idle masters were indebted for all the necessaries of life. The Lacedæmonian youth, trained up in the practice of deceiving and butchering those poor men, were from time to time let loose upon them, in order to show their proficiency in stratagem and massacre. And once, without any provocation, and merely for their own amusement, we are told that they murdered three thousand in one night, not only with the connivance of law, but by its avowed permission. Such, in promoting the happiness of one part of society and the virtue of another, are the effects of slavery."

10
Roman

It has been said, that in Athens and Rome slaves were better treated than in Sparta: but in the former city their treatment cannot have been good, or their lives comfortable, when the Athenians relished that tragedy of Euripides in which Hecuba, the wife of Priam, is introduced as lamenting that she was chained like a dog at Agamemnon's gate? Of the estimation in which slaves were held in Rome, we may form a tolerable notion from the well-known fact, that one of those unhappy beings was often chained at the gate of a great man's house, to give admittance to the guests invited to a feast*. In the early periods of the commonwealth it was customary, in certain sacred shews exhibited on solemn occasions, to drag through the circus a slave, who had been scourged to death holding in his hand a fork in the form of a gibbet†. But we need not multiply proofs of the cruelty of the Romans to their slaves. If the inhuman combats of the gladiators (see GLADIATORS) admit of any apology on account of the martial spirit with which they were thought to inspire the spectators, the conduct of Vedius Pollio must have proceeded from the most wanton and brutal cruelty. This man, who flourished not in the earliest periods of the republic, when the Romans were little better than a savage banditti, but in the polished age of Augustus, frequently threw such slaves as gave him the slightest offence into his fishponds to fatten his lampreys; and yet he was suffered to die in peace! The emperor, indeed, upon coming to the knowledge of his cruelty, ordered his lampreys to be destroyed, and his ponds to be filled up; but we do not recollect that any other punishment was inflicted on the savage master. Till the reign of the same emperor the depositions of slaves were never admitted in the courts of judicature; and then they were received only when persons were accused of treasonable practices.

11
Origin of Roman slavery.

The origin of slavery in Rome was the same as in every other country. Prisoners of war were of course reduced to that state, as if they had been criminals. The dictator Camillus, one of the most accomplished generals of the republic, sold his Hetrurian captives to pay the Roman ladies for the jewels which they had presented to Apollo. Fabius, whose cautious conduct saved his country when Hannibal was victorious in Italy, having subdued Tarentum, reduced 30,000 of the citizens to slavery, and sold them to the highest bidder. Coriolanus, when driven from Rome, and fighting for the Volsci, scrupled not to make slaves of his own countrymen; and Julius Cæsar, among whose faults wanton cruelty has never been reckoned, sold at one time fifty-three thousand captives for slaves. Nor did the slaves in Rome consist only of foreigners taken in war. By one of the laws of the twelve tables, creditors were empowered to seize their insolvent debtors, and keep them in their houses till, by their services or labour, they had discharged the sum they owed: and in the beginning of the commonwealth they were authorised to sell such debtors, and even to put them to death (F). The children of slaves were the property not of the commonwealth, or of their own parents, but of their masters; and thus was slavery perpetuated in the families of such unhappy

(F) After a certain number of citations, the law granted to the debtor thirty days of grace to raise the sum for which he was accountable. The words of the law are: "Æris confessi, rebusque jure judicatis, triginti dies justi sunto. Post dein manum endojacito.—Vincito aut nervo, aut compedibus." When the debt is confessed, and the trial passed, let there be thirty days of forbearance; afterwards lay hands on him; bind him either with a cord or fetters." After the thirty days were expired, if the debtor had not discharged the debt, he was led to the prætor, who delivered him over to the mercy of his creditors; these bound him and kept him in chains for the space of sixty days. Afterwards, for three market-days successively, the debtor was brought to the tribunal of the prætor; then a public crier proclaimed in the forum the debt for which the prisoner was detained. It often happened, that rich persons redeemed the prisoner by paying his debts; but if nobody appeared in behalf of the debtor after the third market-day, the creditor had a right to inflict the punishments appointed by the law. "Tertiis nundinis capite

Slavery.

unhappy men as fell into that state, whether through the chance of war or the cruelty of a sordid creditor (G). The consequence was, that the number of slaves belonging to the rich patricians was almost incredible. Caius Cæcilius Isidorus, who died about seven years before the Christian era, left to his heirs 4116 slaves; and if any one of those wretched creatures made an unsuccessful attempt to regain his liberty, or was even suspected of such a design, he was marked on the forehead with a red-hot iron (H). In Sicily, during the most flourishing periods of the commonwealth, it seems to have been customary for masters to mark their slaves in this manner; at least we know that such was the practice of Damophilus, who, not satisfied with this security, shut up his slaves every night in close prisons, and led them out like beasts in the morning to their daily labour in the field. Hence arose the servile war in Sicily.

12 Its duration.

Though many laws were enacted by Augustus and other patriotic emperors to diminish the power of creditors over their insolvent debtors; though the influence of the mild spirit of Christianity tended much to meliorate the condition of slaves even under Pagan masters; and though the emperor Adrian made it capital to kill a slave without a just reason, yet this infamous commerce prevailed universally in the empire for many ages after the conversion of Constantine to the religion of Christ. It was not indeed completely abolished even in the reign of Justinian; and in many countries which had once been provinces of the empire it continued long after the empire itself had fallen to pieces.

13 Slavery among the ancient Germans.

It has already been observed, that among the ancient Germans it was not uncommon for an ardent gamester to lose his personal liberty by a throw of the dice. This was indeed a strong proof of savage manners; but the general condition of slaves among those savages seems to have been much better than among the polished Greeks and Romans. In Germany the slaves were generally attached to the soil, and only employed in tending cattle, and carrying on the business of agriculture; for the menial offices of every great man's house were performed by his wife and children. Such slaves were seldom beaten, or chained, or imprisoned. Sometimes indeed they were killed by their masters in a fit of sudden passion; but none were considered as materials of commerce, except those who had originally been freemen, and lost their freedom by play. These, indeed, the successful gamester was very ready to sell, both because he felt them an useless burden, and because their presence continually put him in mind of that state to which a throw of the dice might one day reduce himself.

Such is the account which Tacitus gives * of slavery among the ancient Germans. The Anglo-Saxons, however, after they were settled in this island seem not to have carried on that traffic so honourably. By a statute of Alfred the Great†, the purchase of a *man*, a *horse*, or an *ox*, without a voucher to warrant the sale, was strictly forbidden. That law was, doubtless, enacted to prevent the *stealing* of *men* and cattle; but it shows us that so late as the ninth or tenth century a man, when fairly purchased, was, in England, as much the property of the buyer as the horse on which he rode, or the ox which dragged his plough. In the same country, now so nobly tenacious of freedom and the rights of man, a species of slavery similar to that which prevailed among the ancient Germans subsisted even to the end of the sixteenth century. This appears from a commission issued by Queen Elizabeth in 1574, for inquiring into the lands and goods of all her *bond-men* and *bond-women* in the counties of Cornwall, Devon, Somerset, and Gloucester, in order to compound with them for their manumission, that they might enjoy their lands and goods as freemen ‡. In Scotland there certainly existed an order of slaves or bond-men, who tilled the ground, were attached to the soil, and with it were transferable from one proprietor to another, at a period so late as the thirteenth century: but when or how those villains, as they were called, obtained their freedom, seems to be unknown to every lawyer and antiquary of the present day. Coalliers and salters were, in the same country, slaves till little more than 30 years ago, that they were manumitted by an act of the British legislature, and restored to the rights of freemen and citizens. Before that period the sons of coalliers could follow no business but that of their fathers; nor were they at liberty to seek employment in any other mines than those to which they were attached by birth, without the consent of the lord of the manor, who, if he had no use for their services himself, transferred them by a written deed to some neighbouring proprietor.

capite pœnas data aut trans Tiberim peregre venumduito;" that is, "Let him on the third market-day be punished with death, or sold beyond the Tiber as a slave." If there were several creditors, they were allowed, in consequence of this severe law, to divide the body of the prisoner into several parts, and share it among them in proportion to the sum which they demanded.

(G) This is evident from the story of Appius and Virginia. See Rome, N° 113.

(H) How capriciously and unjustly this infamous mark was impressed, we learn from the story of Restio. This man being proscribed, and a reward offered for his head by the triumvirs Octavianus, Antony, and Lepidus, concealed himself from the fury of the tyrants in the best way that he could. A slave whom he had marked with the hot iron having found out the place of his retreat, conducted him to a cave, and there supported him for some time with what he earned by his daily labour. At length a company of soldiers coming that way, and approaching the cave, the faithful slave, alarmed at the danger his master was in, followed them close, and falling upon a poor peasant, killed him in their presence; and cut off his head, crying out, "I am now revenged on my master for the marks with which he has branded me." The soldiers, seeing the infamous marks on his forehead, and not doubting but he had killed Restio, snatched the head out of his hand, and returned with it in all haste to the triumvirs. They were no sooner gone, than the slave conveyed his master to the sea side, where they had the good luck to find one of Sextus Pompeius's vessels, which transported them safe into Sicily.

Slavery.

of history exempted from this opprobrium of our nature which spread over all the rest of the world, the enlightened reader will not suppose. It is indeed in that vast country that slavery has in every age appeared in its ugliest form. We have already observed, that about the era of the Trojan war, a commerce in slaves was carried on between Phœnicia and Libya: and the Carthaginians, who were a colony of Phœnicians, and revered the customs, manners, and religion of their parent state, undoubtedly continued the Tyrian traffic in human flesh with the interior tribes of Africa. Of this we might rest assured, although we had no other evidence of the fact than what results from the practice of human sacrifices so prevalent in the republic of Carthage. The genuine instincts of nature are often subdued by dire superstition, but they cannot be wholly eradicated; and the rich Carthaginian, when a human victim was demanded from him to the gods, would be ready to supply the place of his own child by the son of a poor stranger, perfidiously purchased at whatever price. That this was, indeed, a very common practice among them, we learn from the testimony of various historians*, who assure us, that when Agathocles the tyrant of Syracuse had overthrown their generals Hanno and Bomilcar, and threatened Carthage itself with a siege, the people attributed their misfortunes to the just anger of Saturn for having been worshipped, for some years, by the sacrifices of children meanly born and secretly *bought*, instead of those of noble extraction. These substitutions of one offering for another were considered as a profane deviation from the religion of their forefathers; and therefore to expiate the guilt of so horrid an impiety, a sacrifice of 200 children of the first rank was on that occasion made to the bloody god. As the Carthaginians were a commercial people, we cannot suppose that they purchased slaves only for sacrifices. They undoubtedly condemned many of their prisoners of war to the state of servitude, and either sold them to foreigners, or distributed them among their senators and the leaders of their armies. Hanno, who endeavoured to usurp the supreme power in Carthage whilst that republic was engaged in war with Timoleon in Sicily†, armed 20,000 of his slaves in order to carry his nefarious purpose into execution: and Hannibal, after his decisive victory at Cannæ, sold to the Greeks many of his prisoners whom the Roman senate refused to redeem ‡. That illustrious commander was indeed more humane, as well as more politic, than the generality of his countrymen. Before his days it was customary with the Carthaginians either to massacre their captives in cold blood, that they might never again bear arms against them, or to offer them in sacrifice as a grateful acknowledgement to the gods by whose assistance they believed that they were vanquished; but this was not always done even by their most superstitious or most unprincipled leaders. Among other rich spoils which Agathocles, after his victory already mentioned, found in the camp of Hanno and Bomilcar, were twenty thousand pair of fetters and manacles, which those generals had provided for such of the Sicilian prisoners as they intended to preserve alive and reduce to a state of slavery.

17 And Numidians.

With the ancient state of the other African nations we are but very little acquainted. The Numidians, Mauritanians, Getulians, and Garamantes, are indeed mentioned by the Roman historians, who give us ample details of the battles which they fought in attempting to preserve their national independence; but we have no particular account of their different manners and customs in that age when Rome was disputing with Carthage the sovereignty of the world. All the African states of which we know any thing, were in allianee with one or other of those rival republics; and as the people of those states appear to have been less enlightened than either the Romans or the Carthaginians, we cannot suppose that they had purer morals, or a greater regard for the sacred rights of man, than the powerful nations by whom they were either protected or oppressed. They would, indeed, insensibly adopt their customs; and the ready market which Marius found for the prisoners taken in the town Capsa, although Sallust acknowledges ‡ that the sale was contrary to the laws of war, shows that slavery was then no strange thing to the Numidians. It seems indeed to have prevailed through all Africa from the very first peopling of that unexplored country; and we doubt if in any age of the world the unhappy negro was absolutely secure of his personal freedom, or even of not being sold to a foreign trader.

‡ Bell. Jug. cap. 91.

18 Slave-trade with the coast of Guinea begun not by the Portuguese.

It is the common opinion that the practice of making slaves of the negroes is of a very modern date; that it owes its origin to the incursions of the Portuguese on the western coast of Africa; and that but for the cunning or cruelty of Europeans, it would not now exist, and would never have existed. But all this is a complication of mistakes. A learned writer has lately proved, with a force of evidence which admits of no reply*, that from the coast of Guinea a great trade in slaves was carried on by the Arabs some hundreds of years before the Portuguese embarked in that traffic, or had even seen a woolly-headed negro. Even the wandering Arabs of the desert, who never had any friendly correspondence with the Christians of Europe, have from time immemorial been served by negro slaves. "The Arab must be poor indeed (says M. Saugnier) not to have at least one negro slave. His sole occupation is the care of the herd. They are never employed in war, but they have it in their power to marry. Their wives, who are captive negresses, do all the domestic work, and are roughly treated by the Arabian women, and by the Arabs themselves. Their children are slaves like them, and put to all kinds of drudgery." Surely no man whose judgment is not completely warped by prejudice will pretend that those roving tribes of savages, so remarkable for their independent spirit and attachment to ancient customs, learned to enslave the negroes from the Europeans. In all probability they have, without interruption, continued the practice of slavery from the days of their great ancestor Ishmael; and it seems evident, that *none of the European nations had ever seen a woolly-headed negro till the year* 1100, when the crusaders fell in with a small party of them near the town of Hebron in Judea, and were so struck with the novelty of their appearance, that the army burst into a general fit of laughter ||. Long before the crusades, however, we know with certainty that the natives of Guinea had been exposed to sale in foreign countries. In 651 the Mahometan Arabs of Egypt so harassed the king of Nubia or Ethiopia, who was a Christian, that he agreed to send them annually, by way of tribute, a *vast number of Nubian or Ethiopian*

* Whittaker's Review of Gibbon's Roman History,

Saugnier and Brisson's Voyages.

|| Malmsbury, fol. p. 83.

pian slaves into Egypt. Such a tribute as this at that time, we are told, was more agreeable to the khalif than any other, as the Arabs then made *no small account of those slaves* *.

* *Modern Universal History,* vol. i. 525.

The very proposal of such a tribute, and the estimation in which black slaves were held in Egypt, shows that a commerce in bond-servants could not then be a new branch of trade either to the Arabs or the Ethiopians; but the vast number which the Ethiopian monarch was now compelled to furnish every year, induced him to feed this great drain upon his subjects from the natives of the neighbouring countries. "He ranged accordingly into all that vast *blank of geography* upon the map of the world, the spreading bosom of the African continent; and even pushed through it to its farthest extremities in the west. He thus brought the blacks of Guinea, for the first time, into the service and families of the east; and the slaves which he paid in tribute to the Arabs, whether derived from the nearer neighbourhood of Ethiopia, fetched from the Mediterranean regions of Africa, or brought from the distant shores of the Atlantic, were all denominated *Ethiopians*, from the country by which they were conveyed into Egypt †. "At this time, therefore, according to Mr Whitaker, began that kind of traffic in human flesh

† *Whitaker's Review.*

"Which spoils unhappy Guinea of its sons."

There are not many authors from whom, in questions of antiquity, we differ with greater hesitation; but, as we meet with a female Ethiopian slave in the Eunuch of Terence, we cannot help suspecting that Guinea was occasionally "spoiled of its sons" at a much earlier period.

20 The negroes have enslaved one another from time immemorial.

At any rate, from the observations made by the European travellers who first penetrated into that continent, it appears undeniable that slavery must have prevailed from time immemorial among such of the tribes as had never carried on any commerce with foreign nations. When Battel first visited the Giagas *, those people had never before seen a white man; yet they welcomed him and the English, with whom he had come, to their country, invited them to bring their goods on shore, and without hesitation loaded the ships with slaves. The Giagas were indeed waging war with the kingdom of Benguela; and being cannibals, who prefer human flesh to all others, the slaves whom they had sold to the English were probably prisoners whom they would have killed and eaten if they had not found an opportunity of otherwise disposing of them to greater advantage. But as they had not been incited by the Europeans to eat their prisoners, there can be no reason to suppose that by the Europeans they had been first induced to sell them; for we have seen that this kind of commerce prevailed in Africa among people much more polished than the Giagas so early as in the reign of Jugurtha.

* *Modern Universal History,* vol. xiii. chap. 47. sect. 2.

That it was not introduced among the negroes either by the Arabs or by the Portuguese, appears still more evident from the behaviour of the Dahomans at the conquest of Whidah, and from the manner in which the people of Angola at the earliest stage of their foreign trade procured a supply of slaves for the Portuguese market. The greater part of the slaves whom the Angolans exported from St Paulo de Loanda were brought from interior countries, some hundreds of leagues distant, where they could not have been regularly purchased had that commerce been till then unknown in those countries. The Dahomans, in the beginning of the year 1727, had never seen a white man: and when their victorious prince and his army, in their route through Whidah, first met with some Europeans in the town of Sahi, they were so shocked at their complexion and their dress, that they were afraid to approach them, and could not be persuaded that they were men till they heard them speak, and were assured by the Whidanese that these were the merchants who purchased all the slaves that were sold in Guinea ‡. Slavery, therefore, if it prevailed among the Dahomans before that period, could not have been introduced among them by European or Arabian intrigues: but we are assured by Snelgrave, who was then in the army, that those people treated their captives with such horrid cruelty as was shocking to the natives of the sea-coast, and leaves no room for doubt but that slavery had been practised among them from the earliest ages. A great part of their prisoners were sacrificed to their gods or eaten by the soldiers; and when our author expressed to a colonel of the guard some surprise that a prince so enlightened as the sovereign of Dahomy should sacrifice so many men whom he might have sold to great advantage, he was gravely told, that it had been the custom of their nation, from time immemorial, to offer, after victory, a certain number of prisoners to the gods; and that they selected the old men for victims, because they were of less value at market, and more dangerous from their experience and cunning, than the young men. To those persons who fancy that the wars between the African princes are carried on for the sole purpose of supplying the European ships with slaves, it may be proper to remark, that one of the kings of Dahomy slaughtered at once not only all the captives taken in war, but also 127 prisoners of different kinds, that he might have a sufficiency of skulls to adorn the walls of his palace; though at the very time of that massacre he *knew* that there were six slave-ships in the road of Whidah, from which he could have got for every prime slave a price little short of thirty pounds sterling §.

‡ *Modern Universal History,* vol. xiii.

These facts, and numberless others which the reader will find detailed in the 13th volume of the Modern Universal History, by writers who were at the greatest pains to procure authentic information; who were neither biassed by interest nor blinded by enthusiasm; and who appear to have held the infamous traffic in utter abhorrence—prove beyond the possibility of doubt, that slavery of the worst kind must have prevailed among all the negro nations before they were visited either by the Portuguese or by the Arabs (1). These two nations may

§ *Dalzel's History of the Kingdom of Dahomy.*

(1) The same thing appears from the voyages of M. Saugnier, who had an opportunity of conversing with many tribes of negroes, and who always speaks of slavery as an established practice among them; adding, that such as are sold for crimes are put to death by their own countrymen if they fly from their master. It appears likewise in a still more striking light from Dalzel's History of Dahomy, where we are told that all the Dahomans,

may indeed have been the first who dragged the unhappy negro from his native continent, and made his slavery doubly severe, by compelling him to labour, without his own consent, for masters whom he hardly considered as human beings.

On the beginning of this commerce, or the dreadful cruelty with which it has been carried on to the present day, it is impossible to reflect without horror: but there is some consolation, however small, in knowing that its original authors were not Europeans. The purchase of Guinea blacks for slaves by foreign nations commenced ages before the Portuguese had laid that country open to the intercourse of Europe. Even after they had made many incursions into it, the inhabitants were as regularly purchased for slaves by some of the adjoining states as they are now by the maritime Europeans.

21 The route by which the Arabs carried on the slave-trade. *Whitaker's Review*, p. 5.

"The Arabs of Egypt having reduced all the north of Africa, and carrying with them their love of black servants, would be sure to open a ready communication for themselves to their country. They certainly had one so early as 1512, and before the Europeans had any for that purpose (K). They went from Barbary by a route that was so much practised, as to be denominated expressly 'the way of the camels.' Meeting together at the town of Cape Cantin, or that of Valadie near it, the commercial caravan traversed the vast deserts, those of Sarra, which run like the tropic of Cancer over them in a long line across the country; to a place of great population called Hoden, the *Waden* or *Hoden* of our maps, and a little to the south-west of Cape Blanco. From Hoden they turned to the left, and pushed directly into the interior of the continent, to reach Tegazza, the *Tagazel* or *Tagaza* of our maps, and lying nearly east of Hoden. Here assuredly they did, as the caravan does certainly at this day; and added to the other wares upon their camels a quantity of salt from those mines of rock-salt, which are extraordinary enough to be noticed as rocks in our maps. This they carried, as they still carry it, to Tanbut, the *Tombut* of the maps, and a town in the heart of the African continent. And from this town they turned on the right for the sea coast again, and reached it in the great kingdom of Mele, the *Melli* of our maps, to the south of the Gambia, and just at the springing as it were of that grand arch of sea which curves so deeply into the body of the land, and constitutes the extensive gulf of Guinea. At Melli and at Tombut they received a measure of gold for a measure of salt. The caravan collects gold at Tombut to the present time; but at Melli they purchased gold and also silver, in pieces as large as pebbles. And at Hoden they had *a great mart for slaves*; the blacks being brought thither from the countries adjoining, and bartered away to the traders. Such was the Slave Coast and the Gold Coast of former days. The staple commodity of Hoden is only transferred now to Whidah; and diverted from the Arabs of Barbary to the Christians of Europe," by whom the negroes are carried to the continent of America or to the Sugar Islands in the West Indies. In these countries they are all sold like beasts in a market; but they experience very different degrees of servitude from the different masters who hold them as property. Such of them as are reconciled to the appearance of white men, or have been born in the European colonies, feel themselves as happy under a humane master as they could be in their native continent (L); and we believe that few of them in such circumstances have expressed a desire to return." 22 which is now transferred to the Europeans.

In the French West India islands, before the late revolution in the mother country, which has produced in all its dependencies anarchy and massacre, the condition of the negro slaves was better than that of the bondmen among the ancient Germans. "Those of them who cultivated the plantations were attached to the soil, and could not be drawn off to pay debts, or be sold separately from the estate on which they lived. This gave them a lasting property in their huts and little spots of ground, which they might safely cultivate without dread of being turned out of possession, or transferred contrary to their interest and feelings from one proprietor to another. They were under the protection of law as soon as they arrived in the colony. Proper missionaries were appointed for the purpose of training them up to a certain degree of religious knowledge, and ample funds were allotted for the maintenance of those ecclesiastics. On ill treatment received from his master, or on being deprived of his allowance of food and raiment, the slave was directed to apply to the king's attorney, 23 Condition of slaves in the French West Indies under the old government.

mans, from the lowest to the highest, acknowledge the right of the sovereign to dispose of their persons and properties at pleasure; and where we learn, that the sovereign himself assured Mr Abson the English governor at Whidah, that all his ancestors had from time immemorial put to death every prisoner of war whom they could not sell as a slave.

(K) In the year 1442, Anthony Gonsalez, a Portuguese adventurer, restored to their native country some Moorish prisoners whom he had two years before forcibly carried off from the coast of Africa. He landed them at *Rio del Oro*, and received from the Moors in exchange ten blacks and a quantity of gold dust. This transaction proves, that a commerce in black servants was then regularly carried on by the Moors and not by the Portuguese. So early as the year 1502, the Spaniards began to employ a few negroes in the mines of Hispaniola; but in the year following, Ovando, the governor of that island, forbade the further importation of them, alleging that they taught the Indians all manner of wickedness, and rendered them less tractable than formerly: and it was not till the year 1517 that the supply of negroes to the Spanish American plantations became an established and regular branch of commerce. *Edward's History of the West Indies*, Book IV. chap. ii.

(L) "I have observed many of my slaves go on board the vessel with joy, on my assurance that they would be well treated and happy on the plantation where I was going to send them. When the Banbarans find that they are trusted by the whites, they never think of making their escape, choosing to be the slaves of *Europeans* rather than of a *black man*, who would treat them with the greatest cruelty. *Voyages to the Coast of Africa by Messrs Saugnier and Brisson*, p. 332. 335. English Translation.

Slavery.

torney, who was obliged to prosecute the master forthwith. That officer was also bound to prosecute, if by any other means he heard of the abuse; the law adding as the reason, *This we will to be observed, to check the abuse of power in the master**."

* *Ramsay's Essay on the Treatment and Conversion of Slaves.* Sect. v.

24 In the British islands.

We wish it were in our power to say, that in the British West India colonies slaves are equally protected by law as they were in the French islands under the old government, and that the same care is taken of their moral and religious improvement. This, however, we are afraid, cannot be said with truth. In the island of Jamaica, before the passing of the *consolidated slave act*, not many years ago, a white man, whether proprietor or not, who had killed a negro, or by an act of severity been the cause of his death, was, for the first offence, intitled to benefit of clergy, and not liable to capital punishment till a repetition of the crime. By the present law, it is enacted, "That if any person, whether owner or superintendant of slaves, shall be convicted of having, by any act of passion or cruelty, occasioned the death of any negro, it shall be capital for the *first* offence: and for the greater security of the property, and as a check on those who may have the punishment of slaves in their power, it is particularly required, that every surgeon or doctor belonging to each estate shall swear to the cause of the death of each negro, to the best of his knowledge and belief; and if any negro dies, and is interred by the owner or overseer, without the doctor's having seen or been sent for to such negro, in this case the owner or overseer causing the negro to be so interred is liable to a prosecution for such conduct."

M'Neil's Observations on the Treatment of Negroes in the island of Jamaica.

This law must doubtless be productive of good effects; but being a colonial act, it cannot have the vigour of the *Code Noir;* nor do we know of any attorney in the island who is *obliged* to defend the rights of the negroes, or prosecute the master whose cruelty has by any means come to his knowledge. The justices and vestry of each parish are indeed constituted *a council of protection,* for the express purpose of making full enquiry into the barbarities exercised on slaves, and bringing the authors to punishment at the public expence; and by a new slave act at Grenada, the justices are required annually to nominate three freeholders to be *guardians of the slaves*, who are to take an oath to see the law duly executed†. These are benevolent regulations; but we doubt if protection can be so promptly afforded by a council of guardians as by an individual attorney who has no other employment. In some of the other British islands, we have been confidently told that the unfortunate sons of Africa have no protection whatever against the tyranny of a sordid owner, or the caprice of a boyish overseer (M); though it is added, that the humanity of many masters more than supplies the want of laws in every respect but that of improvement, and that the attachment of others has in them a like effect. In some cases good sense, a regard for their reputation, and a well-informed conviction of their interest, induce men to treat their slaves with discretion and humanity. The slaves of many a planter possess advantages beyond what the labourer even of Britain enjoys‡;" yet these advantages all depend upon the good will of his master; and in no part of the British colonies are the slaves attached to the soil. This single circumstance, together with the total neglect of their moral and religious culture, makes their situation much less eligible than was that of the French slaves under the old government; and affords a striking proof of what the humane author whom we have just quoted well observes, that "those men and nations whom liberty hath exalted, and who therefore ought to regard it tenderly in others, are constantly for restraining its blessings within their own little circle, and delight more in augmenting the train of their dependants than in adding to the rank of fellow-citizens, or in diffusing the benefits of freedom among their neighbours."

† *Edwards's History of the West Indies,* book iv. chap. v.

‡ *Ramsay's Essays,* p. 60. and 91.

25 The lawfulness of slavery inquired into.

Having given this ample detail of the rise and progress of slavery in the world, and shown that it has prevailed in every age, and under all religions, we shall now proceed to enquire whether a practice so general be in any instance lawful; and if it be, how it must be modified, in order to be rendered consistent with the rights of man and the immutable laws of virtue.

That in a state of nature one man has a right to seize upon another, and to compel him by force to labour for his subsistence, is a position which we believe has never been seriously maintained. But independent communities stand to each other in the very same relation that individuals do in a state of nature; and therefore in such a state the man of greater bodily strength or mental sagacity would have no right to convert his weaker neighbour into personal property, neither can the more powerful and enlightened nation have a right to carry off by force, or entice by fraud, the subjects of a weaker and more barbarous community for the purpose of reducing them to a state of servitude. This is a truth so obvious as to admit neither of proof nor of denial.

In thus stating the case between two independent nations, we have in our eye that traffic in slaves which is carried on between the civilized Europeans and the barbarous Africans: and the utmost length which we think an apologist for that trade can go is to contend, that we may lawfully purchase slaves in those countries where from time immemorial they have been a common branch of commerce. But the European right to purchase cannot be better than the African right to sell; and we have never yet been informed what gives one African a right to sell another. Such a right cannot be natural, for the reason which we have elsewhere assigned (see RIGHT): neither can it be adventitious; for adventitious rights are immediately derived from the municipal law, which is the public will of the state. But the state has no authority to deprive an innocent man of his personal freedom, or of the produce of his own labour; for it is only to secure these, by protecting the weak

26 The common apology for it insufficient.

(M) In Barbadoes there is said to be a law for the protection of slaves, which is the most insolent trifling with justice and humanity that the writer of this article has ever seen. It is enacted, forsooth, "That if any man shall, of *wantonness* or only of *bloody-mindedness*, or *cruel intention*, *wilfully kill* a negro or other slave, if his own, he shall pay into the public treasury *fifteen pounds sterling!* See *Dickson's Letters on Slavery*, p. 4.

Slavery.

weak from the violence of the strong, that states are formed, and individuals united under civil government.

It may perhaps be said, that by patiently submitting to governments which authorize the traffic in human flesh, men virtually give up their personal liberty, and vest their governors with a right to sell them as slaves: but no man can vest another with a right which he possesses not himself; and we shall not hesitate to affirm, that in a state of nature where all have equal rights, no individual can submit himself to the absolute disposal of another without being guilty of the greatest crime. The reason is obvious. From the relation in which men stand to one another as fellow-creatures, and to God as their common Creator, there are duties incumbent upon each peculiar to himself; in the performance of which he can be guided only by his own reason, which was given him for that very purpose. But he who renounces his personal freedom, and submits unconditionally to the caprice of a master, impiously attempts to set himself free from the obligation of that law which is interwoven with his very being, and chooses a director of his conduct different from that which God has assigned him. A man therefore cannot put himself in a state of unconditional servitude; and what he cannot do for himself, he surely cannot authorize others to do for him either by a tacit or by an open consent.

27
[margin: ... man ... a right ... give ... self up ... he ab... ... te dis... ... l of an... ... er.]

These considerations have often made us regret that writers, for whose talents and integrity we have the highest respect, should, without accurately defining what they mean by slavery, have peremptorily affirmed, that, consistently with the law of nature men may be reduced to that state as a punishment for crimes, or to discharge debts which they cannot otherwise pay. That a criminal, who has forfeited his life to the laws of his country, may have his punishment commuted for hard labour, till death in the course of nature shall put a period to his terrestrial existence, is a truth which we apprehend cannot be controverted; but to make such a commutation of punishments consistent with the laws of nature and of nature's God, it appears to us that the kind and degree of labour must be precisely ascertained, and the conduct of the criminal not left to the capricious direction of any individual.

28
[margin: W... t kind of ... very m... be employ... d as a punish... me...]

Punishments can be justly inflicted only for one or other of two ends, or for both. They may be calculated either to reform the criminal or to be a warning to the innocent; and those which most effectually answer both these purposes are surely to be preferred to such as answer but one of them. For this reason we consider hard labour as a much fitter punishment for most crimes than death: but to entitle it to preference, the kind and degree of the labour must be ascertained by the law; for if these circumstances be omitted, and the offender delivered over as a slave to the absolute disposal and caprice of a private master, the labour to which he is condemned, instead of operating to his reformation, may be converted into the means of tempting him to the commission of new crimes. A young woman, in the state of servitude, would hardly be able to maintain her virtue against the solicitations of a master who should promise her liberty or a remission of toil upon her yielding to his desires; and the felon, who had long been accustomed to a life of vagrancy and idleness, would not strenuously object to the perpetration of any wickedness to obtain his freedom, or even a diminution of his daily task. Indeed such temptations might be thrown in his way, as human nature could not resist but by means of much better principles than felons can be supposed to possess. He might be scourged into compliance; or his labour might be so increased as to make him for a little respite eagerly embrace the most nefarious proposal which his master could make: for being absolute property, there is no earthly tribunal to which he could appeal for justice; and felons do not commonly support themselves under trials by pious meditations on a future state.

By reasoning in this way, we are far from meaning to insinuate that slave-holders in general torture their slaves into the commission of crimes. God forbid! Many of them we know to be religious, humane, and benevolent: but they are not infallible; and some of them may be instigated, some of them undoubtedly have been instigated, by avarice and other worse principles, to compel creatures, who are so absolutely their dependents, to execute deeds of darkness too hazardous for themselves. But the morality or immorality of any action, and the moral fitness of any state, are to be judged of by their natural tendency, if the one were universally practised and the other universally prevalent (see Moral Philosophy, N° 156.): and as the natural tendency of absolute domestic slavery among such creatures as men is to throw the most powerful temptations to vice in the way both of master and of slave, it must be in every instance, even when employed as a punishment, inconsistent with the fundamental principles of moral virtue.

Some writers indeed have maintained, and the civil law seems to suppose, that children are the property of their parents, and may by them be sold as slaves in cases of urgent necessity: but if we duly consider how property is acquired (see Property), and attend to the natural consequences of slavery, we shall soon be convinced that this opinion is very ill founded. The rights of parents result from their duties; and it is certainly the duty of that man who has been the instrument of bringing into the world an intellectual and moral being, to do every thing in his power to render the existence of that being happy both in the present life and in that which is to come. If this duty be conscientiously discharged, the parent has a manifest right to the gratitude, love, and reasonable obedience, of his child; but he cannot, in consequence of any duty performed, claim a right to transfer that child as property to the uncontrolled disposal of any private master; for this plain reason, that the man who is considered as the private property of another, cannot reasonably be supposed to enjoy happiness in this world, and is under many temptations to do what must necessarily render him miserable in the next. See Moral Philosophy, N° 138. 29
[margin: Children not the property of their parents.]

If criminals cannot be lawfully reduced to a state of absolute private slavery, much less surely can it be lawful to reduce insolvent debtors and prisoners of war to that state. Many a virtuous man, who has contracted debts with the fairest prospect of paying them, has been suddenly rendered insolvent by fire, by shipwreck, or by the bankruptcy of others with whom he was necessarily engaged in the course of his trade. Such a man can be considered in no respect as criminal. He has been indeed unfortunate; but it would be grossly unjust, as well

Slavery.

well as shockingly cruel, to add to his misfortune by reducing him to a state to which we have just seen that the vilest felon cannot be reduced without a violation of the laws of morality. Fraudulent bankrupts indeed, of whom we daily see many, might with great propriety and the strictest justice be compelled to extenuate their debts by labouring for the benefit of those whom they have injured; and criminals of other descriptions might be made to work for the benefit of the public: but in both cases the task to be performed should be ascertained by the law, and the persons of the labourers be protected by the state. If such can be called slaves, their slavery is undoubtedly consistent with every principle of virtue and religion; for they suffer nothing but the due reward of their deeds. Prisoners of war, however, can upon no honest principle be reduced even to this state of mitigated bondage; for they are so far from incurring guilt by fighting for their country, that even to their enemies their courage and conduct in such a cause must appear worthy of reward. A victorious general has certainly a right to prevent the prisoners taken in battle from again drawing their swords against him during the continuance of the war; but there are many ways by which this may be done effectually without chaining the unfortunate captives to the oar, or selling them like cattle to private purchasers, by whom they may be treated with capricious cruelty, and driven to the perpetration of the greatest crimes.

30 Fraudulent bankrupts may be compelled to labour for the benefit of their creditors,

31 Two objections to our conclusions.

To these conclusions, and the reasoning on which they are built, we are aware it may be objected, that if private slavery were in every instance unlawful and inconsistent with the fundamental principles of morality, it would not have prevailed among the ancient patriarchs, and far less have been authorised by the Jewish law.

32 The former answered.

In reply to this objection, it may be observed, that Abraham, Isaac, and Jacob, though excellent men, were not characters absolutely perfect; that as their practice does not authorise polygamy or incest among us, it will not authorise the reducing of our fellow-creatures to a state of hopeless servitude; and that from the circumstances of the age in which they lived, many things were permitted to them, and were indeed harmless, which are forbidden to us, and would now be pernicious. The character of Abraham appears to have been much more perfect than that of his son or grandson; and was certainly equal, if not superior, to that of any other mere man of whom we read either in profane or even in sacred history. We are to remember, however, that he was born amidst idolaters, and was probably an idolater himself till enlightened by the inspiration of Jehovah, and called from his kindred and from his father's house. Before his conversion, he must have had much cattle and many slaves, which constituted the riches of that early period; and his case would indeed have been peculiarly hard, had he been commanded to divest himself of his servants, and to depart into a strange country very thinly inhabited, without people to protect his flocks and herds from beasts of prey. Nor would his loss have contributed in any degree to the benefit of his slaves, who, as the ranks of men were then adjusted, could not long have preserved their liberty. Had they not been forcibly reduced to their former state by their idolatrous countrymen, which in all probability they would have been, they must have soon submitted to it, or perished by hunger. Let it be remembered, too, that the bond-servants of Abraham, though constituting the most valuable part of his property, were not considered as a species of inferior beings, but were treated rather as children than as slaves. This is evident from his speaking of the steward of his house as his heir, when complaining to God of the want of seed. Indeed the manner in which this circumstance is mentioned, shows that it was then the general practice to consider domestic slaves as members of the family; for the patriarch does not say, "I will leave my substance to this Eliezer of Damascus;" but his words are, "Behold to me thou has given no seed; and lo, one born in my house is *my heir**." From this mode of expression we are strongly inclined to think that captives taken in war were in that age of simplicity incorporated into the family or tribe of the conqueror, as they are said to be at present among the North American Indians, to supply the place of those who had fallen in battle. If so, slavery was then a very mild thing, unattended with the evils which are now in its train, and must often have been highly beneficial to the captive.

* Gen. xv. 3.

33 Answer to the other.

The other part of the objection appears at first sight more formidable; but perhaps a little attention to the design of the Mosaic economy may enable us to remove it even more completely than this. We need not inform our theological readers, that one great purpose for which the posterity of Abraham were separated from the heathen nations around them, was to preserve the knowledge of the true God in a world run headlong into idolatry. As idolatry appears to have had something in its forms of worship extremely captivating to rude minds, and as the minds of the Israelites at the era of their departure from Egypt were exceedingly rude, every method was taken to keep their separation from their idolatrous neighbours as complete as possible. With this view they were commanded to sacrifice the animals which their Egyptian masters had worshipped as gods, and were taught to consider hogs and such other creatures as the heathen offered in sacrifice, when celebrating their mystical and magic rites, as too unclean to be eaten or even to be touched. Of this distinction between clean and unclean beasts, God himself assigns the reason: "I am the Lord your God (says he), who have separated you from other people; ye shall therefore put difference between clean and unclean beasts, and between unclean fowls and clean†." For the same reason they were prohibited from intermarrying with the heathen, or having any transaction whatever with them as neighbours; and the seven idolatrous nations of Canaan they were strictly commanded to exterminate. "When the Lord thy God (says Moses) shall deliver them before thee, thou shalt smite them, and utterly destroy them: thou shalt make no covenant with them, nor show mercy unto them: neither shalt thou make marriages with them; thy daughter thou shalt not give unto his son, nor his daughter shalt thou take to thy son; for they will turn away thy son from following me, that they may serve other gods‡."

† Lev. xx. 24, 25, 26.

‡ Deut. vii. 2, 3, 4.

Under these laws, it is plain that no intercourse whatever could have place between an Israelite and a man of any other nation, unless the latter was reduced to such a state as that he could neither tempt the former, nor practise himself the rites of his idolatrous worship. But

Slavery, Slave-trade.

But the Israelites were not separated from the rest of the world for their own sakes only: They were intended to be the repositaries of the lively oracles of God, and gradually spread the light of divine truth through other nations, till the fulness of time should come, when in Christ all things were to be gathered together in one. To answer this end, it was necessary that there should be some intercourse between them and their Gentile neighbours; but we have seen that such an intercourse could only be that which subsists between masters and their slaves.

Should this apology for the slavery which was authorised by the Jewish law be deemed fanciful, we beg leave to submit to the consideration of our readers the following account of that matter, to which the same objection will hardly be made. It was morally impossible that between nations differing so widely in religion, customs, and manners, as the Jews and Gentiles, peace should for ever reign without interruption; but when wars broke out, battles would be fought, and prisoners would be taken. How were these prisoners to be disposed of? Cartels for exchange were not then known: it was the duty of the Israelites to prevent their captives from taking up arms a second time against them; they could not establish them among themselves either as artificers or as husbandmen; for their law enjoined them to have no communication with the heathen. There was therefore no other alternative but either to massacre them in cold blood, or to reduce them to the condition of slaves. It would appear, however, that those slaves were raised to the rank of citizens, or at least that their burdens were much lightened, as soon as they were convinced of the truth of the Mosaic revelation, and received into covenant with God by the rite of circumcision. They were then admitted to the celebration of the passover; concerning which one law was decreed to the stranger, and to him that was home-born. Indeed, when we consider who was the legislator of the Jews; when we reflect upon the number of laws enacted to mitigate slavery among them, and call to mind the means by which the due execution of all their laws was enforced, (see THEOLOGY), we cannot help being of opinion that the heathen, who was reduced to slavery in Judea, might be happier, if he pleased, than when living as a freeman in his own country. But whether this be so or not, is a matter with which we have no concern. On account of the hardness of their hearts, and the peculiarity of their circumstances, many things, of which slavery may have been one, were permitted to the Jews, which, if practised by Christians, would render them highly guilty.

After treating thus largely of slavery in general, we need not occupy much of the reader's time with the

34 Slave-trade. SLAVE-TRADE carried on by the merchants of Europe with the natives of Africa. It is well known that the Portuguese were the first Europeans who embarked in this trade, and that their example was soon followed by the Dutch and the English. Of the rise and progress of the English commerce in slaves, the reader will find a sufficient account in other articles of this work *. That commerce, though long cherished by the government as a source of national and colonial wealth, was from its commencement considered by the thinking part of the nation as a traffic inconsistent with the rights of man, and suspected to be carried on by acts of violence. These suspicions were gradually spread through the people at large, and confirmed, in many instances, by evidence incontrovertible. Laws were in consequence enacted to make the negroes more comfortable on what is called the middle passage, and to protect them against the wanton cruelty of their masters in the West Indies: but the humanity of the nation was roused; and not many years ago a number of gentlemen of the most respectable characters, finding that no adequate protection could be afforded to persons in a state of hopeless servitude, formed themselves into a society at London, for the purpose of procuring a total abolition of the slave-trade. That the motives which influenced the leading men of this society were of the purest kind, cannot, we think, be questioned; for their object was to deliver those who had none to help them, and from whom they could expect no other reward for their labours of love than the blessings of them who were ready to perish. To a cause truly Christian, who did not pray for success? or who but must have felt the most pungent regret, if that success had been rendered doubtful, or even delayed, by the imprudence of some of the agents employed by the society? This we apprehend was really the case. Language calculated only to exasperate the planters could not serve the negroes; and the legislature of Great Britain would never suffer itself to be forced into any measure by the menaces of individuals.

*See Company, and Guinea.

In the year 1793, petitions were presented to parliament for the abolition of this inhuman traffic, which gave a pleasing picture of the philanthrophy of the nation; but, unfortunately for the cause of freedom, it was discovered that many of the names subjoined to those petitions had been collected by means not the most honourable. The discovery, perhaps, would never have been made, had not the insulting epithets indiscriminately heaped upon the slave-holders provoked those men to watch with circumspection over the conduct of their opponents. The consequence was, that suspicions of unfair dealing on the part of the petitioners were excited in the breasts of many who, though they ardently wished well to the cause, chose not to add their names to those of school-boys under age, and of peasants who knew not what they were subscribing. Let the rights of the Africans be maintained with ardour and firmness; but never let their advocates suppose that the cause of humanity requires the support of artifice. Absolute slavery, in which the actions of one man are regulated by the caprice of another, is a state demonstrably inconsistent with the obvious plan of the moral government of the world. It degrades the mental faculties of the slave, and throws, both in his way and in his master's, temptations to vice almost insurmountable. Let these truths be set in a proper light by those who have doubtless seen them exemplified; and they will surely have their full effect on the minds of a generous, and, we trust, not an impious people (N). The trade will be generally abolished; pains will be taken 35 Petitions for the abolition of it.

(N) We have not insisted upon the impolicy of the slave trade, or endeavoured to prove that its abolition would

Slave-trade.

ken to cultivate the minds of the West Indian negroes; and the era may be at no great distance when slavery shall cease through all the British dominions.

36 Objection to the abolition

But what benefit, it will be asked, will the negroes of Africa reap from an abolition of the slave-trade? Should any thing so wildly incredible happen, as that all the nations of Christendom, in one common paroxysm of philanthropy, should abandon this commerce in servants, which has been prosecuted in all ages, and under all religions; they would only abandon it to those who were originally possessed of it, who still penetrate into the country, and who even push up to Gago at the very head of the Slave coast, and leave the wool-headed natives of it to Mahometan masters, in preference to Christian. Under such masters they were in Judea at the time of the crusades. Under such, as we learn from Messrs Saugnier, Brisson, and others, they still are in the deserts of Africa, as well as in the islands of Johanna and Madagascar*; and it is universally known that they enslave one another as a punishment for the most whimsical crimes. Among them, indeed, slavery seems to be reduced to a system, and to descend, as it has done in more polished nations, from father to son; for both Saugnier and Wadstrom† speak of particular families of negroes who are exempted from that degrading state by the laws of the country.

* *Asiatic Researches*, vol. ii.

† *Essay on Colonization.*

37 of no strength.

All this we admit to be true. Most certainly the negroes would not be exempted from the miseries of servitude, though Europe and the West Indies were swallowed up in the ocean. The *customs* of the country, as the king of Dahomy assured Mr Abson ‡, will be *made* as long as black men shall continue to possess their own territories, in their present state of depravity and ignorance; and these customs appear to involve slavery of the cruellest kind. But if slavery be in itself unlawful, is it a sufficient excuse for our continuing the traffic that it is carried on by the rude negroes and the savage Arabs? Are people, whom we sometimes affect to consider as an inferior order of beings, to furnish examples of conduct to those who boast of their advancements in science, in literature, and in refinement? Or will the benevolent Lord of all things pardon us for oppressing our helpless brethren, merely because they are cruelly oppressed by others? It is indeed true that the natives of Guinea cannot be made really free but by introducing among them the blessings of religion and the arts of civil life; but surely they would have fewer temptations than at present to kidnap one another, or to commence unprovoked wars for the purpose of making captives, were the nations of Europe to abandon the commerce in slaves (o). That commerce, we grant, would be continued by the Arabs, and perhaps by others of the eastern nations; but the same number of people could not be carried off by them alone that is now carried off both by them and by the Europeans.

‡ *Dalzel's History.*

Were it indeed possible to put the slave-trade under proper regulations, so as to prevent all kidnapping and unjust wars among the Africans, to supply the markets; and were it likewise possible to ensure to the negroes in the West Indies mild treatment and religious instruction, we are far from being sure that while the natives of Guinea continue so rude, and their neighbours the Arabs so selfishly savage, it would be proper to abandon at once to hordes of barbarians the whole of this commerce in bond servants. "The trade, which in its present form is a reproach to Britain, might be made to take a new shape, and become ultimately a blessing to thousands of wretches who, left in their native country, would have dragged out a life of miserable ignorance, unknowing the hand that framed them, unconscious of the reason of which they were made capable, and heedless of the happiness laid up for them in store §."

§ *Ramsay's Essay*, p. 292, &c.

Slavery is, indeed, in every form an evil; but it seems to be one of those many evils which, having long prevailed in the world, can be advantageously removed only by degrees, and as the moral cultivation of the slaves may enable them to support the rank and discharge the duties of free men. This is doubtless the reason why it was not expressly prohibited by the divine Author of our religion, but suffered to vanish gradually before the mild influence of his Heavenly doctrines. It has vanished before these doctrines in most countries of Europe; and it affords us no small gratification to have it in our power to record, what indeed must be fresh in the memory of our readers, that the abolition of the slave-trade was finally accomplished by the steady perseverance and generous exertions of some of the most enlightened and respectable characters in the kingdom, who, after a long and arduous struggle, obtained a decree of the legislature, prohibiting, after a limited period, the trade in slaves to be continued by subjects of Britain. The bill originated in the house of lords, and having undergone considerable discussion in the house of commons, finally passed on the 16th of March, and received his majesty's assent

38 Abolition of the slave-trade in Britain.

would be *advantageous* to the sugar-planters; for the planters surely understand their own interest better than those can do, who, having never been in the West Indies, are obliged to content themselves with what information they can glean on the subject from a number of violent and contradictory publications. To countenance slavery under any form is undoubtedly immoral. This we know: and therefore upon this ground have we opposed the slave-trade, which cannot be continued without preferring interest to virtue.

(o) In a speech which Mr Dalzel says the king of Dahomy made to Mr Abson, when he was informed of what had passed in England on the subject of the slave-trade, are these remarkable words: "In the name of my ancestors and myself, I aver that no Dahoman ever embarked in war merely for the sake of procuring wherewithal to purchase your commodities." We must take the liberty to question the truth of this solemn averment. That the slave-trade is not the *sole* cause of the Dahoman wars every man will admit, who does not fancy that those people have neither passions nor appetites, but for the commodities of Europe: but the bare affirmation of this bloody despot, who boasted of having killed many thousands at the *customs*, will not convince those who have read either Wadstrom's Essay on Colonization, or the evidence respecting the slave-trade given at the bar of the house of commons, "that no Dahoman *ever* embarked in war merely to procure slaves to barter for European commodities."

assent on the 25th March 1807. The time fixed by the bill, for the total abolition of the trade, we believe, was the beginning of the following year, viz. January 1808.

We cannot conclude without expressing a hope, that the period is not very distant when the slaves in the West Indies shall be so much improved in moral and religious knowledge, as that they may be safely trusted with their own freedom. To set them free in their present state of ignorance and depravity, is one of the wildest proposals that the ardour of innovation has ever made. Such freedom would be equally ruinous to themselves and to their masters; and we may say of it what Cicero said of some unseasonable indulgences proposed to be granted to the slaves in Sicily: *Quæ cum accidunt, nemo est, quin intelligat ruere illam rempublicam; hæc ubi veniunt, nemo est, qui ullam spem salutis reliquam esse arbitretur.*

Those of our readers who wish to enter into a detail of this subject, may consult, with much advantage, The History of the Rise, Progress, and Accomplishment of the Abolition of the African Slave-Trade, by Mr Clarkson, 2 vols 8vo.

SLAUGHTER. See MANSLAUGHTER, HOMICIDE, MURDER, &c.

SLEDGE, a kind of carriage without wheels, for the conveyance of very weighty things, as huge stones, bells, &c. The sledge for carrying criminals, condemned for high treason, to execution, is called HURDLE. The Dutch have a kind of sledge on which they can carry a vessel of any burden by land. It consists of a plank of the length of the keel of a moderate ship, raised a little behind, and hollow in the middle; so that the sides go a little aslope, and are furnished with holes to receive pins, &c. The rest is quite even.

SLEDGE is a large smith's hammer, to be used with both hands: of this there are two sorts, the up-hand sledge, which is used by under workmen, when the work is not of the largest sort; it is used with both the hands before, and they seldom raise it higher than their head. But the other, which is called the about-sledge, and which is used for battering or drawing out the largest work, is held by the handle with both hands, and swung round over their heads, at their arm's end, to strike as hard a blow as they can.

SLEEP, that state of the body in which, though the vital functions continue, the senses are not affected by the ordinary impressions of external objects. See DREAMS and PHYSIOLOGY.

SLEEP-Walker, one who walks in his sleep. Many instances might be related of persons who were addicted to this practice; but it will be sufficient to select one remarkable instance from a report made to the Physical Society of Lausanne, by a committee of gentlemen appointed to examine a young man who was accustomed to walk in his sleep.

"The disposition to sleep-walking seems, in the opinion of this committee, to depend on a particular affection of the nerves, which both seizes and quits the patient during sleep. Under the influence of this affection, the imagination represents to him the objects that struck him while awake, with as much force as if they really affected his senses; but does not make him perceive any of those that are actually presented to his senses, except in so far as they are connected with the dreams which engross him at the time. If, during this state, the imagination has no determined purpose, he receives the impression of objects as if he were awake; only, however, when the imagination is excited to bend its attention towards them. The perceptions obtained in this state are very accurate, and, when once received, the imagination renews them occasionally with as much force as if they were again acquired by means of the senses. Lastly, these academicians suppose, that the impressions received during this state of the senses disappear entirely when the person awakes, and do not return till the return of the same disposition in the nervous system.

Sleep-walker.

"Their remarks were made on the Sieur Devaud, a lad thirteen years and a half old, who lives in the town of Vevey, and who is subject to that singular affection or disease called *Somnambulism* or sleep-walking. This lad possesses a strong and robust constitution, but his nervous system appears to be organised with peculiar delicacy, and to discover marks of the greatest sensibility and irritability. His senses of smell, taste, and touch, are exquisite; he is subject to fits of immoderate and involuntary laughter, and he sometimes likewise weeps without any apparent cause.

"This young man does not walk in his sleep every night; several weeks sometimes pass without any appearance of a fit. He is subject to the disease generally two nights successively, one fit lasting for several hours. The longest are from three to four hours, and they commonly begin about three or four o'clock in the morning.

"The fit may be prolonged, by gently passing the finger or a feather over his upper lip, and this slight irritation likewise accelerates it. Having once fallen asleep upon a staircase, his upper lip was thus irritated with a feather, when he immediately ran down the steps with great precipitation, and resumed all his accustomed activity. This experiment was repeated several times.

"The young Devaud thinks he has observed, that, on the evenings previous to a fit, he is sensible of a certain heaviness in his head, but especially of a great weight in his eyelids.

"His sleep is at all times unquiet, but particularly when the fits are about to seize him. During his sleep, motions are observable in every part of his body, with starting and palpitations; he utters broken words, sometimes sits up in his bed, and afterwards lies down again. He then begins to pronounce words more distinctly, he rises abruptly, and acts as he is instigated by the dream that then possesses him. He is sometimes in sleep subject to continued and involuntary motions.

"The departure of the fit is always preceded by two or three minutes of calm sleep, during which he snores. He then awakes rubbing his eyes like a person who has slept quietly.

"It is dangerous to awaken him during the fit, especially if it is done suddenly; for then he sometimes falls into convulsions. Having risen one night with the intention of going to eat grapes, he left the house, passed through the town, and went to a vineyard where he expected good cheer. He was followed by several persons, who kept at some distance from him, one of whom fired a pistol, the noise of which instantly awakened him, and he fell down without sense. He was carried home and brought to himself, when he recollected very well the having

Sleep-walker.

having been awakened in the vineyard; but nothing more, except the fright at being found there alone, which had made him swoon.

"After the fits he generally feels a degree of lassitude: sometimes, though rarely, of indisposition. At the end of one of those fits, of which the gentlemen of the committee were witnesses, he was affected with vomitings; but he is always soon restored.

"When he is awaked, he never for the most part recollects any of the actions he has been doing during the fit.

"The subject of his dreams is circumscribed in a small circle of objects, that relate to the few ideas with which at his age his mind is furnished; such as his lessons, the church, the bells, and especially tales of ghosts. It is sufficient to strike his imagination the evening before a fit with some tale, to direct his somnambulism towards the object of it. There was read to him while in this situation the story of a robber; he imagined the very next moment that he saw robbers in the room. However, as he is much disposed to dream that he is surrounded with them, it cannot be affirmed that this was an effect of the reading. It is observed, that when his supper has been more plentiful than usual, his dreams are more dismal.

"In their report, the gentlemen of the committee dwell much on the state of this young man's senses, on the impression made upon them by strange objects, and on the use they are of to him.

"A bit of strong smelling wood produced in him a degree of restlessness; the fingers had the same effect, whether from their smell or their transpiration. He knew wine in which there was wormwood by the smell, and said that it was not wine for his table. Metals make no impression on him.

"Having been presented with a little common wine while he was in a state of apathy, and all his motions were performed with languor, he drank of it willingly; but the irritation which it occasioned produced a deal of vivacity in all his words, motions, and actions, and caused him to make involuntary grimaces.

"Once he was observed dressing himself in perfect darkness. His clothes were on a large table, mixed with those of some other persons; he immediately perceived this, and complained of it much; at last a small light was brought, and then he dressed himself with sufficient precision. If he is teased or gently pinched, he is always sensible of it, except he is at the time strongly engrossed with some other thing, and wishes to strike the offender; however, he never attacks the person who has done the ill, but an ideal being whom his imagination presents to him, and whom he pursues through the chamber without running against the furniture, nor can the persons whom he meets in his way divert him from his pursuit.

"While his imagination was employed on various subjects, he heard a clock strike, which repeated at every stroke the note of the cuckoo. There are cuckoos here, said he; and upon being desired, he imitated the song of that bird immediately.

"When he wishes to see an object, he makes an effort to lift his eyelids; but they are so little under his command, that he can hardly raise them a line or two, while he draws up his eyebrows; the iris at that time appears fixed, and his eye dim. When any thing is presented to him, and he is told of it, he always half opens his eyes with a degree of difficulty, and then shuts them after he has taken what was offered to him.

Sleep-walker.

"The report infers from these facts, and from many others relative to the different senses, that their functions are not suspended as to what the sleep-walker wishes to see, that is, as to all those perceptions which accord with the objects about which his imagination is occupied; that he may also be disposed to receive those impressions, when his imagination has no other object at the time; that in order to see, he is obliged to open his eyes as much as he can, but when the impression is once made, it remains; that objects may strike his sight without striking his imagination, if it is not interested in them; and that he is sometimes informed of the presence of objects without either seeing or touching them.

"Having engaged him to write a theme, say the committee, we saw him light a candle, take pen, ink, and paper, from the drawer of his table, and begin to write, while his master dictated. As he was writing, we put a thick paper before his eyes, notwithstanding which he continued to write and to form his letters very distinctly; showing signs, however, that something was incommoding him, which apparently proceeded from the obstruction which the paper, being held too near his nose, gave to his respiration.

"Upon another occasion, the young somnambulist arose at five o'clock in the morning, and took the necessary materials for writing, with his copy-book. He meant to have begun at the top of a page; but finding it already written on, he came to the blank part of the leaf, and wrote some time from the following words, *Fiunt ignari pigritia—Ils deviennent ignorans par la paresse;* and, what is remarkable, after several lines he perceived he had forgotten the *s* in the word *ignorans*, and had put erroneously a double *r* in *paresse;* he then gave over writing, to add the *s* he had forgotten, and to erase the superfluous *r*.

"Another time he had finished, of his own accord, a piece of writing, in order, as he said, to please his master. It consisted of three kinds of writing, text, half text, and small hand; each of them performed with the proper pen. He drew, in the corner of the same paper, the figure of a hat; he then asked for a penknife to take out a blot of ink which he had made between two letters, and he erased it without injuring them. Lastly, he made some arithmetical calculations with great accuracy.

"In order to explain some of the facts observed by the academicians which we have here mentioned, they establish two general observations, which result from what they have said with respect to the senses and the dreams of this sleep-walker.

"1. That he is obliged to open his eyes, in order to recognise objects which he wishes to see; but the impression once made, although rapidly, is vivid enough to supersede the necessity of his opening them again, to view the same objects anew; that is, the same objects are afterwards presented to his imagination with as much force and precision as if he actually saw them.

"2. That his imagination, thus warmed, represents to him objects, and such as he figures to himself, with as much vivacity as if he really saw them; and, lastly, that all his senses, being subordinate to his imagination, seem

seem concentrated in the object with which it is occupied, and have at that time no perception of any thing but what relates to that object.

"These two causes united seem to them sufficient for explaining one of the most singular facts that occurred to their observation, to wit, how the young Devaud can write, although he has his eyes shut, and an obstacle before them. His paper is imprinted on his imagination, and every letter which he means to write is also painted there, at the place in which it ought to stand on the paper, and without being confounded with the other letters; now it is clear that his hand, which is obedient to the will of his imagination, will trace them on the real paper, in the same order in which they are represented on that which is pictured in his head. It is thus that he is able to write several letters, several sentences, and entire pieces of writing; and what seems to confirm the idea, that the young Devaud writes according to the paper painted on his imagination is, that a certain sleep-walker, who is described in the French *Encyclopédie* (article *Somnambulism*), having written something on a paper, another piece of paper of the same size was substituted in its stead, which he took for his own, and made upon this blank paper the corrections he meant to have made on the other which had been taken away, precisely in the places where they would have been.

"It appears from the recital of another fact, that Devaud, intending to write at the top of the first leaf of a white paper book, *Vevey le* — stopped a moment as if to recollect the day of the month, left a blank space, and then proceeded to *Decembre* 1787; after which he asked for an almanac: a little book, such as is given to children for a new year's gift, was offered to him; he took it, opened it, brought it near his eyes, then threw it down on the table. An almanac which he knew was then presented to him; this was in German, and of a form similar to the almanac of Vevey: he took it, and then said, 'What is this they have given me; here, there is your German almanac.' At last they gave him the almanac of Berne; he took this likewise, and went to examine it at the bottom of an alcove that was perfectly dark. He was heard turning over the leaves, and saying 24, then a moment afterwards 34. Returning to his place, with the almanac open at the month of December, he laid it on the table and wrote in the space which he had left blank the 24th. This scene happened on the 23d; but as he imagined it to be the 24th, he did not mistake. The following is the explication given of this fact by the authors of the report.

"The dates 23d, 24th, and 25th, of the month of December, had long occupied the mind of the young Devaud. The 23d and 25th were holidays, which he expected with the impatience natural to persons of his age, for the arrival of those moments when their little daily labours are to be suspended. The 25th especially was the object of his hopes; there was to be an illumination in the church, which had been described to him in a manner that quite transported him. The 24th was a day of labour, which came very disagreeably between the two happy days. It may easily be conceived, how an imagination so irritable as that of the young Devaud would be struck with those pleasing epochs. Accordingly, from the beginning of the month he had been perpetually turning over the almanac of Vevey. He calculated the days and the hours that were to elapse before the arrival of his wished for holidays; he showed to his friends and acquaintance the dates of those days which he expected with so much impatience; every time he took up the almanac, it was only to consult the month of December. We now see why that date presented itself to his mind. He was performing a task, because he imagined the day to be the Monday which had so long engrossed him. It is not surprising, that it should have occurred to his imagination, and that on opening the almanac in the dark he might have thought he saw this date which he was seeking, and that his imagination might have represented it to him in as lively a manner as if he had actually seen it. Neither is it surprising that he should have opened the almanac at the month of December; the custom of perusing this month must have made him find it in the dark by a mere mechanical operation. Man never seems to be a machine so much as in the state of somnambulism; it is then that habit comes to supply those of the senses that cannot be serviceable, and that it makes the person act with as much precision as if all his senses were in the utmost activity. These circumstances destroy the idea of there being any thing miraculous in the behaviour of young Devaud with respect to the date and the month that he was in quest of; and the reader, who has entered into our explanations, will not be surprised at his knowing the German almanac; the touch alone was sufficient to point it out to him; and the proof of this is the shortness of the time that it remained in his hands.

"An experiment was made by changing the place of the ink-standish during the time that Devaud was writing. He had a light beside him, and had certified himself of the place where his ink-holder was standing by means of sight. From that time he continued to take ink with precision, without being obliged to open his eyes again: but the ink-standish being removed, he returned as usual to the place where he thought it was: It must be observed, that the motion of his hand was rapid till it reached the height of the standish, and then he moved it slowly, till the pen gently touched the table as he was seeking for the ink: he then perceived that a trick had been put on him, and complained of it; he went in search of his ink-standish and put it in its place. This experiment was several times repeated, and always attended with the same circumstances. Does not what we have here stated prove, that the standish, the paper, the table, &c. are painted on his imagination in as lively a manner as if he really saw them, as he sought the real standish in the place where his imagination told him it ought to have been? Does it not prove that the same lively imagination is the cause of the most singular actions of this sleep-walker? And lastly, does it not prove, that a mere glance of his eye is sufficient to make his impressions as lively as durable?

"The committee, upon the whole, recommend to such as wish to repeat the same experiments, 1. To make their observations on different sleep-walkers. 2. To examine often whether they can read books that are unknown to them in perfect darkness. 3. To observe whether they can tell the hours on a watch in the dark. 4. To remove when they write the ink-standish from its place, to see whether they will return to the same place in in order to take ink. 5. And, lastly, to take notice whether they walk with the same confidence in a dark and unknown place, as in one with which they are acquainted.

"They likewise recommend to such as would confirm or invalidate the above observations, to make all their experiments in the dark; because it has been hitherto supposed that the eyes of sleep-walkers are of no use to them."

SLEEPERS, in *Natural History*, a name given to those animals which sleep all winter; such as bears, marmots, dormice, bats, hedgehogs, swallows, &c. These do not feed in winter, have no sensible evacuations, breathe little or none at all, and most of the viscera cease from their functions. Some of these animals seem to be dead, and others return to a state like that of the fœtus before birth: in this state they continue, till by an increase of heat the animal is restored to its former functions.

SLEEPERS, in a ship, timbers lying before and aft in the bottom of the ship, as the rungheads do: the lowermost of them is bolted to the rungheads, and the uppermost to the futtocks and rungs.

SLEIDAN, JOHN, an excellent German historian, born of obscure parents, in 1506, at Sleidan, a small town on the confines of the duchy of Juliers. After studying some time in his own country, together with his townsman the learned John Sturmius, he went to France, and in 1525 entered into the service of the cardinal and archbishop John du Bellay. He retired to Strasburg in 1542, where he acquired the esteem and friendship of the most considerable persons, particularly of James Sturmius; by whose advice and assistance he was enabled to write the history of his own time. He was employed in some public negociations; but the death of his wife, in 1555, plunged him into so deep a melancholy, that he lost his memory entirely, and died the year following. In 1555 came out, in folio, *De statu Religionis et Reipublicæ sub Carolo Quinto*, &c. in 15 books; from the year 1517, when Luther began to preach, to the year of its publication; which history was presently translated into most of the languages of Europe. Besides this great work, he wrote, *De quatuor summis Imperiis, libri tres;* with some other historical and political pieces.

SLEIGHT *of* HAND. See LEGERDEMAIN.

SLESWICK, an ancient and considerable town of Denmark, the metropolis of a duchy of the same name, in the province of Gottorp, the see of a bishop, which was secularized in the year 1586. The old palace of Gottorp is close to it, which was formerly the ducal residence, but afterwards inhabited by the governor. This town at one period was much more extensive than it is now, having suffered greatly by the German wars. It is seated on the gulf of Sley, where there is a commodious harbour, 60 miles north-west of Lubeck, and 125 south-west of Copenhagen. The people boast that the German language is here spoken with as much accuracy as at Vienna, of which, however, a good German scholar can alone be judge. Sleswick has but little trade, as none but small boats can have access to it, the passage of the Sley having been long since choked up with sand and mud; before which period it was both flourishing and populous. It is now chiefly inhabited by the officers of the castle, and the poorer classes, or the attendants on the court and on them. The present population is said to be about 7000. E. Long. 10. 0. N. Lat. 54. 40.

SLESWICK, the duchy of, or *South Jutland*, is about 100 miles in length and 60 in breadth, and contains 3600 square English miles, and in 1802 about 340,800 inhabitants. It is bounded on the north by North Jutland, on the east by the Baltic sea, on the south by Holstein, and on the west by the ocean. It contains 14 cities, 17 towns, 13 castles, 278 parishes, 1480 villages, 162 farms, 116 water-mills, and 106 gentlemen's seats. It is a pleasant, fertile, populous country, and a sovereign duchy. Formerly the king of Denmark had half of it, and the other belonged to the house of Holstein-Gottorp; but the former having conquered this duchy, had the possession of it confirmed to him by the treaty of the north in 1720.

SLEUT-HOUNDE, the ancient Scots name of the blood-hound. The word is from the Saxon *slot*, "the impression that a deer leaves of its foot in the mire," and *hound*, "a dog;" so they derive their name from following the track. See the article *BLOOD-HOUND*.

SLICH, in *Metallurgy*, the ore of any metal, particularly of gold, when it has been pounded, and prepared for farther working.

The manner of preparing the slich at Chremnitz in Hungary is this; they lay a foundation of wood three yards deep, upon this they place the ore, and over this there are 24 beams, armed at their bottoms with iron; these, by a continual motion, beat and grind the ore, till it is reduced to powder: during this operation, the ore is covered with water. There are four wheels used to move these beams, each wheel moving six; and the water, as it runs off, carrying some of the metalline particles with it, is received into several basons, one placed behind another; and finally, after having passed through them all, and deposited some sediment in each, it is let off into a very large pit, almost half an acre in extent; in which it is suffered to stand so long as to deposit all its sediment, of whatever kind, and after this it is let out. This work is carried on day and night, and the ore taken away and replaced by more as often as occasion requires. That ore which lies next the beams, by which it was pounded, is always the cleanest or richest.

When the slich is washed as much as they can, a hundred weight of it usually contains about an ounce, or perhaps but half an ounce of metal, which is not all gold; for there is always a mixture of gold and silver, but the gold is in the largest quantity, and usually is two-thirds of the mixture: they then put the slich into a furnace with some limestone, and slacken, or the scoria of former meltings, and run them together. The first melting produces a substance called *lech;* this lech they burn with charcoal, to make it lighter, to open its body, and render it porous, after which it is called *rost;* to this rost they add sand in such quantity as they find necessary, and then melt it over again.

At Chremnitz many other ways are practised of reducing gold out of its ore, but particularly one, in which they employ no lead during the whole operation; whereas, in general, lead is always necessarily, after the before-mentioned processes. See *ORES, Reduction of.*

SLIDING RULE, a mathematical instrument, serving to work questions in gauging, measuring, &c. without

Sliding || Sloane.

out the use of compasses; merely by the sliding of the parts of the instrument one by another, the lines and divisions whereof give the answer by inspection.

This instrument is variously contrived, and applied by various authors, particularly Everard, Coggeshall, Gunter, Hunt, and Partridge; but the most common and useful are those of Everard and Coggeshall.

SLIGO, a county in the province of Connaught, Ireland, 31 miles in length, and 29 in breadth; bounded on the east by that of Leitrim, on the west by the county of Mayo, on the north and north-west by the western ocean, and on the south and south-west by Roscommon and Mayo. It contains 11,500 houses, 41 parishes, 60,000 inhabitants, and sends two members to parliament.

Sligo, the only market town in the county, contains 8000 inhabitants, and enjoys a considerable trade, is seated on a bay of the same name, 30 miles west of Killalla, and 110 north-east of Dublin. W. Long, 8. 26. N. Lat. 54. 13.

SLING, an instrument serving for casting stones with great violence. The inhabitants of the Balearic islands were famous in antiquity for the dexterons management of the sling; it is said they used three kinds of slings, some longer, others shorter, which they used according as their enemies were either nearer or more remote. It is added, that the first served them for a head-band, the second for a girdle, and that the third they constantly carried in their hand.

SLINGING is used variously at sea; but chiefly for hoisting up casks or other heavy things with slings, i. e. contrivances of ropes spliced into themselves at either end, with one eye big enough to receive the cask or whatever is to be slung. There are other slings, which are made longer, and with a small eye at each end; one of which is put over the breech of a piece of ordnance, and the other eye comes over the end of an iron crow, which is put into the mouth of the piece, to weigh and hoist the gun as they please. There are also slings by which the yards are bound fast to the cross-tree aloft, and to the head of the mast, with a strong rope or chain, that if the tie should happen to break, or to be shot to pieces in fight, the yard, nevertheless, may not fall upon the hatches.

Slinging a Man overboard, in order to stop a leak in a ship, is done thus: the man is trussed up about the middle in a piece of canvas, and a rope to keep him from sinking, with his arms at liberty, a mallet in one hand, and a plug, wrapped in oakum and well tarred in a tarpawling clout, in the other, which he is to beat with all dispatch into the hole or leak.

SLOANE, Sir Hans, Baronet, eminently distinguished as a physician and a naturalist, was of Scotch extraction, his father Alexander Sloane being at the head of that colony of Scots which King James I. settled in the north of Ireland, where our author was born, at Killieagh, on the 19th of April 1660. At a very early period, he displayed a strong inclination for natural history; and this propensity being encouraged by a suitable education, he employed those hours which young people generally lose by pursuing low and trifling amusements, in the study of nature, and contemplating her works. When about sixteen, he was attacked by a spitting of blood, which threatened to be attended with considerable danger, and which interrupted the regular course of his application for three years; he had, however, already learned enough of physic to know that a malady of this kind was not to be removed suddenly, and he prudently abstained from wine and other liquors that were likely to increase it.

Sloane.

By strictly observing this severe regimen, which in some measure he continued ever after, he was enabled to prolong his life beyond the ordinary bounds; being an example of the truth of his own favourite maxim, that sobriety, temperance, and moderation, are the best and most powerful preservatives that nature has granted to mankind.

As soon as he recovered from this infirmity, he resolved to perfect himself in the different branches of physic, which was the profession he had made choice of; and with this view he repaired to London, where he hoped to receive that assistance which he could not find in his own country.

On his arrival in the metropolis, he entered himself as a pupil to the great Stafforth, an excellent chemist, bred under the illustrious Stahl; and by his instructions he gained a perfect knowledge of the composition and preparation of the different kinds of medicines then in use. At the same time, he studied botany at the celebrated garden at Chelsea, assiduously attended the public lectures of anatomy and physic, and in short neglected nothing that he thought likely to prove serviceable to him in his future practice. His principal merit, however, was his knowledge of natural history; and it was this part of his character which introduced him early to the acquaintance of Mr Boyle and Mr Ray, two of the most eminent naturalists of that age. His intimacy with these distinguished characters continued as long as they lived; and as he was careful to communicate to them every object of curiosity that attracted his attention, the observations which he occasionally made often excited their admiration and obtained their applause.

After studying four years at London with unremitting severity, Mr Sloane determined to visit foreign countries for farther improvement. In this view he set out for France in the company of two other students, and having crossed to Dieppe, proceeded to Paris. In the way thither they were elegantly entertained by the famous M. Lemery the elder; and in return Mr Sloane presented that eminent chemist with a specimen of four different kinds of phosphorus, of which, upon the credit of other writers, M. Lemery had treated in his book of chemistry, though he had never seen any of them.

At Paris Mr Sloane lived as he had done in London. He attended the hospitals, heard the lectures of Tournefort, De Verney, and other eminent masters; visited all the literati, who received him with particular marks of esteem, and employed himself wholly in study.

From Paris Mr Sloane went to Montpelier; and, being furnished with letters of recommendation from M. Tournefort to M. Chirac, then chancellor of that university, he found easy access, through his means, to all the learned men of the province, particularly to M. Magnol, whom he always accompanied in his botanical excursions in the environs of that city, where he beheld with pleasure and admiration the spontaneous productions of nature, and learned under his instructions to class them in a proper manner.

Sloane.

Having here found an ample field for contemplation, which was entirely suited to his taste, he took leave of his two companions, whom a curiosity of a different kind led into Ialy.

After spending a whole year in collecting plants, he travelled through Languedoc with the same design; and passing through Thoulouse and Bourdeaux, returned to Paris, where he made a short stay. About the end of the year 1684 he set out for England, with an intention of settling there as a physician. On his arrival in London, he made it his first business to visit his two illustrious friends Mr Ray and Mr Boyle, in order to communicate to them the discoveries he had made in his travels. The latter he found at home, but the former had retired to Essex; to which place Mr Sloane transmitted a great variety of plants and seeds, which Mr Ray has described in his History of Plants, and for which he makes a proper acknowledgement.

About the year 1706 our author became acquainted with the celebrated Sydenham; who soon contracted so warm an affection for him that he took him into his house, and recommended him in the strongest manner to his patients. He had not been long in London before he was proposed by Dr Martin Lister as a candidate to be admitted a member of the Royal Society, on the 26th of November 1684; and being approved, he was elected on the 21st of January following.

In 1685 he communicated some curiosities to the Society; and in July the same year he was a candidate for the office of their assistant secretary, but without success, as he was obliged to give way to the superior interest of his competitor Dr Halley. On the 12th of April 1687, he was chosen a fellow of the college of physicians in London; and the same year his friend and fellow traveller Dr Tancred Robinson, having mentioned to the Society the plant called the *star of the earth*, as a remedy newly discovered for the bite of a mad dog, Dr Sloane acquainted them that this virtue of the plant was to be found in a book called *De Grey's Farriery;* and that he knew a man who had cured with it twenty couple of dogs. This observation he made on the 13th of July, and on the 12th of September following he embarked at Portsmouth for Jamaica with the duke of Albemarle, who had been appointed governor of that island. The doctor attended his grace in quality of physician, and arrived at Jamaica on the 19th of December following.

Here a new field was opened for fresh discoveries in natural productions; but the world would have been deprived of the fruits of them, had not our author, by incredible application, converted, as we may say, his minutes into hours. The duke of Albemarle died soon after he landed, and the duchess determined to return to England whenever an answer should be received to the letter she had sent to court on that melancholy occasion. As Dr Sloane could not think of leaving her grace in her distress, whilst the rest of her retinue were preparing for their departure, he improved it in making collections of natural curiosities; so that, though his whole stay at Jamaica was not above fifteen months, he brought together such a prodigious number of plants, that on his return to England, Mr Ray was astonished that one man could procure in one island, and in so short a space, so vast a variety.

On his arrival in London, he applied himself to the practice of his profession; and soon became so eminent, that he was chosen physician to Christ's hospital on the 17th October 1694: and this office he held till the year 1730, when, on account of his great age and infirmities, he found it necessary to resign. It is somewhat singular, and redounds much to the doctor's honour, that though he received the emoluments of his office punctually, because he would not lay down a precedent which might hurt his successors, yet he constantly applied the money to the relief of those who were the greatest objects of compassion in the hospital, that it might never be said he enriched himself by giving health to the poor. He had been elected secretary to the Royal Society on the 30th of November 1693; and upon this occasion he revived the publication of the Philosophical Transactions, which had been omitted for some time. He continued to be the editor of this work till the year 1712; and the volumes which appeared during that period are monuments of his industry and ingenuity, many of the pieces contained in them being written by himself.

In the mean time he published *Catalogus Plantarum quæ in Insula Jamaica sponte proveniunt*, &c.; *seu Prodromi Historiæ Naturalis pars prima*; which he dedicated to the Royal Society and College of Physicians. About the same time he formed the plan of a dispensary, where the poor might be furnished at prime cost with such medicines as their several maladies might require; which he afterwards carried into execution, with the assistance of the president and other members of the college of physicians.

Our author's thirst for natural knowledge seems to have been born with him, so that his cabinet of curiosities may be said to have commenced with his being. He was continually enriching and enlarging it; and the fame which, in the course of a few years, it had acquired, brought every thing that was curious in art or nature to be first offered to him for purchase. These acquisitions, however, increased it but very slowly in comparison of the augmentation it received in 1701 by the death of William Courten, Esq. a gentleman who had employed all his time, and the greater part of his fortune, in collecting rarities, and who bequeathed the whole to Dr Sloane, on condition of his paying certain debts and legacies with which he had charged it. These terms our author accepted, and he executed the will of the donor with the most scrupulous exactness; on which account some people have said, that he purchased Mr Courten's curiosities at a dear rate.

In 1707 the first volume of Dr Sloane's Natural History of Jamaica appeared in folio, though the publication of the second was delayed till 1725. By this very useful as well as magnificent work, the materia medica was enriched with a great number of excellent drugs not before known. In 1708 the Doctor was elected a foreign member of the Royal Academy of Sciences at Paris, in the room of Mr Tschirnaus; an honour so much the greater, as we were then at war with France, and the queen's express consent was necessary before he could accept it. In proportion as his credit rose among the learned, his practice increased among the people of rank: Queen Anne herself frequently consulted him, and in her last illness was blooded by him.

On the advancement of George I. to the throne, that prince, on the 3d of April 1716, created the Doctor a baronet, an hereditary title of honour to which no

Sloane.

no English physician had before attained; and at the same time made him physician general to the army, in which station he continued till 1727, when he was appointed physician in ordinary to George II. He attended the royal family till his death; and was particularly favoured by Queen Caroline, who placed the greatest confidence in his prescriptions. In the mean time he had been unanimously chosen one of the elects of the college of physicians June 1. 1716, and he was elected president of the same body on September 30. 1719, an office which he held for sixteen years. During that period he not only gave the highest proofs of his zeal and assiduity in the discharge of his duty, but in 1721 made a present to that society of 100l.; and so far remitted a very considerable debt, which the corporation owed him, as to accept it in such small sums as were least inconvenient to the state of their affairs. Sir Hans was no less liberal to other learned bodies. He had no sooner purchased the manor of Chelsea, than he gave the company of apothecaries the entire freehold of their botanical garden there, upon condition only that they should present yearly to the Royal Society fifty new plants, till the number should amount to 2000 (A). He gave besides several other considerable donations for the improvement of this garden; the situation of which, on the banks of the Thames, and in the neighbourhood of the capital, was such as to render it useful in two respects: First, by producing the most rare medicinal plants; and, secondly, by serving as an excellent school for young botanists; an advantage which he himself had derived from it in the early part of his life.

The death of Sir Isaac Newton, which happened in 1727, made way for the advancement of Sir Hans to the presidency of the Royal Society. He had been vice-president, and frequently sat in the chair for that great man; and by his long connection with this learned body he had contracted so strong an affection for it, that he made them a present of an hundred guineas, caused a curious bust of King Charles II. its founder, to be erected in the great hall where it met, and, as is said, was very instrumental in procuring Sir Godfrey Copley's benefaction of a medal of the value of five guineas, to be annually given as an honorary mark of distinction to the person who communicates the best experiments to the Society.

On his being raised to the chair, Sir Hans laid aside all thoughts of further promotion, and applied himself wholly to the faithful discharge of the duties of the offices which he enjoyed. In this laudable occupation he employed his time from 1727 to 1740, when, at the age of fourscore, he formed a resolution of quitting the service of the public, and of living for himself. With this view he resigned the presidency of the Royal Society much against the inclination of that respectable body, who chose Martin Folkes, Esq. to succeed him, and in a public assembly thanked him for the great and eminent services he had rendered them. In the month of January 1741, he began to remove his library, and his cabinet of rarities, from his house in Bloomsbury to that at Chelsea; and on the 12th of March following, having settled all his affairs, he retired thither himself, to enjoy in peaceful tranquillity the remains of a well-spent life. He did not, however, bury himself in that solitude which excludes men from society. He received in Chelsea, as he had done in London, the visits of people of distinction, of all learned foreigners, and of the royal family, who sometimes did him the honour to wait on him; but, what was still more to his praise, he never refused admittance or advice to rich or poor who came to consult him concerning their health. Not contented with this contracted method of doing good, he now, during his retreat, presented to the public such useful remedies as success had warranted, during the course of a long continued practice. Among these is the efficacious receipt for distempers in the eyes, and his remedy for the bite of a mad dog.

During the whole course of his life, Sir Hans had lived with so much temperance, as had preserved him from feeling the infirmities of old age; but in his 90th year he began to complain of pains, and to be sensible of an universal decay. He was often heard to say, that the approach of death brought no terrors along with it; that he had long expected the stroke; and that he was prepared to receive it whenever the great Author of his being should think fit. After a short illness of three days, he died on the 11th of January 1752, and was interred on the 18th at Chelsea, in the same vault with his lady, the solemnity being attended with the greatest concourse of people, of all ranks and conditions, that had ever been seen before on the like occasion.

Sir Hans being extremely solicitous lest his cabinet of curiosities, which he had taken so much pains to collect, should be again dissipated at his death, and being at the same time unwilling that so large a portion of his fortune should be lost to his children, he bequeathed it to the public, on condition that 20,000l. should be made good by parliament to his family. This sum, though large in appearance, was scarcely more than the intrinsic value of the gold and silver medals, the ores and precious stones that were found in it; for in his last will he declares, that the first cost of the whole amounted at least to 50,000l. Besides his library, consisting

(A) This garden was first established by the company in 1673; and having after that period been stocked by them with a great variety of plants, for the improvement of botany, Sir Hans, in order to encourage so serviceable an undertaking, granted to the company the inheritance of it, being part of his estate and manor of Chelsea, on condition that it should be for ever preserved as a physic garden. As a proof of its being so maintained, he obliged the company, in consideration of the said grant, to present yearly to the Royal Society, in one of their weekly meetings, fifty specimens of plants that had grown in the garden the preceding year, and which were all to be specifically distinct from each other, until the number of two thousand should be completed. This number was completed in the year 1761. In 1733 the company erected a marble statue of Sir Hans, executed by Rysbrac, which is placed upon a pedestel in the centre of the garden, with a Latin inscription, expressing his donation, and the design and advantages of it.

sisting of more than 50,000 volumes, 347 of which were illustrated with cuts finely engraven and coloured from nature, there were 3560 manuscripts, and an infinite number of rare and curious works of every kind. The parliament accepted the legacy, and fulfilled the conditions.

SLOANEA, a genus of plants belonging to the class of polyandria, and order of monogynia; and in the natural system ranging under the 50th order, *Amentaceæ*. See BOTANY *Index*.

SLOE. See PRUNUS, BOTANY *Index*.

SLOOP, a small vessel furnished with one mast, the mainsail of which is attached to a gaff above, or to the mast on its foremost edge, and to a long boom below, by which it is occasionally shifted to either quarter. See SHIP.

SLOOP of War, a name given to the smallest vessels of war except cutters. They are either rigged as ships or snows.

SLOT, in the sportsman's language, a term used to express the mark of the foot of a stag or other animal proper for the chace in the clay or earth, by which they are able to guess when the animal passed, and which way he went. The slot, or treading of the stag, is very nicely studied on this occasion; if the slot be large, deep printed in the ground, and with an open cleft, and, added to these marks, there is a large space between mark and mark, it is certain that the stag is an old one. If there be observed the slots or treadings of two, the one long and the other round, and both of one size, the long slot is always that of the larger animal. There is also another way of knowing the old ones from the young ones by the treading; which is, that the hinder feet of the old ones never reach to their fore feet, whereas those of the young ones do.

SLOTH, See BRADYPUS, MAMMALIA *Index*.

SLOUGH, a deep muddy place. The cast skin of a snake, the damp of a coal-pit, and the scar of a wound, are also called by the same appellation. The slough of a wild boar is the bed, soil, or mire, wherein he wallows, or in which he lies in the day-time.

SLUCZK, a large and populous town in Russian Poland, in Lithuania, and formerly capital of a duchy of the same name; famous for three battles gained here by Constantine duke of Ostrog over the Tartars, in the reign of Sigismund I. It is seated on the river Sluczk, 72 miles south-east of Minski, and 70 south of Novogrodeck. E. Long. 27. 44. N. Lat. 53. 2.

SLUG. See LIMAX, HELMINTHOLOGY *Index*.

SLUICE, a frame of timber, stone, or other matter, serving to retain and raise the water of a river, &c. and on occasion to let it pass.

Such is the sluice of a mill, which stops and collects the water of a rivulet, &c. to let it fall at length in the greater plenty upon the mill-wheel; such also are those used as vents or drains to discharge water off land. And such are the sluices of Flanders, &c. which serve to prevent the waters of the sea from overflowing the lower lands.

Sometimes there is a kind of canal inclosed between two gates or sluices, in artificial navigations, to save the water, and render the passage of boats equally easy and safe, upwards and downwards; as in the sluices of Briare in France, which are a kind of massive walls built parallel to each other, at the distance of 20 or 24 feet, closed with strong gates at each end, between which is a kind of canal or chamber, considerably longer than broad; wherein a vessel being inclosed, the water is let out at the first gate, by which the vessel is raised 15 or 16 feet, and passed out of this canal into another much higher. By such means a boat is conveyed out of the Loire into the Seine, though the ground between them rise above 150 feet higher than either of those rivers *.

* See Canal.

Sluices are made different ways, according to the use for which they are intended: when they serve for navigation, they are shut with two gates, presenting an angle towards the stream; when they are made near the sea, two pair of gates are made, the one to keep the water out and the other in, as occasion requires: in this case, the gates towards the sea present an angle that way, and the others the contrary way; and the space inclosed by those gates is called the *chamber*. When sluices are made in the ditches of a fortress, to keep up the water in some parts instead of gates, shutters are made so as to slide up and down in grooves; and when they are made to raise an inundation, they are then shut by means of square timbers let down in cullises, so as to lie close and firm.

The word *sluice* is formed of the French *escluse*, which Menage derives from the Latin *exclusa*, found in the Salic law in the same sense. But this is to be restrained to the sluices of mills, &c. for as to those serving to raise vessels, they were wholly unknown to the ancients.

SLUR, in *Music*, a mark like the arch of a circle, drawn from one note to another, comprehending two or more notes in the same or different degrees. If the notes are in different degrees, it signifies that they are all to be sung to one syllable; for wind instruments, that they are to be made in one continued breath; and for stringed instruments, that are struck with a bow, as a violin, &c. that they are made with one stroke. If the notes are in the same degree, it signifies that it is all one note, to be made as long as the whole notes so connected; and this happens most frequently betwixt the last note of one line and the first of the next; which is particularly called *syncopation*.

SLUYS, a town of Dutch Flanders, opposite the island of Cadsand, with a good harbour, 10 miles north of Bruges, containing 14,000 inhabitants. E. Long. 3. 25. N. Lat. 51. 19.

SMACK, a small vessel, commonly rigged as a sloop or hoy, used in the coasting or fishing trade, or as a tender in the king's service.

SMALAND, or CALMAR, a province in the south of Sweden, which makes part of Gothland. It is about 112 miles in length, and 62 in breadth, and contains about 4200 square miles. In 1808 it contained 66,121 tunnas or about 80,000 acres of arable land, and 136,296 inhabitants. Calmar is the capital town.

SMALKALD, a town of Germany, in Franconia, and in the county of Henneberg; famous for the confederacy entered into by the German Protestants against the emperor, commonly called the *league of Smalkald*. The design of it was to defend their religion and liberties. It is seated on the river Werra, 25 miles south-west of Erford, and 50 north-west of Bamberg. E. Long. 10. 53. N. Lat. 50. 49. It is subject to the prince of Hesse-Cassel.

SMALLAGE. See APIUM, BOTANY *Index*.

SMALT,

Smalt || Smeaton.

SMALT, a kind of glass of a dark blue colour, which when levigated appears of a most beautiful colour; and if it could be made sufficiently fine, would be an excellent succedaneum for ultramarine, as not only resisting all kinds of weather, but even the most violent fires. It is prepared by melting one part of calcined cobalt with two of flint powder, and one of potash. At the bottoms of the crucibles in which the smalt is manufactured, we generally find a regulus of a whitish colour inclined to red, and extremely brittle. This is melted afresh, and when cold separates into two parts; that at the bottom is the cobaltic regulus, which is employed to make more of the smalt; the other is bismuth.

SMARAGDITE, a species of mineral belonging to the magnesian genus. See MINERALOGY, p. 197.

SMARAGDUS, an old name for the emerald. See EMERALD, MINERALOGY, p. 159.

SMEATON, JOHN, an eminent civil engineer, was born the 28th of May 1724, O. S. at Austhorpe, near Leeds, in a house built by his grandfather, and where his family have resided ever since.

The strength of his understanding and the originality of his genius appeared at an early age; his playthings were not the playthings of children, but the tools which men employ; and he appeared to have greater entertainment in seeing the men in the neighbourhood work, and asking them questions, than in any thing else. One day he was seen (to the distress of his family) on the top of his father's barn, fixing up something like a windmill; another time, he attended some men fixing a pump at a neighbouring village, and observing them cut off a piece of bored pipe, he was so lucky as to procure it, and he actually made with it a working pump that raised water. These anecdotes refer to circumstances that happened while he was in petticoats, and most likely before he attained his sixth year.

About his 14th and 15th year, he made for himself an engine for turning, and made several presents to his friends of boxes in ivory or wood very neatly turned. He forged his iron and steel, and melted his metal; he had tools of every sort for working in wood, ivory, and metals. He made a lathe, by which he cut a perpetual screw in brass, a thing little known at that day, which was the invention of Mr Henry Hindley of York; with whom Mr Smeaton soon became acquainted, and they spent many a night at Mr Hindley's house till day-light, conversing on those subjects.

Thus had Mr Smeaton, by the strength of his genius and indefatigable industry, acquired, at the age of 18, an extensive set of tools, and the art of working in most of the mechanical trades, without the assistance of any master. A part of every day was generally occupied in forming some ingenious piece of mechanism.

Mr Smeaton's father was an attorney, and desirous of bringing him up to the same profession; Mr Smeaton therefore came up to London in 1742, and attended the courts in Westminster hall; but finding (as his common expression was) that the law did not suit the bent of his genius, he wrote a strong memorial to his father on that subject; whose good sense from that moment left Mr Smeaton to pursue the bent of his genius in his own way.

In 1751, he began a course of experiments to try a machine of his invention to measure a ship's way at sea, and also made two voyages in company with Dr Knight to try it, and a compass of his own invention and making, which was made magnetical by Dr Knight's artificial magnets: the second voyage was made in the Fortune sloop of war, commanded at that time by Captain Alexander Campbell.

Smeaton.

In 1753 he was elected member of the Royal Society; the number of papers published in their Transactions will show the universality of his genius and knowledge. In 1759 he was honoured by an unanimous vote with their gold medal for his paper intitled "An Experimental Inquiry concerning the Natural Powers of Water and Wind to turn Mills, and other Machines depending on a Circular Motion."

This paper, he says, was the result of experiments made on working models in the years 1752 and 1753, but not communicated to the Society till 1759; before which time he had an opportunity of putting the effect of these experiments into real practice, in a variety of cases, and for various purposes, so as to assure the Society he had found them to answer.

In December 1755, the Eddystone lighthouse was burnt down: Mr Weston, the chief proprietor, and the others, being desirous of rebuilding it in the most substantial manner, inquired of the earl of Macclesfield (then president of the Royal Society) whom he thought the most proper to rebuild it; his lordship recommended Mr Smeaton.

Mr Smeaton undertook the work, and completed it in the summer of 1759. Of the preparation for this extraordinary work, of its commencement and progress, Mr Smeaton has given an ample and interesting description in a splendid folio volume which was first published in 1791. The same volume contains the history of the different buildings which have been erected on the Eddystone rock. See EDDYSTONE.

Though Mr Smeaton completed the building of the Eddystone lighthouse in 1759 (a work that does him so much credit) yet it appears he did not soon get into full business as a civil engineer; but in 1764, while in Yorkshire, he offered himself a candidate for one of the receivers of the Derwentwater estate, and on the 31st of December in that year, he was appointed at a full board of Greenwich hospital, in a manner highly flattering to himself, when two other persons strongly recommended and powerfully supported were candidates for the employment. In this appointment he was very happy, by the assistance and abilities of his partner Mr Walton one of the receivers, who taking upon himself the management and accounts, left Mr Smeaton leisure and opportunity to exert his abilities on public works, as well as to make many improvements in the mills and in the estates of Greenwich hospital. By the year 1775 he had so much business as a civil engineer, that he wished to resign this appointment; and would have done it then, had not his friend the late Mr Stuart the hospital surveyor, and Mr Ibbetson their secretary, prevailed upon him to continue in the office about two years longer.

Mr Smeaton having now got into full business as a civil engineer, performed many works of general utility. He made the river Calder navigable; a work that required great skill and judgment, owing to the very impetuous floods in that river: He planned and attended

Smeaton.

tended the execution of the great canal in Scotland for conveying the trade of the country either to the Atlantic or German ocean; and having brought it to the place originally intended, he declined a handsome yearly salary, in order that he might attend to the multiplicity of his other business.

On the opening of the great arch at London bridge, the excavation around and under the sterlings was so considerable, that the bridge was thought to be in great danger of falling. He was then in Yorkshire, and was sent for by express, and arrived with the utmost dispatch: "I think (says Mr Holmes, the author of his life) it was on a Saturday morning, when the apprehension of the bridge falling was so general that few would pass over or under it. He applied himself immediately to examine it, and to sound about the sterlings as minutely as he could; and the committee being called together, adopted his advice, which was to repurchase the stones that had been taken from the middle pier, then lying in Moorfields, and to throw them into the river to guard the sterlings." Nothing shows the apprehensions concerning the falling of the bridge more than the alacrity with which this advice was pursued; the stones were repurchased that day, horses, carts, and barges were got ready, and they began the work on Sunday morning. Thus Mr Smeaton, in all human probability, saved London bridge from falling, and secured it till more effectual methods could be taken.

The vast variety of mills which Mr Smeaton constructed, so greatly to the satisfaction and advantage of the owners, will show the great use which he made of his experiments in 1752 and 1753; for he never trusted to theory in any case where he could have an opportunity to investigate it by experiment. He built a steam engine at Austhorpe, and made experiments thereon, purposely to ascertain the power of Newcomen's steam-engine, which he improved and brought to a greater degree of perfection, both in its construction and powers, than it was before.

Mr Smeaton during many years of his life was a frequent attendant on parliament, his opinion being continually called for; and here his strength of judgment and perspicuity of expression had its full display: it was his constant custom, when applied to, to plan or support any measure, to make himself fully acquainted with it, to see its merits before he would engage in it: by this caution, added to the clearness of his description and the integrity of his heart, he seldom failed to obtain for the bill which he supported an act of parliament. No one was heard with more attention, nor had any one ever more confidence placed in his testimony. In the courts of law he had several compliments paid him from the bench by Lord Mansfield and others, for the new light which he threw on difficult subjects.

About the year 1785 Mr Smeaton's health began to decline; and he then took the resolution to endeavour to avoid all the business he could, so that he might have leisure to publish an account of his inventions and works, which was certainly the first wish of his heart; for he has often been heard to say, that "he thought he could not render so much service to his country as by doing that." He got only his account of the Eddystone lighthouse completed, and some preparations to his intended Treatise on Mills; for he could not resist the solicitations of his friends in various works: and Mr Aubert, whom he greatly loved and respected, being chosen chairman of Ramsgate harbour, prevailed upon him to accept the place of engineer to that harbour; and to their joint efforts the public is chiefly indebted for the improvements that have been made there within these few years, which fully appears in a report that Mr Smeaton gave in to the board of trustees in 1791, which they immediately published.

Smeaton || Smelling.

Mr Smeaton being at Austhorpe, walking in his garden on the 16th of September 1792, was struck with the palsy, and died the 28th of October. "In his illness (says Mr Holmes) I had several letters from him, signed with his name, but written and signed by another's pen; the diction of them showed that the strength of his mind had not left him. In one written the 26th of September, after minutely describing his health and feelings, he says, "in consequence of the foregoing, I conclude myself nine-tenths dead; and the greatest favour the Almighty can do me (as I think), will be to complete the other part; but as it is likely to be a lingering illness, it is only in His power to say when that is likely to happen."

Mr Smeaton had a warmth of expression that might appear to those who did not know him well to border on harshness; but these more intimately acquainted with him, knew it arose from the intense application of his mind, which was always in the pursuit of truth, or engaged in investigating difficult subjects. He would sometimes break out hastily, when any thing was said that did not tally with his ideas; and he would not give up any thing he argued for, till his mind was convinced by sound reasoning.

In all the social duties of life he was exemplary; he was a most affectionate husband, a good father, a warm, zealous, and sincere friend, always ready to assist those whom he respected, and often before it was pointed out to him in what way he could serve them. He was a lover and encourager of merit wherever he found it; and many men are in a great measure indebted to his assistance and advice for their present situation. As a companion, he was always entertaining and instructive; and none could spend any time in his company without improvement.

SMELL; this word has in most languages two meanings, signifying either that sensation of mind of which we are conscious, in consequence of certain impressions made on the nostrils, and conveyed to the brain by the olfactory nerves; or that unknown virtue, or quality in bodies, which is the cause of our sensations of smell.

SMELLING is the act by which we perceive smells, or become sensible of the presence of odorous bodies. The sensations of smell are excited by certain effluvia, which, in the open air, are always issuing from the surfaces of most bodies, and striking on the extremities of the olfactory nerves, give them a peculiar sort of impression, which is communicated to the brain. The particles which issue thus from bodies are extremely volatile, and produce sensation by a degree of contact, which, though insensible, is still more efficient than if it were more gross and palpable. It is by a similar species of insensible contact that the eyes and ears are affected by external objects; whilst, in the excitation of the sensations of touch and of taste, an actual and sensible contact of the object with the organ is necessary.

Smelling. sary. The organs of smelling are the nostrils and olfactory nerves; the minute ramifications of the latter being distributed throughout the whole concavity of the former. For a description of these, see ANATOMY.

The effluvia from odorous bodies are constantly floating about in the atmosphere, and must of course be drawn into the nostrils along with the air in inspiration; "so that there is," as Dr Reid observes, "a manifest appearance of design in placing the organ of smell in the inside of that canal, through which the air is continually passing in inspiration and expiration." It has been affirmed by Boerhaave, that the matter in animals, vegetables, fossils, &c. which chiefly affects the sense of smelling, is that attenuated substance, inherent in their oily parts, called *spirits*; because, when this is taken away from the most fragrant bodies, what remains has scarcely any smell at all; but this, he says, if poured on the most inodorous bodies, gives them a fragrancy *. We cannot, however, enter at present upon this inquiry.

* See also Dunmell's Anatomical Questions, vol. book i. chap. 9.

The sense of smell has a close alliance with that of taste; and it seems probable from the proximity in the situation of their organs in all animals, that both are principally intended to guide them in the choice of their food; so that from this close connection, they are better enabled to choose what is good for them, and to reject what would be injurious. This is the opinion of Dr Reid, as it was, in a very early period of the history of philosophy, that of Socrates and of Cicero (A). Dr Reid also remarks, that the sense of smell probably serves the same purpose in the natural state of man; but it is not always a sure guide for this purpose. The organs of smell differ, like those of the other senses, according to the destination of the animals to which they belong; and we know, that this sense is in man much less acute, than it is in many other animals. We see, that in the choice of their food, they are guided by the senses of smell and of taste, except when man has brought them into a sort of unnatural state by domestication. And this circumstance renders it probable, that both these senses were intended to serve the same purpose in the natural state of our species, although less calculated for this end than they were in the brutes, on account of the great superiority of their smelling organs. Besides, since it is probable that man, in the natural state, acts more by instinct than when civilized in society, so also it is reasonable to think, that he may possess some of the senses, (this of smell for instance), in greater acuteness than we do. This indeed we are assured to be a fact; for we are told in the *Histoire des Antilles*, that there are negroes who, by the smell alone, can distinguish the footsteps of a Frenchman from those of a negro. Smelling.

The sense of smell is much more obtuse in man than in some of the lower animals. Dogs we know possess a power of smelling, of which we can scarcely form a conception, and which, it is happy for us we do not possess (B); and birds of prey are said to possess this sense in still greater acuteness. But although this be more perfect, still the sense of smelling in man, who has other means of judging of his food, &c. is such as to fit him for deriving enjoyment from a diversity of scents, particularly those of flowers and perfumes, to which dogs and other animals seem perfectly insensible. It has been said, we are aware, that some animals, the elephant for instance, are capable of this enjoyment (C); but of this fact we cannot help being very doubtful.

There is a very great sympathy between the organs of smell and of taste; for any defect or disease of one is generally attended with some corresponding defect or disease of the other. There is also a greater similarity between the sensations of both these, than between those of any other two senses: and hence it is, that we can sometime tell the taste of an object from its smell, and *vice versa*. Hence also the reason why we apply the same epithets to the names of both these classes of sensations; as a sweet smell or taste, &c.

It deserves also to be remarked, that both these senses seem subservient to the preservation of the animal existence, rather than to any other purpose. They accordingly constitute an object of the natural history of man, rather than of intellectual or of moral philosophy. The other three senses, on the contrary, seem rather intended for (as they certainly are essential to) our intellectual improvement, and become, of course, a proper object of investigation in the sciences of moral philosophy, or metaphysics.

The advantages derived by man and the other animals from the sense of smelling are not confined to the assistance which it affords them in the choice of their food. Most bodies in nature, when exposed to the open air, are constantly sending forth emanations or effluvia of such extreme minuteness as to be perfectly invisible. These diffuse themselves through the air, and however noxious or salutary, would not be perceived without the sense of smelling, which if not vitiated by unnatural habits, is not only a faithful monitor when danger is at hand, but conveys to us likewise the most exquisite pleasures.

(A) "Ut gustus (says a learned physiologist) cibi itineri, sic olfactus ostio viarum, quas aër subire debet, custos præponitur, moniturus ne quid noxii, via quæ semper patet, in corpus admittatur. Porro, ut gustus, sic quoque olfactus ad salutarem cibum invitat, à noxio aut corrupto, putrido imprimis vel rancido, deterret."

"When thou seest the mouth, through which animals take in whatever they desire, always placed near the nose and eyes, thinkest thou not, says Socrates to Aristodemus, that this is the work of a providence." Xenophon's Memorables, book i. chap. 4.

(B) "The excessive eagerness which dogs express on smelling their game, seems to be but little connected with the appetite for food, and wholly independent of any preconceived ideas of the objects of their pursuit being fit for it. Hence several kinds of them will not eat the game which they pursue with such wild impetuosity; and of which the scent seems to animate them to a degree of ecstasy far beyond what the desire of food can produce." Knight on Taste.

(C) There is an animal to which, naturalists say, perfume is so agreeable and so necessary, that nature has provided it with a little bag stored with an exquisite odour. "On pretend, (says Buffon), que la mangouste ouvre cette poche, pour se refraichir lorsqu' elle a trop chaud."

pleasures. The fragrance of a rose, and of many other flowers, is not only pleasant, but gives a refreshing and delightful stimulus to the whole system, whilst the odours proceeding from hemlock, or any noxious vegetable, or other substance, are highly offensive to our nostrils. Hence we are naturally led to seek the one class of sensations, and to avoid the other.

In some species of animals the sense of smell seems to be connected with certain mental sympathies, as those of hearing and sight are in all that possess them in any high degree: for not only their sexual desires appear to be excited by means of it, but other instinctive passions, which, according to the usual system of nature, should be still more remote from its influence. Dogs, although wholly unacquainted with lions, will shudder at their roar; and an elephant that has never seen a tiger, will in the same manner show the strongest symptoms of horror and affright at the smell of it. "The late Lord Clive (says an ingenious writer), exhibited a combat between two of these animals at Calcutta; but the scent of the tiger had such an effect upon the elephant, that nothing could either force or allure him to go along the road, where the cage in which the tiger was inclosed, had passed, until a gallon of arrack was given him. Upon this, his horror suddenly turning into fury, he broke down the paling to get at his enemy, and killed him without difficulty."

If riding along a road, near which a dead horse, or part of its carcass, happens to be lying, we know, that our horse, although he sees it not, cannot be made to pass the place but with difficulty. Where blood has been shed, particularly that of their own species, oxen will assemble, and upon smelling it, roar and bellow, and show the most manifest signs of horror and distress. And yet these symptoms could not arise from any associated notions of danger or death, since they appear in such as never had any opportunities of acquiring them. They must therefore be instinctive, like other instinctive antipathies and propensities. But although in their mutual intercourse, animals make much use of the sense of smell, still it does not seem to be further concerned in exciting their sexual desires, than in indicating their object.

Some of those splenetic philosophers, who are ready upon all occasions to quarrel with the constitution of nature, have taken the liberty of condemning their Maker, because it has pleased his unfathomable wisdom to bestow in some instances upon the brutes senses and instincts more perfect than he has given to man, without reflecting that he has given to man an ample equivalent; for it may be asked with the poet,

"Is not his reason all these powers in one ?
"Is Heaven unkind to man and man alone ?
"Shall he alone, whom rational we call,
"Be pleased with nothing if not blessed with all."

With respect to that unknown peculiarity of bodies, which is the cause of our sensations of smell, the opinions of philosophers have been very various. Until of late, the doctrine of Descartes and Locke on this subject was pretty generally received; but, since the publication of Doctor Reid's works, his opinion, which we deem the most correct and satisfactory, has become very popular. We will endeavour to abridge his account of this matter. For this purpose, let us suppose a person, who has grown up without the sense of smell, to be immediately endowed with the use of this organ, and placed near some flowers of an exquisite savour. When he examines what he feels in such a situation, he can find no resmblance between this new sensation, and any thing with which he is already acquainted. He finds himself unable to explain its nature, and cannot ascribe to it figure, extension, or any known property of matter. It is a simple affection, or feeling of mind, and, considered abstractedly, can have no necessary connection with the nerves, the nostrils, or effluvia, or with any thing material whatever. By the nature of his constitution he is, however, led to refer this peculiar sensation to the nostrils, as its organ; and when, from experience, and by means of touch, he learns that external objects have the power of exciting this sensation, he concludes, that there must exist in bodies some unknown cause by which it is excited. In the first part of this process he considers the feeling, or sensation, abstractedly. As such it exists in the mind only; and cannot exist there but when the mind is conscious of it. His consciousness soon enables him to distinguish different sorts of smells, all of them very distinct from one another, but, conformably to the nature of all sensation, extremely simple. He concludes, that each of these must have a distinct cause; and finding, by experience, that this cause is an unknown something in bodies, he concludes, that it must be a property of matter, and, for want of another, gives it the name of smell. When he removes an odorous body from the organ, the sensation vanishes: when the body is again applied, the sensation is excited: and hence it is, that he is led naturally to connect the sensation with this unknown peculiarity of bodies by which it is produced. But since we see, that the sensation is, in a great degree, related to other objects besides its unknown cause, to the mind in which it exists, for instance, and to the organ which is its instrument, it may be asked why it becomes associated in the mind with its cause only? The reason seems pretty obvious. No single sensation or class of sensations, is more connected with the mind, than any others of which it is susceptible. Nor is the connection subsisting between the organ and any of the sensations peculiar to it greater than that which subsists between it and every other sensation of which it is the inlet. Hence the connection between the smell of an orange and the mind, or between it and the nostrils, is very general, and cannot, in the former instance, distinguish it from any other sensation of whatever kind, nor, in the latter from any other particular smell. But the connexion between this sensation and the orange is peculiar and permanent; and we accordingly find them always associated in the mind, just as we associate the notion of fire with the sensation of burning. The relation which a sensation of smell, or any sensation, bears to the mind, to an organ, or to the memory and conception of itself, is common to all sensations. The relation which any sensation bears to its own cause, suppose of the sensation of smell to a particular virtue or quality of bodies, is common to it with every other sensation, when considered with respect to its peculiar cause. And finally, a sensation of any kind bears the same sort of relation to the memory and conception of itself, that any other feeling or operation of mind bears to the conception and memory of that particular feeling or operation.

Whatever then be the nature of the minute particles of of bodies by which our sensations of smell are excited, we cannot help considering their unknown cause as a virtue or quality of matter. Like all other modifications of material substance, it must be confessed, that this can have no resemblance to the sensations of mind. But we are not therefore, to conclude with the followers of Des Cartes and Locke, that this secondary quality is a mere sensation; especially as we can readily conceive it existing where it is not smelled, or even after supposing the annihilation of every sentient being throughout the universe. The existence of the sensation we know to be momentary and fugitive; but in the existence of its cause we can, without difficulty, or inconsistency, conceive a permanency independent of mind and of its sensations.

The doctrine we have been illustrating has of late been called in question by a sceptical writer, who, it appears to us, has upon this occasion been entirely deficient in his accustomed acuteness. Dr Reid's account of this affair seems so full, so clear and convincing, that we are at a loss to conceive how his meaning can be misunderstood; and yet the arguments and objections of the writer to whom we allude, derive all their plausibility from a misinterpretation of Dr Reid's meaning, and from a deviation from the established use of language. "An eminent metaphysician * (says this author) has declared that he has not the least difficulty in conceiving the air perfumed with aromatic odours in the deserts of Arabia; and he has decided, that the man who maintains smells to exist only in the mind, must be mad, or must abuse language and disgrace philosophy. There are some authors, nevertheless, who differ widely on this subject from the learned metaphysician. Is it possible for a sensation to exist where there is no sentient? The authors to whom I allude think it impossible." And so, we may tell this learned author, does Dr Reid, if he will take his word for it. Of the sensation of smell he remarks: "It is indeed impossible, that it can be in any body: it is a sensation; and a sensation can be in a sentient thing only †." Again, "I can think of the smell of a rose when I do not smell it; and it is possible that when I think of it there is no rose any where existing; but, when I smell it, I am necessarily determined to believe that the sensation really exists. This is common to all sensations, that, *as they cannot exist but in being perceived*, so they cannot be perceived but they must exist ‡." But continues this acute metaphysician, "a smell is nothing else than a sensation. It is a feeling, which may be agreeable or disagreeable; which may, as some think, be excited by various combinations of elements; but which, since it is a feeling, cannot be those elements which are said to cause it, and cannot exist where there is no creature to perceive it. What is to be understood, in philosophical strictness, by the perfumes of the desert? We can excuse the poet when he makes the ocean smile *, the winds dance †, and the flowers respire ‡; or even were he to perfume the desert. But the philosopher is no such magician, and had better not wander through the regions of fancy in search of sensations where there is no sentient." And is it then true that the word smell means only a sensation? A sensation is no more than an effect; it is a transient modification of the mind, which the mind itself can never produce. It must then have some cause which is external to the mind. Now, it is to this cause, and not to the sensation, that the name *smell* is most frequently applied in all languages; and it is this cause which Dr Reid supposes capable of existing in the deserts of Arabia, where there is no sentient being to perceive it. But let us hear himself: "We have considered smell as signifying a sensation, feeling, or impression upon the mind; and in this sense it can only be in a mind or sentient being: but it is evident that mankind give the name of *smell* much more frequently to something which they conceive to be external, and to be a quality of body; they understand by it something which does not at all infer a mind, and have not the least difficulty in conceiving the air perfumed with aromatic odours in the deserts of Arabia, or some uninhabited island where the human foot never trod *." "The faculty of smelling is something very different from the actual sensation of smelling; for the faculty may remain when we have no sensation. And the mind is no less different from the faculty, for it continues the same individual being when the faculty is lost. What is smell in the rose? It is a quality or virtue of the rose, or of something proceeding from it, which we perceive by the sense of smelling; and this is all we know of the matter. But what is smelling? It is an act of the mind, but is never imagined to be a quality of the mind. Again, the sensation of smelling is conceived to infer necessarily a mind or sentient being; but smell in the rose infers no such thing. We say, this body smells sweet and that stinks; but we do not say, this mind smells sweet and that stinks; therefore, smell in the rose, and the sensation which it causes, are not conceived, even by the vulgar, to be things of the same kind, although they have the same name †."

There are some other remarks on Dr Reid's opinion in the work upon which we have been commenting, which we shall pass by; we may, however, notice the author's concluding argument: after mentioning some examples, he observes, "Now in these instances we see men and animals that must have perception of smell, if I may be permitted to say so, altogether different from each other. Is not smell sensation when the spaniel finds sport in the field for his master; when the shark pursues through the ocean its expected victim; and when the camel conducts the thirsty wanderer to a fountain of fresh water across the burning sands of the Arabian desert? If no animal had the sensation of smell, there would be no odour; for *aroma* and oils may be thought to be material compositions, but are neither agreeable nor disagreeable feelings." If men and animals differ in their perceptions of smell, (and no doubt, difference of organization will cause them to do so) the conclusion should not be, we think, that smell is merely sensation, but that there is actually something external which is the cause of their sensations, and about which they differ. A rose put to the nostrils of a man and then to those of a dog, may excite very different sensations; but we cannot think that the peculiarity of the rose, which excites those different sensations, varies by thus changing the position of the rose. If at table one person mistakes mutton for beef, and another thinks that it is venison, the conclusion may be, that it is neither venison nor beef; but no man in his senses can conclude that there is no meat at the table. But, "is not smell sensation when the spaniel finds sport for his master in the field?" There is sensation no doubt; but we may be permitted to ask, what would become of the spaniel's sensation of smell and of his master's sport, were there no game in the

the field? What of the shark's sensation of smell and pursuit, were there no victim in the ocean? and what of the camel and the thirsty wanderer, were there no fountain of fresh water in the Arabian deserts? "The *smell of a rose* signifies two things, says Dr Reid; *First*, A sensation which can have no existence but when it is perceived, and can only be in a sentient being or mind. *Secondly*, It signifies some power, quality, or virtue, in the rose, or in effluvia proceeding from it, which hath a permanent existence independent of the mind; and which, by the constitution of nature, produces the sensation in us. By the original constitution of our nature we are both led to believe that there is a permanent cause of the sensation, and prompted to seek after it; and experience determines us to place it in the rose. The names of all smells, tastes, sounds, as well as heat and cold, have a like ambiguity in all languages; but it deserves our attention, that these names are but rarely, in common language, used to signify the sensations; for the most part, they signify the external qualities which are indicated by the sensations*. We have been induced thus to discuss this topic at some length, because we regretted to see Dr Reid's opinion and reasoning misrepresented; and we shall now conclude, not as this modern Berkleian does, "that, if no animal had the sensation of smell, there would be no odour;" but, if that there were no odour or external cause of smell, no animal would have this sensation.

* *Inquiry*, chap ii. sect. 9.

The sense of smell becomes sometimes too acute, either in consequence of some defect or disease of the organ, or from too great a sensibility of the whole nervous system, such as we sometimes observe in fevers, in phrenitis, and in hysterical diseases. It is however more frequently blunted in consequence of affections of the brain and nerves, arising from blows on the head, or from internal causes; or this may happen on account of too great a dryness of the organ, owing to a suppression of the accustomed humours, or to their being conveyed off by some other channel: or it may arise from too great a quantity of tears and of mucus choking up the nostrils. We have instances of both in cases of common cold, in which, at the beginning of the disease, the nostrils are dry, but as it advances, begin to discharge a great deal of humour, or become obstructed by a thick mucus. Whatever hinders the free entrance of the air into the nostrils or its passage through them, must also injure the sense of smell. It is also sometimes so depraved as to perceive smells when there is no odorous body present, or to perceive smells different from those that are really present. Some of the particles of the odorous effluvia, after having remained for some time in the caverns of the nostrils, issuing forth again and affecting the organ, will sometimes cause this species of false perception, even in the most healthy persons.

The sense of smelling may be diminished or destroyed by diseases; as by the moisture, dryness, inflammation, or suppuration of the olfactory membrane, the compression of the nerves which supply it, or some fault in the brain itself at their origin. A defect, or too great a degree of solidity of the small spongy bones of the upper jaw, the caverns of the forehead, &c. may likewise impair this sense; and it may be also injured by a collection of fetid matter in these caverns, which is continually exhaling from them, and also by immoderate use of snuff. When the nose abounds with moisture, after

gentle evacuations, such things as tend to take off irritation and coagulate the thin sharp serum may be applied; as the oil of anise mixed with fine flour, camphor dissolved in oil of almonds, &c. the vapours of amber, frankincense, gum-mastic, and benjamin, may likewise be received into the nose and mouth. For moistening the mucus when it is too dry, some recommend snuff made of the leaves of marjoram, mixed with oil of amber, marjoram, and aniseed; or a sternutatory of calcined white vitriol, twelve grains of which may be mixed with two ounces of marjoram water and filtrated. The steam of vinegar upon hot iron, and received up the nostrils, is also of use for softening the mucus, removing obstructions, &c. If there be an ulcer in the nose, it ought to be dressed with some emollient ointment, to which, if the pain be very great, a little laudanum may be added. If it be a venereal ulcer, 12 grains of corrosive sublimate may be dissolved in a pint and a half of brandy, a table spoonful of which may be taken twice a-day. The ulcer ought likewise to be washed with it, and the fumes of cinnabar may be received up the nostrils.

If there be reason to suspect that the nerves which supply the organs of smelling are inert, or want stimulating, volatile salts, or strong snuffs, and other things which occasion sneezing, may be applied to the nose; the forehead may likewise be anointed with balsam of Peru, to which may be added a little oil of amber.

SMITH, SIR THOMAS, was born at Walden in Essex in 1512. At 14 he was sent to Queen's college Cambridge, where he distinguished himself so much, that he was made Henry VIII.'s scholar, together with John Cheke. He was chosen a fellow of his college in 1531, and appointed two years after to read the public Greek lecture. The common mode of reading Greek at that time was very faulty; the same sound being given to the letters and diphthongs, ι, η, υ, ει, οι, υι. Mr Smith and Mr Cheke had been for some time sensible that this pronunciation was wrong: and after a good deal of consultation and research, they agreed to introduce that mode of reading which prevails at present. Mr Smith was lecturing on *Aristotle de Republica* in Greek. At first he dropped a word or two at intervals in the new pronunciation, and sometimes he would stop as if he had committed a mistake, and correct himself. No notice was taken of this for two or three days; but as he repeated more frequently, his audience began to wonder at the unusual sounds, and at last some of his friends mentioned to him what they had remarked. He owned that something was in agitation, but that it was not yet sufficiently digested to be made public. They entreated him earnestly to discover his project: he did so; and in a short time great numbers resorted to him for information. The new pronunciation was

Smith. was adopted with enthusiasm, and soon became universal at Cambridge. It was afterwards opposed by Bishop Gardiner the chancellor; but its superiority to the old mode was so visible, that in a few years it spread over all England.

In 1539 he travelled into foreign countries and studied for some time in the universities of France and Italy. On his return he was made regius professor of civil law at Cambridge. About this time he published a treatise on the mode of pronouncing English. He was useful likewise in promoting the reformation. Having gone into the family of the duke of Somerset, the protector during the minority of Edward VI. he was employed by that nobleman in public affairs; and in 1548 was made secretary of state, and received the honour of knighthood. While that nobleman continued in office, he was sent ambassador, first to Brussels and afterwards to France.

Upon Mary's accession he lost all his places, but was fortunate enough to preserve the friendship of Gardiner and Bonner. He was exempted from persecution, and was allowed, probably by their influence, a pension of 100l. During Elizabeth's reign he was employed in public affairs, and was sent three times by that princess as her ambassador to France. He died in 1577. His abilities were excellent, and his attainments uncommonly great: He was a philosopher, a physician, a chemist, mathematician, linguist, historian, and architect. He wrote, 1. A treatise called the *English Commonwealth*. 2. A letter *De Recta et Emendata Linguæ Græcæ Pronunciatione*. 3. *De Moribus Turcarum*. 4. *De Druidum Moribus*.

Smith, *Edmund*, an English poet, the only son of Mr Neale an eminent merchant, by a daughter of Baron Lechmere, was born in 1668. By his father's death he was left young to the care of Mr Smith, who had married his father's sister, and who treated him with so much tenderness, that at the death of his generous guardian he assumed his name. His writings are not many, and those are scattered about in miscellanies and collections: his celebrated tragedy of Phædra and Hippolitus was acted in 1707; and being introduced at a time when the Italian opera so much engrossed the polite world, gave Mr Addison, who wrote the prologue, an opportunity to rally the vitiated taste of the public. However, notwithstanding the esteem it has always been held in, it is perhaps rather to be considered as a fine poem than as a good play. This tragedy, with a Poem to the memory of Mr John Philips, three or four Odes, with a Latin oration spoken at Oxford *in laudem Thomæ Bodleii*, were published as his works by his friend Mr Oldisworth. Mr Smith died in 1710, sunk into indolence and intemperance by poverty and disappointments: the hard fate of many a man of genius.

Smith, *John*, an excellent mezzotinter, flourished about 1700; but neither the time of his birth nor death is accurately known. He united softness with strength, and finished with freedom. He served his time with one Tillet a painter in Moorfields; and as soon as he became his own master, learned from Becket the secret of mezzotinto, and being farther instructed by Van der Vaart, was taken to work in Sir Godfrey Kneller's house; and as he was to be the publisher of that master's works, doubtless received considerable hints from him, which he amply repaid. "To posterity perhaps his prints (says Mr Walpole) will carry an idea of something burlesque; perukes of an enormous length flowing over suits of armour, compose wonderful habits. It is equally strange that fashion could introduce the one, and establish the practice of representing the other when it was out of fashion. Smith excelled in exhibiting both, as he found them in the portraits of Kneller, who was less happy in what he substituted to armour. In the Kit-cat club he has poured full bottoms chiefly over night-gowns. If those streams of hair were *incommode* in a battle, I know nothing (he adds) they were adapted to that can be done in a night-gown. Smith composed two large volumes, with proofs of his own plates, for which he asked 50l. His finest works are Duke Schomberg on horseback; that duke's son and successor Maynhard: the earls of Pembroke, Dorset, and Albemarle; three plates with two figures in each, of young persons or children, in which he shone: William Cowper; Gibbons and his wife; Queen Anne; the duke of Gloucester, a whole length, with a flower-pot; a very curious one of Queen Mary, in a high head, fan, and gloves; the earl of Godolphin; the duchess of Ormond, a whole length, with a black; Sir George Rooke, &c. There is a print by him of James II. with an anchor, but no inscription; which not being finished when the king went away, is so scarce that it is sometimes sold for above a guinea. Smith also performed many historic pieces: as the loves of the gods, from Titian, at Blenheim, in ten plates; Venus standing in a shell, from a picture by Corregio, and many more, of which perhaps the most delicate is the holy family with angels, after Carlo Maratti." Smith. *Walpole's Catalogue of Engravers.*

Smith, *Dr Adam*, the celebrated author of the Inquiry into the Nature and Causes of the Wealth of Nations, was the only son of Adam Smith comptroller of the customs at Kirkaldy, and of Margaret Douglas daughter of Mr Douglas of Strathenry. He was born at Kirkaldy on the 5th June 1723, a few months after the death of his father. His constitution during his infancy was infirm and sickly, and required all the care of his surviving parent. When only three years old he was carried by his mother to Strathenry on a visit to his uncle Mr Douglas; and happening one day to be amusing himself alone at the door of the house, he was stolen by a party of those vagrants who in Scotland are called *tinkers*. Luckily he was missed immediately, and the vagrants pursued and overtaken in Leslie wood; and thus Dr Smith was preserved to extend the bounds of science, and reform the commercial policy of Europe. *Philosophical Transactions of the Royal Society of Edinburgh, vol. iii.*

He received the rudiments of his education in the school of Kirkaldy under David Miller, a teacher of considerable eminence, and whose name deserves to be recorded on account of the great number of eminent men which that seminary produced while under his direction. Dr Smith, even while at school, attracted notice by his passionate attachment to books, and by the extraordinary powers of his memory; while his friendly and generous disposition gained and secured the affection of his schoolfellows. Even then he was remarkable for those habits which remained with him through life, of speaking to himself when alone and of absence in company. He was sent in 1737 to the university of Glasgow, where he remained till 1740, when he went to to Baliol college Oxford, as an exhibitioner on Snell's foundation. His favourite pursuits while at the university were mathematics and natural philosophy. After his removal to England he frequently employed himself in translating, particularly from the French, with a view to the improvement of his own style: a practice which he often recommended to all who wished to cultivate the art of composition. It was probably then also that he applied himself with the greatest care to the study of languages, of which, both ancient and modern, his knowledge was uncommonly extensive and accurate.

After seven years residence at Oxford he returned to Kirkaldy, and lived two years with his mother without any fixed plan for his future life. He had been designed for the church of England; but disliking the ecclesiastical profession, he resolved to abandon it altogether, and to limit his ambition to the prospect of obtaining some of those preferments to which literary attainments lead in Scotland. In 1748 he fixed his residence in Edinburgh, and for three years read a course of lectures on rhetoric and belles lettres under the patronage of Lord Kames. In 1751 he was elected professor of logic in the university of Glasgow, and the year following was removed to the professorship of moral philosophy, vacant by the death of Mr Thomas Craigie, the immediate successor of Dr Hutcheson. In this situation he remained 13 years, a period he used frequently to look back to as the most useful part of his life. His lectures on moral philosophy were divided into four parts: The first contained natural theology; in which he considered the proofs of the being and attributes of God, and those truths on which religion is founded: the second comprehended ethics, strictly so called, and consisted chiefly of those doctrines which he afterwards published in his theory of moral sentiments: in the third part he treated more at length of that part of morality called *justice;* and which, being susceptible of precise and accurate rules, is for that reason capable of a full and accurate explanation: in the last part of his lectures he examined those political regulations which are founded, not upon the principle of justice, but of expediency; and which are calculated to increase the riches, the power, and the prosperity of a state. Under this view he considered the political institutions relating to commerce, to finances, to ecclesiastical and military governments: this contained the substance of his *Wealth of Nations*. In delivering his lectures he trusted almost entirely to extemporary elocution: his manner was plain and unaffected, and he never failed to interest his hearers. His reputation soon rose very high, and many students resorted to the university merely upon his account.

When his acquaintance with Mr Hume first commenced is uncertain; but it had ripened into friendship before the year 1752.

In 1759 he published his Theory of Moral Sentiments; a work which deservedly extended his reputation: for, though several of its conclusions be ill-founded, it must be allowed by all to be a singular effort of invention, ingenuity, and subtilty. Besides, it contains a great mixture of important truth; and, though the author has sometimes been misled, he has had the merit of directing the attention of philosophers to a view of human nature, which had formerly in a great measure escaped their notice. It abounds everywhere with the purest and most elevated maxims concerning the practical conduct of life; and when the subject of his work leads him to address the imagination and the heart, the variety and felicity of his illustrations, the richness and fluency of his eloquence, and the skill with which he wins the attention and commands the passions of his readers, leave him among our British moralists without a rival.

Towards the end of 1763 Dr Smith received an invitation from Mr Charles Townsend to accompany the duke of Buccleugh on his travels; and the liberal terms in which this proposal was made induced him to resign his office at Glasgow. He joined the duke of Buccleugh at London early in the year 1764, and set out with him for the continent in the month of March following. After a stay of about ten days at Paris, they proceeded to Thoulouse, where they fixed their residence for about 18 months; thence they went by a pretty extensive route through the south of France to Geneva, where they passed two months. About Christmas 1765 they returned to Paris, and remained there till October following. The society in which Dr Smith passed these ten months may be conceived in consequence of the recommendation of Mr Hume. Turgot, Quesnai, Necker, d'Alembert, Helvetius, Marmontel, Madame Riccoboni, were among the number of his acquaintances; and some of them he continued ever after to reckon among the number of his friends. In October 1766 the duke of Buccleugh returned to England.

Dr Smith spent the next ten years of his life with his mother at Kirkaldy, occupied habitually in intense study, but unbending his mind at times in the company of some of his old schoolfellows, who still continued to reside near the place of their birth. In 1776 he published his *Inquiry into the Nature and Causes of the Wealth of Nations;* a book so universally known, that any panegyric on it would be useless. The variety, importance, and (may we not add), novelty, of the information which it contains; the skill and comprehensiveness of mind displayed in the arrangement; the admirable illustrations with which it abounds; together with a plainness and perspicuity which make it intelligible to all—render it unquestionably the most perfect work which has yet appeared on the general principles of any branch of legislation.

He spent the next two years of his life in London, where he enjoyed the society of some of the most eminent men of the age: but he removed to Edinburgh in 1778, in consequence of having been appointed, at the request of the duke of Buccleugh, one of the commissioners of the customs in Scotland. Here he spent the last twelve years of his life in an affluence which was more than equal to all his wants. But his studies seemed entirely suspended till the infirmities of old age reminded him, when it was too late, of what he yet owed to the public and to his own fame. The principal materials of the works which he had announced had long ago been collected, and little probably was wanting but a few years of health and retirement to complete them. The death of his mother, who had accompanied him to Edinburgh in 1784, together with that of his cousin Miss Douglas in 1788, contributed to frustrate these projects. They had been the objects of his affection

for

Smith | Smoke.

for more than 60 years, and in their society he had enjoyed from his infancy all that he ever knew of the endearments of a family. He was now alone and helpless; and though he bore his loss with equanimity, and regained apparently his former cheerfulness, yet his health and strength gradually declined till the period of his death, which happened in July 1790. Some days before his death he ordered all his papers to be burnt except a few essays, which have since been published.

Of the originality and comprehensiveness of his views; the extent, the variety, and the correctness of his information; the inexhaustible fertility of his invention—he has left behind him lasting monuments. To his private worth, the most certain of all testimonies may be found in that confidence, respect, and attachment, which followed him through all the various relations of life. He was habitually absent in conversation, and was apt when he spoke to deliver his ideas in the form of a lecture. He was rarely known to start a new topic himself, or to appear unprepared upon those topics that were introduced by others. In his external form and appearance there was nothing uncommon. When perfectly at ease, and when warmed with conversation, his gestures were animated and not ungraceful; and in the society of those he loved, his features were often brightened by a smile of inexpressible benignity. In the company of strangers, his tendency to absence, and perhaps still more his consciousness of that tendency, rendered his manners somewhat embarrassed; an effect which was probably not a little heightened by those speculative ideas of propriety which his recluse habits tended at once to perfect in his conception, and to diminish his power of realizing.

SMITHIA, a genus of plants belonging to the diadelphia class; and in the natural method ranking under the 32d order, *Papilionaceæ*. See BOTANY *Index*.

SMITHERY, a smith's shop; also the art of a smith, by which iron is wrought into any shape by means of fire, hammering, filing, &c.

SMITING-LINE, in a ship, is a small rope fastened to the mizen-yard-arm, below at the deck, and is always furled up with the mizen-sail, even to the upper end of the yard, and thence it comes down to the poop. Its use is to loose the mizen-sail without striking down the yard, which is easily done, because the mizen-sail is furled up only with rope-yarns; and therefore when this rope is pulled hard, it breaks all the rope-yarns, and so the sail falls down of itself. The sailor's phrase is, *smite the mizen* (whence this rope takes its name), that is, hale by this rope that the sail may fall down.

SMOKE, a dense elastic vapour, arising from burning bodies. As this vapour is extremely disagreeable to the senses, and often prejudicial to the health, mankind have fallen upon several contrivances to enjoy the benefit of fire, without being annoyed by smoke. The most universal of these contrivances is a tube leading from the chamber in which the fire is kindled to the top of the building, through which the smoke ascends, and is dispersed into the atmosphere. These tubes are called *chimneys*; which, when constructed in a proper manner, carry off the smoke entirely; but, when improperly constructed, they carry off the smoke imperfectly, to the great annoyance of the inhabitants. As our masons at present seem to have a very imperfect knowledge of the manner in which chimneys ought to be built; we can hardly perform a more acceptable service to the public than to point out the manner in which they ought to be constructed, so as to carry off the smoke entirely; as well as to explain the causes from which the defects so often complained of generally proceed, and the method of removing them.

Those who would be acquainted with this subject, should begin by considering on what principle smoke ascends in any chimney. At first many are apt to think that smoke is in its nature, and of itself, specifically lighter than air, and rises in it for the same reason that cork rises in water. These see no cause why smoke should not rise in the chimney though the room be ever so close. Others think there is a power in chimneys to *draw* up the smoke, and that there are different forms of chimneys which afford more or less of this power. These amuse themselves with searching for the best form. The equal dimensions of a funnel in its whole length is not thought artificial enough, and it is made, for fancied reasons, sometimes tapering and narrowing from below upwards, and sometimes the contrary, &c. &c. A simple experiment or two may serve to give more correct ideas. Having lighted a pipe of tobacco, plunge the stem to the bottom of a decanter half filled with cold water; then putting a rag over the bowl, blow through it, and make the smoke descend in the stem of the pipe, from the end of which it will rise in bubbles through the water; and being thus cooled, will not afterwards rise to go out through the neck of the decanter, but remain spreading itself and resting on the surface of the water. This shows that smoke is really heavier than air, and that it is carried upwards only when attached to or acted upon by air that is heated, and thereby rarefied and rendered specifically lighter than the air in its neighbourhood.

Transactions of the American Philosophical Society.

Smoke being rarely seen but in company with heated air, and its upward motion being visible, though that of the rarefied air that drives it is not so, has naturally given rise to the error. It is now well known that air is a fluid which has weight as well as others, though about 800 times lighter than water; that heat makes the particles of air recede from each other, and take up more space, so that the same weight of air heated will have more bulk than equal weights of cold air which may surround it, and in that case must rise, being forced upwards by such colder and heavier air, which presses to get under it and take its place. That air is so rarefied or expanded by heat, may be proved to their comprehension by a lank blown bladder, which laid before a fire, will soon swell, grow tight, and burst.

Another experiment may be to take a glass tube about an inch in diameter, and 12 inches long, open at both ends, and fixed upright on legs so that it need not be handled, for the hands might warm it. At the end of a quill fasten five or six inches of the finest light filament of silk, so that it may be held either above the upper end of the tube or under the lower end, your warm hand being at a distance by the length of the quill. If there were any motion of air through the tube, it would manifest itself by its effect on the silk; but if the tube and the air in it are of the same temperature with the surrounding air, there will be no such motion, whatever may be the form of the tube, whether crooked or straight, narrow below and widening upwards,

Plate CCCCXCVII.

wards, or the contrary, the air in it will be quiescent. Warm the tube, and you will find as long as it continues warm, a constant current of air entering below and passing up through it till discharged at the top; because the warmth of the tube being communicated to the air it contains, rarefies that air, and makes it lighter than the air without; which therefore presses in below, forces it upwards, follows and takes its place, and is rarefied in its turn. And, without warming the tube, if you hold under it a knob of hot iron, the air thereby heated will rise and fill the tube, going out at its top; and this motion in the tube will continue as long as the knob remains hot, because the air entering the tube below, is heated and rarefied by passing near and over that knob.

That this motion is produced merely by the difference of specific gravity between the fluid within and that without the tube, and not by any fancied form of the tube itself, may appear by plunging it into water contained in a glass jar a foot deep, through which such motion might be seen. The water within and without the tube being of the same specific gravity, balance each other, and both remain at rest. But take out the tube, stop its bottom with a finger, and fill it with olive oil, which is lighter than water; then stopping the top, place it as before, its lower end under water, its top a very little above. As long as you keep the bottom stopped the fluids remain at rest; but the moment it is unstopt, the heavier enters below, forces up the lighter, and takes its place: and the motion then ceases, merely because the new fluid cannot be successively made lighter, as air may be by a warm tube.

In fact, no form of the funnel of a chimney has any share in its operation or effect respecting smoke except its height. The longer the funnel, if erect, the greater its force when filled with heated and rarefied air to draw in below and drive up the smoke, if one may, in compliance with custom, use the expression *draw*, when in fact it is the superior weight of the surrounding atmosphere that pressed to enter the funnel below, and so drives up before it the smoke and warm air it meets with in its passage.

What is it then which makes a smoky chimney, that is, a chimney which, instead of conveying up all the smoke, discharges a part of it into the room, offending the eyes and damaging the furniture?

The causes of this effect may be reduced to *nine*, differing from each other, and therefore requiring different remedies.

1. *Smoky chimneys in a new house are such frequently from mere want of air.* The workmanship of the rooms being all good, and just out of the workman's hands, the joints of the boards of the flooring, and of the pannels of wainscotting, are all true and tight; the more so as the walls, perhaps not yet thoroughly dry, preserve a dampness in the air of the room which keeps the woodwork swelled and close. The doors and the sashes too, being worked with truth, shut with exactness, so that the room is as tight as a snuff-box, no passage being left open for air to enter except the key-hole, and even that is sometimes covered by a little dropping shutter. Now if smoke cannot rise but as connected with rarefied air, and a column of such air, suppose it filling the funnel, cannot rise unless other air be admitted to supply its place; and if therefore no current of air enter the opening of the chimney—there is nothing to prevent the smoke from coming out into the room. If the motion upwards of the air in a chimney that is freely supplied be observed by the rising of the smoke or a feather in it, and it be considered that in the time such feather takes in rising from the fire to the top of the chimney, a column of air equal to the content of the funnel must be discharged, and an equal quantity supplied from the room below, it will appear absolutely impossible that this operation should go on if the tight room is kept shut; for were there any force capable of drawing constantly so much air out of it, it must soon be exhausted like the receiver of an air-pump, and no animal could live in it. Those therefore who stop every crevice in a room to prevent the admission of fresh air, and yet would have their chimney carry up the smoke, require inconsistencies, and expect impossibilities. Yet under this situation it is not uncommon to see the owner of a new house in despair, and ready to sell it for much less than it cost; conceiving it uninhabitable because not a chimney in any one of its rooms will carry off the smoke unless a door or window be left open. Much expence has also been made to alter and amend new chimneys which had really no fault: in one house particularly which Dr Franklin knew that belonged to a nobleman in Westminster, that expence amounted to no less than 300l. after his house had been, as he thought, finished and all charges paid. And after all, several of the alterations were ineffectual, for want of understanding the true principles.

Remedies. When you find on trial that opening the door or a window enables the chimney to carry up all the smoke, you may be sure that want of air from without is the cause of its smoking. "I say from *without*, (adds Dr Franklin), to guard you against a common mistake of those who may tell you the room is large, contains abundance of air sufficient to supply any chimney, and therefore it cannot be that the chimney wants air. These reasoners are ignorant that the largeness of a room, if tight, is in this case of small importance, since it cannot part with a chimneyfull of its air without occasioning so much vacuum; which it requires a great force to effect, and could not be borne if effected."

It appearing plainly then, that some of the outward air must be admitted, the question will be, how much is absolutely necessary? for you would avoid admitting more, as being contrary to one of your intentions in having a fire, viz. that of warming your room. To discover this quantity, shut the door gradually while a middling fire is burning, till you find that before it is quite shut the smoke begins to come out into the room; then open it a little till you perceive the smoke comes out no longer. There hold the door, and observe the width of the open crevice between the edge of the door and the rabbet it should shut into. Suppose the distance to be half an inch, and the door eight feet high; you find thence that your room requires an entrance for air equal in area to 96 half inches, or 48 square inches, or a passage of 6 inches by 8. This, however, is a large supposition; there being few chimneys that, having a moderate opening and a tolerable height of funnel, will not be satisfied with such a crevice of a quarter of an inch: Dr Franklin found a square of 6 by 6, or 36 square inches, to be pretty good medium that

Smoke.

that will serve for most chimneys. High funnels with small and low openings may indeed be supplied through a less space; because, for reasons that will appear hereafter, the force of levity, if one may so speak, being greater in such funnels, the cool air enters the room with greater velocity, and consequently more enters in the same time. This, however, has its limits; for experience shows, that no increased velocity so occasioned has made the admission of air through the key hole equal in quantity to that through an open door, though through the door the current moves slowly, and through the key-hole with great rapidity.

It remains then to be considered, how and where this necessary quantity of air from without is to be admitted so as to be least inconvenient: for if at the door, left so much open, the air thence proceeds directly to the chimney, and in its way comes cold to your back and heels as you sit before your fire. If you keep the door shut, and raise a little the sash of your window, you feel the same inconvenience. Various have been the contrivances to avoid this; such as bringing in fresh air through pipes in the jams of the chimney, which pointing upwards should blow the smoke up the funnel; opening passages into the funnel above, to let in air for the same purpose. But these produce an effect contrary to that intended: for as it is the constant current of air passing from the room through the opening of the chimney into the funnel which prevents the smoke from coming out into the room, if you supply the funnel by other means or in other ways with the air which it wants, and especially if that air be cold, you diminish the force of that current, and the smoke in its efforts to enter the room finds less resistance.

The wanted air must then indispensably be admitted into the room, to supply what goes off through the opening of the chimney. M. Gauger, a very ingenious and intelligent French writer on the subject, proposes with judgment to admit it above the opening of the chimney; and to prevent inconvenience from its coldness, he directs that it may be so made, that it shall pass in its entrance through winding cavities made behind the iron back and sides of the fire-place, and under the iron hearth-plate; in which cavities it will be warmed, and even heated, so as to contribute much, instead of cooling, to the warming of the room. This invention is excellent in itself, and may be used with advantage in building new houses; because the chimneys may then be so disposed as to admit conveniently the cold air to enter such passages: but in houses built without such views, the chimneys are often so situated as not to afford that convenience without great and expensive alterations. Easy and cheap methods, though not quite so perfect in themselves, are of more general utility; and such are the following.

In all rooms where there is a fire, the body of air warmed and rarefied before the chimney is continually changing place, and making room for other air that is to be warmed in its turn. Part of it enters and goes up the chimney, and the rest rises and takes place near the ceiling. If the room be lofty, that warm air remains above our heads as long as it continues warm, and we are little benefited by it, because it does not descend till it is cooler. Few can imagine the difference of climate between the upper and lower parts of such a room, who have not tried it by the thermometer, or by going up a ladder till their heads are near the ceiling. It is then among this warm air that the wanted quantity of outward air is best admitted, with which being mixed, its coldness is abated, and its inconvenience diminished so as to become scarce observable. This may be easily done by drawing down about an inch the upper sash of a window; or, if not moveable, by cutting such a crevice through its frame; in both which cases it will be well to place a thin shelf of the length to conceal the opening, and sloping upwards, to direct the entering air horizontally along and under the ceiling. In some houses the air may be admitted by such a crevice made in the wainscot, cornice, or plastering, near the ceiling and over the opening of the chimney. This, if practicable, is to be chosen, because the entering cold air will there meet with the warmest rising air from before the fire, and be soonest tempered by the mixture. The same kind of shelf should also be placed here. Another way, and not a very difficult one, is to take out an upper pane of glass in one of your sashes, set it in a tin frame, giving it two springing angular sides, and then replacing it, with hinges below on which it may be turned to open more or less above. It will then have the appearance of an internal sky-light. By drawing this pane in, more or less, you may admit what air you find necessary. Its position will naturally throw that air up and along the ceiling. This is what is called in France a *Was ist das?* As this is a German question, the invention is probably of that nation, and takes its name from the frequent asking of that question when it first appeared. In England some have of late years cut a round hole about five inches diameter in a pane of the sash, and placed against it a circular plate of tin hung on an axis, and cut into vanes; which, being separately bent a little obliquely, are acted upon by the entering air, so as to force the plate continually round like the vanes of a windmill. This admits the outward air, and by the continual whirling of the vanes, does in some degree disperse it. The noise only is a little inconvenient. Fig. 2.

2. A second cause of the smoking of chimneys is, *their openings in the room being too large*; that is, too wide, too high, or both. Architects in general have no other ideas of proportion in the opening of a chimney than what relate to symmetry and beauty respecting the dimensions of the room; while its true proportion respecting its function and utility depends on quite other principles; and they might as properly proportion the step in a staircase to the height of the story, instead of the natural elevation of men's legs in mounting. The proportion then to be regarded, is what relates to the height of the funnel. For as the funnels in the different stories of a house are necessarily of different heights or lengths, that from the lowest floor being the highest or longest, and those of the other floors shorter and shorter, till we come to those in the garrets, which are of course the shortest; and the force of draft being, as already said, in proportion to the height of funnel filled with rarefied air, and a current of air from the room into the chimney, sufficient to fill the opening, being necessary to oppose and prevent the smoke from coming out into the room; it follows, that the openings of the longest funnels may be larger, and that those of the shorter funnels should be smaller. For if there be a large opening to a chimney that does not draw strongly, the funnel may

Smoke.

may happen to be furnished with the air which it demands by a partial current entering on one side of the opening, and leaving the other side free of any opposing current, may permit the smoke to issue there into the room. Much too of the force of draft in a funnel depends on the degree of rarefaction in the air it contains, and that depends on the nearness to the fire of its passage in entering the funnel. If it can enter far from the fire on each side, or far above the fire, in a wide or high opening, it receives little heat in passing by the fire, and the contents of the funnel are by those means less different in levity from the surrounding atmosphere, and its force in drawing consequently weaker. Hence if too large an opening be given to chimneys in upper rooms, those rooms will be smoky: On the other hand, if too small openings be given to chimneys in the lower rooms, the entering air operating too directly and violently on the fire, and afterwards strengthening the draft as it ascends the funnel, will consume the fuel too rapidly.

Remedy. As different circumstances frequently mix themselves in these matters, it is difficult to give precise dimensions for the openings of all chimneys. Our fathers made them generally much too large: we have lessened them; but they are often still of greater dimensions than they should be, the human eye not being easily reconciled to sudden and great changes. If you suspect that your chimney smokes from the too great dimension of its opening, contract it by placing moveable boards so as to lower and narrow it gradually till you find the smoke no longer issues into the room. The proportion so found will be that which is proper for that chimney, and you may employ the bricklayer or mason to reduce it accordingly. However, as in building new houses something must be sometimes hazarded, Dr Franklin proposes to make the openings in the lower rooms about 30 inches square and 18 deep, and those in the upper only 18 inches square and not quite so deep; the intermediate ones diminishing in proportion as the height of the funnel is diminished. In the larger openings, billets of two feet long, or half the common length of cordwood, may be burnt conveniently; and for the smaller, such wood may be sawed into thirds. Where coals are the fuel, the grates will be proportioned to the openings. The same depth is nearly necessary to all, the funnels being all made of a size proper to admit a chimney-sweeper. If in large and elegant rooms custom or fancy should require the appearance of a larger chimney, it may be formed of expensive marginal decorations, in marble, &c. But in time perhaps, that which is fittest in the nature of things may come to be thought handsomest.

3. Another cause of smoky chimneys is *too short a funnel.* This happens necessarily in some cases, as where a chimney is required in a low building; for, if the funnel be raised high above the roof, in order to strengthen its draft, it is then in danger of being blown down, and crushing the roof in its fall.

Remedies. Contract the opening of the chimney, so as to oblige all the entering air to pass through or very near the fire; whereby it will be more heated and rarefied, the funnel itself be more warmed, and its contents have more of what may be called the force of levity, so as to rise strongly and maintain a good draft at the opening.

Or you may in some cases, to advantage, build additional stories over the low building, which will support a high funnel.

If the low building be used as a kitchen, and a contraction of the opening therefore inconvenient, a large one being necessary, at least when there are great dinners, for the free management of so many cooking utensils; in such case the best expedient perhaps would be to build two more funnels joining to the first, and having three moderate openings, one to each funnel, instead of one large one. When there is occasion to use but one, the other two may be kept shut by sliding plates, hereafter to be described; and two or all of them may be used together when wanted. This will indeed be an expence, but not an useless one, since your cooks will work with more comfort, see better than in a smoky kitchen what they are about, your victuals will be cleaner dressed and not taste of smoke, as is often the case; and to render the effect more certain, a stack of three funnels may be safely built higher above the roof than a single funnel.

The case of too short a funnel is more general than would be imagined, and often found where one would not expect it. For it is not uncommon, in ill-contrived buildings, instead of having a funnel for each room or fire-place, to bend and turn the funnel of an upper room so as to make it enter the side of another funnel that comes from below. By these means the upper room funnel is made short of course, since its length can only be reckoned from the place where it enters the lower room funnel; and that funnel is also shortened by all the distance between the entrance of the second funnel and the top of the stack: for all that part being readily supplied with air through the second funnel, adds no strength to the draft, especially as that air is cold when there is no fire in the second chimney. The only easy remedy here is, to keep the opening of that funnel shut in which there is no fire.

4. Another very common cause of the smoking of chimneys is, *their overpowering one another.* For instance, if there be two chimneys in one large room, and you make fires in both of them, the doors and windows close shut, you will find that the greater and stronger fire shall overpower the weaker, from the funnel of which it will draw air down to supply its own demand; which air descending in the weaker funnel, will drive down its smoke, and force it into the room. If, instead of being in one room, the two chimneys are in two different rooms, communicating by a door, the case is the same whenever that door is open. In a very tight house, a kitchen chimney on the lowest floor, when it had a great fire in it, has been known to overpower any other chimney in the house, and draw air and smoke into its room as often as the door communicating with the staircase was opened.

Remedy. Take care that every room have the means of supplying itself from without with the air which its chimney may require, so that no one of them may be obliged to borrow from another, nor under the necessity of lending. A variety of these means have been already described.

5. Another cause of smoking is, *when the tops of chimneys are commanded by higher buildings, or by a hill,* so that the wind blowing over such eminences falls like water over a dam, sometimes almost perpendicularly on the

Smoke. Fig. 3. the tops of the chimneys that lie in its way, and beats down the smoke contained in them.

To illustrate this, let A (fig. 3.) represent a small building at the side of a great rock B, and the wind coming in the direction CD; when the current of air comes to the point D, being hurried forward with great velocity, it goes a little forward, but soon descends downward, and gradually is reflected more and more inward, as represented by the dotted lines EE, &c. so that, descending downwards upon the top of the chimney A, the smoke is beat back again into the apartments.

It is evident that houses situated near high hills or thick woods will be in some measure exposed to the same inconvenience; but it is likewise plain, that if a house be situated upon the slope of a hill (as at F, fig. 3.), it will not be in any danger of smoke when the wind blows towards that side of the hill upon which it is situated; for the current of air coming over the house-top in the direction GH, is immediately changed by the slope of the hill to the direction HC, which powerfully draws the smoke upward from the top of the chimney. But it is also evident, that a house in this situation will be liable to smoke when the wind blows from the hill; for the current of air coming downwards in the direction CH, will beat downward on the chimney F, and prevent the smoke from ascending with freedom. The effect will be much heightened if the doors and windows are chiefly in the lowermost side of the house.

Remedy. That commonly applied in this case is a turncap made of tin or plate iron, covering the chimney above and on three sides, open on one side, turning on a spindle; and which being guided or governed by a vane always presents its back to the current. This may be generally effectual, though not certain, as there may be cases in which it will not succeed. Raising your funnels if practicable, so as their tops may be higher, or at least equal, with the commanding eminence, is more to be depended on. But the turning cap, being easier and cheaper should first be tried. "If obliged to build in such a situation, I would choose (says Dr Franklin) to place my doors on the side next the hill, and the backs of my chimneys on the farthest side; for then the column of air falling over the eminence, and of course pressing on that below, and forcing it to enter the doors or *was-ist-dases* on that side, would tend to balance the pressure down the chimneys, and leave the funnels more free in the exercise of their functions."

6. There is another case which is the reverse of that last mentioned. It is where the commanding eminence is farther from the wind than the chimney commanded. To explain this a figure may be necessary. Suppose then a building whose side AB happens to be exposed to the wind, and forms a kind of dam against its progress. Suppose the wind blowing in the direction FE. The air obstructed by this dam or building AB will like water press and search for passages through it; but finding none, it is beat back with violence, and spreads itself on every side, as is represented by the curved lines *e, e, e, e, e, e.* It will therefore force itself down the small chimney C, in order to get through by some door or window open on the other side of the building. And if there be a fire in such chimney, its smoke is of course beat down, and fills the room.

Remedy. There is but one remedy, which is to raise such a funnel higher than the roof, supporting it if necessary by iron bars. For a turncap in this case has no effect, the dammed-up air pressing down through it in whatever position the wind may have placed its opening.

Smoke.

Dr Franklin mentions a city in which many houses are rendered smoky by this operation. For their kitchens being built behind, and connected by a passage with the houses, and the tops of the kitchen chimneys lower than the tops of the houses, the whole side of a street when the wind blows against its back forms such a dam as above described; and the wind so obstructed forces down those kitchen-chimneys (especially when they have but weak fires in them) to pass through the passage and house into the street. Kitchen-chimneys so formed and situated have another inconvenience. In summer, if you open your upper room windows for air, a light breeze blowing over your kitchen chimney towards the house, though not strong enough to force down its smoke as aforesaid, is sufficient to waft it into your windows, and fill the rooms with it; which, besides the disagreeableness, damages your furniture.

7. Chimneys, otherwise drawing well, are sometimes made to smoke by *the improper and inconvenient situation of a door.* When the door and chimney are on the same side of the room, if the door being in the corner is made to open against the wall, which is common, as being there, when open, more out of the way, it follows, that when the door is only opened in part, a current of air rushing in passes along the wall into and across the opening of the chimney, and flirts some of the smoke out into the room. This happens more certainly when the door is shutting, for then the force of the current is augmented, and becomes very inconvenient to those who, warming themselves by the fire, happen to sit in its way.

The *remedies* are obvious and easy. Either put an intervening screen from the wall round great part of the fireplace; or, which is perhaps preferable, shift the hinges of your door, so as it may open the other way, and when open throw the air along the other wall.

8. A room that has no fire in its chimney is sometimes filled with *smoke which is received at the top of its funnel, and descends into the room.* Funnels without fires have an effect according to their degree of coldness or warmth on the air that happens to be contained in them. The surrounding atmosphere is frequently changing its temperature; but stacks of funnels covered from winds and sun by the house that contains them, retain a more equal temperature. If, after a warm season, the outward air suddenly grows cold, the empty warm funnels begin to draw strongly upward; that is, they rarefy the air contained in them, which of course rises, cooler air enters below to supply its place, is rarefied in its turn, and rises; and its operation continues till the funnel grows cooler, or the outward air warmer, or both, when the motion ceases. On the other hand, if after a cold season the outward air suddenly grows warm and of course lighter, the air contained in the cool funnels being heavier descends into the room; and the warmer air which enters their tops being cooled in its turn, and made heavier, continues to descend; and this operation goes on till the funnels are warmed by the passing of warm air through them, or the air itself grows cooler.

Smoke.

cooler. When the temperature of the air and of the funnels is nearly equal, the difference of warmth in the air between day and night is sufficient to produce these currents: the air will begin to ascend the funnels as the cool of the evening comes on, and this current will continue till perhaps nine or ten o'clock the next morning, when it begins to hesitate; and as the heat of the day approaches, it sets downwards, and continues so till towards evening, when it again hesitates for some time, and then goes upwards constantly during the night, as before mentioned. Now when smoke issuing from the tops of neighbouring funnels passes over the tops of funnels which are at the time drawing downwards, as they often are in the middle part of the day, such smoke is of necessity drawn into these funnels, and descends with the air into the chamber.

The remedy is to have a sliding plate that will shut perfectly the offending funnel. Dr Franklin has thus described it: "The opening of the chimney is contracted by brick-work faced with marble slabs to about two feet between the jams, and the breast brought down to within about three feet of the hearth. An iron frame is placed just under the breast, and extending quite to the back of the chimney, so that a plate of the same metal may slide horizontally backwards and forwards in the grooves on each side of the frame. This plate is just so large as to fill the whole space, and shut the chimney entirely when thrust quite in, which is convenient when there is no fire. Draw it out, so as to leave between its further edge and the back a space of about two inches; this space is sufficient for the smoke to pass; and so large a part of the funnel being stopt by the rest of the plate, the passage of warm air out of the room, up the chimney, is obstructed and retarded; and by those means much cold air is prevented from coming in through crevices, to supply its place. This effect is made manifest three ways. 1. When the fire burns briskly in cold weather, the howling or whistling noise made by the wind, as it enters the room through the crevices, when the chimney is open as usual, ceases as soon as the plate is slid in to its proper distance. 2. Opening the door of the room about half an inch, and holding your hand against the opening, near the top of the door, you feel the cold air coming in against your hand, but weakly, if the plate be in. Let another person suddenly draw it out, so as to let the air of the room go up the chimney, with its usual freedom where chimneys are open, and you immediately feel the cold air rushing in strongly. 3. If something be set against the door, just sufficient, when the plate is in, to keep the door nearly shut, by resisting the pressure of the air that would force it open: then, when the plate is drawn out, the door will be forced open by the increased pressure of the outward cold air endeavouring to get in to supply the place of the warm air that now passes out of the room to go up the chimney. In our common open chimneys, half the fuel is wasted, and its effect lost; the air it has warmed being immediately drawn off."

9. Chimneys which generally draw well, do nevertheless sometimes give smoke into the rooms, *it being driven down by strong winds passing over the tops of their funnels*, though not descending from any commanding eminence. This case is most frequent where the funnel is short and the opening turned from the wind. It is the more grievous, when it happens to be a cold wind that produces the effect, because when you most want your fire you are sometimes obliged to extinguish it. To understand this, it may be considered that the rising light air, to obtain a free issue from the funnel, must push out of its way or oblige the air that is over it to rise. In a time of calm or of little wind this is done visibly; for we see the smoke that is brought up by that air rise in a column above the chimney: but when a violent current of air, that is, a strong wind, passes over the top of a chimney, its particles have received so much force, which keeps them in a horizontal direction and follow each other so rapidly, that the rising light air has not strength sufficient to oblige them to quit that direction and move upwards to permit its issue.

Remedies. In Venice, the custom is to open or widen the top of the flue, rounding it in the true form of a funnel. In other places the contrary is practised; the tops of the flues being narrowed inwards, so as to form a slit for the issue of the smoke, long as the breadth of the funnel, and only four inches wide. This seems to have been contrived on a supposition that the entry of the wind would thereby be obstructed; and perhaps it might have been imagined, that the whole force of the rising warm air being condensed, as it were, in the narrow opening, would thereby be strengthened, so as to overcome the resistance of wind. This, however, did not always succeed; for when the wind was at north-east and blew fresh, the smoke was forced down by fits into the room where Dr Franklin commonly sat, so as to oblige him to shift the fire into another. The position of the slit of this funnel was indeed north-east and south-west. Perhaps if it had lain across the wind, the effect might have been different. But on this we can give no certainty. It seems a matter proper to be referred to experiment. Possibly a turncap might have been serviceable, but it was not tried.

With all the science, however, that a man shall suppose himself possessed of in this article, he may sometimes meet with cases that shall puzzle him. "I once lodged (says Dr Franklin) in a house at London, which in a little room had a single chimney and funnel. The opening was very small, yet it did not keep in the smoke, and all attempts to have a fire in this room were fruitless. I could not imagine the reason, till at length observing that the chamber over it, which had no fireplace in it, was always filled with smoke when a fire was kindled below, and that the smoke came through the cracks and crevices of the wainscoat; I had the wainscot taken down, and discovered that the funnel which went up behind it had a crack many feet in length, and wide enough to admit my arm; a breach very dangerous with regard to fire, and occasioned probably by an apparent irregular settling of one side of the house. The air entering this breach freely, destroyed the drawing force of the funnel. The remedy would have been, filling up the breach, or rather rebuilding the funnel: but the landlord rather chose to stop up the chimney.

"Another puzzling case I met with at a friend's country house near London. His best room had a chimney in which, he told me, he never could have a fire, for all the smoke came out into the room. I flattered myself I could easily find the cause and prescribe the cure. I opened the door, and perceived it was not want of air. I made a temporary contraction of the opening of the chimney, and found that it was not its being

being too large that caused the smoke to issue. I went out and looked up at the top of the chimney: Its funnel was joined in the same stalk with others; some of them shorter, that drew very well, and I saw nothing to prevent its doing the same. In fine, after every other examination I could think of, I was obliged to own the insufficiency of my skill. But my friend, who made no pretension to such kind of knowledge, afterwards discovered the cause himself. He got to the top of the funnel by a ladder, and looking down found it filled with twigs and straw cemented by earth and lined with feathers. It seems the house after being built, had stood empty some years before he occupied it; and he concluded that some large birds had taken the advantage of its retired situation to make their nest there. The rubbish, considerable in quantity, being removed, and the funnel cleared, the chimney drew well, and gave satisfaction."

Chimneys whose funnels go up in the north wall of a house, and are exposed to the north winds, are not so apt to draw well as those in a south wall; becanse when rendered cold by those winds, they draw downwards.

Chimneys inclosed in the body of a house are better than those whose funnels are exposed in cold walls.

Chimneys in stacks are apt to draw better than separate funnels, because the funnels that have constant fires in them warm the others in some degree that have none.

Smoke-Jack. This ingenious machine is of German origin, and Messinger, in his *Collection of Mechanical Performances*, says it is very ancient, being represented in a painting at Nurenbergh, which is known to be older than the year 1350.

Plate cccxvii. fig. 5. Its construction is abundantly simple. An upright iron spindle GA (fig. 5.), placed in the narrow part of the kitchen chimney, turns round on two points H and I. The upper one H passes through an iron bar, which is built in across the chimney; and the lower pivot I is of tempered steel, and is conical or pointed, resting in a conical bell metal socket fixed on another cross bar. On the upper end of the spindle is a circular fly G, consisting of 4, 6, 8, or more thin iron plates, set obliquely on the spindle like the sails of a windmill, as we shall describe more particularly by and by. Near the lower end of the spindle is a pinion A, which works in the teeth of a contrate or face wheel B, turning on a horizontal axis BC. One pivot of this axis turns in a cock fixed on the cross bar, which supports the lower end of the upright spindle HI, and the other pivot turns in a cock fixed on the side wall of the chimney; so that this axle is parallel to the front of the chimney. On the remote end of this horizontal axle there is a small pulley C, having a deep angular groove. Over this pulley there passes a chain CDE, in the lower bight of which hangs the large pulley E of the spit. This end of the spit turns loosely between the branches of the fork of the rack or raxe F, but without resting on it. This is on the top of a moveable stand, which can be shifted nearer to or farther from the fire. The other end turns in one of the notches of another rack. The number of teeth in the pinion A and wheel B, and the diameters of the pulleys C and E, are so proportioned that the fly G makes from 12 to 20 turns for one turn of the spit.

Smoke-Jack. The manner of operation of this useful machine is easily understood. The air which contributes to the burning of the fuel, and passes through the midst of it, is greatly heated, and expanding prodigiously in bulk, becomes lighter than the neighbouring air, and is therefore pushed by it up the chimney. In like manner, all the air which comes near the fire is heated, expanded, becomes lighter, and is driven up the chimney. This is called the *draught* or *suction*, but would with greater propriety be termed the *drift* of the chimney. As the chimney gradually contracts in its dimensions, and as the same quantity of heated air passes through every section of it, it is plain that the rapidity of its ascent must be greatest in the narrowest place. There the fly G should be placed, because it will there be exposed to the strongest current. The air, striking the fly vanes obliquely pushes them aside, and thus turns them round with a considerable force. If the joint of meat is exactly balanced on the spit, it is plain that the only resistance to the motion of the fly is what arises from the friction of the pivots of the upright spindle, the friction of the pinion and wheel, the friction of the pivots of the horizontal axis, the friction of the small end of the spit, and the friction of the chain in the top pulleys. The whole of this is but a mere trifle. But there is frequently a considerable inequality in the weight of the meat on different sides of the spit: there must therefore be a sufficient overplus of force in the impulse of the ascending air on the vanes of the fly, to overcome this want of equilibrium occasioned by the unskilfulness or negligence of the cook. There is, however, commonly enough of power when the machine is properly constructed. The utility of this machine will, we hope, procure us the indulgence of some of our readers, while we point out the circumstances on which its performance depends, and the maxims which should be followed in its construction.

The upward current of air is the moving power, and should be increased as much as possible, and applied in the most advantageous manner. Every thing will increase the current which improves the draught of the chimney and secures it from smoking. A smoky chimney must always have a weak current. For this particular, therefore, we refer to what has been delivered in the article Pneumatics, N° 359; and the article Smoke.

With respect to the manner of applying this force, it is evident that the best construction of a windmill sails will be nearly the best construction for the fly. According to the usual theory of the impulse of fluids, the greatest effective impulse (that is, in the direction of the fly's motion) will be produced if the plane of the vane be inclined to the axis in an angle of 54 degrees 46 minutes. But, since we have pronounced this theory to be so very defective, we had better take a determination founded on the experiments on the impulse of fluids made by the academy of Paris. These authorise us to say, that $49\frac{1}{2}$ or 50 degrees will be the best angle to give the vane: but this must be understood only of that part of it which is close adjoining to the axis. The vane itself must be twisted, or *weathered* as the millwrights term it, and must be much more oblique at its outer extremity. The exact position cannot be determined with any precision; because this depends on the proportion

Smoke-Jack.

proportion of the velocity of the vane to that of the current of heated air. This is subject to no rule, being changed according to the load of the jack. We imagine that an obliquity of 65 degrees for the outer ends of the vanes will be a good position for the generality of cases. Messinger describes an ingenious contrivance for changing this angle at pleasure, in order to vary the velocity of the motion. Each vane is made to turn round a midrib, which stands out like a radius from the spindle, and the vane is moved by a stiff wire attached to one of the corners adjoining to the axle. These wires are attached to a ring which slides on the spindle like the spreader of an umbrella; and it is stopped on any part of the spindle by a pin thrust through a hole in the spindle and ring. We mention this briefly, it being easily understood by any mechanic, and but of little consequence, because the machine is not susceptible of much precision.

It is easy to see that an increase of the surface of the vanes will increase the power: therefore they should occupy the whole space of the circle, and not consist of four narrow arms like the sails of a windmill. It is better to make many narrow vanes than a few broad ones; as will appear plain to one well acquainted with the mode of impulse of fluids acting obliquely. We recommend eight or twelve at least; and each vane should be so broad, that when the whole is held perpendicular between the eye and the light, no light shall come through the fly, the vanes overlapping each other *a very small matter*. We also recommend the making them of stiff plate. Their weight contributes to the steady motion, and enables the fly, which has acquired a considerable velocity during a favourable position of things, to retain a momentum sufficient to pull round the spit while the heavy side of the meat is rising from its lowest position. In such a situation a light fly soon loses its momentum, and the jack staggers under its load.

It is plain, from what has been said, that the fly should occupy the whole of that section of the vent where it is placed. The vent must therefore be brought to a round form in that place, that none of the current may pass uselessly by it.

It is an important question where the fly should be placed. If in a wide part of the vent, it will have a great surface, and act by a long lever; but the current in that place is slow, and its impulse weak. This is a fit subject of calculation. Suppose that we have it in our choice to place it either as it is drawn in the figure, or farther up at *g*, where its diameter must be one half of what it is at G. Since the same quantity of heated air passes through both sections, and the section *g* has only one-fourth of the area of the section G, it is plain that the air must be moving four times faster, and that its impulse is 16 times greater. But the surface on which it is acting is the fourth part of that of the fly G; the actual impulse therefore is only four times greater, supposing both flies to be moving with the same relative velocity in respect of the current; that is, the rim of each moving with the same portion of the velocity of the current. This will be the case when the small fly turns eight times as often in a minute as the large fly: for the air is moving four times as quick at *g*, and the diameter of *g* is one-half of that of G. Therefore, when the small fly is turning eight times as quick as the great one, there is a quadruple impulse acting at half the distance from the axis. The momentum or energy therefore of the current is double. Therefore, supposing the pinion, wheel, and pulleys of both jacks to be the same, the jack with the small fly, placed in the narrow part of the vent, will be 16 times more powerful.

By this example, more easily understood than a general process, it appears that it is of particular importance to place the fly in an elevated part of the vent, where the area may be much contracted. In order still farther to increase the power of the machine, it would be very proper to lengthen the spindle still more, and to put another fly on it at a considerable distance above the first, and a third above this, &c.

As the velocity of the current changes by every change of the fire, the motion of this jack must be very unsteady. To render it as adjustable as may be to the particular purpose of the cook, the pulley E has several grooves of different diameters, and the spit turns more or less slowly, by the same motion of the fly, according as it hangs in the chain by a larger or smaller pulley or groove.

Such is the construction of the smoke-jack in its most simple form. Some are more artificial and complicated, having, in place of the pulleys and connecting chain, a spindle coming down from the horizontal axis BC. On the upper end of this spindle is a horizontal contrate wheel, driven by a pinion in place of the pulley C. On the lower end is a pinion, driving a contrate wheel in place of the pulley E. This construction is represented in fig. 6. Others are constructed more simply, in Fig. 6.
the manner represented in fig. 7. But our first con- Fig. 7.
struction has great advantage in point of simplicity, and allows a more easy adjustment of the spit, which may be brought nearer to the fire or removed farther from it without any trouble; whereas, in the others, with a train of wheels and pinions, this cannot be done without several changes of pins and screws. The only imperfection of the pulley is, that by long use the grooves become slippery, and an ill-balanced joint is apt to hold back the spit, while the chain slides in the grooves. This may be completely prevented by making the grooves flat instead of angular (which greatly diminishes the friction), and furnishing them with short studs or pins which take into every third or fourth link of the chain. If the chain be made of the simplest form, with flat links, and each link be made of an exact length (making them all on a mould), the motion will be as easy as with any wheelwork, and without the least chance of slipping.

It is always of importance to avoid this slipping of the chain by balancing the loaded spit. For this purpose it will be extremely convenient to have what is called a *balance-skewer*. Let a part of the spit, immediately adjoining to the pulley, be made round, and let an arm be made to turn on it stiffly, so that it may be made fast in any position by a screw. Let a leaden ball be made to slide along this arm, with a screw to fasten it at any distance from the spit. When the meat is spitted, lay it on the racks, and the heaviest side will immediately place itself undermost. Now turn round the balance-skewer, so that it may point straight upwards, and make it fast in that position by the screw. Put the leaden ball on it, and slide it inwards or outwards

Smoke-Jack.

wards till it exactly balances the heavy side, which will appear by the spit's remaining in any position in which it is put.

The greatest difficulty is to keep the machine in repair. The essential part of it, the first mover, the fly, and the pinion and wheel, by which its motion is transmitted to the rest of the machine, are situated in a place of difficult access, and where they are exposed to violent heat and to the smoke and soot. The whole weight of the fly, resting on the lower pivot I, must exert a great pressure there, and occasion great friction, even when this pinion is reduced to the smallest size that is compatible with the necessary strength. The pivot must be of hardened steel, tapered like an obtuse cone, and must turn in a conical socket, also of hardened steel or of bell-metal; and this seat of pressure and friction must be continually supplied with oil, which it consumes very quickly. It is not sufficient that it be from time to time smeared with an oiled feather; there must be an iron cup formed round the socket, and kept filled with oil. It is surprising how quickly it disappears; it soon becomes clammy by evaporation, and by the soot which gathers about it. The continued rubbing of the pivot and socket wears them both very fast; and this is increased by hard powders, such as sandy dust, that are hurried up by the rapid current every time that the cook stirs the fire. These, getting between the rubbing parts, cause them to grind and wear each other prodigiously. It is a great improvement to invert these rubbing parts. Let the lower end of the spindle be of a considerable thickness, and have a conical hollow nicely drilled in its extremity. Let a blunt-pointed conical pin rise up in the middle of the oil cup, on which the conical hollow of the spindle may rest. Here will be the same steady support, and the same friction as in the other way; but no grinding dust can now lodge between the pivot and its socket: and if this upright pin be screwed up through the bottom of the cup, it may be screwed farther up in proportion as it wears; and thus the upper pivot *g* will never desert its hole, a thing which soon happens in the common way. We can say from experience, that a jack constructed in this way will not require the fifth part of the repairs of one done in the other way.

It is of importance that the whole be so put together as to be easily taken down, in order to sweep the vent, or to be repaired, &c. For this purpose, let the cross bar which carries the lower end of the upright spindle be placed a little on one side of the perpendicular line from the upper pivot hole. Let the cock which carries the oil cup and the pivot of the horizontal axis BC be screwed to one side of this cross bar, so that the centre of the cup may be exactly under the upper pivot hole. By this construction we have only to unscrew this cock, and then both axles come out of their places at once, and may be replaced without any trouble. We have sketched in fig. 8. the manner in which this may be done, where M represents a section of the lower cross bar. BCDE is the cock, fixed to the bar by the pins which go through both, with finger nuts *a* and *b* on the opposite side. F *i* is the hard steel pin with the conical top *i*, on which the lower end I of the upright spindle AG rests, in the manner recommended as the best and most durable. The pivot of the horizontal axis turns in a hole at E the top of the cock.

Fig

After all, we must acknowledge that the smoke-jack is inferior to the common jack that is moved by a weight. It is more expensive at first, and requires more frequent repairs; its motion is not so much under command; it occasions soot to be thrown about the fire, to the great annoyance of the cook; and it is a great encumbrance when we would clean the vent.

Smoke-Jack || Smollet.

Smoke-Farthings. The pentecostals or customary oblations offered by the dispersed inhabitants within a diocese when they made their procession to the mother or cathedral church, came by degrees into a standing annual rent called *smoke farthings*.

Smoke Silver. Lands were holden in some places by the payment of the sum of 6d. yearly to the sheriff, called *smoke-silver* (Par. 4. Edw. VI.). Smoke-silver and smoke-penny are to be paid to the ministers of divers parishes as a *modus* in lieu of tithe-wood: and in some manors formerly belonging to religious houses, there is still paid, as appendant to the said manors, the ancient Peter-pence, by the name of *Smoke-money* (*Twisd. Hist. Vindicat.* 77.).—The bishop of London *anno* 1444, issued out his commission, *Ad levandum le* smoke-farthings, &c.

SMOLENSKO, a large and strong city of Russia, and capital of a government of the same name, with a castle seated on a mountain, and a bishop's see. It is strong by its situation. It has been taken and retaken several times by the Poles and Russians; but these last have had possession of it ever since the year 1687. It was taken by the French in their irruption into Russia in 1812. It is seated on the river Nieper, near the frontiers of Lithuania, 188 miles south-west of Moscow. E. Long. 31. 22. N. Lat. 54. 50.

Smolensko, a government of Russia, bounded on the north by Twer, on the east by Moscow, on the south by Kalouga, and on the west by Witepsk. It is full of forests and mountains, but is fertile in grain. The population in 1815 was 965,000.

SMOLLET, Dr Tobias, an author whose writings will transmit his name with honour to posterity, was born in the year 1720 at a small village within two miles of Cameron, on the banks of the river Leven. He appears to have received a classical education, and was bred to the practice of physic and surgery; and in the early part of his life served as a surgeon's mate in the navy.

The incidents that befel him during his continuance in this capacity served as a foundation for Roderic Random, one of the most entertaining novels in the English tongue. He was present at the siege of Carthagena; and in the before-mentioned novel he has given a faithful, though not very pleasing, account of the management of that ill-conducted expedition, which he censures in the warmest terms, and from circumstances which fell under his own particular observation.

His connection with the sea seems not to have been of long continuance; and it is probable that he wrote several pieces before he became known to the public by his capital productions. The first piece we know of with certainty is a Satire in two parts, printed first in the years 1746 and 1747, and reprinted in a Collection of his Plays and Poems in 1777. About this period, or some time before, he wrote for Mr Rich an opera intitled Alceste, which has never been performed nor printed.

At the age of 18 he wrote a tragedy intitled The Regicide, Smollet.

Regicide, founded on the story of the assassination of James I. of Scotland. In the preface to this piece, published by subscription in the year 1749, he bitterly exclaimed against false patrons, and the duplicity of theatrical managers. The warmth and impetuosity of his temper hurried him, on this occasion, into unjust reflections against the late George Lord Lyttleton and Mr Garrick: the character of the former he characterised in the novel of Peregrine Pickle, and he added a burlesque of the Monody written by that nobleman on the death of his lady. Against Mr Garrick he made illiberal ill-founded criticisms; and in his novel of Roderick Random gave a very unfair representation of his treatment of him respecting this tragedy. Of this conduct he afterwards repented, and acknowledged his errors; though in the subsequent editions of the novel the passages which were the hasty effusions of disappointment were not omitted.

However, in giving a sketch of the liberal arts in his History of England, he afterwards remarked, "the exhibitions of the stage were improved to the most exquisite entertainment by the talents and management of Garrick, who greatly surpassed all his predecessors of this and perhaps every other nation, in his genius for acting, in the sweetness and variety of his tones, the irresistible magic of his eye, the fire and vivacity of his action, the eloquence of attitude, and the whole pathos of expression.

Not satisfied with this public declaration, he wrote an apology to Mr Garrick in still stronger terms. With these ample concessions, Mr Garrick was completely satisfied; so that in 1757, when Dr Smollet's comedy of the Reprisals, an afterpiece of two acts, was performed at Drury Lane theatre, the latter acknowledged himself highly obliged for the friendly care of Mr Garrick exerted in preparing it for the stage; and still more for his acting the part of Lusignan in Zara for his benefit, on the sixth instead of the ninth night, to which he was only intitled by the custom of the theatre.

The Adventures of Roderic Random, published in 1748, 2 vols 12mo, a book which still continues to have a most extensive sale, first established the Doctor's reputation. All the first volume and the beginning of the second appear to consist of real incident and character, though certainly a good deal heightened and disguised. The Judge his grandfather, Crab and Potion the two apothecaries, and 'Squire Gawky, were characters well known in that part of the kingdom where the scene was laid. Captains Oakhum and Whiffle, Doctors Mackshane and Morgan, were also said to be real personages; but their names we have either never learned or have now forgotten. A bookbinder and barber long eagerly contended for being shadowed under the name of *Strap*. The Doctor seems to have enjoyed a peculiar felicity in describing sea characters, particularly the officers and sailors of the navy. His Trunnion, Hatchway, and Pipes, are highly finished originals; but what exceeds them all, and perhaps equals any character that has yet been painted by the happiest genius of ancient or modern times, is his Lieutenant Bowling. This is indeed nature itself; original, *unique* and *sui generis*.

By the publication of this work the Doctor had acquired so great a reputation, that henceforth a certain degree of success was insured to every thing known or suspected to proceed from his hand. In the course of a few years, the Adventures of Peregrine Pickle appeared; a work of great ingenuity and contrivance in the composition, and in which an uncommon degree of erudition is displayed, particularly in the description of the entertainment given by the Republican Doctor, after the manner of the ancients. Under this personage the late Dr Akenside, author of The Pleasures of Imagination, is supposed to be typified; and it would be difficult to determine whether profound learning or genuine humour predominate most in this episode. Another episode of the Adventures of a Lady of Quality, likewise inserted in this work, contributed greatly to its success, and is indeed admirably executed; the materials, it is said, the lady herself (the celebrated Lady *Vane*) furnished.

These were not the only original compositions of this stamp with which the Doctor has favoured the public. Ferdinand Count Fathom, and Sir Launcelot Greaves, are still in the list of what may be called *reading novels*, and have gone through several editions; but there is no injustice in placing them in a rank far below the former. No doubt invention, character, composition, and contrivance, are to be found in both; but then situations are described which are hardly possible, and characters are painted which, if not altogether unexampled, are at least incompatible with modern manners; and which ought not to be, as the scenes are laid in modern times.

The last work which we believe the Doctor published was of much the same species, but cast into a different form—The Expedition of Humphrey Clinker. It consists of a series of letters, written by different persons to their respective correspondents. He has here carefully avoided the faults which may be justly charged to his two former productions. Here are no extravagant characters nor unnatural situations. On the contrary, an admirable knowledge of life and manners is displayed; and most useful lessons are given applicable to interesting but to very common situations.

We know not whether the remark has been made, but there is certainly a very obvious similitude between the characters of the three heroes of the Doctor's chief productions. Roderic Random, Peregrine Pickle, and Matthew Bramble, are all brothers of the same family. The same satirical, cynical disposition, the same generosity and benevolence, are the distinguishing and characteristical features of all three: but they are far from being servile copies or imitations of each other. They differ as much as the Ajax, Diomed, and Achilles of Homer. This was undoubtedly a great effort of genius; and the Doctor seems to have described his own character at the different stages and situations of his life.

Before he took a house at Chelsea, he attempted to settle as practitioner of physic at Bath; and with that view wrote a treatise on the waters; but was unsuccessful, chiefly because he could not render himself agreeable to the women, whose favour is certainly of great consequence to all candidates for eminence, whether in medicine or divinity. This, however, was a little extraordinary; for those who remembered Dr Smollet at that time, cannot but acknowledge that he was as graceful and handsome a man as any of the age he lived in; besides, Smollet. besides, there was a certain dignity in his air and manner which could not but inspire respect wherever he appeared. Perhaps he was too soon discouraged; in all probability, had he persevered, a man of his great learning, profound sagacity, and intense application, besides being endued with every other external as well as internal accomplishment, must have at last succeeded, and, had he attained to common old age, been at the head of his profession.

Abandoning physic altogether as a profession, he fixed his residence at Chelsea, and turned his thoughts entirely to writing. Yet, as an author, he was not near so successful as his happy genius and acknowledged merit certainly deserved. He never acquired a patron among the great, who by his favour or beneficence relieved him from the necessity of writing for a subsistence. The truth is, Dr Smollet possessed a loftiness and elevation of sentiment and character which appear to have disqualified him for paying court to those who were capable of conferring favours. It would be wrong to call this disposition pride or haughtiness; for to his equals and inferiors he was ever polite, friendly, and generous. Booksellers may therefore be said to have been his only patrons; and from them he had constant employment in translating, compiling, and reviewing. He translated Gil Blas and Don Quixote, both so happily, that all the former translations of these excellent productions of genius have been almost superseded by his. His name likewise appears to a translation of Voltaire's Prose Works; but little of it was done by his own hand; he only revised it, and added a few notes. He was concerned in a great variety of compilations. His History of England was the principal work of that kind. It had a most extensive sale; and the Doctor is said to have received 2000l. for writing it and the continuation.

In 1755 he set on foot the Critical Review, and continued the principal manager of it till he went abroad for the first time in the year 1763. He was perhaps too acrimonious sometimes in the conduct of that work; and at the same time displayed too much sensibility when any of the unfortunate authors attempted to retaliate whose works he had perhaps justly censured.

Among other controversies in which his engagements in this publication involved him, the most material in its consequences was that occasioned by his remarks on a pamphlet published by Admiral Knowles. That gentleman, in defence of his conduct on the expedition to Rochfort, published a vindication of himself; which falling under the Doctor's examination, produced some very severe strictures both on the performance and on the character of the writer. The admiral immediately commenced a prosecution against the printer; declaring at the same time that he desired only to be informed who the writer was, that if he proved to be a gentleman he might obtain the satisfaction of one from him. In this affair the Doctor behaved both with prudence and with spirit. Desirous of compromising the dispute with the admiral in an amicable manner, he applied to his friend Mr Wilkes to interpose his good offices with his opponent. The admiral, however, was inflexible; and just as sentence was going to be pronounced against the printer, the Doctor came into court, avowed himself the author of the Strictures, and declared himself ready to give Mr Knowles any satisfaction he chose.

The admiral immediately commenced a fresh action against the Doctor, who was found guilty, fined 100l. and condemned to three months imprisonment in the King's Bench. It is there he is said to have written the Adventures of Sir Launcelot Greaves, in which he has described some remarkable characters, then his fellow-prisoners.

When Lord Bute was called to the chief administration of affairs, he was prevailed upon to write in defence of that nobleman's measures; which he did in a weekly paper called the *Briton*. This gave rise to the famous North Briton; wherein, according to the opinion of the public, he was rather baffled. The truth is the Doctor did not seem to possess the talents necessary for political altercation. He wanted temper and coolness; and his friends accused his patron of having denied him the necessary information, and even neglected the fulfilling of some of his other engagements with him. Be that as it will, the Doctor is said not to have forgotten him in his subsequent performances,

Besides the Briton, Dr Smollet is supposed to have written other pieces in support of the cause he espoused. The Adventures of an Atom, in two volumes, are known to be his production,

His constitution being at last greatly impaired by a sedentary life and assiduous application to study, he went abroad for his health in June 1763, and continued in France and Italy two years. He wrote an account of his travels in a series of letters to some friends, which were afterwards published in two volumes octavo, 1766. During all that time he appears to have laboured under a constant fit of chagrin. A very slight perusal of these letters will sufficiently evince that this observation is founded in fact, and is indeed a melancholy instance of the influence of bodily distemper over the best disposition.

His relation of his travels is actually cynical; for which Sterne, in his Sentimental Journey, has animadverted on him under the character of Smelfungus. The Doctor lived to return to his native country: but his health continuing to decline, and meeting with fresh mortifications and disappointments, he went back to Italy, where he died October 21. 1771. He was employed, during the last years of his life, in abridging the Modern Universal History, great part of which he had originally written himself, particularly the histories of France, Italy, and Germany.

He certainly met with many mortifications and disappointments; which, in a letter to Mr Garrick, he thus feelingly expresses: "I am old enough to have seen and observed, that we are all playthings of Fortune; and that it depends upon something as insignificant and precarious as the tossing up of a halfpenny, whether a man rises to affluence and honours, or continues to his dying day struggling with the difficulties and disgraces of life."

It would be needless to expatiate on the character of a man so well known as Dr Smollet, who has, besides, given so many strictures of his own character and manner of living in his writings, particularly in Humphrey Clinker; where he appears under the appellation of *Mr Serle*, and has an interview with Mr Bramble; and his manner of living is described in another letter, where young Melford is supposed to dine with him at his house in Chelsea. No doubt he made money by his connections

Smollet, Smugglers.

tions with the booksellers; and had he been a rigid economist, or endued with the gift of retention (an expression of his own), he might have lived and died very independent. However, to do justice to his memory, his difficulties, whatever they were, proceeded not from extravagance or want of economy. He was hospitable, but not ostentatiously so; and his table was plentiful, but not extravagant. No doubt he had his failings; but still it would be difficult to name a man who was so respectable for the qualities of his head, or more amiable for the virtues of his heart.

Since his death a monument has been erected to his memory near Leghorn, on which is inscribed an epitaph written in Latin by his friend Dr Armstrong, author of The Art of Preserving Health, and many other excellent pieces. An inscription written in Latin was likewise inscribed on a pillar erected to his memory on the banks of the Leven by one of his relations.

To these memoirs we are extremely sorry to add, that so late as 1785 the widow of Dr Smollet was residing in indigent circumstances at Leghorn. On this account the tragedy of Venice Preserved was acted for her benefit at Edinburgh on the 5th of March, and an excellent prologue spoken on that occasion.

The pieces inserted in the posthumous collection of Dr Smollet's plays and poems are, The Regicide, a tragedy: The Reprisal, a comedy; Advice and Reproof, two satires; The Tears of Scotland; Verses on a Young Lady; a Love Elegy, in imitation of Tibullus; two Songs; a Burlesque Ode; Odes to Mirth, to Sleep, to Leven Water, to Blue-ey'd Ann, and to Independence.

SMUGGLERS, persons who import or export prohibited goods without paying the duties appointed by the law.

The duties of customs, it is said, were originally instituted, in order to enable the king to afford protection to trade against pirates: they have since been continued as a branch of the public revenue. As duties imposed upon the importation of goods necessarily raise their price above what they might otherwise have been sold for, a temptation is presented to import the commodity clandestinely and to evade the duty. Many persons, prompted by the hopes of gain, and considering the violation of a positive law of this nature as in no respect criminal (an idea in which they have been encouraged by a great part of the community, who make no scruple to purchase smuggled goods), have engaged in this illicit trade. It was impossible that government could permit this practice, which is highly injurious to the fair trader, as the smuggler is enabled to undersell him, while at the same time he impairs the national revenue, and thus wholly destroys the end for which these duties were appointed. Such penalties are therefore inflicted as it was thought would prevent smuggling.

Burn's Law Dictionary, vol. ii.

Many laws have been made with this view. If any goods be shipped or landed without warrant and presence of an officer, the vessel shall be forfeited, and the wharfinger shall forfeit 100l. and the master or mariner of any ship inward bound shall forfeit the value of the goods: and any carman, porter, or other assisting, shall be committed to gaol, till he find surety of his good behaviour, or until he shall be discharged by the court of exchequer (13 and 14 C. II. c. 11.). If goods be relanded after drawback, the vessel and goods shall be forfeited; and every person concerned therein shall forfeit double the value of the drawback (8 An. c. 13.). Goods taken in at sea shall be forfeited, and also the vessel into which they are taken; and every person concerned therein shall forfeit treble value (9 G. II. c. 35.). A vessel hovering near the coast shall be forfeited, if under 50 tons burden; and the goods shall also be forfeited, or the value thereof (5 G. III. c. 43.). Persons receiving or buying run goods shall forfeit 20l. (8 G. c. 18.). A concealer of run goods shall forfeit treble value (8 G. c. 18.). Offering run goods to sale, the same shall be forfeited, and the person to whom they are offered may seize them; and the person offering them to sale shall forfeit treble value (11 G. c. 30.). A porter or other person carrying run goods shall forfeit treble value (9 G. II. c. 35.). Persons armed or disguised carrying run goods shall be guilty of felony, and transported for seven years (8 G. c. 18. 9 G. II. c. 35.).

But the last statute, 19 G. II. c. 34. is for this purpose *instar omnium;* for it makes all forcible acts of smuggling, carried on in defiance of the laws, or even in disguise to evade them, felony without benefit of clergy: enacting, that if three or more persons shall assemble, with fire-arms or other offensive weapons, to assist in the illegal exportation or importation of goods, or in rescuing the same after seizure, or in rescuing offenders in custody for such offences; or shall pass with such goods in disguise; or shall wound, shoot at, or assault, any officers of the revenue when in the execution of their duty; such persons shall be felons, without the benefit of clergy.

When we consider the nature, and still more the history of mankind, we must allow that the enacting of severe penal laws is not the way to prevent crimes. It were indeed much to be wished that there were no such thing as a political crime; for the generality of men, but especially the lower orders, not discerning the propriety or utility of such laws, consider them as oppressive and tyrannical, and never hesitate to violate them when they can do it with impunity. Instead therefore of punishing smugglers, it would be much better to remove the temptation But the high duties which have been imposed upon the importation of many different sorts of foreign goods, in order to discourage their consumption in Great Britain, have in many cases served only to encourage smuggling; and in all cases have reduced the revenue of the customs below what more moderate duties would have afforded. The saying of Dr Swift, that in the arithmetic of the customs two and two, instead of making four, make sometimes only one, holds perfectly true with regard to such heavy duties, which never could have been imposed, had not the mercantile system taught us, in many cases, to employ taxation as an instrument, not of revenue, but of monopoly.

Smith's Wealth of Nations, vol. iii.

The bounties which are sometimes given upon the exportation of home produce and manufactures, and the drawbacks which are paid upon the re-exportation of the greater part of foreign goods, have given occasion to many frauds, and to a species of smuggling more destructive of the public revenue than any other. In order to obtain the bounty or drawback, the goods, it is well known, are sometimes shipped and sent to sea, but soon

soon afterwards clandestinely relanded in some other part of the country.

Heavy duties being imposed upon almost all goods imported, our merchant importers smuggle as much, and make entry of as little as they can. Our merchant exporters, on the contrary, make entry of more than they export; sometimes out of vanity, and to pass for great dealers in goods which pay no duty; and sometimes to gain a bounty or a drawback. Our exports, in consequence of these different frauds, appear upon the customhouse books greatly to overbalance our imports; to the unspeakable comfort of those politicians who measure the national prosperity by what they call the balance of trade.

SMUT, in *Husbandry*, a disease in corn, when the grains, instead of being filled with flour, are full of a stinking black powder. See WHEAT.

SMYRNA, or ISMIR, at present the largest and richest city of Asia Minor, is situated in north latitude 38° 28′, and in E. Long. 27° 25′ from Greenwich, and about 183 miles west by south of Constantinople. The town extends along the shore about half a mile on a gentle declivity. The houses of the English, French, and Dutch consuls, are handsome structures; these, with most of those occupied by the Christian merchants, are washed on one side by the sea, forming a street named *Frank-street*, from its being solely inhabited by European Christians. In the year 1763 the whole of this quarter was consumed by fire: the loss sustained by this calamity in merchandise was estimated at a million and a half of Turkish dollars, or near 200,000l. sterling. The port is one of the finest of the Levant, it being able to contain the largest fleet; and indeed there are seldom in it fewer than 100 ships of different nations.

A castle stands at its entrance, and commands all the shipping which sail in or out. There is likewise an old ruinous castle, near a mile in circumference, which stands in the upper part of the city, and according to tradition, was built by the empress Helena: and near it is an ancient structure, said to be the remains of a palace where the Greek council was held when Smyrna was the metropolis of Asia Minor. They also show the ruins of an amphitheatre, where it is said St Polycarp, the first bishop, fought with lions.

This city is about four miles in circumference, and nearly of a triangular form; but the side next the mountain is much longer than the other sides. The houses are low, and mostly built with clay walls, on account of the earthquakes to which the country is subject; but the caravanseras and some other of the public buildings have an air of magnificence. The streets are wide, and almost a continued bazar, in which a great part of the merchandise of Europe and Asia is exposed to sale, with plenty of provisions; though these are not so cheap as in many other parts of Turkey, on account of the populousness of the place, and the great resort of foreigners. It is said to contain 15,000 Turks, 10,000 Greeks, 1800 Jews, 200 Armenians, and 200 Franks: but the whole population is computed at 120,000. The Turks have 19 mosques; two churches belong to the Greeks; one to the Armenians; and the Jews have eight synagogues. The Romanists have three convents. There is also one of the fathers Della Terra Santa. Here resides an archbishop of the Greek church; a Latin bishop who has a salary from Rome, with the title of bishop of Smyrna *in partibus infidelium*; and the English and Dutch factories have each their chaplain.

The walks about the town are extremely pleasant, particularly on the west side of Frank street, where there are several little groves of orange and lemon trees, which being always clothed with leaves, blossoms, and fruit, regale several of the senses at the same time. The vines which cover the little hills about Smyrna afford both a delightful prospect and plenty of grapes, of which good wine is made. These hills are agreeably interspersed with fertile plains, little forests of olives and other fruit-trees, and many pleasure-houses, to which the Franks usually retire during the summer. In the neighbourhood of Smyrna is great plenty of game and wild-fowl, and particularly deer and wild-hogs. The sea also abounds with a variety of good fish. The European Christians are here allowed all imaginable liberties, and usually clothe themselves after the European manner.

The chief commerce of this city consists in raw silk, silk-stuffs, grograms, and cotton yarn.

However, the unhealthfulness of the situation, and more especially the frequent earthquakes, from which, it is said, they are scarcely ever free for two years together, and which have been felt 40 days successively, are an abatement of the pleasure that might otherwise be enjoyed here. A very dreadful one happened in June 1668, which overthrew a great number of the houses; and the rock opening where the castle stood, swallowed it up, and no less than 5000 persons perished on this occasion.

In the year 1758, so desolating a plague raged here, that scarcely a sufficient number of the inhabitants survived to gather in the fruits of the earth. In the year 1772, three-fourth parts of the city were consumed by fire; and six years after it was visited by the most dreadful earthquakes, which continued from the 25th of June to the 5th of July; by which successive calamities the city has been so much reduced, that its former consequence is never likely to be restored.

The ladies here wear the oriental dress, consisting of large trowsers or breeches, which reach to the ancle; long vests of rich silk or velvet, lined in winter with costly furs; and round their waist an embroidered zone with clasps of silver or gold. Their hair is plaited, and descends down the back often in great profusion. The girls have sometimes above twenty thick tresses, besides two or three encircling the head as a cornet, and set off with flowers and plumes of feathers, pearls, or other jewels. They commonly stain it of a chesnut colour, which is the most desired. Their apparel and carriage are alike antique. It is remarkable that the trowsers are mentioned in a fragment of Sappho as part of the female dress.

SMYRNIUM, ALEXANDERS; a genus of plants belonging to the class of pentandria, and to the order of digynia; and in the natural system ranging under the 45th order, *Umbellatæ*. See BOTANY *Index*.

SNAFFLE, in the manege, is a very slender bit-mouth without any branches, much used in England; the true bridles being reserved for war.

SNAIL, in *Zoology*. See HELIX, CONCHOLOGY *Index*, and LIMAX, HELMINTHOLOGY *Index*.

SNAKE, in *Zoology*. See ANGUIS and SERPENS, OPHIOLOGY *Index*.

SNAKE-*Stones*, *Ammonitæ*, in *Natural History*, the name of a large genus of fossil shells, very few if any of which are yet known in their recent state, or living either on our own or any other shores; so that it seems wonderful whence so vast a number and variety of them should be brought into our subterranean regions. They seem indeed dispersed in great plenty throughout the world, but nowhere are found in greater numbers, beauty, and variety, than in our island.

Mr Harenberg found prodigious numbers of them on the banks of a river in Germany. He traced this river through its several windings for many miles; and among a great variety of belemnitæ, cornua ammonis, and cochlitæ, of various kinds, he found also great quantities of wood of recent petrifaction, which still preserved plain marks of the axe by which it had been cut from the trees then growing on the shore. The water of this river he found in dry seasons, when its natural springs were not diluted with rains, to be considerably heavier than common water; and many experiments showed him that it contained ferruginous, as well as stony particles, in great quantity, whence the petrifactions in it appeared the less wonderful, though many of them of recent date.

Of the cornua ammonis, or serpent-stones, he there observed more than 30 different species. They lie immersed in a bluish fossil stone, of a soft texture and fatty appearance, in prodigious numbers, and of a great variety of sizes, from the larger known sorts down to such as could not be seen without very accurate inspection or the assistance of a microscope. Such as lie in the softest of these stones are soft like their matrix, and easily crumble to pieces; others are harder. In a piece of this stone, of the bigness of a finger, it is common to find 30 or more of these fossils; and often they are seen only in form of white specks, so minute that their figure cannot be distinguished till examined by the microscope.

They all consist of several volutæ, which are different in number in the different species, and their striæ also are extremely various; some very deep with very high ridges between them, others very slight; some straight, others crooked; others undulated, and some terminating in dots, tubercles, or cavities, towards the back, and others having tubercles in two or three places. They are all composed of a great number of chambers or cells, in the manner of the *nautilus Græcorum*, each having a communication with the others, by means of a pipe or siphunculus. There is a small white shell fish of Barbadoes, which seems truly a recent animal of this genus; and in the East Indies there is another also, small and grayish; but the large and beautifully marked ones are found only fossil.

They are composed of various fossil bodies, often of quarry stone, sometimes of the matter of the common pyrites, and of a great variety of other substances; and though they appear usually mere stones, yet in some the pearly part of the original shell is preserved in all its beauty. Sometimes also, while the outer substance is of the matter of the pyrites, or other coarse, stony, or mineral matter, the inner cavity is filled with a pure white spar of the common plated texture. This gives a great beauty to the specimen. The cornua ammonis, or snake-stones, are found in many parts of England, particularly in Yorkshire, where they are very plentiful in the alum rocks of several sizes.

SNAPEDRAGON. See ANTIRRHINUM, BOTANY *Index*.

SNEEZING, a convulsive motion of the muscles of the breast, whereby the air is expelled from the nose with much vehemence and noise. It is caused by the irritation of the upper membrane of the nose, occasioned by acrid substances floating in the air, or by medicines called *sternutatory*.

This irritation is performed either externally, by strong smells, as marjorum, roses, &c. or by dust floating in the air, and taken in by inspiration; or by sharp pungent medicines, as cresses and other sternutatories, which vellicate the membrane of the nose; or internally, by the acrimony of the lympha or mucus, which naturally moistens that membrane. The matters cast forth in sneezing come primarily from the nose and throat; the pituitary membrane continually exuding a mucus thither; and, secondarily, from the breast, the trachea, and the bronchia of the lungs.

The practice of saluting the person who sneezed existed in Africa, among nations unknown to the Greeks and Romans. The accounts we have of Monomotapa inform us *, that when the prince sneezes, all his subjects in the capital are advertised of it, that they may offer up prayers for his safety. The author of the Conquest of Peru assures us, that the cacique of Guachoia having sneezed in presence of the Spaniards, the Indians of his train fell prostrate before him, stretched forth their hands, and displayed to him the accustomed marks of respect, while they invoked the sun to enlighten him, to defend him, and to be his constant guard.

Every body knows that the Romans saluted each other on these occasions: and Pliny relates †, that Tiberius exacted these signs of homage when drawn in his chariot. Superstition, whose influence can debase every thing, had degraded this custom for several ages, by attaching favourable or unfavourable omens to sneezing according to the hour of the day or night, according to the signs of the zodiac, according as a work was more or less advanced, or according as one had sneezed to the right or to the left ‡. If a man sneezed at rising from table or from his bed, it was necessary for him to sit or lie down again. You are struck with astonishment, said Timotheus to the Athenians, who wished to return into the harbour with their fleet §, because he had sneezed; you are struck with astonishment, because among 10,000 there is one man whose brain is moist.

Polydore Virgil pretends, that in the time of Gregory the Great, there reigned in Italy an epidemic distemper, which carried off by sneezing all those who were seized by it; and that this pontiff ordered prayers to be made against it, accompanied by certain signs of the cross. But besides that, there are very few cases in which sneezing can be considered as dangerous, and that it is frequently a favourable symptom ||, it is evident, that we ought not to date from the sixth century the origin of a custom which loses itself in the obscurity of antiquity. Avicenna and Cardan say, it is a sort of convulsion, which gives occasion to dread an epilepsy, and that

|| Hippocrat. Halleri Phys.

that this disease is endeavoured to be warded off by prayers. Clement of Alexandria considers it as a mark of intemperance and effeminacy, which ought to be proscribed. And he inveighs bitterly against those who endeavour to procure sneezing by external aid. Montaigne, on the contrary, explains this fact in a tone rather cynical. It is singular enough, that so many ridiculous, contradictory, and superstitious opinions, have not abolished those customary civilities which are still preserved equally among high and low; and which only the Anabaptists and Quakers have rejected, because they have renounced salutations in every case.

Among the Greeks sneezing was almost always a good omen. It excited marks of tenderness, of respect, and attachment. The genius of Socrates informed him by sneezing, when it was necessary to perform any action*. The young Parthenis, hurried on by her passion, resolved to write to Sarpedon an avowal of her love †; she sneezes in the most tender and impassioned part of her letter: This is sufficient for her; this incident supplies the place of an answer, and persuades her that Sarpedon is her lover. Penelope, harassed by the vexatious courtship of her suitors, begins to curse them all, and to pour forth vows for the return of Ulysses ‡. Her son Telemachus interrupts her by a loud sneeze. She instantly exults with joy, and regards this sign as an assurance of the approaching return of her husband. Xenophon was haranguing his troops; a soldier sneezed in the moment when he was exhorting them to embrace a dangerous but necessary resolution. The whole army, moved by this presage, determined to pursue the project of their general; and Xenophon orders sacrifices to Jupiter the preserver §.

‡ Homeri Odyss. lib. xvii.

§ Xenoph. Anab.

This religious reverence for sneezing, so ancient and so universal even in the times of Homer, always excited the curiosity of the Greek philosophers and of the rabbins. These last have spread a tradition, that, after the creation of the world, God made a general law to this purport, that every living man should sneeze but once in his life, and that at the same instant he should render up his soul into the hand of his Creator ||, without any preceding indisposition. Jacob obtained an exemption from the common law, and the favour of being informed of his last hour: He sneezed and did not die; and this sign of death was changed into a sign of life. Notice of this was sent to all the princes of the earth; and they ordained that in future sneezing should be accompanied with forms of blessing, and vows for the persons who sneezed.

|| Acad. des Inscr. vol.

Aristotle remounts likewise to the sources of natural religion. He observes, that the brain is the origin of the nerves, of our sentiments, our sensations, the seat of the soul, the image of the Divinity *; that upon all these accounts, the substance of the brain has ever been held in honour; that the first men swore by their head; that they durst not touch nor eat the brains of any animal; that it was even a sacred word which they dared not to pronounce. Filled with these ideas, it is not wonderful that they extended their reverence even to sneezing. Such is the opinion of the most ancient and sagacious philosophers of Greece.

* Aristot. in Pb.

According to mythology, the first sign of life Prometheus's artificial man gave was by sternutation. This supposed creator is said to have stolen a portion of the solar rays; and filling with them a phial, which he had made on purpose, sealed it up hermetically. He instantly flies back to his favourite automaton, and opening the phial holds it close to the statue; the rays still retaining all their activity, insinuate themselves through the pores, and set the fictitious man a sneezing. Prometheus, transported with the success of his machine, offers up a fervent prayer, with wishes for the preservation of so singular a being. His automaton observed him, remembering his ejaculations, was very careful, on the like occasions, to offer these wishes in behalf of his descendants, who perpetuated it from father to son in all their colonies.

SNIGGLING, a method of fishing for eels, chiefly used in the daytime, when they are found to hide themselves near wears, mills, or flood-gates. It is performed thus: Take a strong line and hook, baited with a garden worm, and observing the holes where the eels lie hid, thrust your bait into them by the help of a stick; and if there be any, you shall be sure to have a bite; and may, if your tackling hold, get the largest eels.

SNIPE, in *Ornithology*. See SCOLOPAX and SHOOTING.

SNORING, in *Medicine*, otherwise called *stertor*, is a sound like that of the cerchnon, but greater and more manifest.

Many confound those affections, and make them to differ only in place and magnitude, calling by the name of *stertor* that sound or noise which is heard or supposed to be made in the passage between the palate and the nostrils, as in those who sleep; that boiling or bubbling noise, which in respiration proceeds from the larynx or head, or orifice of the aspera arteria, they call *cerchnon*; but if the sound comes from the aspera arteria itself, it is called *cerchnos*, that is, as some understand it, a rattling, or as others a stridulous or wheezing roughness of the aspera arteria. In dying persons this affection is called by the Greeks ρεγχος, *rhenchos*, which is a snoring or rattling kind of noise, proceeding as it were from a conflict between the breath and the humours in the aspera arteria.

This and such like affections are owing to a weakness of nature, as when the lungs are full of pus or humours: to which purpose we read in the Prognostics of Hippocrates, "it is a bad sign when there is no expectoration, and no discharge from the lungs, but a noise as from an ebullition is heard in the aspera arteria from a plenitude of humour." Expectoration is suppressed either by the viscidity of the humour, which requires to be discharged, and which adhering to the aspera arteria, and being there agitated by the breath, excites that bubbling noise or stertor; or by an obstruction of the bronchia; or, lastly, by a compression of the aspera arteria and throat, whence the passage is straitened, in which the humours being agitated, excite such a kind of noise as before described. Hence Galen calls those who are strait-breasted *stertorous*. That author assigns but two causes of this symptom, which are either the straitness of the passage of respiration or redundance of humours, or both together; but it is necessary to add a third, to wit, the weakness of the faculty, which is the cause of the rhenchos in dying persons, where nature is too weak to make discharges.

From what has been said we conclude, that this symptom or this sort of fervour or ebullition in the throat, Snoring, Snow.

throat, is not always mortal, but only when nature is oppressed with the redundance of humour, in such a manner, that the lungs cannot discharge themselves by spitting; or the passage appointed for the breath (being the aspera arteria) is very much obstructed, upon which account many dying persons labour under a stertor with their mouths gaping.

SNOW, a well known meteor, formed by the freezing of the vapour of water in the atmosphere. It differs from hail and hoar-frost, in being as it were crystallized, which they are not. This appears in examining a flake of snow by a magnifying glass; when the whole of it will appear to be composed of fine shining spicula diverging like rays from a centre. As the flakes fall down through the atmosphere, they are continually joined by more of these radiated spicula, and thus increase in bulk like the drops of rain or hailstones. Dr Grew, in a discourse of the nature of snow, observes, that many parts thereof are of a regular figure, for the most part stars of six points, and are as perfect and transparent ice as any we see on a pond, &c. Upon each of these points are other collateral points, set at the same angles as the main points themselves: among which there are divers other irregular, which are chiefly broken points, and fragments of the regular ones. Others also, by various winds, seem to have been thawed and frozen again into irregular clusters; so that it seems as if the whole body of snow were an infinite mass of icicles irregularly figured. That is, a cloud of vapours being gathered into drops, the said drops forthwith descend; upon which descent, meeting with a freezing air as they pass through a colder region, each drop is immediately frozen into an icicle, shooting itself forth into several points; but these still continuing their descent, and meeting with some intermitting gales of warmer air, or in their continual waftage to and fro touching upon each other, some of them are a little thawed, blunted, and again frozen into clusters, or entangled so as to fall down in what we call *flakes*.

The lightness of snow, although it is firm ice, is owing to the excess of its surface, in comparison to the matter contained under it; as gold itself may be extended in surface till it ride upon the least breath of air.

The whiteness of snow is owing to the small particles into which it is divided; for ice, when pounded, will become equally white. An artificial snow has been made by the following experiment. A tall phial of aquafortis being placed by the fire till it is warm, and filings of pure silver, a few at a time, being put into it; after a brisk ebullition, the silver will dissolve slowly. The phial being then placed in a cold window, as it cools the silver particles will shoot into crystals, several of which running together will form a flake of snow, which will descend to the bottom of the phial. While they are descending, they represent perfectly a shower of silver snow, and the flakes will lie upon one another at the bottom, like real snow upon the ground.

According to Signior Beccaria, clouds of snow differ in nothing from clouds of rain, but in the circumstance of cold that freezes them. Both the regular diffusion of the snow, and the regularity of the structure of its parts (particularly some figures of snow or hail which fall about Turin, and which he calls *rosette*) show that clouds of snow are acted upon by some uniform cause like electricity; and he endeavours to show how electricity is capable of forming these figures. He was confirmed in his conjectures by observing, that his apparatus for observing the electricity of the atmosphere never failed to be electrified by snow as well as rain. Professor Winthrop sometimes found his apparatus electrified by snow when driven about by the wind, though it had not been affected by it when the snow itself was falling. A more intense electricity, according to Beccaria, unites the particles of hail more closely than the more moderate electricity does those of snow, in the same manner as we see that the drops of rain which fall from thunder-clouds are larger than those which fall from others, though the former descend through a less space.

Snow.

But we are not to consider snow merely as a curious and beautiful phenomenon. The Great Dispenser of universal bounty has so ordered it, that it is eminently subservient, as well as all the works of creation, to his benevolent designs. Were we to judge from appearances only, we might imagine, that so far from being useful to the earth, the cold humidity of snow would be detrimental to vegetation. But the experience of all ages asserts the contrary. Snow, particularly in those northern regions where the ground is covered with it for several months, fructifies the earth, by guarding the corn or other vegetables from the intenser cold of the air, and especially from the cold piercing winds. It has been a vulgar opinion, very generally received, that snow fertilizes the lands on which it falls more than rain, in consequence of the nitrous salts which it is supposed to acquire by freezing. But it appears from the experiments of Margraaf, in the year 1751, that the chemical difference between rain and snow water is exceedingly small; that the latter contains a less proportion of earth than the former; but neither of them contain either earth or any kind of salt in any quantity which can be sensibly efficacious in promoting vegetation. Allowing, therefore, that nitre is a fertilizer of lands, which many are upon good grounds disposed utterly to deny, yet so very small is the quantity of it contained in snow, that it cannot be supposed to promote the vegetation of plants upon which the snow has fallen. The peculiar agency of snow, as a fertilizer in preference to rain, may admit of a very rational explanation, without recurring to nitrous salts supposed to be contained in it. It may be rationally ascribed to its furnishing a covering to the roots of vegetables, by which they are guarded from the influence of the atmospheric cold, and the internal heat of the earth is prevented from escaping.

The internal part of the earth, by some principle which we do not understand, is heated uniformly to the 48th degree of Fahrenheit's thermometer. This degree of heat is greater than that in which the watery juices of vegetables freeze, and it is propagated from the inward parts of the earth to the surface, on which the vegetables grow. The atmosphere being variably heated by the action of the sun in different climates, and in the same climate at different seasons, communicates to the surface of the earth and to some distance below it the degree of heat or cold which prevails in itself. Different vegetables are able to preserve life under different degrees of cold, but all of them perish when the cold which reaches their roots is extreme. Providence has therefore, in the coldest climates, provided a covering of

Snow.

of snow for the roots of vegetables, by which they are protected from the influence of the atmospherical cold. The snow keeps in the internal heat of the earth, which surrounds the roots of vegetables, and defends them from the cold of the atmosphere.

Snow or ice water is always deprived of its fixed air, which escapes during the process of congelation. Accordingly, as some of the inhabitants of the Alps who use it for their constant drink have enormous wens upon their throats, it has been ascribed to this circumstance. If this were the cause of these wens, it would be easy to remove it by exposing the snow-water to the air for some time. But several eminent physicians have rejected the notion that snow-water is the cause of these wens; for in Greenland, where snow-water is commonly used, the inhabitants are not affected with such swellings: on the other hand, they are common in Sumatra where snow is never seen.

SNOW, in sea-affairs, is generally the largest of all two-masted vessels employed by Europeans, and the most convenient for navigation.

The sails and rigging on the mainmast and foremast of a snow are exactly similar to those on the same masts in a ship; only that there is a small mast behind the mainmast of the former, which carries a sail nearly resembling the mizen of a ship. The root of the mast is fixed on a block of wood on the quarter-deck abaft the mainmast; and the head of it is attached to the aftertop of the maintop. The sail, which is called the *trysail*, is extended from its mast towards the stern of the vessel.

When the sloops of war are rigged as snows, they are furnished with a horse, which answers the purpose of the trysail-mast, the fore-part of the sail being attached by rings to the said horse, in different parts of its height.

Snow-Grotto, an excavation made by the waters on the side of Mount Etna, by making their way under the layers of lava, and by carrying away the bed of pozzolana below them. It occurred to the proprietor, that this place was very suitable for a magazine of snow: for in Sicily, at Naples, and particularly at Malta, they are obliged for want of ice to make use of snow for cooling their wine, sherbert, and other liquors, and for making sweetmeats.

This grotto was hired or bought by the knights of Malta, who having neither ice nor snow on the burning rock which they inhabit, have hired several caverns on Etna, into which people whom they employ collect and preserve quantities of snow to be sent to Malta when needed. The grotto has therefore been repaired within at the expence of that order; flights of steps are cut into it, as well as two openings from above, by which they throw in the snow, and through which the grotto is enlightened. Above the grotto they have also levelled a piece of ground of considerable extent: this they have inclosed with thick and lofty walls, so that when the winds, which at this elevation blow with great violence, carry the snow from the higher parts of the mountains, and deposit it in the inclosure, it is retained and amassed by the walls. The people then remove it into the grotto through the two openings; and it is there laid up, and preserved in such a manner as to resist the force of the summer heats; as the layers of lava with which the grotto is arched above prevent them from making any impression.

Snow, Snowdon-Hill.

When the season for exporting the snow comes on, it is put into large bags, into which it is pressed as closely as possible; it is then carried by men out of the grotto, and laid upon mules, which convey it to the shore, where small vessels are waiting to carry it away.

But before those lumps of snow are put into bags, they are wrapped in fresh leaves; so that while they are conveyed from the grotto to the shore, the leaves may prevent the rays of the sun from making any impression upon them.

The Sicilians carry on a considerable trade in snow, which affords employment to some thousands of mules, horses and men. They have magazines of it on the summits of their loftiest mountains, from which they distribute it through all their cities, towns, and houses; for every person in the island makes use of snow. They consider the practice of cooling their liquors as absolutely necessary for the preservation of health; and in a climate the heat of which is constantly relaxing the fibres, cooling liquors, by communicating a proper tone to the fibres of the stomach, must greatly strengthen them for the performance of their functions.

In this climate a scarcity of snow is no less dreaded than a scarcity of corn, wine, or oil. We are informed by a gentleman who was at Syracuse in the year 1777, when there was a scarcity of snow, the people of the town learned that a small vessel loaded with that article was passing the coast: without a moment's deliberation they ran in a body to the shore, and demanded her cargo; which, when the crew refused to deliver up, the Syracusans attacked and took, though with the loss of several men.

Snow-Drop. See CHIONANTHUS, BOTANY *Index*.

SNOWDON HILL, the name of a mountain in Caernarvon-shire in Wales, generally thought to be the highest in Britain; though some have been of opinion that its height is equalled, or even exceeded, by mountains in the Highlands of Scotland. The mountain is surrounded by many others, called in the Welsh language *Crib Coch*, *Crib y Distill*, *Lliweddy yr Arran*, &c.

According to Mr Pennant *, this mountainous tract yields scarcely any corn. Its produce is cattle and sheep; which, during summer, keep very high in the mountains, followed by their owners with their families, who reside during that season in *havodtys*, or "summer dairy-houses," as the farmers in the Swiss Alps do in their *sennes*. These houses consist of a long low room, with a hole at one end to let out the smoke from the fire which is made beneath. Their furniture is very simple; stones are substituted for stools and their beds are of hay ranged along the sides. They manufacture their own clothes, and dye them with the *lichen omphaloides* and *lichen parietinus*, mosses collected from the rocks. During summer the men pass their time in tending their herds or in making hay, &c. and the women in milking or in making butter and cheese. For their own use they milk both ewes and goats, and make cheese of the milk. Their diet consists of milk, cheese, and butter; and their ordinary drink is whey; though they have, by way of reserve, a few bottles of very strong beer, which they use as a cordial when sick. They are people of good understanding, wary, and circumspect; tall, thin,

* *Journey to Snowdon.*

Snowdon-Hill.

thin, and of strong constitutions. In the winter-time they descend into the *hen-dref*, or, "old dwelling," where they pass their time in inactivity.

The view from the highest peak of Snowden is very extensive. From it Mr Pennant saw the county of Chester, the high hills of Yorkshire, part of the north of England, Scotland, and Ireland; a plain view of the isle of Man; and that of Anglesea appeared like a map extended under his feet, with every rivulet visible. Our author took much pains to have this view to advantage; sat up at a farm on the west till about 12, and walked up the whole way. The night was remarkably fine and starry; towards morning the stars faded away, leaving an interval of darkness, which, however, was soon dispelled by the dawn of day. The body of the sun appeared most distinct, with the roundness of the moon, before it appeared too brilliant to be looked at. The sea, which bounded the western part of the prospect, appeared gilt with the sun-beams, first in slender streaks, and at length glowed with redness. The prospect was disclosed like the gradual drawing up of a curtain in a theatre; till at last the heat became sufficiently strong to raise mists from the various lakes, which in a slight degree obscured the prospect. The shadow of the mountain extended many miles, and showed its bicapitated form; the Wyddfa making one head, and Crib y Distill the other. At this time he counted between 20 and 30 lakes either in Caernarvon or in Merionethshire. In making another visit, the sky was obscured very soon after he got up. A vast mist involved the whole circuit of the mountain, and the prospect down was horrible. It gave an idea of numbers of abysses, concealed by a thick smoke furiously circulating around them. Very often a gust of wind made an opening in the clouds, which gave a fine and distinct vista of lake and valley. Sometimes they opened in one place, at others in many at once; exhibiting a most strange and perplexing sight of water, fields, rocks, and chasms. They then closed again, and every thing was involved in darkness; in a few minutes they would separate again, and repeat the above-mentioned scene with infinite variety. From this prospect our traveller descended with great reluctance; but before he had reached the place where his horses were left, he was overtaken by a thunder storm. The rolling of the thunder-claps, being reiterated by the mountains, was inexpressibly awful; and after he had mounted, he was in great danger of being swept away by the torrents which poured down in consequence of a very heavy rain.

It is very rare (Mr Pennant observes) that the traveller gets a proper day to ascend this hill: it indeed often appears clear; but by the evident attraction of the clouds by this lofty mountain, it becomes suddenly and unexpectedly enveloped in mist, when the clouds have just before appeared very high and very remote. At times he observed them lower to half their height; and notwithstanding they have been dispersed to the right and left, yet they have met from both sides, and united to involve the summit in one great obscurity.

The height of Snowden was measured, in 1682, by Mr Caswell, with instruments made by Flamstead: according to his mensuration, the height is 3720 feet; but more moderate computations make it only 3568, reckoning from the quay at Caernarvon to the highest peak. The stone that composes this mountain is excessively hard. Large coarse crystals, and frequently cubic pyrites, are found in the fissures. An immense quantity of water rushes down the sides of Snowdon and the neighbouring mountains, insomuch that Mr Pennant supposes, if collected into one stream, they would exceed the waters of the Thames.

Snowdon-Hill ‖ Soap.

SNUFF, a powder chiefly made of tobacco, the use of which is too well known to need any description here.

Tobacco is usually the basis of snuff; other matters being only added to give it a more agreeable scent, &c. The kinds of snuff, and their several names, are infinite, and new ones are daily invented; so that it would be difficult, not to say impossible, to give a detail of them. We shall only say, that there are three principal sorts: the first granulated; the second an impalpable powder; and the third the bran, or coarse part remaining after sifting the second sort.

"Every professed, inveterate, and incurable snuff-taker (says Lord Stanhope, at a moderate computation, takes one pinch in ten minutes. Every pinch, with the agreeable ceremony of blowing and wiping the nose and other incidental circumstances, consumes a minute and a half. One minute and a half out of every ten, allowing 16 hours to a snuff-taking day, amounts to two hours and 24 minutes out of every natural day, or one day out of every ten. One day out of every 10 amounts to 36 days and a half in a year. Hence if we suppose the practice to be persisted in 40 years, two entire years of the snuff-taker's life will be dedicated to tickling his nose, and two more to blowing it. The expence of snuff, snuff-boxes, and handkerchiefs, will be the subject of a second essay; in which it will appear, that this luxury encroaches as much on the income of the snuff-taker as it does on his time; and that by a proper application of the time and money thus lost to the public, a fund might be constituted for the discharge of the national debt." See NICOTIANA.

SNYDERS, FRANCIS, a Flemish painter, born at Antwerp in 1579, and bred under his countryman Henry Van Balen. His genius first displayed itself in painting fruit: he afterwards attempted animals, huntings, &c. in which he exceeded all his predecessors. He also painted kitchens, &c. and gave dignity to subjects that seemed incapable of it. He was made painter to Ferdinand and Isabella, archduke and duchess, and became attached to the house of the cardinal infant of Spain. The king of Spain and the elector Palatine adorned their palaces with huntings by this artist. Rubens, Jordaens, and Snyders, used to co-operate in the enriching of each other's pictures according to their several talents; and thus they became more valuable than if finished by either of them singly. Snyders died in 1657.

SOAL-FISH. See PLEURONECTES, ICHTHYOLOGY *Index*.

SOAP, a composition of caustic, fixed alkaline salt, and oil, sometimes hard and dry, sometimes soft and liquid; much used in washing, whitening linens, and by dyers and fullers.—Soap may be made by several methods, which, however, all depend upon the same principle. The soap which is used in medicine is made without heat.

In manufactures where large quantities of it are prepared, soap is made with heat. A lixivium of quicklime and

Soap.

and soda is made, but is less concentrated than that above referred to, and only so much that it can sustain a fresh egg. A part of this lixivium is to be even diluted and mixed with an equal weight of oil of olives. The mixture is to be put on a gentle fire, and agitated, that the union may be accelerated. When the mixture begins to unite well, the rest of the lixivium is to be added to it; and the whole is to be digested with a very gentle heat, till the soap be completely made. A trial is to be made of it, to examine whether the just proportion of oil and alkali has been observed. Good soap of this kind ought to be firm, and very white when cold; not subject to become moist by exposure to air, and entirely miscible with pure water, to which it communicates a milky appearance, but without any drops of oil floating on the surface. When the soap has not these qualities, the combination has not been well made, or the quantity of salt or oil is too great, which faults must be corrected.

In soft or liquid soaps, green or black soaps, cheaper oils are employed, as oil of nuts, of hemp, of fish, &c. These soaps, excepting in consistence, are not essentially different from white soap.

Fixed alkalies are much disposed to unite with oils that are not volatile, both vegetable and animal, since this union can be made even without heat. The compound resulting from this union partakes at the same time of the properties of oil and of alkali; but these properties are modified and tempered by each other, according to the general rule of combinations. Alkali formed into soap has not nearly the same acrimony as when it is pure; it is even deprived of almost all its causticity, and its other saline alkaline properties are almost entirely abolished. The same oil contained in soap is less combustible, than when pure, from its union with the alkali, which is an inflammable body. It is miscible, or even soluble, in water, to a certain degree, by means of the alkali. Soap is entirely soluble in spirit of wine; and still better in aquavitæ sharpened by a little alkaline salt, according to an observation of Mr Geoffroy.

The manufacture of soap in London first began in the year 1524; before which time this city was served with white soap from foreign countries, and with gray soap speckled with white from Bristol, which was sold for a penny a pound; and also with black soap, which sold for a halfpenny the pound.

The principal soaps of our own manufacture are the soft, the hard, and the ball soap. The soft soap is either white or green. The process of making each of these shall now be described.

Green soft soap. The chief ingredients used in making this are lees drawn from potash and lime, boiled up with tallow and oil. First, the ley of a proper degree of strength (which must be estimated by the weight of the liquor), and tallow, are put into the copper together, and as soon as they boil up the oil is added; the fire is then damped or stopped up, while the ingredients remain in the copper to unite; when they are united, the copper is again made to boil, being fed or filled with lees as it boils, till there be a sufficient quantity put into it; then it is boiled off and put into casks. When this soap is first made it appears uniform; but in about a week's time the tallow separates from the oil into those white grains which we see in common soap. Soap thus made would appear yellow, but by a mixture of indigo added at the end of the boiling, it is rendered green, that being the colour which results from the mixture of yellow and blue.

White soap. Of this one sort is made after the same manner as green soft soap, oil alone excepted, which is not used in white. The other sort of white soft soap is made from the lees of ashes of lime boiled up two different times with tallow. First, a quantity of lees and tallow are put into the copper together, and kept boiling, being fed with lees as they boil, until the whole is boiled sufficiently; then the lees are separated or discharged from the tallowish part, which part is removed into a tub, and the lees are thrown away; this is called the *first half-boil:* then the copper is filled again with fresh tallow and lees, and the first half-boil is put out of the tub into the copper a second time, where it is kept boiling with fresh lees and tallow till the soap is produced. It is then put out of the copper into the same sort of casks as are used for green soft soap. The common soft soap used about London, generally of a greenish hue, with some white lumps, is prepared chiefly with tallow: a blackish sort, more common in some other places, is said to be made with whale oil.

Hard soap is made with lees from ashes and tallow, and is most commonly boiled twice: the first, called the *half-boil,* hath the same operation as the first half-boil of soft white soap. Then the copper is charged with fresh lees again, and the first half-boil put into it, where it is kept boiling, and fed with lees as it boils, till it grains or is boiled enough: then the ley is discharged from it, and the soap put into a frame to cool and harden. Common salt is made use of for the purpose of graining the soap; for when the oil or tallow has been united with the ley, after a little boiling, a quantity of salt is thrown into the mass, which dissolving readily in water, but not in the oil or tallow, draws out the water in a considerable degree, so that the oil or tallow united with the salt of the ley swims on the top. When the ley is of a proper strength, less salt is necessary to raise the curd than when it is too weak. It must be observed, that there is no certain time for bringing off a boiling of any of these sorts of soap: it frequently takes up part of two days.

Ball soap, commonly used in the north, is made with lees from ashes and tallow. The lees are put into the copper, and boiled till the watery part is quite gone, and there remains nothing in the copper but a sort of saline matter (the very strength or essence of the ley): to this the tallow is put, and the copper is kept boiling and stirring for above half an hour, in which time the soap is made; and then it is put out of the copper into tubs or baskets with sheets in them, and immediately (whilst soft) made into balls. It requires near 24 hours in this process to boil away the watery part of the ley.

When oil unites with alkali in the formation of soap, it is little altered in the connection of its principles; for it may be separated from the alkali by decomposing soap with any acid, and may be obtained nearly in its original state.

Concerning the decomposition of soap by means of acids, we must observe, first, that all acids, even the weakest vegetable acids, may occasion this decomposition, because every one of them has a greater affinity than

Soap.

than oil with fixed alkali. Secondly, these acids, even when united with any basis, excepting fixed alkali, are capable of occasioning the same decomposition; whence all ammoniacal salts, all salts with bases of earth, and all those with metallic bases, are capable of decomposing soap, in the same manner as disengaged acids are; with this difference, that the oil separated from the fixed alkali, by the acid of these salts, may unite more or less intimately with the substance which was the basis of the neutral salt employed for the decomposition.

Soap may also be decomposed by distillation, as Lemery has done. When first exposed to fire, it yields a phlegm called by him a *spirit;* which nevertheless is neither acid nor alkaline, but some water which enters into the composition of soap. It becomes more and more coloured and empyreumatic as the fire is increased, which shows that it contains the most subtle part of the oil. It seems even to raise along with it, by help of the oil and action of the fire, a small part of the alkali of the soap: for as the same chemist observes, it occasions a precipitate in a solution of corrosive sublimate. After this phlegm the oil rises altered, precisely as if it had been distilled from quicklime, that is, empyreumatic, soluble in spirit of wine, at first sufficiently subtle and afterwards thicker. An alkaline residuous coal remains in the retort, consisting chiefly of the mineral alkali contained in the soap, and which may be disengaged from the coal by calcination in an open fire, and obtained in its pure state.

Alkaline soaps are very useful in many arts and trades, and also in chemistry and medicine. Their principal utility consists in a detersive quality that they receive from their alkali, which, although it is in some measure saturated with oil, is yet capable of acting upon oily matters, and of rendering them saponaceous and miscible with water. Hence soap is very useful to cleanse any substances from all fat matters with which they happen to be soiled. Soap is therefore daily used for the washing and whitening of linen, for the cleansing of woollen cloths from oil, and for whitening silk and freeing it from the resinous varnish with which it is naturally covered. Pure alkaline lixiviums being capable of dissolving oils more effectually than soap, might be employed for the same purposes; but when this activity is not mitigated by oil, as it is in soap, they are capable of altering, and even of destroying entirely by their causticity, most substances, especially animal matters, as silk, wool, and others: whereas soap cleanses from oil almost as effectually as pure alkali, without danger of altering or destroying; which renders it very useful.

Woodville's Medical Botany, p. 390.

Soap was imperfectly known to the ancients. It is mentioned by Pliny as made of fat and ashes, and as an invention of the Gauls. Aretæus and others inform us, that the Greeks obtained their knowledge of its medical use from the Romans. Its virtues, according to Bergius, are detergent, resolvent, and aperient, and its use recommended in jaundice, gout, calculous complaints, and in obstructions of the viscera. The efficacy of soap in the first of these diseases was experienced by Sylvius, and since recommended very generally by various authors who have written on this complaint; and it has also been thought of use in supplying the place of bile in the primæ viæ. The utility of this medicine in icterical cases was inferred chiefly from its supposed power of dissolving biliary concretions; but this medicine has lost much of its reputation in jaundice, since it is now known that gall-stones have been found in many after death who had been daily taking soap for several months and even years. Of its good effects in urinary calculous affections, we have the testimony of several, especially when dissolved in lime-water, by which its efficacy is considerably increased; for it thus becomes a powerful solvent of mucus, which an ingenious modern author supposes to be the chief agent in the formation of calculi; it is, however, only in the incipient state of the disease that these remedies promise effectual benefit; though they generally abate the more violent symptoms where they cannot remove the cause. With Boerhaave soap was a general medicine: for as he attributed most complaints to viscidity of the fluids, he, and most of the Boerhaavian school, prescribed it in conjunction with different resinous and other substances, in gout, rheumatism, and various visceral complaints. Soap is also externally employed as a resolvent, and gives name to several officinal preparations.

From the properties of soap we may know that it must be a very effectual and convenient anti-acid. It absorbs acids as powerfully as pure alkalies and absorbent earths, without having the causticity of the former, and without oppressing the stomach by its weight like the latter.

Lastly, we may perceive that soap must be one of the best of all antidotes to stop quickly, and with the least inconvenience, the bad effects of acid corrosive poisons, as aquafortis, corrosive sublimate, &c.

Soap imported is subject by 10 Ann. cap. 19. to a duty of 2d. a pound (over and above former duties); and by 12 Ann. stat. 2. cap. 9. to the farther sum of 1d. a pound. And by the same acts, the duty on soap made in the kingdom is 1½d. a pound. By 19 G. III. cap. 52. no person within the limits of the head office of excise in London shall be permitted to make any soap unless he occupy a tenement of 10l. a-year, be assessed, and pay the parish rates; or elsewhere, unless he be assessed, and pay to church and poor. Places of making are to be entered on pain of 50l. and covers and locks to be provided under a forfeiture of 100l.; the furnace-door of every utensil used in the manufacture of soap shall be locked by the excise officer, as soon as the fire is damped or drawn out, and fastenings provided, under the penalty of 50l.; and opening or damaging such fastening incurs a penalty of 100l. Officers are required to enter and survey at all times, by day or night, and the penalty of obstructing is 20l.; and they may unlock and examine every copper, &c. between the hours of five in the morning and eleven in the evening, and the penalty of obstructing is 100l. Every maker of soap before he begins any making, if within the bills of mortality, shall give 12 hours, if elsewhere 24 hours, notice in writing to the officer, of the time when he intends to begin, on pain of 50l. No maker shall remove any soap unsurveyed on pain of 20l. without giving proper notice of his intention. And if any maker shall conceal any soap or materials, he shall forfeit the same, and also 500l. Every barrel of soap shall contain 256lb. avoirdupois, half barrel 128 lb. firkin 64 lb. half-firkin 32 lb. besides the weight or tare of each cask: and all soap, excepting hard cake soap and ball soap, shall be put into such casks and no other, on pain of forfeiture, and 5l. The maker shall weekly

weekly enter in writing at the next office the soap made by him in each week, with the weight and quantity at each boiling, on pain of 50l.; and within one week after entry clear off the duties, on pain of double duty. See, besides the statutes above cited, 5 Geo. III, cap. 43. 12 Geo. III. cap. 46. 11 Geo. cap. 30. 1 Geo. stat. 2. cap. 36.

Acid Soap. This is formed by the addition of concentrated acids to the expressed oils. Thus the oil is rendered partially soluble in water; but the union is not sufficiently complete to answer any valuable purpose.

Soap-Berry Tree. See Sapindus, Botany *Index.*

Soap-Earth. See Steatites, Mineralogy *Index.*

SOAPWORT. See Saponaria, Botany *Index.*

SOC (Sax.). signifies power or liberty to minister justice or execute laws; also the circuit or territory wherein such power is exercised. Whence our law-Latin word *socca* is used for a seigniory or lordship enfranchised by the king, with the liberty of holding or keeping a court of his *sockmen:* And this kind of liberty continues in divers parts of England to this day, and is known by the names of *soke* and *soken.*

SOCAGE, in its most general and extensive signification, seems to denote a tenure by any certain and determinate service. And in this sense it is by our ancient writers constantly put in opposition to chivalry or knight-service, where the render was precarious and uncertain. The service must therefore be certain, in order to denominate it socage; as to hold by fealty and 20s. rent; or, by homage, fealty, and 20s. rent; or, by homage and fealty without rent; or, by fealty and certain corporal service, as ploughing the lord's land for three days; or, by fealty only without any other service: for all these are tenures in socage.

Blackst. Comment. vol. ii.

Socage is of two sorts: *free*-socage, where the services are not only certain but honourable; and *villein*-socage, where the services, though certain, are of a baser nature (see Villenage). Such as hold by the former tenure are called, in Glanvil and other subsequent authors, by the name of *liberi sokemanni*, or tenants in free-socage. The word is derived from the Saxon appellation *soc*, which signifies liberty or privilege; and, being joined to an usual termination, is called *socage*, in Latin *socagium;* signifying thereby a free or privileged tenure.

It seems probable that the socage-tenures were the relics of Saxon liberty; retained by such persons as had neither forfeited them to the king, nor been obliged to exchange their tenure for the more honourable, as it was called, but at the same time more burthensome, tenure of knight-service. This is peculiarly remarkable in the tenure which prevails in Kent, called *gavelkind*, which is generally acknowledged to be a species of socage-tenure; the preservation whereof inviolate from the innovations of the Norman conqueror is a fact universally known. And those who thus preserved their liberties were said to hold in free and common socage.

As therefore the grand criterion and distinguishing mark of this species of tenure are the having its renders or services ascertained, it will include under it all other methods of holding free lands by certain and invariable rents and duties; and in particular, *Petit Serjeanty, Tenure in Burgage*, and Gavelkind. See these articles.

1 Definition.

SOCIETY, a number of rational and moral beings, united for their common preservation and happiness.

2 How far brutes are capable of a social state.

There are shoals of fishes, herds of quadrupeds, and flocks of birds. But till observation enable us to determine with greater certainty, how far the inferior animals are able to look through a series of means to the end which these are calculated to produce, how far their conduct may be influenced by the hope of reward and the fear of punishment, and whether they are at all capable of moral distinctions—we cannot with propriety apply to them the term *Society.* We call crows and beavers, and several other species of animals, *gregarious;* but it is hardly good English to say that they are *social.*

3 Mankind the only social beings subject to our observation.

It is only human society, then, that can become the subject of our present investigation. The phenomena which it presents are highly worthy of our notice.

4 A social and a savage state.

Such are the advantages which each individual evidently derives from living in a social state; and so helpless does any human being appear in a solitary state, that we are naturally led to conclude, that if there ever was a period at which mankind were solitary beings, that period could not be of long duration; for their aversion to solitude and love of society would soon induce them to enter into social union. Such is the opinion which we are led to conceive, when we compare our own condition as members of civilized and enlightened society with that of the brutes around us, or with that of savages in the earlier and ruder periods of social life. When we hear of Indians wandering naked through the woods, destitute of arts, unskilled in agriculture, scarce capable of moral distinctions, void of all religious sentiments, or possessed with the most absurd notions concerning superior powers, and procuring means of subsistence in a manner equally precarious with that of the beasts of prey—we look down with pity on their condition, or turn from it with horror. When we view the order of cultivated society, and consider our institutions, arts, and manners—we rejoice over our superior wisdom and happiness.

Man in a civilized state appears a being of a superior order to man in a savage state; yet some philosophers tell us, that it is only he who, having been educated in society, has been taught to depend upon others, that can be helpless or miserable when placed in a solitary state. They view the savage who exerts himself with intrepidity to supply his wants, or bears them with fortitude, as the greatest hero, and possessing the greatest happiness. And therefore if we agree with them, that the propensities of nature may have prompted men to enter into social union, though they may have hoped to enjoy superior security and happiness by engaging to protect and support each other, we must conclude that the Author of the universe has destined man to attain greater dignity and happiness in a savage and solitary than in a social state; and therefore that those dispositions and views which lead us to society are fallacious and inimical to our real interest.

Whatever be the supposed advantages of a solitary state, certain it is that mankind, at the earliest periods, were united in society. Various theories have been formed concerning the circumstances and principles which gave rise to this union: but we have elsewhere shown, that the greater part of them are founded in error; that they suppose the original state of man to have

Society.

been that of savages; and that such a supposition is contradicted by the most authentic records of antiquity. For though the records of the earlier ages are generally obscure, fabulous, and imperfect; yet happily there is *one* free from the imperfections of the rest, and of undoubted authenticity, to which we may safely have recourse *. This record is the Pentateuch of Moses, which presents us with a genuine account of the origin of man and of society, perfectly consonant to what we have laid down in the article referred to (see SAVAGE).

* See *Scripture*, N° 7—15.

5
First state of society according to authentic history.

According to Moses, the first society was that of a husband and wife united in the bonds of marriage: the first government that of a father and husband, the master of his family. Men lived together under the patriarchal form of government while they employed themselves chiefly in tending flocks and herds. Children in such circumstances cannot soon rise to an equality with their parents, where a man's importance depends on his property, not on his abilities. When flocks and herds are the chief articles of property, the son can only obtain these from his father; in general therefore, the son must be entirely dependent on the father for the means of subsistence. If the parent during his life bestow on his children any part of his property, he may do it on such conditions as shall make their dependence upon him continue till the period of his death. When the community are by this event deprived of their head, instead of continuing in a state of union, and selecting some one from among themselves whom they may invest with the authority of a parent, they separate into so many distinct tribes, each subjected to the authority of a different lord, the master of the family, and the proprietor of all the flocks and herds belonging to it. Such was the state of the first societies which the narrative of Moses exhibits to our attention.

6
Theories of philosophers concerning the origin of society,

Those philosophers who have made society, in its various stages between rudeness and refinement, the subject of their speculations, have generally considered mankind, in whatever region of the globe, and under whatever climate, as proceeding uniformly through certain regular gradations from one extreme to the other. They regard them, first, as gaining a precarious subsistence by gathering the spontaneous fruits of the earth, preying on the inhabitants of the waters, if placed on the seashore, or along the banks of large rivers; or hunting wild beasts, if in a situation where these are to be found in abundance; without foresight or industry to provide for future wants when the present call of appetite is gratified. Next, they say, man rises to the shepherd state, and next to that of husbandmen, when they turn their attention from the management of flocks to the cultivation of the ground. Next, these husbandmen improve their powers, and better their condition, by becoming artizans and merchants; and the beginning of this period is the boundary between barbarity and civilization.

These are the stages through which they who have employed themselves on the natural history of society have generally conducted mankind in their progress from rudeness to refinement: but they seem to have overlooked the manner in which mankind were at first established on this earth; for the circumstances in which the parents of the human race were originally placed; for the degree of knowledge communicated to them; and for the instruction which they must have been capable of communicating to their posterity. They rather appear to consider the inhabitants of every different region of the globe as aborigines, springing at first from the ground, or dropped on the spot which they inhabit; no less ignorant than infants of the nature and relations of the objects around them, and of the purposes which they may accomplish by the sacrifice of their organs and faculties.

7
are fanciful.

The absurdity of this theory has been fully demonstrated in another place: and if we agree to receive the Mosaic account of the original establishment of mankind, we shall be led to view the phenomena of social life in a light very different. We must first allow, that though many of the rudest tribes are found in the state of *hunters* or *fishers*; yet the hunting or fishing state cannot have been invariably the primary form of society. Notwithstanding the powers with which we are endowed, we are in a great measure the creatures of circumstances. Physical causes exert, though indirectly, a mighty influence in forming the character and directing the exertions of the human race. From the information of Moses we gather, that the first societies of men lived under the patriarchal form of government, and employed themselves in the cultivation of the ground and the management of flocks. And as we know that mankind, being subjected to the influence both of physical and moral causes, are no less liable to degeneracy than capable of improvement; we may easily conceive, that though descending all from the same original pair, and though enlightened with much traditionary knowledge relative to the arts of life, the order of society, moral distinctions, and religious obligations; yet as they were gradually, and by various accidents, dispersed over the earth, being removed to situations in which the arts with which they were acquainted could but little avail them, where industry was overpowered, or indolence encouraged, by the severity or the profusion of nature, they might degenerate and fall into a condition almost as humble and precarious as that of the brutal tribes. Other moral causes might also concur to debase or elevate the human character in that early period. The particular character of the original settlers in any region, the manner in which they were connected with one another, and the arts which they were best qualified to exercise, with various other causes of a similar nature, would have considerable influence in determining the character of the society.

When laying aside the spirit of theory and system, we set ourselves, with due humility, to trace facts, and to listen to evidence, though our discoveries may be fewer than we should otherwise fancy them; yet the knowledge which we thus acquire will be more useful and solid, and our speculations more consistent with the spirit of true philosophy. Here, though we learn from the information of the sacred writings, that the first family of mankind was not cruelly exposed in this world, as children whom the inhumanity of their parents induces them to desert; yet we are not, in consequence of admitting this fact, laid under any necessity of denying or explaining away any of the other phenomena which occur to our observation when tracing the natural history of society. Tradition may be corrupted; arts and sciences may be lost; the sublimest religious doctrines may be debased into absurdity.

If then we are desirous of surveying society in its rudest

dest form, we must look, not to the earliest period of its existence, but to those districts of the globe where external circumstances concur to drive them into a state of stupidity and wretchedness. Thus in many places of the happy clime of Asia, which a variety of ancient records concur with the sacred writings in representing as the first peopled quarter of the globe, we cannot trace the form of society backwards beyond the shepherd state. In that state indeed the bonds which connect society extend not to a wide range of individuals, and men remain for a long period in distinct families; but yet that state is highly favourable to knowledge, to happiness, and to virtue. Again, the torrid and the frozen regions of the earth, though probably peopled at a later period, and by tribes sprung from the same stock with the shepherds of Asia, have yet exhibited mankind in a much lower state. It is in the parched deserts of Africa and the wilds of America that human beings have been found in a condition approaching the nearest to that of the brutes.

8 Yet in some particular instances retarded.

We may therefore with some propriety desert the order of time, and take a view of the different stages through which philosophers have considered mankind as advancing, beginning with that of rudeness, though we have shown that it cannot have been the first in the progress.

9 Rudest state, or first stage of society.

Where the human species are found in the lowest and rudest state, their rational and moral powers are very faintly displayed; but their external senses are acute and their bodily organs active and vigorous. Hunting and fishing are then their chief employments on which they depend for support. During that portion of their time which is not spent in these pursuits, they are sunk in listless indolence. Destitute of foresight, they are roused to active exertion only by the pressure of immediate necessity or the urgent calls of appetite. Accustomed to endure the severity of the elements, and but scantily provided with the means of subsistence, they acquire habits of resignation and fortitude, which are beheld with astonishment by those who enjoy the plenty and indulgence of cultivated life. But in this state of want and depression, when the powers and possessions of every individual are scarcely sufficient for his own support, when even the calls of appetite are repressed because they cannot always be gratified, and the more refined passions, which either originate from such as are merely animal, or are intimately connected with them, have not yet been felt—in this state all the milder affections are unknown; or if the breast is at all sensible to their impulse, it is extremely feeble. Husband and wife, parent and child, brother and brother, are united by the weakest ties. Want and misfortune are not pitied. Why indeed should they, where they cannot be relieved? It is impossible to determine how far beings in this condition can be capable of moral distinctions. One thing certain is, that in no state are the human race entirely incapable of these. If we listen, however, to the relations of respectable travellers, we must admit that human beings have sometimes been found in that abject state where no proper ideas of subordination, government, or distinction of ranks, could be formed. No distinct notions of Deity can be here entertained. Beings in so humble a condition cannot look through the order of the universe and the harmony of nature to that Eternal Wisdom and Goodness which contrived, and that Almighty Power which brought into existence, the system of things. Of arts they must be almost totally destitute. They may use some instruments for fishing or the chace; but these must be extremely rude and simple. If they be acquainted with any means to shelter them from the inclemency of the elements, both their houses and clothing will be awkward and inconvenient.

10 Second stage in the progress of society.

But human beings have not been often found in so rude a state as this. Even those tribes which we denominate savage, are for the most part farther removed from mere animal life. They generally appear united under some species of government, exercising the powers of reason, capable of morality, though that morality be not always very refined; displaying some degree of social virtues, and acting under the influence of religious sentiments. Those who may be considered as but one degree higher in the scale than the stupid and wretched beings whose condition we have surveyed, are to be found still in the hunting and fishing state; but they are farther advanced towards social life, and are become more sensible to the impulse of social affection. By unavoidable intercourse in their employments, a few individual hunters or fishers contract a certain degree of fondness for each other's company, and are led to take some part in each other's joys and sorrows; and when the social affections thus generated (see Passion) begin to exert themselves, all the other powers of the mind are at the same time called forth, and the circumstances of the little society are immediately improved. We behold its members in a more comfortable condition, and find reason to view the human character with more complacency and respect. Huts are now built, more commodious clothes are fashioned, instruments for the annoyance of wild beasts and even of enemies are contrived; in short, arts, and science, and social order, and religious sentiment, and ceremonies, now make their appearance in the rising society, and serve to characterize it by the particular form which distinguishes each of them. But though social order is no longer unknown nor unobserved, yet the form of government is still extremely simple, and its ties are but loose and feeble. It will perhaps bear some resemblance to the patriarchal; only all its members are on a more equal footing, and at the same time less closely connected than in the shepherd state, to which that form of government seems almost peculiar. The old men are treated with veneration; but the young are not entirely subject to them. They may listen respectfully to their advice; but they do not submit to their arbitrary commands. Where mankind are in the state of hunters and fishers, where the means of subsistence are precariously acquired, and prudent foresight does not prompt to accumulate much provision for the future, no individual can acquire comparative wealth. As soon as the son is grown up, he ceases to be dependent on his father, as well as on the society in general. Difference of experience therefore constitutes the only distinction between the young and the old; and if the old have experience, the young have strength and activity. Here, then, neither age nor property can give rise to any striking distinction of ranks. All who have attained to manhood, and are not disabled by unusual deficiency of strength or agility, or by the infirmities of old age, are on an equal footing; or if any one possess a pre-eminence over the rest, he owes it to superior

Society.

superior address or fortitude. The whole tribe deliberate; the old give their advice; each individual of the assembly receives or rejects it at his pleasure (for the whole body think not of exercising any compulsatory power over the will of individuals); and the warrior who is most distinguished for strength, address, and valour, leads out the youth of the tribe to the chace or against the enemy. War, which in the former stage did not prevail, as they who were strangers to social sentiments were, at the same time, scarce capable of being enemies, now first begins to depopulate the thinly inhabited regions where those hunters and fishers pursue their prey. They are scattered, possibly in scanty and separate tribes, over an immense tract of country; but they know no medium between the affection which brethren of the same tribe bear to each other and the hatred of enemies. Though thinly scattered over the earth, yet the hunting parties of different tribes will sometimes meet as they range the forests; and when they meet, they will naturally view each other with a jealous eye; for the success of the one party in the chace may cause the other to be unsuccessful; and while the one snatches the prey, the other must return home to all the pangs of famine. Inveterate hostility will therefore long prevail among neighbouring tribes in the hunting state.

If we find them not incapable of social order, we may naturally expect that their conduct will be influenced by some sentiments of religion. They have at this period ideas of superior beings. They also practise certain ceremonies to recommend them to those beings; but both their sentiments and ceremonies are superstitious and absurd.

We have elsewhere shown (see POLYTHEISM) how savage tribes have probably degenerated from the pure worship of the one true God to the adoration of a multitude of imaginary divinities in heaven, earth, and hell. We have traced this idolatrous worship from that of the heavenly bodies, through all the gradations of dæmon-worship, hero-worship, and statue-worship, to that wonderful instance of absurd superstition which induced the inhabitants of some countries to fall prostrate in adoration before the vilest reptiles. But though we are convinced that the heavenly bodies have by all idolaters been considered as their first and greatest gods, we pretend not that the progress through the other stages of polytheism has been everywhere in the very same order. It is indeed impossible to exhibit under one general view an account of arts, manners, and religious sentiments, which may apply to some certain period in the history of every nation. The characters and circumstances of nations are scarce less various and anomalous than those of individuals. Among many of the American tribes, among the ancient inhabitants of the forests of Germany, whose manners have been so accurately delineated by the masterly pen of Tacitus, and in some of the islands scattered over the southern ocean, religion, arts, and government, have been found in that state which we have described as characterising the second stage of social life. But neither can we pretend that all those simple and rude societies have been described by historians and travellers as agreeing precisely in their arts, manners, and religious sentiments; or that the difference of circumstances always enables us to account in a satisfactory manner for the distinction of their characters. There is a variety of facts in the history of the early periods of society, which no ingenuity, no industry, however painful, can reduce under general heads. Here, as well as when we attempt to philosophize on the phenomena of the material world, we find reason to confess that our powers are weak, and our observation confined within a narrow sphere.

11 Third stage in the progress of society, in which ideas of property and inequality of ranks appear.

But we may now carry our views a little forward, and survey human life as approaching somewhat nearer to a civilized and enlightened state. As property is acquired, inequality and subordination of ranks necessarily follow: and when men are no longer equal, the many are soon subjected to the will of the few. But what gives rise to these new phenomena is, that after having often suffered from the precariousness of the hunting and fishing state, men begin to extend their cares beyond the present moment, and to think of providing some supply for future wants. When they are enabled to provide such a supply, either by pursuing the chace with new eagerness and perseverance, by gathering the spontaneous fruits of the earth, or by breeding tame animals—these acquisitions are at first the property of the whole society, and distributed from a common store to each individual according to his wants: But as various reasons will soon concur to convince the community, that by this mode of distribution, industry and activity are treated with injustice, while negligence and indolence receive more than their due, each individual will in a short time become his own steward, and a community of goods will be abolished. As soon as distinct ideas of property are formed, it must be unequally distributed; and as soon as property is unequally distributed, there arises an inequality of ranks. Here we have the origin of the depression of the female sex in rude ages, of the tyrannical authority exercised by parents over their children, and perhaps of slavery. The women cannot display the same perseverance, or activity, or address, as the men, in pursuing the chace. They are therefore left at home; and from that moment are no longer equals, but slaves and dependants, who must subsist by the bounty of the males, and must therefore submit with implicit obedience to all their capricious commands. Even before the era of property, the female sex were viewed as inferiors; but till that period they were not reduced to a state of abject slavery.

In this period of society new notions are formed of the relative duties. Men now become citizens, masters, and servants, husbands, parents, &c. It is impossible to enumerate all the various modes of government which take place among the tribes who have advanced to this stage; but one thing certain is, that the authority of the few over the many is now first established, and that the rise of property first introduces inequality of ranks. In one place, we shall perhaps find the community subjected during this period to the will of a single person; in another, power may be lodged in the hands of a number of chiefs; and in a third, every individual may have a voice in creating public officers, and in enacting laws for the support of public order. But as no code of laws is formed during this period, justice is not very impartially administered, nor are the rights of individuals very faithfully guarded. Many actions, which will afterwards be considered as heinously immoral, are now considered as praise-worthy or indifferent. This is the age of hero-worship, and of household and tutelary gods*; for

Society.

for it is in this stage of society that the invention of arts, which gave rise to that worship, contributes most conspicuously to the public good. War, too, which we considered as beginning first to ravage the earth during the former period, and which is another cause of the deification of dead men, will still prevail in this age, and be carried on with no less ferocity than before, though in a more systematic form.

The prevalence of war, and the means by which subsistence is procured, cannot but have considerable influence on the character and sentiments of societies and individuals. The hunter and the warrior are characters in many respects different from the shepherd and the husbandman. Such, in point of government, arts, and manners, religious and moral sentiments, were several of the German tribes described by Tacitus; and the Britons whose character has been sketched by the pen of Cæsar: such, too, were the Romans in the early period of their history; such too the inhabitants of Asia Minor about the time of the siege of Troy, as well as the Greeks whom Homer celebrates as the destroyers of the Trojan state: the northern tribes also, who poured through Asia, Africa, and Europe, and overthrew the Roman empire, appear to have been of a nearly similar character. It seems to be a general opinion among those who have directed their attention to the history of society, that, in the scale ascending from the lowest condition of human beings to the most civilized and enlightened state of society, the shepherd state is the next in order above the hunting; and that as mankind improve in knowledge and in moral sentiments, and as the forests are gradually depopulated of their inhabitants, instead of destroying the inferior animals, men become their guardians and protectors. But we cannot unreservedly subscribe to this opinion: we believe, that in the shepherd state societies have been sometimes found superior to the most polished tribes of hunters; but upon viewing the annals of mankind in early ages, we observe that there is often no inconsiderable resemblance even between hunters and shepherds in point of the improvement of the rational faculties and the moral sense; and we are therefore led to think, that these two states are sometimes parallel: for instance, several of the American tribes, who still procure their subsistence by hunting, appear to be nearly in the state which we have described as the third stage in the progress of society; and the ancient shepherds of Asia do not appear to have been much more cultivated and refined. We even believe that men have sometimes turned their attention from hunting to agriculture, without passing through any intermediate state. Let us remember, that much depends upon local circumstances, and somewhat undoubtedly on original inspiration and traditionary instruction. In this period of society the state of the arts well deserves our attention. We shall find, that the shepherds and the hunters are in that respect on a pretty equal footing. Whether we examine the records of ancient history, or view the islands scattered through the South sea, or range the wilds of America, or survey the snowy wastes of Lapland and the frozen coast of Greenland—still we find the useful arts in this period, though known and cultivated, in a very rude state; and the fine arts, or such as are cultivated merely to please the fancy or to gratify caprice, displaying an odd and fantastic, not a true or natural, taste; yet this is the period in which eloquence

2

shines with the truest lustre: all is metaphor or glowing sentiment. Languages are not yet copious; and therefore speech is figurative, expressive, and forcible. The tones and gestures of nature, not being yet laid aside, as they generally are, from regard to decorum, in more polished ages, give a degree of force and expression to the harangues of the rustic or savage orator, which the most laborious study of the rules of rhetoric and elocution could not enable even a more polished orator to display.

12 Fourth stage; in which agriculture flourishes, the arts are subdivided, commerce and regular government are introduced.

But let us advance a little farther, and contemplate our species in a new light, where they will appear with greater dignity and amiableness of character. Let us view them as husbandmen, artizans, and legislators. Whatever circumstances might turn the attention of any people from hunting to agriculture, or cause the herdsman to yoke his oxen for the cultivation of the ground, certain it is that this change in the occupation would produce a happy change on the character and circumstances of men; it would oblige them to exert a more regular and persevering industry. The hunter is like one of those birds that are described as passing the winter in a torpid state. The shepherd's life is extremely indolent. Neither of these is very favourable to refinement. But different is the condition of the husbandman. His labours succeed each other in regular rotation through the year. Each season with him has its proper employments: he therefore must exert active persevering industry; and in this state we often find the virtues of rude and polished ages united. This is the period where barbarism ends and civilization begins. Nations have existed for ages in the hunting or the shepherd state, fixed as by a kind of stagnation, without advancing farther. But scarcely any instances occur in the history of mankind of those who once reached the state of husbandmen, remaining long in that condition without rising to a more civilized and polished state. Where a people turn their attention in any considerable degree to the objects of agriculture, a distinction of occupations naturally arises among them. The husbandman is so closely employed through the several seasons of the year in the labours of the field, that he has no longer leisure to exercise all the rude arts known among his countrymen. He has not time to fashion the instruments of husbandry, to prepare his clothes, to build his house, to manufacture household utensils, or to tend those tame animals which he continues to rear. Those different departments therefore now begin to employ different persons; each of whom dedicates his whole time and attention to his own occupation. The manufacture of cloth is for a considerable time managed exclusively by the women; but smiths and joiners arise from among the men. Metals begin now to be considered as valuable materials. The intercourse of mankind is now placed on a new footing. Before, every individual practised all the arts that were known, as far as was necessary for supplying himself with the conveniencies of life. Now he confines himself to one or to a few of them; and, in order to obtain a necessary supply of the productions of those arts which he does not cultivate himself, he gives in exchange a part of the productions of his own labours. Here we have the origin of commerce.

After continuing perhaps for some time in this state, as arts and distinctions multiply in society, the exchange

Society.

change of one commodity for another is found troublesome and inconvenient. It is ingeniously contrived to adopt a medium of commerce, which being estimated not by its intrinsic value, but by a certain nominal value which it receives from the agreement of the society among whom it is used, serves to render the exchange of property, which is so necessary for the purposes of social life, easy and expeditious. Wherever metals have been known, they appear to have been adopted as the medium of commerce almost as soon as such a medium began to be used: and this is one important purpose for which they serve; but they have still more important uses. Almost all the necessary arts depend on them. Where the metals are known, agriculture practised, and the necessary arts distributed among different orders of artisans—civilization and refinement, if not obstructed by some accidental circumstances, advance with a rapid progress. With regard to the first applying of the precious metals as the medium of commerce, we may observe, that this was probably not accomplished by means of a formal contract. They might be first used as ornaments; and the love of ornament, which prevails among rude as much as among civilized nations, would render every one willing to receive them in exchange for such articles as he could spare. Such might be the change produced on society with regard to the necessary arts by the origin of agriculture. As soon as ornament and amusement are thought of, the fine arts begin to be cultivated. In their origin therefore they are not long posterior to the necessary and useful arts. They appear long before men reach the comfortable and respectable condition of husbandmen; but so rude is their character at their first origin, that our *Dilettanti* would probably view the productions of that period with unspeakable contempt and disgust. But in the period of society which we now consider, they have aspired to a higher character; yet poetry is now perhaps less generally cultivated than during the shepherd state. Agriculture, considered by itself, is not directly favourable either to refinement of manners or to the fine arts. The conversation of shepherds is generally supposed to be far more elegant than that of husbandmen; but though the direct and immediate effects of this condition of life be not favourable to the fine arts, yet indirectly it has a strong tendency to promote their improvement. Its immediate influence is extremely favourable to the necessary and useful arts; and these are no less favourable to the fine arts.

One of the noblest changes which the introduction of the arts by agriculture produces on the form and circumstances of society, is the introduction of regular government and laws. In tracing the history of ancient nations, we scarcely ever find laws introduced at an earlier period. Minos, Solon, and Lycurgus, do not appear to have formed codes of wisdom and justice for regulating the manners of their countrymen, till after the Cretans, the Athenians, and even the Lacedæmonians, had made some progress in agriculture and the useful arts.

Religion, under all its various forms, has in every stage of society a mighty influence on the sentiments and conduct of men (see RELIGION); and the arts cultivated in society have on the other hand some influence on the system of religious belief. One happy effect which will result from the invention of arts, though perhaps not immediately, will be, to render the character of the deities more benevolent and amiable, and the rites of their worship more mild and humane.

The female sex in this period generally find the yoke of their slavery somewhat lightened. Men now become easier in their circumstances; the social affections assume stronger influence over the mind; plenty, and security, and ease, at once communicate both delicacy and keenness to the sensual desires. All these circumstances concur to make men relax in some degree that tyrannic sway by which they before depressed the softer sex. The foundation of that empire, where beauty triumphs over both wisdom and strength, now begins to be laid. Such are the effects which history warrants as to attribute to agriculture and the arts; and such the outlines of the character of that which we reckon the fourth stage in the progress of society from rudeness to refinement.

13
Fifth stage in the progress of society; in which literature, arts, and sciences, are much cultivated, and religion assumes a mild and engaging aspect.

Let us advance one step farther. We have not yet surveyed mankind in their most polished and cultivated state. Society is rude at the period when the arts first begin to show themselves, in comparison of that state to which it is raised by the industrious cultivation of them. The neighbouring commonwealths of Athens and Lacedæmon afford us a happy opportunity of comparing this with the former stage in the progress of society. The chief effect produced by the institutions of Lycurgus seems to have been, to fix the manners of his countrymen for a considerable period in that state to which they had attained in his days. Spartan virtue has been admired and extolled in the language of enthusiasm; but in the same manner has the character and the condition of the savage inhabitants of the wilds of America, been preferred by some philosophers, to the virtues and the enjoyments of social life in the most polished and enlightened state. The Spartans in the days of Lycurgus had begun to cultivate the ground, and were not unacquainted with the useful arts. They must soon have advanced farther had not Lycurgus arisen, and by effecting the establishment of a code of laws, the tendency of which appears to have been in many particulars directly opposite to the designs of nature, retarded their progress towards complete civilization and refinement. The history of the Lacedæmonians, therefore, while the laws of Lycurgus continued in force, exhibits the manners and character of a people in that which we have denominated the fourth stage in the progress of society. But if we turn our eyes to their neighbours the Athenians, we behold in their history the natural progress of opinions, arts, and manners. The useful arts are first cultivated with such steady industry, as to raise the community to opulence, and to furnish them with articles for commerce with foreign nations. The useful arts cannot be raised to this height of improvement without leading men to the pursuit of science. Commerce with foreign nations, skill in the useful arts, and a taste for science, mutually aid each other, and conspire to promote the improvement of the fine arts. Hence magnificent buildings, noble statues, paintings expressive of life, action, and passion; and poems in which imagination adds new grace and sublimity to nature, and gives the appearances of social life more irresistible power over the affections of the heart. Hence are moral distinctions more carefully studied, and the

Society.

the rights of every individual and every order in society better understood and more accurately defined. Moral science is generally the first scientific pursuit which strongly attracts the attention of men. Lawgivers appear before geometricians and astronomers. Some particular circumstances may cause these sciences to be cultivated at a very early period. In Egypt the overflowing of the Nile caused geometry to be early cultivated. Causes no less favourable to the study of astronomy, concurred to recommend that science to the attention of the Chaldeans long before they had attained the height of refinement. But, in general, we find, that the laws of morality are understood, and the principles of morals inquired into, before men make any considerable progress in physical science, or even prosecute it with any degree of keenness. Accordingly, when we view the state of literature in this period (for it is now become an object of so much importance as to force itself on our attention), we perceive that poetry, history, and morals, are the branches chiefly cultivated. Arts are generally casual inventions, and long practised before rules and principles on which they are founded assume the form of science. But morality, if considered as an art, is that art which men have soonest and most constantly occasion to practise. Besides, we are so constituted by the wisdom of nature, that human actions, and the events which befal human beings, have more powerful influence than any other object to engage and fix our attention. Hence we are enabled to explain why morality, and those branches of literature more immediately connected with it, are almost always cultivated in preference to physical science. Though poetry, history, and morals, be pursued with no small eagerness and success in that period of society which we now consider, we need not therefore be greatly surprised that natural philosophy is neither very generally nor very successfully cultivated. Were we to consider each particular in that happy change which is now produced on the circumstances of mankind, we should be led into a too minute and perhaps unimportant detail. This is the period when human virtue and human abilities shine with most splendour. Rudeness, ferocity, and barbarism, are now banished. Luxury has made her appearance; but as yet she is the friend and the benefactress of society. Commerce has stimulated and rewarded industry, but has not yet contracted the heart and debased the character. Wealth is not yet become the sole object of pursuit. The charms of social intercourse are known and relished; but domestic duties are not yet deserted for public amusements. The female sex acquire new influence, and contribute much to refine and polish the manners of their lords. Religion now assumes a milder and more pleasing form; splendid rites, magnificent temples, pompous sacrifices, and gay festivals, give even superstition an influence favourable to the happiness of mankind. The gloomy notions and barbarous rites of former periods fall into disuse. The system of theology produced in former ages still remains: but only the mild and amiable qualities of the deities are celebrated; and none but the gay, humane, and laughing divinities, are worshipped. Philosophy also teaches men to discard such parts of their religion as are unfriendly to good morals, and have any tendency to call forth or cherish unsocial sentiments in the heart. War (for in this period of society enough of causes will arise to arm one nation against another)—war, however, no longer retains its former ferocity; nations no longer strive to extirpate one another: to procure redress for real or imaginary injuries; to humble, not to destroy, is now its object. Prisoners are no longer murdered in cold blood, subjected to horrid and excruciating tortures, or condemned to hopeless slavery. They are ransomed or exchanged; they return to their country, and again fight under its banners. In this period the arts of government are likewise better understood, and practised so as to contribute most to the interests of society. Whether monarchy, or democracy, or aristocracy, be the established form, the rights of individuals and of society are in general respected. The interests of society are so well understood, that the few, in order to preserve their influence over the many, find it necessary to act rather as the faithful servants than the imperious lords of the public. Though the liberties of a nation in this state be not accurately defined by law, nor their property guaranteed to them by any legal institutions, yet their governors dare not violate their liberties, nor deprive them wantonly of their properties. This is truly the golden age of society: every trace of barbarism is entirely effaced; and vicious luxury has not yet begun to sap the virtue and the happiness of the community. Men live not in listless indolence; but the industry in which they are engaged is not of such a nature as to overpower their strength or exhaust their spirits. The social affections have now the strongest influence on men's sentiments and conduct.

14 Degeneracy and decline of society.

But human affairs are scarcely ever stationary. The circumstances of mankind are almost always changing, either growing better or worse. Their manners are ever in the same fluctuating state. They either advance towards perfection or degenerate. Scarcely have they attained that happy period in which we have just contemplated them, when they begin to decline till they perhaps fall back into a state nearly as low as that from which we suppose them to have emerged. Instances of this unhappy degeneracy occur more than once in the history of mankind; and we may finish this short sketch of the history of society by mentioning in what manner this degeneracy takes place. Perhaps, strictly speaking, every thing but the simple necessaries of life may be denominated luxury: For a long time, however, the welfare of society is best promoted, while its members aspire after something more than the mere necessaries of life. As long as these superfluities are to be obtained only by active and honest exertion; as long as they only engage the leisure hours, without becoming the chief objects of pursuit—the employment which they give to the faculties is favourable both to the virtue and the happiness of the human race.

The period arrives, however, when luxury is no longer serviceable to the interests of nations; when she is no longer a graceful, elegant, active form, but a languid, overgrown, and bloated carcase. It is the love of luxury, which contributed so much to the civilization of society, that now brings on its decline. Arts are cultivated and improved, and commerce extended, till enormous opulence be acquired: the effect of opulence is to awaken the fancy, to conceive ideas of new and capricious wants, and to inflame the breast with new desires. Here we have the origin of that selfishness which, operating in conjunction with caprice and the violence of unbridled

Society.

unbridled passions, contributes so much to the corruption of virtuous manners. Selfishness, caprice, indolence, effeminacy, all join to loosen the bonds of society. to bring on the degeneracy both of the useful and the fine arts, to banish at once the mild and the austere virtues, to destroy civil order and subordination, and to introduce in their room anarchy or despotism.

Scarcely could we have found an example of the beautiful form of society which we last attempted to describe. Never, at least, has any nation continued long to enjoy such happy circumstances, or to display so amiable and respectable a character. But when we speak of the declining state of society, we have no difficulty in finding instances to which we may refer. History tells of the Assyrians, the Egyptians, and the Persians, all of them once flourishing nations, but brought low by luxury and an unhappy corruption of manners. The Greeks, the Romans, and the Assyrians, owed their fall to the same causes; and we know not if a similar fate does not now threaten many of those nations who have long made a distinguished figure in the system of Europe. The Portuguese, the Venetians, and the Spaniards, have already fallen; and what is the present state of our neighbours the French? They have long been a people destitute of religion, corrupted in morals, unsteady in conduct, and slaves to pleasure and public amusements. Among them luxury had arrived at its highest pitch; and the consequence has been, that after capriciously shaking off the yoke of despotism, they have established, or rather set up (for established it cannot be), a motley kind of government, which, in the course of a few years, has exhibited scenes of tyranny and oppression, to which we doubt if the annals of the world can furnish any parallel. Yet this is the people whose manners the other nations of Europe were ambitious to imitate. May those nations take warning in time, and avoid the rocks upon which they have split.

15 Concluding remarks.

THUS have we viewed the several stages in which society appears in its progress from rudeness to refinement and decay. The intelligent reader will perceive, that the various and anomalous phenomena which occur in the natural history of society, cannot easily be solved; because the necessary information cannot be obtained. Others have been well accounted for by the researches of curious philosophical inquirers. Local circumstances, the influence of climate, the intercourse of nations in different states of civilization, have been taken notice of, as causes serving to accelerate or retard the progress of arts and manners. But our proper business here was merely to mark the gradations between barbarism and refinement: and as the painter who is to exhibit a series of portraits representing the human form in infancy, puerility, youth, and manhood, will not think of delineating all that variety of figures and faces which each of those periods of life affords, and will find himself unable to represent in any single figure all diversities of form and features; so we have not once thought of describing particularly under this article, all the various national characters reducible to any one of those divisions under which we have viewed the progress of society, nor have found it possible to comprehend under one consistent view, all the particulars which may be gathered from the remains of antiquity, from the relations of later travellers, and the general records of history concerning the progressive character of mankind in various regions, and under the influence of various accidents and circumstances. This indeed would even have been improper, as all that information appears under other articles in this Work.

Society, Societies.

SOCIETIES, associations voluntarily formed by a number of individuals for promoting knowledge, industry, or virtue. They may therefore be divided into three classes; societies for promoting science and literature, societies for encouraging and promoting arts and manufactures, and societies for diffusing religion and morality and relieving distress. Societies belonging to the first class extend their attention to all the sciences and literature in general, or devote it to one particular science. The same observation may be applied to those which are instituted for improving arts and manufactures. Those of the third class are established, either with a view to prevent crimes, as the Philanthropic Society; for the diffusion of the Christian religion among unenlightened nations, as the Society for the Propagation of the Gospel in Foreign Parts; or for introducing arts and civilization, along with a knowledge of the Christian religion, as the Sierra Leona Company.

The honour of planning and instituting societies for those valuable purposes is due to modern times. A literary association is said to have been formed in the reign of Charlemagne (see ACADEMY); but the plan seems to have been rude and defective. Several others were instituted in Italy in the 16th century; but from the accounts which we have seen of them, they seem to have been far inferior to those which are most flourishing at present. The most enlarged idea of literary societies seems to have originated with the great Lord Bacon, the father of modern philosophy, who recommended to the reigning prince to institute societies of learned men, who should give to the world from time to time a regular account of their researches and discoveries. It was the idea of this great philosopher, that the learned world should be united, as it were, into one immense republic; which, though consisting of many detached states, should hold a strict union and preserve a mutual intelligence with each other, in every thing that regards the common interest. The want of this union and intelligence he laments as one of the chief obstacles to the advancement of science; and, justly considering the institution of public societies, in the different countries of Europe, under the auspices of the sovereign, to be the best remedy for that defect, he has given, in his fanciful work, the New Atlantis, the delineation of a philosophical society on the most extended plan, for the improvement of all arts and sciences; a work which, though written in the language, and tinctured with the colouring of romance, is full of the noblest philosophic views. The plan of Lord Bacon, which met with little attention from the age in which he lived, was destined to produce its effect in a period not very distant. The scheme of a philosophical college by Cowley is acknowledged to have had a powerful influence in procuring the establishment of the Royal Society of London by charter from Charles II. †; and Cowley's plan is manifestly copied in almost all its parts from that in the New Atlantis. The institution of the Royal Society of London was soon followed by the establishment of the Royal Academy

† Sprat's History of the Royal Society, 2d edit. p. 59.

demy of Sciences at Paris: and these two have served as models to the philosophical academies of highest reputation in the other kingdoms of Europe.

The experience of ages has shown, that improvements of a public nature are best carried on by societies of liberal and ingenious men, uniting their labours without regard to nation, sect, or party, in one grand pursuit alike interesting to all, whereby mutual prejudices are worn off, and a humane philosophical spirit is cherished. Men united together, and frequently meeting for the purposes of advancing the sciences, the arts, agriculture, manufactures, and commerce, may oftentimes suggest such hints to one another as may be improved to important ends; and such societies, by being the repositories of the observations and discoveries of the learned and ingenious, may from time to time furnish the world with useful publications which might otherwise be lost: for men of ingenuity and modesty may not choose to risk their reputation, by sending abroad unpatronized what a learned society might judge richly worth the public eye; or perhaps their circumstances being straitened, they may not be able to defray the expence of publication. Societies instituted for promoting knowledge may also be of eminent service, by exciting a spirit of emulation, and by enkindling those sparks of genius which otherwise might for ever have been concealed; and if, when possessed of funds sufficient for the purpose, they reward the exertions of the industrious and enterprising with pecuniary premiums or honorary medals, many important experiments and useful discoveries will be made, from which the public may reap the highest advantages.

Eminent instances of the beneficial effects of such institutions we have in the Royal Academy of Sciences at Paris, the Royal Society, and the Society instituted for the Encouragement of Arts, Manufactures, and Commerce, in London, and many others of a similar kind. Hereby a spirit of discovery and improvement has been excited among the ingenious in almost every nation; knowledge of various kinds, and greatly useful to mankind, has taken place of the dry and uninteresting speculations of schoolmen; and bold and erroneous hypothesis has been obliged to give way to demonstrative experiment. In short, since the establishment of these societies, solid learning and philosophy have more increased than they had done for many centuries before.

As to those societies established for promoting industry, religion and morality, and relieving distress, the design is laudable and excellent, and presents a beautiful picture of the philanthropy of modern times. We are happy to find, from the minutes of some of these societies, that their beneficial effects are already conspicuous.

We will now give some account of the most eminent societies; arranging them under the three classes into which we have divided them: I. *Religious and Humane Societies.* II. *Societies for Promoting Science and Literature.* III. *Societies for Encouraging Arts, Manufactures*, &c.

I. Religious and Humane Societies.

1. *Society for the Propagation of the Gospel in Foreign Parts*, was instituted by King William III. in 1701, in order to secure a maintenance for an orthodox clergy, and to make other provisions for propagating the gospel in the plantations, colonies, and factories beyond the seas. To that end he incorporated the archbishops, several of the bishops, and others of the nobility, gentry, and clergy, to the number of 90, into one body, which, by the name of *The Society for the Propagation of the Gospel in Foreign Parts*, was to plead and be impleaded; to have perpetual succession, with privilege to purchase 2000l. a-year inheritance, and estates for lives or years, with other goods and chattels to any value. By its charter the society is authorised to use a common seal; and to meet annually on the third Friday in February for the purpose of choosing a president, vice president, and officers for the year ensuing; and on the third Friday in every month, or oftener if there should be occasion, to transact business, and to depute persons to take subscriptions, and collect money contributed for the purposes aforesaid; and of all moneys received and laid out, it is obliged to give account yearly to the lord-chancellor or keeper, the lord-chief-justice of the King's-bench, the lord-chief-justice of the Common-pleas, or to any two of these magistrates. Of this society there is a standing committee at St Paul's chapter-house, to prepare matters for the monthly meeting, which is held at St Martin's library.

Before the incorporation of the society for the propagation of the gospel in foreign parts, there had been formed, for the promoting of Christian knowledge both at home and in the colonies, a voluntary association of persons of rank and respectability, who in March 1699 began to hold stated meetings in London for that purpose, regulating themselves by the laws of the land and the canons of the church; and when the new society was formed, they had already transmitted to America and the West Indies 800l. worth of Bibles, Books of Common Prayer, and treatises of practical religion, besides securing a tolerable maintenance to several clergymen on that continent. This association still subsists under the denomination of *The Society for Promoting Christian Knowledge*, and has been productive of much good in the cities of London and Westminster; but upon the formation of the new society, into which all its original members were incorporated by name, the care which the voluntary association had taken of the colonies devolved of course upon the incorporated society; of which incorporation we believe the object has been sometimes mistaken, and the labours of its missionaries grossly misrepresented. It has by many been supposed that the society was incorporated for the *sole* purpose of converting the savage Americans; and it has been much blamed for sending missionaries into provinces where, in the common language of the complainers, a *gospel ministry* was already established. But an impartial view of the rise and progress of the American provinces, now become independent states, will show the folly and injustice of those complaints.

The English colonies in North America were in the last century formed and first peopled by religious men; who, made uneasy at home by their intolerant brethren, left the *old world* to enjoy in peace that first and chief prerogative of man, *the free worship of God according to his own conscience.* At one time Puritans were driven across the Atlantic by the episcopal church; at another, Churchmen were forced away by the presbyterians, just as the revolutions of state threw the civil power into the hands of the one or the other party; and not a few

Religious and Humane Societies.

members of the CHURCH OF ROME were chased to the wilds of America by the united exertions of both. It has been often observed, that people persecuted for their religion become for the most part enthusiastically attached to it; and the conduct of those colonists was in perfect harmony with this observation. Their zeal, inflamed by their violent removal to the other hemisphere, kept religion alive and active among themselves; but their poverty disabled them from supplying fuel to the flame, by making provision for a ministry to instruct their offspring. The consequence was, that the new Christian commonwealth, without the kindly assistance of its mother country, would have been, in the words of the Roman historian, *Res unius ætatis*. Against this danger a timely aid was to be provided by the society; which, as it consisted not of fanatical members, would not intrust the important business of the mission to fanatical preachers, who, though always ready for such spiritual enterprises, are never qualified to carry them on with success.

It was therefore thought fit to assign a decent maintenance for clergymen of the church of England, who might preach the gospel to their brethren in America: and though those missionaries in general carefully avoided the conduct of those of Rome, whose principal aim is to reduce all churches under submission to the papal tyranny; yet so lately as 1765, did some of the colonies, in which the puritanic spirit of the last century characterised the church established by law, raise a hideous outcry against the society for sending a mission into their quarters, though only for the service of the dispersed members of the Episcopal church residing among them, and for the conversion of those men whom their rigid fanaticism had prejudiced against Christianity itself.

Indeed the commodity called FREETHINKING, as Bishop Warburton expresses it, was at an early period imported by the opulent and fashionable colonists. The celebrated Berkeley, who had resided some years in Rhode Island, and at his return was called upon to preach the anniversary sermon before the society *, informs us, that the island where he lived was inhabited by an English colony, consisting chiefly of sectaries of many different denominations; that several of the better sort of the inhabitants of towns were accustomed to assemble themselves regularly on the Lord's day for the performance of divine worship; but that most of those who were dispersed through the colony rivalled some well-bred people of other countries, in a thorough indifference for all that is sacred, being equally careless of outward worship and of inward principles. He adds, that the missionaries had done, and were continuing to do, good service in bringing those planters to a serious sense of religion. "I speak it knowingly (says he), that the ministers of the gospel, in those provinces which go by the name of New England, sent and supported at the expence of the society, have, by their sobriety of manners, discreet behaviour, and a competent degree of useful knowledge, shown themselves worthy of the choice of those who sent them." We have the honour to be acquainted with some of the missionaries sent at a later period, and have reason to believe that, down to the era of the American revolution, they had the same virtues, and were doing the same good services, which procured to their predecessors this honourable testimony from one of the greatest and the best of men. Surely such a mission deserved not to be evil spoken of by sectarists of any denomination who believe in Christ; especially as the very charter of incorporation assigns as a reason for missionaries being sent to the colonies, "that by reason of their poverty those colonies were destitute and unprovided of a MAINTENANCE for ministers and the public worship of God."

* See his *Sermon*, vol. ii. of his *Works*, 4to.

The society, however, was incorporated for other purposes than this. It was obliged by its charter to attempt the conversion of the native Americans and the negro slaves; and we have reason to believe, that, as soon as the spiritual wants of the colonists were decently supplied, it was not inattentive to these glorious objects. Its success indeed in either pursuit has not been so great as could be wished; but it would be rash and unfair to attribute this failure to the president, vice-president, or other officers of the corporation at home. An erroneous notion, that the being baptized is inconsistent with a state of slavery, rendered the selfish colonists for a long time averse from the conversion of their negroes, and made them throw every obstacle in the way of all who made the attempt; while the difficulties of the Indian mission are such as hardly any clergyman educated in a Protestant country can be supposed able to surmount.

He who hopes successfully to preach the gospel among a tribe of savage wanderers, must have an ardent zeal and unwearied diligence; appetites subdued to all the distresses of want; and a mind superior to all the terrors of mortality. These qualities and habits may be acquired in the church of Rome by him who from infancy has been trained up in the severities of some of the monastic orders, and afterwards sent to the college *de propaganda fide* to be instructed in the languages, and inured to the manners and customs, of the barbarous nations whose conversion he is destined to attempt. But in the reformed churches of Britain there are no monastic orders, nor any college *de propaganda fide*; and yet without the regular preparation, which is to be looked for in such institutions alone, it is not in nature, whatever grace may effect, for any man cheerfully, and at the same time soberly, to undergo all the accumulated distresses ever ready to overtake a faithful missionary among savage idolators. A fanatic zealot will indeed undertake it, though he is totally unqualified for every sober and important work; and a man of ruined fortunes may be pressed into the service, though the impotency of his mind has shown him unable to bear either poverty or riches. The failure of the society therefore in its attempts to convert the American Indians may be attributed, we think, in the first instance, to the want of a college *de propaganda* for training up young men for the American mission.

Perhaps another cause of this failure may be found in the conduct of the missionaries, who, it is to be presumed, have not always employed in a proper manner even the scanty qualifications which they actually possessed. The gospel, plain and simple as it is, and fitted in its nature for what it was ordained to effect, cannot be apprehended but by an intellect somewhat raised above that of a savage. Such of the missionaries therefore as began their work with *preaching to savage and brutal men*, certainly set out at the wrong end; for to make the gospel understood, and much more to propa-

 gate

Religious and Humane Societies.

gate and establish it, those savages should have been first taught the necessary arts of civil life, which, while they improve every bodily accommodation, tend at the same time to enlarge and enlighten the understanding. For want of this previous culture, we doubt not, it hath happened that such of the savages as have been baptized into the faith have so seldom persevered themselves, or been able in any degree to propagate among their tribes the Christianity which they had been taught, and that successive missions have always found it necessary to begin anew the work of conversion.

To one or other of these causes, or to both, may justly be attributed the little progress which reformed Christianity has made among the Indians of North America; and not to any want of zeal, attention, or liberality, in the directors of the society at home. During the dependence of the United States on the mother-country, great part of the society's funds was properly expended in keeping alive a just sense of religion among the Christian colonists from Europe, who had surely the first claims upon this best of charities; but now that America has separated herself from Great Britain, and shown that she is able to maintain her independence, and to make ample provision for a regular clergy of her own, the members of the corporation must feel themselves at liberty to bestow greater attention, and to expend more money than they could formerly do, on the conversion of such Indians as have any intercourse with the settlements which we still possess. To a body so respectable, we presume not to offer advice; but we cannot help thinking, with Bishop Berkeley, that the most successful missionaries would be children of Indians, educated in a considerable number together from the age of ten or twelve in a college *de propaganda fide*, where they should be in no danger of losing their mother-tongue while they were acquiring a competent knowledge of religion, morality, history, practical mathematics, and agriculture. "If there were a yearly supply (says he) of a dozen such missionaries sent abroad into their respective countries, after they had received the degree of master of arts, and been admitted into holy orders, it is hardly to be doubted but that in a little time the world would see good and great effects of their mission."

Proposal for the better supplying of Churches in our Foreign Plantations, &c.

2. *Society in Scotland for Propagating Christian Knowledge*, was instituted in the beginning of the 18th century. At that period the condition of the Scotch Highlanders was truly deplorable. Shut up in desolate islands by tempestuous seas, or dispersed over a wide extent of country, intersected by high mountains, rapid rivers, and arms of the sea, without bridges or highways, by which any communication could be kept open either with remote or neighbouring districts, they lived in small detached companies in hamlets or solitary huts. Being thus secluded from intercourse with the more civilized part of the island, they could not enjoy the advantages of trade and manufactures. As their soil was barren and their climate severe, in agriculture no progress was to be expected: and as they were acquainted with no language but Gaelic, in which no books were then written, to possess knowledge was impossible. Their parishes being of great extent, often 30 or 40 miles long and of a proportionable breadth, and sometimes consisting of several islands separated by seas, which are often impassable, a considerable number of the inhabitants was entirely deprived of religious instruction or fell a prey to Popish emissaries. A single school in such extensive parishes could be of little benefit; yet many parishes were entirely destitute even of this resource; and where schools were established, the want of books prevented them from producing the useful effects otherwise to have been expected from them (A). To all this we must add, that they lived in a state of the greatest oppression: For though the Highlands formed a part of the British empire, the blessings of the British constitution had not reached them. The feudal system reigned in its utmost rigour; the chieftains exercising the most despotic sway over the inferior Highlanders, whom at their pleasure they deprived of their lives or property (B).

Religious and Humane Societies.

Thus the Highlanders were ignorant, oppressed, and uncivilized; slaves rather than subjects; and either entirely destitute of the advantages of the Christian religion, or unqualified to improve them. Hitherto they had been unhappy and useless to themselves and dangerous to the state; for they were ready at the call of their chieftains to issue from their mountains, and to turn their arms against their lawful king and his loyal subjects. This character, however, arose from their situation. It was therefore impossible for benevolent minds to contemplate this unhappy situation of their countrymen without feeling a desire to raise them to the dignity of rational beings, and to render them useful as citizens.

Accordingly, in the year 1701, some private gentlemen of the city of Edinburgh, who had formed themselves into a society for the reformation of manners, directed their attention to the Highlands of Scotland, and endeavoured to devise some plan for alleviating the distresses of the inhabitants. The remedy which promised to be most efficacious was, to establish charity schools in different places. But as the exigency was great, it was no easy matter to raise a sufficient fund for this purpose. They began therefore with what voluntary subscriptions they could procure, hoping afterwards to increase their capital by vacant stipends and public contributions. A memorial with this view was presented to the General Assembly in 1704, which received their approbation; and they accordingly passed an act, recommending a general contribution. In 1706 the General Assembly appointed some of their number to inquire more carefully into the state of the Highlands, and the year following appointed a select committee to confer with the gentlemen who had suggested the plan. The result of these conferences was the publication of proposals "for propagating Christian knowledge

(A) Even so late as the year 1758, not fewer than 175 parishes, within the bounds of 39 presbyteries, had no parochial school. We are sorry to add, that even in the present enlightened and benevolent age the complaint is not entirely removed.

(B) The feudal system was at length abolished in the year 1748 by the jurisdiction act.

Religious and Humane Societies.

ledge in the Highlands and Islands of Scotland, and in foreign parts of the world." Copies of these proposals, with subscription papers, were distributed through the kingdom; and the contributions having soon amounted to 1000l. her majesty Queen Anne encouraged this infant society by her royal proclamation, and at the same time issued letters patent under the great seal of Scotland for erecting certain of the subscribers into a corporation; the first nomination of whom was lodged with the lords of council and session.

This corporation held its first meeting on Thursday 3d November 1709. It was attended by several of the nobility, fourteen of the lords of session, many gentlemen of rank, together with most of the ministers of the city of Edinburgh and neighbourhood. A president, secretary, and treasurer, with a committee of fifteen directors were appointed for the dispatch of business. At their second meeting in January 1710, a scheme of management was formed and approved; in which it was proposed, 1. To erect and maintain schools in such places of Scotland, particularly in the Highlands and Islands, as should be found to need them most; in which schools all persons whatsoever should be taught by fit and well qualified schoolmasters, appointed by the society, to read the Holy Scriptures and other pious books; as also to write, and to understand the common rules of arithmetic, with such other things as should be thought suitable to their circumstances. 2. That the schoolmasters should be particularly careful to instruct their scholars in the principles of the Christian reformed religion; and for that end should be obliged to catechise them at least twice a week, and to pray publicly with them twice a-day. 3. That not only such as were unable to pay should be taught gratis, but that those whose circumstances required it, should have such farther encouragement as the society should think fit in a consistency with their patent. 4. To name some prudent persons, ministers and others, to be overseers of those schools, who should take care that the schoolmasters do their duty, and that the instructions to be given from time to time by the society or their committee be punctually observed; which overseers should make their report to the society quarterly or half-yearly at farthest. 5. To give suitable encouragement to such ministers or catechists as should be willing to contribute their assistance towards the farther instruction of the scholars remote from church, by not only catechising, but preaching to them; which ministers or catechists should take the same care of the other inhabitants as of the scholars. 6. To extend their endeavours for the advancement of the Christian religion to heathen nations; and for that end to give encouragement to ministers to preach the gospel among them.

Having thus formed a plan, they immediately proceeded to establish schools in the most useful and economical manner; and as the capital continued to accumulate, the interest was faithfully applied, and the utility of the institution was more extensively diffused.

Until the year 1738 the attention of the society had been wholly directed to the establishment of schools; but their capital being then considerably augmented, they began to extend their views of utility much farther. The grand object of all public associations ought certainly to be the promoting of religion and morality. It must, however, be evident to every man of reflection, that these can neither be propagated nor preserved among a people without agriculture, unaccustomed to commerce and manufactures, and consequently without labour or exertion. Languor and debility of mind must always be the companions of idleness. While the Highlanders roved about with arms in their hands, the latent vigour of their minds must often have been called forth into action; but when their arms were taken away, and themselves confined to a domestic life, where there was nothing to rouse their minds, they must have sunk into indolence and inactivity. All attempts therefore to instruct them in religion and morality, without introducing among them some of the necessary arts of life, would probably have been unavailing. The society accordingly resolved to adopt what appeared to them the most effectual methods of introducing industry among the Highlanders. But as their patent did not extend far enough, they applied to his majesty George II. for an enlargement of their powers; and accordingly obtained a second patent, by which they are empowered, "besides fulfilling the purposes of their original patent, to cause such of the children as they shall think fit to be bred to husbandry and housewifery, to trades and manufactures, or in such manual occupations as the society shall think proper."

The objects of this second patent the society have not failed to pursue; and though many obstacles and discouragements to their efforts occurred among a rude and barbarous people, yet their perseverance, and the obvious utility of their plans, at length so far overcame the reluctance of the inhabitants, that not fewer than 94 schools of industry in various parts of the Highlands and Islands are now upon their establishment, at which are educated 2360 scholars.

The society, while anxiously endeavouring to diffuse a spirit of industry through the Highlands, were still equally solicitous to promote the knowledge of the Christian religion. As the English language had been the only channel by which knowledge was conveyed to them (a language which, being not used in conversation, was in all respects foreign to them), it was judged requisite that they should have the Scriptures in their vernacular tongue. The society therefore first appointed a translation of the New Testament to be made into Gaelic: A translation was accordingly undertaken by the Rev. Mr Stewart, minister of Killin in Perthshire, and printed in 1767, which is said to be executed with much fidelity. Of this work many thousand copies have been distributed in the Highlands. The greater part of the Old Testament has also been translated by the Rev. Dr Smith of Campbelton and others, but chiefly by the Rev. Dr Stewart of Luss, by the appointment and at the expence of the society: and as soon as the remaining part can be got ready, the whole will be sold at so low a price as the poor may without difficulty afford. This plan the society have judiciously chosen, in order to prevent discontent and murmuring; effects which the diffusion of the Scriptures ought never to produce; but which could not possibly have been prevented, had the distribution been gratuitous, and of course partial.

For some years past the funds of the society have rapidly

Religious and Humane Societies.

pidly accumulated, from the very liberal donations of several individuals.

Lady Glenorchy, -	L. 5,000
By a person unknown, -	10,000
Lord Van Vryhouven of Holland,	20,000
Miss Gray of Teasses, -	3,500

In consequence of these great additions to their stock, insinuations have been thrown out that the society have become so wealthy as to be at a loss for proper objects on which to bestow their increased revenue. If such an opinion be *seriously* entertained by any one, we must beg him to remember, that the society have erected and endowed not fewer than 323 schools for religion, the first principles of literature and industry, at the annual expence of 3214l. 10s. sterling; and that at these seminaries are educated from 14,000 to 15,000 children; who, but for the means of instruction thus obtained, would in all probability be bred up in ignorance and idleness: That they employ 12 missionary ministers and catechists in remote parts of the Highlands and islands, or among the ignorant Highlanders settled in the great towns of Scotland, at the annual expence of 296l.: That they bestow a bursary or pension of 15l. per annum on each of six students of divinity having the Gaelic language: That they employ two missionary ministers and one schoolmaster among the Oneida and Stockbridge Indians of North America (being the destination of certain legacies bequeathed to them for that purpose), at the annual expence of 140l. Such is their fixed scheme of annual expenditure, amounting in all to 3740l. 10s. sterling—a sum it will be acknowledged of very considerable magnitude. The whole of their incidental expences arising from the Gaelic translation of the Scriptures of the Old Testament; from annuities which they have to pay, in consequence of sums left them as residuary legatees; from land and house taxes; from enabling candidates for the office of schoolmaster to come to Edinburgh for examination; from furnishing books to poor scholars in their various schools; and from removing schoolmasters from one station to another, is generally about 875l. which added to the former sum makes the whole annual expence amount to 4615l. 10s.

If it be inquired at what expence, in the *management* of it, this extensive and complicated charity is annually conducted, we are authorised to say, that the treasurer, bookholder, and clerk, are allowed each 25l. per annum, the same salaries which were annexed to these offices from the commencement of the society. The beadle or officer is allowed 12l. per annum. No salary whatever is enjoyed by any of the other officers of the society. The secretary, comptroller, accountant, and librarian, although subjected, some of them especially, to no small expence of time and labour, have no pecuniary recompense or emolument. Theirs are labours of love, for which they seek and expect no other reward than the consciousness of endeavouring to promote the best interests of mankind. The whole amount of the expence of managing the business of the society, including the above salaries, and coals, candle, stationary ware, postages, and other incidents, exceeds not at an average 115l. per annum. From this statement it appears, that hitherto at least the directors have been at no loss for important objects within the proper sphere of their institution on which to bestow their increased funds. They have, it is true, the disposal of very considerable sums for promoting the objects of the institution; but they are so far from accumulating wealth, that every year their expenditure, notwithstanding the late increase of their capital, exceeds rather than falls short of their income. They have depended upon a kind Providence and a generous public to refund these anticipations of their revenue, and hitherto they have never been disappointed.

Thus has the Society for Propagating Christian Knowledge proceeded for almost a century. It was founded by the pious exertions of a few private individuals, whose names are unknown to the world; and its funds, by faithful and judicious management, as well as by generous contributions, have now become of such magnitude, as to excite the hope that they will be productive of the most valuable effects. The benefits arising from public societies, it is well known, depend entirely upon the management of their directors. If so, the advantages which have accrued from this society intitle it to the praise and gratitude of the nation. While eager to increase the number of schools, the society have not been inattentive to their prosperity. In the year 1771 Mr Lewis Drummond, a gentleman in whom they placed great confidence, was commissioned by them to visit their schools, and to make an exact report of their state and circumstances. Again, in the year 1790, a commission was granted to the Rev. Dr Kemp, one of the ministers of Edinburgh and secretary to the society, to visit all the schools on their establishment. This laborious and gratuitous task he accomplished in the course of four summers with much ability and care, and highly to the satisfaction of the society. At his return he communicated a variety of important information respecting the state of the Highlands and Islands, and the means necessary for their improvement in religion, literature, and industry; an abstract of which was published by the society in appendixes to the anniversary sermons preached before them in the years 1789, 90, 91, and 92 (c).

The following table will exhibit at a glance the funds, establishment, and expenditure, of the society, from a few years after its commencement to the present time. Where

(c) It is well known, that the number of Roman Catholics in the Highlands is considerable; but it must give much pleasure to the Protestant reader to be informed, that the ancient malignant spirit of Popery has in that district given place to mildness and liberality. This is chiefly owing to the gentleman who superintends the priests in that quarter, whose mind is enlightened by science and learning. So far from being hostile to the views of the society, he recommended to his clergy to promote them. They accordingly received the secretary with much politeness; exhorted the people to send their children to the Protestant schools to be instructed in literature, to be taught to read the Scriptures in their own language, and to be made acquainted with those great principles of religion in which all Christians are agreed. What a blessed reformation!

Religious and Humane Societies.

Where the number of scholars is not mentioned, the defect may be supplied by taking an average from those years where a computation has been made. Where the capital is not mentioned, it may easily be made out by considering the salaries as the interest.

Hitherto we have taken no notice of the corresponding board which was established at London so early as the year 1729, to receive subscriptions and lay out sums. That board indeed remained long inactive; but in 1773 its members began to co-operate more cordially with their brethren in Scotland. Since that period an annual sermon has been preached in recommendation of the charity; and the preacher is now selected without any regard to the religious denomination to which he belongs; sometimes from the church of England, sometimes from the church of Scotland, and sometimes from sectaries of different persuasions. The meetings of the correspondent board have been attended by many of the nobility and gentry, who have made great exertions to promote the views of the society. From its present flourishing state therefore, from the indefatigable exertion and laudable zeal of the managers, and from the countenance and support which they have received from persons of the first rank and respectability in the nation, the benevolent mind may look forward with much confidence and satisfaction to a period not very distant, when its beneficial effects shall be felt not only in the Highlands, but shall be communicated to the rest of the nation. We have been thus particular in our account of the Society for Propagating Christian Knowledge, because we have had access to the most authentic sources of information, and because we know it to be an institution calculated to enlighten and improve a considerable part of the British nation.

3. *Society of the Sons of the Clergy*, was incorporated by King Charles II. in 1678, by the name of *The Governors of the Charity for Relief of the Poor Widows and Children of Clergymen*. This society is under the direction and management of a president and vice-president, three treasurers, and a court of assistants composed of forty members. Several hundreds of widows and children of the clergy have annually received considerable relief from this useful charity.

4. *Society for the Sons of the Clergy of the Established Church of Scotland*, was instituted at Edinburgh in February 1790, and was constituted a body corporate by his majesty's royal charter in 1792. The society, after several meetings, are of opinion, that the period in which the families of clergymen feel most urgently the need both of friends and of pecuniary aid, is that which commences with the introduction of the sons either to an university or to business, and terminates with their establishment in their respective professions; that many of the ministers of this church, living at great distances from the seats either of universities or of business, possess incomes which, in the present state of the country, are inadequate to the purposes of procuring for their sons either the literary or professional education which might enable them to come forward with credit and success in the world; that the sons of clergymen, from domestic tuition and example, have in general very advantageous means of receiving in their early years the impressions of virtue and honour, together with the rudiments of liberal knowledge; and that of course the public interest may be promoted, by enabling this class of young men to obtain their share in the respectable situations of life. The views of the society have been limited to the sons only of clergymen; as they are of opinion, that within the limits which they have fixed, the field of beneficence will be still very extensive, and the claims for aid as many and as great as their funds can be supposed able to answer, at least for many years to come. If the society shall ever be in a situation to undertake more than the aids which will be necessary in bringing forward the sons of the clergy, it may then be considered in what manner the daughters also may become sharers in its bounty.

A society of the same nature, and having the same objects in view, was instituted at Glasgow we think the year before; and both societies, we know, have in many cases proved highly beneficial in promoting the views for which they were instituted.

5. *Royal Humane Society*, was instituted in London in 1774, for the recovery of persons drowned or otherwise suffocated. We have already given some account of societies instituted in other countries with the same views, and have also copied the directions of this society for the recovery of life, for which see the article DROWNING. We have therefore only to state, that the plan of this society is so averse to any private interested views, that it acquits its founders of all sordid motives. For the medical practitioners accept no pecuniary recompense for the time which they devote to a difficult and tedious process; for the anxiety which they feel while the event is doubtful: for the mortification which they too often undergo, when death, in spite of all their efforts, at last carries off his prey; nor for the insults to which they willingly expose themselves from vulgar incredulity. Their sole reward is in the holy joy of doing good. Of an institution thus free in its origin from the suspicion of ambitious views, and in its plan renouncing self-interest in every shape, philanthropy must be the only basis. The good intention therefore of the society is proved by its constitution; the wisdom and utility of the undertaking are proved by its success: not fewer than 3000 fellow-creatures having since its commencement been (1794) restored to the community by its timely and indefatigable exertions. For it is to be observed, that the benefit of this society is by no means confined to the two cases of drowning and suspension. Its timely succours have roused the lethargy of opium taken in immoderate and repeated doses; they have rescued the wretched victims of intoxication; rekindled the life extinguished by the sudden stroke of lightning; recovered the apoplectic; restored life to the infant that had lost it in the birth; they have proved efficacious

Religious and Humane Societies.

efficacious in cases of accidental smothering and of suffocation by noxious damps; in instances in which the tenderness of the infant body or the debility of old age greatly lessened the previous probability of success: insomuch that no species of death seems to be placed beyond the reach of this society's assistance, where the mischief had gone no farther than an obstruction of the movements of the animal machine without any damage of the organs themselves. In consequence of every necessary assistance afforded by this society, similar institutions have been established at Algiers, Lisbon, Philadelphia, Boston, Jamaica, Dublin, Leith, Glasgow, Paisley, Aberdeen, Birmingham, Gloucester, Shropshire, Northamptonshire, Lancaster, Bristol, Whitehaven, Norwich, Exeter, Kent, and Newcastle. The society has published an 8vo volume with plates, consisting of cases, correspondence, and a variety of interesting matter relating to the object of this benevolent institution.

6. *The Philanthropic Society*, was instituted in September 1788. It aims at the prevention of crimes, by removing out of the way of evil counsel, and evil company, those children who are, in the present state of things, destined to ruin. It proposes to educate and instruct in some useful trade or occupation the children of convicts or other infant poor who are engaged in vagrant or criminal courses; thus to break the chain of those pernicious confederacies, deprive the wicked of successors, the gaols of inhabitants, justice of its victims, and by all these means add citizens to society. This institution is not only calculated to decrease vice and infamy, but to increase useful industry; so that those children who would otherwise succeed to their parents hereditary crimes, and become the next race of beggars and thieves, will now be taught to supply by honest means their own wants and the wants of others.

To carry into effect these desirable purposes, it is the first business of the society to select from prisons, and from the haunts of vice, profligacy, and beggary, such objects as appear most likely to become obnoxious to the laws, or prejudicial to the community; and, in the execution of this duty, the assistance of the magistrates, the clergy, and all who are interested in the promotion of good morals and good government, is most earnestly requested. For the employment of the children, several houses are supported, at Cambridge Heath, near Hackney, in each of which a master-workman is placed for the purpose of teaching the children some useful trade. The trades already established are those of a printer, carpenter, shoemaker, and taylor. The girls are at present educated as menial servants.

In the year 1791 not fewer than 70 children were under the protection of this society, among whom were many who have been guilty of various felonies, burglaries, and other crimes. Yet, singular as it may appear, in less than two years those very children became no less remarkable for industry, activity, decency, and obedience, than they formerly were for the contrary vices. Such are the grounds on which the Philanthropic Society now claims the attention and solicits the patronage of the public. If we regard humanity and religion, this institution opens an asylum to the most forlorn and abject of the human race; it befriends the most friendless; it saves from the certain and fatal consequences of infamy and vicious courses orphans and deserted children. If we regard national prosperity and the public welfare, it is calculated to increase industry; and it directs that industry into the most useful and necessary channels. If we regard self-interest, its immediate object is to protect our persons from assault and murder, our property from depredation, and our peaceful habitations from the desperate fury of midnight incendiaries.

One guinea per annum constitutes a member of the society; and 10l. at one payment a member for life. A life-subscription, or an annual payment of at least two guineas, is a necessary qualification for being elected into the committee.

II. Societies for Promoting Science and Literature.

1. *The Royal Society of London* is an academy or body of persons of eminent learning, instituted by Charles II. for the promoting of natural knowledge. The origin of this society is traced by Dr Sprat, its earliest historian, no farther back than to "some space after the end of the civil wars" in the 17th century. The scene of the first meetings of the learned men who laid the foundation of it, is by him fixed in the university of Oxford, at the lodgings of Dr Wilkens warden of Wadham college. But Dr Birch, on the authority of Dr Wallis, one of its earliest and most considerable members, assigns it an earlier origin. According to him, certain worthy persons, residing in London about the year 1645, being "inquisitive into natural and the new and experimental philosophy, agreed to meet weekly on a certain day, to discourse upon such subjects, and were known by the title of *The Invisible* or *Philosophical College*." In the years 1648 and 1649, the company who formed these meetings was divided, part retiring to Oxford and part remaining in London; but they continued the same pursuits as when united, corresponding with each other, and giving a mutual account of their respective discoveries. About the year 1659 the greater part of the Oxford society returned to London, and again uniting with their fellow-labourers, met once, if not twice, a-week at Gresham college, during term time, till they were scattered by the public distractions of that year, and the place of their meeting made a quarter for soldiers. On the restoration 1660 their meetings were revived, and attended by a greater concourse of men eminent for their rank and learning. They were at last taken notice of by the king, who having himself a considerable taste for physical science, was pleased to grant them an ample charter, dated the 15th of July 1662, and afterwards a second dated 15th April 1763, by which they were erected into a corporation, consisting of a president, council, and fellows, for promoting natural knowledge; and to give their investigations, against which strange prejudices were entertained, every possible support, he sometimes honoured their meetings with his presence.

Their manner of electing fellows is by balloting. Their council are in number 21, including the president, vice-president, treasurer, and two secretaries; 11 of which are continued for the next year, and 10 more added to them; all chosen on St Andrew's day. Each member at his admission subscribes an engagement that he will endeavour to promote the good of the society; from which he may be freed at any time, by signifying to the president that he desires to withdraw. The charges have been different at different times, and were at at first irregularly paid: but they are now five guineas paid to the treasurer at admission, and 13s. per quarter so long as the person continues a member; or, in lieu of the annual subscription, a composition of 25 guineas in one payment.

Their design is, to "make faithful records of all the works of nature or art which come within their reach; so that the present as well as future ages may be enabled to put a mark on errors which have been strengthened by long prescription; to restore truths that have been neglected; to push those already known to more various uses; to make the way more passable to what remains unrevealed," &c. To this purpose they have made a great number of experiments and observations on most of the works of nature; and also numbers of short histories of nature, arts, manufactures, useful engines, contrivances, &c. The services which they have rendered to the public are very great. They have improved naval, civil, and military architecture; advanced the security and perfection of navigation; improved agriculture; and put not only this kingdom, but also Ireland, the plantations, &c. upon planting. They have registered experiments, histories, relations, observations, &c. and reduced them into one common stock; and have, from time to time, published those which they reckoned most useful, under the title of *Philosophical Transactions*, &c. and laid the rest up in public registers, to be nakedly transmitted to posterity, as a solid ground-work for future systems.

They have a library adapted to their institution; towards which Mr Henry Howard, afterwards duke of Norfolk, contributed the Norfolcian library, and which is, at this time, greatly increased by a continual series of benefactions. The museum or repository of natural and artificial rarities, given them by Daniel Colwal, Esq. and since enriched by many others, is now removed to the British museum, and makes a part of that great repository. Their motto is *Nullius in verba;* and their place of assembling is Somerset house in the Strand. Sir Godfrey Copley, baronet, left five guineas to be given annually to the person who should write the best paper in the year, under the head of experimental philosophy. This reward, which is now changed to a gold medal, is the highest honour the society can bestow. It is conferred on St Andrew's day.

2. *The Royal Society of Edinburgh*, was incorporated by royal charter on the 29th of March 1783, and has for its object the cultivation of every branch of science, erudition, and taste. Its rise and progress towards its present state was as follows: In the year 1718 a literary society was established in Edinburgh by the learned Ruddiman and others, which in 1731 was succeeded by a society instituted for the improvement of medical knowledge. In the year 1739 the celebrated Maclaurin conceived the idea of enlarging the plan of this society, by extending it to subjects of philosophy and literature. The institution was accordingly new-modelled by a printed set of laws and regulations, the number of members was increased, and they were distinguished from that time by the title of *The Society for Improving Arts and Sciences*, or more generally by the title of *The Philosophical Society of Edinburgh*. Its meetings, however, were soon interrupted by the disorders of the country during the rebellion in 1745; and they were not renewed till the year 1752. Soon after this period the first volume of the Transactions of the Philosophical Society of Edinburgh was published, under the title of *Essays and Observations, Physical and Literary*, and was followed by other volumes of acknowledged merit. About the end of the year 1782, in a meeting of the professors of the university of Edinburgh, many of whom are likewise members of the Philosophical Society, and warmly attached to its interests, a scheme was proposed by the Rev. Dr Robertson, principal of the university, for the establishment of a new society on a more extended plan, and after the model of some of the foreign academies. It appeared an expedient measure to solicit the royal patronage to an institution of this nature, which promised to be of national importance, and to request an establishment by charter from the crown. The plan was approved and adopted; and the Philosophical Society, joining its influence as a body in seconding the application from the university, his majesty, as we have already observed, was most graciously pleased to incorporate The Royal Society of Edinburgh by charter.

The society consists of ordinary and honorary members; and the honorary places are restricted to persons residing out of Great Britain and Ireland. The election of new members is appointed to be made at two stated general meetings, which are to be held on the fourth Monday of January and the fourth Monday of June. A candidate for the place of an ordinary member must signify by a letter, addressed to one of the members, his wish to be received into the society. He must then be publicly proposed at least a month before the day of election. If the proposal be seconded by two of the members present, his name to be inserted in the list of candidates, and hung up in the ordinary place of meeting. The election is made by ballot, and is determined in favour of a candidate, if he shall have the votes of two thirds of those present, in a meeting consisting of at least 21 members. The general business of the society is managed by a president, two vice-presidents, with a council of 12, a general secretary, and a treasurer. These officers are chosen by ballot annually on the last Monday of November. All public deeds, whether of a civil or of a literary nature, are transacted by this board, and proceed in the name of the president or vice-president.

As it was thought that the members would have a greater inducement to punctual attendance on the meetings of the society, if they had some general intimation of the nature of the subjects which were to be considered, and made the topics of conversation, it was therefore resolved to divide the society into two classes, which should meet and deliberate separately. One of these classes is denominated the *Physical Class*, and has for its department the sciences of mathematics, natural philosophy, chemistry, medicine, natural history, and whatever relates to the improvement of arts and manufactures. The other is denominated the *Literary Class*, and has for its department literature, philology, history, antiquities, and speculative philosophy. Every member is desired at his admission to intimate which of those classes he wishes to be more particularly associated with; but he is at the same time intitled to attend the meetings of the other class, and to take part in all its proceedings. Each of the classes has four presidents and two secretaries, who officiate by turns. The meetings of

Societies for Promoting Science and Literature.

of the physical class are held on the first Mondays of January, February, March, April, July, August, November, and December; and the meetings of the Literary class are held on the third Mondays of January, February, March, April, June, July, November, and December, at 7 o'clock afternoon.

At these meetings the written essays and observations of the members of the society, or their correspondents, are read publicly, and become the subjects of conversation. The subjects of these essays and observations are announced at a previous meeting, in order to engage the attendance of those members who may be particularly interested in them. The author of each dissertation is likewise desired to furnish the society with an abstract of it, to be read at the next ensuing meeting, when the conversation is renewed with increased advantage, from the knowledge previously acquired of the subject. At the same meetings are exhibited such specimens of natural or artificial curiosities, such remains of antiquity, and such experiments, as are thought worthy of the attention of the society. All objects of natural history presented to the society, are ordered by the charter of the institution, to be deposited, on receipt, in the museum of the university of Edinburgh; and all remains of antiquity, public records, or ancient manuscripts, in the library belonging to the faculty of advocates at Edinburgh.

The ordinary members, whose usual residence is in the city of Edinburgh or its immediate neighbourhood, are expected to attend regularly the monthly meetings; and are required to defray, by an annual contribution, the current expences of the institution. The members who reside at such a distance from Edinburgh, that they cannot enjoy the advantages arising from a regular attendance on the meetings of the society, are not subjected to any contribution for defraying its expences, but have a right to attend those meetings when occasionally in Edinburgh, and to take part in all their proceedings.

Five volumes of the Transactions of the society have been published, which bear ample testimony to the learning and acuteness of their various authors.

3. *Medical Society* of London, instituted in the year 1752, on the plan recommended by Lord Bacon (*De Augm. Scient.* lib. iv. cap. 2.), to revive the Hippocratic method of composing narratives of particular cases, in which the nature of the disease, the manner of treating it, and the consequences, are to be specified; to attempt the cure of those diseases which, in his opinion, have been too boldly pronounced incurable; and, lastly, to extend their inquiries after the powers of particular medicines in the cure of particular cases; the collections of this society have been already published, under the title of *Medical Observations and Inquiries*, in several volumes.

4. *The Medical Society* of Edinburgh was incorporated by royal charter in 1778; but there appears to have been in that city a voluntary association of the same name from the first establishment of a regular school of physic in the university. To the voluntary society the public is indebted for six volumes of curious and useful essays, collected principally by the late Dr Monro from June 1731 to June 1736; but in the year 1739 that society was united to another, as we have already observed in a former article. The ordinary members of the present medical society are elected by ballot, and three dissentients exclude a candidate; an ordinary member may also be elected an honorary member, who enjoys the privileges of the others, and receives a diploma, but is freed from the obligation of attendance, delivering papers in rotation, &c. to which the ordinary members are subject; but in this case the votes must be unanimous. The meetings of this society are held every Friday evening (formerly Saturday) in their own hall, during the winter season, when papers on medical subjects are delivered by the several members in rotation; and four of these are annually elected to fill the chair in rotation, with the title of annual presidents. This society possesses an excellent library of books on subjects connected with its pursuits.

5. *The Royal Medical Society* of Paris was instituted in 1776. The members are divided into associates ordinary, limited to 30, honorary to 12, extraordinary to 60, and foreign to 60, and correspondents. This society has published several volumes of Memoirs in 4to.

6. *Asiatic Society*, an institution planned by the late illustrious Sir William Jones, and actually formed at Calcutta on the 15th of January 1784, for the purpose of tracing the history, antiquities, arts, sciences, and literature, of the immense continent of Asia. As it was resolved to follow as nearly as possible the plan of the Royal Society of London, of which the king is *patron*, the patronage of the Asiatic Society was offered to the governor-general and council, as the executive power in the territories of the company. By their acceptance of this offer, Mr Hastings, as governor-general, appeared among the patrons of the new society; "but he seemed in his private station, as the first liberal promoter of useful knowledge in Bengal, and especially as the great encourager of Persian and Shanscrit literature, to deserve a particular mark of distinction:" he was requested, therefore, to accept the honorary title of president. This was handsomely declined in a letter from Mr Hastings, in which he requested "to yield his pretensions to the gentleman whose genius planned the institution, and was most capable of conducting it to the attainment of the great and splendid purposes of its formation." On the receipt of this letter, Sir William Jones was nominated president of the society; and we cannot give the reader a view of the object of the institution in clearer language than that which he employed in his first discourse from the chair.

"It is your design, I conceive (said the president), to take an ample space for your learned investigations, bounding them only by the geographical limits of Asia; so that, considering Hindostan as a centre, and turning your eyes in idea to the north, you have on your right many important kingdoms in the eastern peninsula, the ancient and wonderful empire of China with all her Tartarian dependencies, and that of Japan, with the cluster of precious islands, in which many singular curiosities have too long been concealed: before you lies that prodigious chain of mountains, which formerly perhaps were a barrier against the violence of the sea, and beyond them the very interesting country of Tibet, and the vast regions of Tartary, from which, as from the Trojan horse of the poets, have issued so many consummate warriors, whose domain has extended at least from the banks of the Ilyssus to the mouths of the Ganges; on your left are the beautiful and celebrated provinces of of Iran or Persia, the unmeasured and perhaps unmeasurable deserts of Arabia, and the once flourishing kingdom of Yemen, with the pleasant isles that the Arabs have subdued or colonized; and farther westward, the Asiatic dominions of the Turkish sultans, whose moon seems approaching rapidly to its wane. By this great circumference the field of your useful researches will be inclosed; but since Egypt had unquestionably an old connection with this country, if not with China, since the language and literature of the Abyssinians bear a manifest affinity to those of Asia, since the Arabian arms prevailed along the African coast of the Mediterranean, and even erected a powerful dynasty on the continent of Europe, you may not be displeased occasionally to follow the streams of Asiatic learning a little beyond its natural boundary; and, if it be necessary or convenient that a short name or epithet be given to our society, in order to distinguish it in the world, that of *Asiatic* appears both classical and proper, whether we consider the place or the object of the institution, and preferable to *Oriental*, which is in truth a word merely relative, and though commonly used in Europe, conveys no very distinct idea.

"If now it be asked, What are the intended objects of our inquiries within these spacious limits? we answer, MAN and NATURE; whatever is performed by the *one* or produced by the *other*. Human knowledge has been elegantly analysed according to the three great faculties of the mind, *memory*, *reason*, and *imagination*, which we constantly find employed in arranging and retaining, comparing and distinguishing, combining and diversifying, the ideas, which we receive through our senses, or acquire by reflection; hence the three main branches of learning are, *history*, *science*, and *art*; the first comprehends either an account of natural productions, or the genuine records of empires and states; the second embraces the whole circle of pure and mixed mathematics, together with ethics and law, as far as they depend on the reasoning faculty; and the third includes all the beauties of imagery and the charms of invention, displayed in modulated language, or represented by colour, figure, or sound.

"Agreeable to this analysis, you will investigate whatever is rare in the stupendous fabric of nature, will correct the geography of Asia by new observations and discoveries; will trace the annals and even traditions of those nations who from time to time have peopled or desolated it; and will bring to light their various forms of government, with their institutions civil and religious; you will examine their improvements and methods in arithmetic and geometry; in trigonometry, mensuration, mechanics, optics, astronomy, and general physics; their systems of morality, grammar, rhetoric, and dialect; their skill in chirurgery and medicine; and their advancement, whatever it may be, in anatomy and chemistry. To this you will add researches into their agriculture, manufactures, trade; and whilst you inquire with pleasure into their music, architecture, painting, and poetry, will not neglect those inferior arts by which the comforts and even elegancies of social life are supplied or improved. You may observe, that I have omitted their languages, the diversity and difficulty of which are a sad obstacle to the progress of useful knowledge; but I have ever considered languages as the mere instruments of real learning, and think them improperly confounded with learning itself: the attainment of them is, however, indispensably necessary; and if to the Persian, Armenian, Turkish, and Arabic, could be added not only the Shanscrit, the treasures of which we may now hope to see unlocked, but even the Chinese, Tartarian, Japanese, and the various insular dialects, an immense mine would then be open, in which we might labour with equal delight and advantage."

Of this society three volumes of the Transactions have been published, which are replete with information in a high degree curious and important; and we hope that the European world shall soon be favoured with another. The much-to-be-lamented death of the accomplished president may indeed damp the spirit of investigation among the members; for to conquer difficulties so great as they must meet with, a portion seems to be necessary of that enthusiasm which accompanied all the pursuits of Sir William Jones; but his successor is a man of great worth and learning, and we trust will use his utmost endeavours to have the plan completed of which Sir William gave the outlines.

5. *The American Philosophical Society*, held at Philadelphia, was formed in January 1769 by the union of two societies which had formerly subsisted in that city. This society extends its attention to geography, mathematics, natural philosophy, and astronomy; medicine and anatomy; natural history and chemistry; trade and commerce; mechanics and architecture; husbandry and American improvements. Its officers are a patron, president, three vice-presidents, one treasurer, four secretaries, and three curators, who are annually chosen by ballot. The duty of the president, vice-presidents, treasurer, and secretaries, is the same as in other societies. The business of the curators is to take the charge of all specimens of natural productions, whether of the animal, vegetable, or fossil kingdom; all models of machines and instruments; and all other matters belonging to the society which shall be intrusted to them. The ordinary meetings are held on the first and third Fridays of every month from October to May inclusive. This society was incorporated by charter 15th March 1780; and has published three volumes of its Transactions, containing many ingenious papers on general literature and the sciences, as well as respecting those subjects peculiar to America. It is a delightful prospect to the philosopher to consider, that Asia, Europe, and America, though far separated and divided into a variety of political states, are all three combined to promote the cause of knowledge and truth.

6. *A Literary and Philosophical Society* of considerable reputation has been lately established at Manchester, under the direction of two presidents, four vice-presidents, and two secretaries. The number of members is limited to 50; besides whom there are several honorary members, all of whom are elected by ballot; and the officers are chosen annually in April. Five volumes of valuable essays have been already published by this society.

A society on a similar plan has been established at Newcastle. It is composed of a number of most respectable members, and possesses a very valuable library and philosophical apparatus. Lectures on the different branches of natural philosophy have been delivered for several years at this institution.

7. *Society for Promoting the Discovery of the Interior Parts*

Societies for Promoting Science and Literature.

Parts of Africa. This society or association for exploring the internal districts of Africa, of which so little is at present known, was formed in London by some opulent individuals in 1788; who, strongly impressed with a conviction of the practicability and utility of thus enlarging the fund of human knowledge, determined if possible to rescue the age from that stigma which attaches to its ignorance of so large and so near a portion of the globe. The founders of this society resolved to admit no man a member for a shorter period than three years, during which he must pay annually into the public fund five guineas. After three years, any member, upon giving a year's notice, may withdraw himself from the association. During the first 12 months each of the members was allowed to recommend for the approbation of the society such of his friends as he might think proper to be admitted into it; but since that period we believe all additional members have been elected by a ballot of the association at large. A committee was chosen by ballot to manage the funds of the society, to choose proper persons to be sent on the discovery of the interior parts of Africa, and to carry on the society's correspondence, with express injunctions to disclose no intelligence received from their agents but to the society at large. But a fuller account of the nature of this establishment, and the very happy efforts they have made, may be seen in the superb edition of their proceedings printed in 1790, 4to, for their own use; or in the 8vo edition since made public. They soon found two gentlemen, Mr Lucas and Mr Ledyard, who were singularly well qualified for the important mission. The information they have acquired will be found in the above work; with a new map by Mr Rennel, exhibiting the geographical knowledge collected by the African association. Mr Ledyard very unfortunately died during his researches at Cairo.

Few of our readers are unacquainted with the travels of Mr Park under the patronage of the society. For an account of which see AFRICA. A second journey was undertaken by the same gentleman within these three years; but as he has not been heard of for a long time, the most serious apprehensions are entertained that he and his companions have fallen victims either to the inhospitable climate, or to the watchful jealousy of the Moors. Another enterprising traveller, Mr Horneman, was sent out by the society about 1800. He departed from Cairo with a caravan, and reached Mourzouk, a place situated south from Tripoli; and from thence sent a communication to his constituents which has since been published by the society. This is the last account that was received of this traveller, from which it is feared that he has also perished.

8. *The Society of Antiquaries of London*, was founded about the year 1572 by Archbishop Parker, a munificent patron of learned men. For the space of 20 years it assembled in the house of Sir Robert Cotton; in 1589 they resolved to apply to Queen Elizabeth for a charter, and a public building where they might hold their meetings; but it is uncertain whether any such application was ever made. In the mean time, the reputation of the society gradually increased, and at length it excited the jealousy of James I. who was afraid lest it should presume to canvas the secret transactions of his government. He accordingly dissolved it. But in the beginning of the last century, the Antiquarian society began to revive; and a number of gentlemen, eminent for their affection to this science, had weekly meetings, in which they examined the antiquities and history of Great Britain preceding the reign of James I. but without excluding any other remarkable antiquities that might be offered to them. From this time the society grew in importance; and in 1750 they unanimously resolved to petition the king for a charter of incorporation. This they obtained the year following, by the influence of the celebrated earl of Hardwicke, then lord chancellor, and Martin Folkes, Esq; who was then their president. The king declared himself their founder and patron, and empowered them to have a body of statutes, and a common seal, and to hold in perpetuity lands, &c. to the yearly value of 1000l.

The chief object of the inquiries and researches of the society are British antiquities and history; not, however, wholly excluding those of other countries. It must be acknowledged, that the study of antiquity offers to the curious and inquisitive a large field for research and amusement. The inquirer in this branch furnishes the historian with his best materials, while he distinguishes from truth the fictions of a bold invention, and ascertains the credibility of facts; and to the philosopher he presents a fruitful source of ingenious speculation, while he points out to him the way of thinking, and the manners of men, under all the varieties of aspect in which they have appeared.

An antiquarian ought to be a man of solid judgment, possessed of learning and science, that he may not be an enthusiastic admirer of every thing that is ancient merely because it is ancient; but be qualified to distinguish between those researches which are valuable and important, and those which are trifling and useless. It is from the want of these qualifications that some men have contracted such a blind passion for every thing that is ancient, that they have exposed themselves to ridicule, and their study to contempt. But if a regard to utility were always to regulate the pursuits of the antiquarian, the shafts of satire would no longer be levelled at him; but he would be respected as the man who labours to restore or to preserve such ancient productions as are suited to illuminate religion, philosophy, and history, or to improve the arts of life.

We by no means intend to apply these observations to any particular society of antiquarians; but we throw them out, because we know that an assiduous study of antiquity is apt, like the ardent pursuit of money, to lose sight of its original object, and to degenerate into a passion which mistakes the mean for the end, and considers possession without a regard to utility as enjoyment.

An association similar to that of the Antiquarian Society of London was founded in *Edinburgh* in 1780, and received the royal charter in 1783. A volume of the Transactions of this society has been published; but with the exception of two or three memoirs, it contains little worthy of notice; and accordingly, it has never attracted the attention of the public.

Besides these literary societies here mentioned, there are a great number more in different parts of Europe, some of which are noticed under the article ACADEMY. Those which are omitted are not omitted on account of any idea of their inferior importance; but either because

cause we have had no access to authentic information, or because they resemble the societies already described so closely, that we could have given nothing but their names.

III. Societies for Encouraging and Promoting Arts, Manufactures, &c.

1. *London Society for the Encouragement of Arts, Manufactures, and Commerce*, was instituted in the year 1754 by Lord Folkstone, Lord Romney, Dr Stephen Hales, and a few private gentlemen; but the merit of this institution chiefly belonged to Mr William Shipley, an ingenious mechanic; who, though deriving no advantages from learning, by unwearied personal attendance found means to engage a few persons of rank and fortune to meet at Peele's coffeehouse in Fleet-street, and to adopt a plan for promoting arts and manufactures.

The office-bearers of this society are a president, 12 vice-presidents, a secretary, and register. Their proceedings are regulated by a body of rules and orders established by the whole society, and printed for the use of the members. All questions and debates are determined by the holding up of hands, or by ballot if required; and no matter can be confirmed without the assent of a majority at two meetings. They invite all the world to propose subjects for encouragement; and whatever is deemed deserving of attention is referred to the consideration of a committee, which, after due inquiry and deliberation, make their report to the whole society, where it is approved, rejected, or altered. A list is printed and published every year of the matters for which they propose to give premiums; which premiums are either sums of money, and those sometimes very considerable ones; or the society's medal in gold or silver, which they consider as the greatest honour they can bestow. All possible care is taken to prevent partiality in the distribution of their premiums, by desiring the claimants names to be concealed, and by appointing committees (who when they find occasion call to their assistance the most skilful artists) for the strict examination of the real merit of all matters and things brought before them, in consequence of their premiums.

The chief objects of the attention of the Society for the Encouragement of Arts, Manufactures, and Commerce, in the application of their revenues, are ingenuity in the several branches of the polite and liberal arts, useful discoveries and improvements in agriculture, manufactures, mechanics, and chemistry, or the laying open of any such to the public; and, in general, all such useful inventions, discoveries, or improvements (though not mentioned in the book of premiums) as may appear to have a tendency to the advantage of trade and commerce.

The following are some of the most important regulations of this society. It is required that the matters for which premiums are offered be delivered in without names, or any intimation to whom they belong; that each particular thing be marked in what manner each claimant thinks fit, such claimant sending with it a paper sealed up, having on the outside a corresponding mark, and on the inside the claimant's name and address; and all candidates are to take notice, that no claim for a premium will be attended to, unless the conditions of the advertisement are fully complied with. No papers shall be opened but such as shall gain premiums, unless where it appears to the society absolutely necessary for the determination of the claim: all the rest shall be returned unopened, with the matters to which they belong, if inquired after by the marks within two years; after which time, if not demanded, they shall be publicly burnt unopened at some meeting of the society. All the premiums of this society are designed for that part of Great Britain called England, the dominion of Wales, and the town of Berwick upon Tweed, unless expressly mentioned to the contrary. No person shall receive any premium, bounty, or encouragement, from the society for any matter for which he has obtained or proposes to obtain a patent. No member of this society shall be a candidate for or intitled to receive any premium, bounty, or reward whatever, except the honorary medal of the society.

The respectability of the members who compose it may be seen by perusing the list which generally accompanies their Transactions. In the last volume (vol. xii.) it occupies no less than 43 pages. Some idea may be formed of the wealth of this society, by observing that the list of their premiums fills 96 pages, and amounts to 250 in number. These consist of gold medals worth from 30 to 50, and in a few instances to 100 guineas; and silver medals valued at 10 guineas.

This society is one of the most important in Great Britain. Much money has been expended by it, and many are the valuable effects of which it has been productive. Among these we reckon not only the discoveries which it has excited, but the institution of other societies on the same principles to which it has given birth; and we do not hesitate to conclude, that future ages will consider the founding of this society as one of the most remarkable epochs in the history of the arts. We contemplate with pleasure the beneficial effects which must result to this nation and to mankind by the diffusion of such institutions; and rejoice in the hope that the active minds of the people of Great Britain, instead of being employed as formerly in controversies about religion, which engender strife, or in discussions concerning the theory of politics, which lead to the adoption of schemes inconsistent with the nature and condition of man, will soon be more generally united into associations for promoting useful knowledge and solid improvement, and for alleviating the distresses of their fellow creatures.

1. *Society instituted at Bath for the Encouragement of Agriculture, Arts, Manufactures, and Commerce.* It was founded in the year 1777 by several gentlemen who met at the city of Bath. This scheme met with a very favourable reception both from the wealthy and learned. The wealthy subscribed very liberally, and the learned communicated many important papers. On application to the London and provincial societies instituted for the like purposes, they very politely offered their assistance. Seven volumes of their Transactions have already been published, containing very valuable experiments and observations, particularly respecting agriculture, which well deserve the attention of all farmers in the kingdom. We have consulted them with much satisfaction on several occasions, and have frequently referred to them in the course of this work; and therefore, with pleasure, embrace

embrace the present opportunity of repeating our obligations. We owe the same acknowledgments to the Society for the Improvement of Arts, &c. of London.

3. *Society for working Mines*, an association lately formed on the continent of Europe. This institution arose from the accidental meeting of several mineralogists at Skleno near Schemnitz in Hungary, who were collected in order to examine a new method of amalgamation. Struck with the shackles imposed on mineralogy by monopolizers of new and useful processes, they thought no method so effectual to break them, as forming a society, whose common labours should be directed to fix mining on its surest principles; and whose memoirs, spread all over Europe, might offer to every adventurer the result of the researches, of which they are the object. By these means they supposed, that there would be a mass of information collected; the interests of individuals would be lost in the general interest; and the one would materially assist the other. Imposture and quackery would, by the same means, be banished from a science, which must be improved by philosophy and experience; and the society, they supposed, would find, in the confidence which they inspired, the reward and the encouragement of their labours. They design, that the memoirs which they publish shall be short and clear; truth must be their basis, and every idle discussion, every foreign digression, must be banished; politics and finance must be avoided, though the dissertations may seem to lead towards them; and they oblige themselves to oppose the affectation of brilliancies, and the ostentation of empty speculation, when compared with plain, simple, and useful facts.

The object of the society is physical geography; mineralogy founded on chemistry; the management of ore in the different operations which it undergoes; subterraneous geometry; the history of mining; founderies, and the processes for the extraction of metals from the ores, either by fusion or amalgamation, in every instance applied to practice. The end of this institution is to collect, in the most extensive sense, every thing that can assist the operations of the miner, and to communicate it to the different members, that they may employ it for the public good, in their respective countries. Each member must consider himself as bound to send to the society every thing which will contribute to the end of its institution; to point out, with precision, the several facts and observations; to communicate every experiment which occurs, even the unsuccessful ones, if the relation may seem to be advantageous to the public; to communicate to the society their examination of schemes, and their opinions on questions proposed by it; and to pay annually two ducats (about 18s. 6d.) to the direction every Easter. The society on the other hand, is bound to publish every novelty that shall be communicated to it; to communicate to each member, at the member's expence, the memoirs, designs, models, productions, and every thing connected with the institution; to answer all the necessary demands made, relating in any respect to mining; and to give its opinion on every plan or project communicated through the medium of an honorary member.

The great centre of all intelligence is to be at Zellerfield in Hartz, Brunswick; but the society is not fixed to any one spot; for every particular state some practical mineralogist is nominated as director. Among these are the names of Baron Born, M. Pallas, M. Charpentier, M. Prebra, and M. Henkel. Their office is to propose the members; to take care that the views of the society are pursued in the different countries where they reside; to answer the requests of the members of their country who are qualified to make them; in case of the death of a director, to choose another; and the majority is to determine where the archives and the strong box is to be placed.

All the eminent mineralogists in Europe are members of this society. It is erected on so liberal and so extensive a plan, that we entertain the highest hopes of its success; and have only to add, that we wish much to see the study of several other sciences pursued in the same manner.

4. *The Society for the Improvement of Naval Architecture*, was founded in 1791. The object of it is to encourage every useful invention and discovery relating to naval architecture as far as shall be in their power, both by honorary and pecuniary rewards. They have in view particularly to improve the theories of floating bodies and of the resistance of fluids; to procure draughts and models of different vessels, together with calculations of their capacity, centre of gravity, tonnage, &c.; to make observations and experiments themselves, and to point out such observations and experiments as appear best calculated to further their designs, and most deserving those premiums which the society can bestow. But though the improvement of naval architecture in all its branches be certainly the principal object of this institution, yet the society do not by any means intend to confine themselves merely to the form and structure of vessels. Every subordinate and collateral pursuit will claim a share of the attention of the society in proportion to its merits; and whatever may have any tendency to render navigation more safe, salutary, and even pleasant, will not be neglected.

This institution owes its existence to the patriotic disposition and extraordinary attention of Mr Sewel a private citizen of London, who (though engaged in a line of business totally opposite to all concerns of this kind) has been led, by mere accident, to take such ocular notice of, and make such observations on, the actual state of naval architecture in this country, as naturally occurred to a man of plain understanding, zealous for the honour and interest of his country, and willing to bestow a portion of that time for the public good, which men of a different description would rather have devoted to their own private advantage. His attention was the more seriously excited by finding that it was the opinion of some private ship-builders, who, in a debate on the failure of one of our naval engagements, pronounced, that such "would ever be the case while that business (the construction of our ships of war) was not studied as a science, but carried on merely by precedent; that there had not been one improvement in our navy that did not originate with the French, who had naval schools and seminaries for the study of it; and that our ships were not a match for those of that nation either singly or in a fleet," &c. &c.

In a short time the society were enabled to offer very considerable premiums for particular improvements in the construction of our shipping, &c. &c. and also to encourage our philosophers, mathematicians, and mechanics, to make satisfactory experiments, tending to ascertain

certain the laws of resistance of water to solids of different forms, in all varieties of circumstance. On this head the reward is not less than one hundred pounds or a gold medal. Other premiums of 50, 30, and 20 guineas, according to the importance or difficulty of the particular subject or point of investigation, are likewise offered, for different discoveries, inventions, or improvements. The terms of admission into the society are a subscription of two guineas annually, or twenty guineas for life.

5. *Society of Artists of Great Britain*, which consists of directors and fellows, was incorporated by charter in 1765, and empowered to purchase and hold lands, not exceeding 1000l. a-year. The directors of this society, annually elected, are to consist of 24 persons, including the president, vice-president, treasurer, and secretary; and it is required that they be either painters, sculptors, architects, or engravers by profession.

6. *British Society for extending the Fisheries and Improving the Sea-Coasts of this Kingdom*, was instituted in 1786. The end and design of this society will best appear from their charter, of which we present an abstract.

The preamble states, "the great want of improvement in fisheries, agriculture, and manufactures, in the Highlands and Islands of North Britain; the prevalence of emigration from the want of employment in those parts; the prospect of a new nursery of seamen, by the establishment of fishing towns and villages in that quarter. The act therefore declares, that the persons therein named, and every other person or persons who shall thereafter become proprietors of the joint stock mentioned therein, shall be a distinct and separate body politic and corporate, by the name of *The British Society for Extending the Fisheries and Improving the Sea-coasts of this Kingdom*: That the said society may raise a capital joint stock not exceeding 150,000l. to be applied to purchasing or otherwise acquiring lands and tenements in perpetuity, for the building thereon, and on no other land whatever, free towns, villages, and fishing stations: That the joint stock shall be divided into shares of 50l. each: That no one person shall in his or her name possess more than ten shares, or 500l.: That the society shall not borrow any sum or sums of money whatsoever: That the sums to be advanced for this undertaking, and the profits arising therefrom, shall be divided proportionally to the sum subscribed; and that no person shall be liable for a larger sum than he or she shall have respectively subscribed; That one or two shares shall entitle to one vote, and no more, in person or by proxy, at all meetings of proprietors; three or four shares to two votes; five, six, or seven shares, to three votes; eight or nine shares to four votes; and ten shares to five votes and no more: That more persons than one inclining to hold in their joint names one or more shares shall be intitled to vote, by one of such persons, according to the priority of their names, or by proxy: That bodies corporate shall vote by proxy under their seal: That all persons holding proxies shall be proprietors, and that no one person shall hold more than five votes by proxy: That the affairs of the society shall be managed by a governor, deputy governor, and 13 other directors, to be elected annually on the 25th of March, from among the proprietors of the society, holding at least one full share, by signed lists of their names to be transmitted by the proprietors to the secretary of the society: That five proprietors, not being governor, director, or other officer, shall be in like manner annually elected to audit the accounts of the society: That there shall be one general meeting of the proprietors annually on the 25th of March: That occasional general meetings shall be called on the request of nine or more proprietors: That the general meetings of the proprietors shall make all bye-laws and constitutions for the government of the society, and for the good and orderly carrying on of the business of the same: That no transfer shall be made of the stock of the society for three years from the 10th of August 1786: That the cash of the society shall be lodged in the bank of England, bank of Scotland, or the royal bank of Scotland: That no director, proprietor, agent, or officer of the society, shall retain any sum or sums of money in his hands beyond the space of 30 days on any account whatsoever: That all payments by the society shall be made by drafts on the said banks, under the hands of the governor or deputy-governor, countersigned by the secretary or his deputy, and two or more directors: And that the books in which the accounts of the society shall be kept shall be open to all the proprietors."

The institution of this public-spirited society was in a great measure owing to the exertions of the patriotic John Knox; who in the course of 23 years traversed and explored the Highlands of Scotland not fewer than 16 times, and expended several thousand pounds of his own fortune in pursuing his patriotic designs.

7. *British Wool* Society. See *British Wool Society*.

Society Isles, a cluster of isles, so named by Captain Cook in 1769. They are situated between the latitudes of 16. 10. and 16. 55. south, and between the longitudes of 150. 57. and 152. west. They are eight in number; namely, Otaheite, Huaheine, Ulietea, Otaha, Bolabola, Maurua, Toobouai, and Tabooyamanoo or Saunders's island. The soil, productions, people, their language, religion, customs, and manners, are so nearly the same as at Otaheite, that little need be added here on that subject. Nature has been equally bountiful in uncultivated plenty, and the inhabitants are as luxurious and as indolent. A plaintain branch is the emblem of peace, and exchanging names the greatest token of friendship. Their dances are more elegant, their dramatic entertainments have something of plot and consistency, and they exhibit temporary occurrences as the objects of praise or satire; so that the origin of ancient comedy may be already discerned among them. The people of Huaheine are in general stouter and fairer than those of Otaheite, and this island is remarkable for its populousness and fertility. Those of Ulietea, on the contrary, are smaller and blacker, and much less orderly. Captain Cook put on shore a Cape ewe at Bolabola, where a ram had been left by the Spaniards; and also an English boar and sow, with two goats, at Ulietea. If the valuable animals which have been transported thither from Europe should be suffered to multiply, no part of the world will equal these islands in variety and abundance of refreshments for future navigators.

SOCINIANS, in church history, a sect of Christian heretics, so called from their founder Faustus Socinus (see Socinus). They maintain, "That Jesus Christ was a mere man, who had no existence before he was conceived by the Virgin Mary; that the Holy Ghost is no no distinct person, but that the Father is truly and properly God. They own, that the name of God is given in the Holy Scriptures to Jesus Christ; but contend, that it is only a deputed title, which, however, invests him with an absolute sovereignty over all created beings, and renders him an object of worship to men and angels. They deny the doctrines of satisfaction and imputed righteousness; and say that Christ only preached the truth to mankind, set before them in himself an example of heroic virtue, and sealed his doctrines with his blood. Original sin and absolute predestination they esteem scholastic chimeras. They likewise maintain the sleep of the soul, which they say becomes insensible at death, and is raised again with the body at the resurrection, when the good shall be established in the possession of eternal felicity, while the wicked shall be consigned to a fire that will not torment them eternally, but for a certain duration in proportion to their demerits."

This sect has long been indignant at being styled *Socinians*. They disclaim every human leader; and professing to be guided solely by the word of God and the deductions of reason, they call themselves *Unitarians*, and affect to consider all other Christians, even their friends the Arians, as *Polytheists*. Modern Unitarianism, as taught by Dr Priestley, is, however, a very different thing from Socinianism, as we find it in the Racovian catechism and other standard works of the sect. This far-famed philosopher has discovered, what escaped the sagacity of all the *fratres poloni*, that Jesus Christ was the son of Joseph as well as Mary; that the evangelists mistook the meaning of Isaiah's prophecy, that "a virgin shall conceive and bear a son;" that the applying of this prophecy to the birth of our Saviour, led them to conclude that his conception was miraculous; and that we are not to wonder at this mistake, as the apostles were not always inspired, and were in general inconclusive reasoners. The modesty of the writer in claiming the merit of such discoveries will appear in its proper colours to all our readers: the truth of his doctrine shall be considered in another place. See THEOLOGY.

SOCINUS, LÆLIUS, the first author of the sect of the Socinians, was born at Sienna in Tuscany in 1525. Being designed by his father for the law, he began very early to search for the foundation of that science in the Word of God; and by that study discovered that the Romish religion taught many things contrary to revelation; when, being desirous of penetrating farther into the true sense of the scriptures, he studied Greek, Hebrew, and even Arabic. In 1547 he left Italy, to go and converse with the Protestants; and spent four years in travelling through France, England, the Netherlands, Germany, and Poland, and at length settled at Zurich. He by this means became acquainted with the most learned men of his time, who testified by their letters the esteem they had for him: but as he discovered to them his doubts, he was greatly suspected of heresy. He, however, conducted himself with such address, that he lived among the capital enemies of his opinions, without receiving the least injury. He met with some disciples, who heard his instructions with respect; these were Italians who left their native country on account of religion, and wandered about in Germany and Poland. He communicated likewise his sentiments to his relations by his writings, which he caused to be conveyed to them at Sienna. He died at Zurich in 1562. Those who were of sentiments opposite to his, and were personally acquainted with him, confess that his outward behaviour was blameless. He wrote a paraphrase on the first chapter of St John; and other works are ascribed to him.

SOCINUS, *Faustus*, nephew of the preceding, and principal founder of the Socinian sect, was born at Sienna in 1539. The letters which his uncle Lælius wrote to his relations, and which infused into them many seeds of heresy, made an impression upon him; so that, knowing himself not innocent, he fled as well as the rest when the inquisition began to persecute that family. He was at Lyons when he heard of his uncle's death, and departed immediately to take possession of his writings. He returned to Tuscany; and made himself so agreeable to the grand duke, that the charms which he found in that court, and the honourable posts he filled there, hindered him for twelve years from remembering that he had been considered as the person who was to put the last hand to the system of samosatenian divinity, of which his uncle Lælius had made a rough draught. At last he went into Germany in 1574, and paid no regard to the grand duke's advices to return. He staid three years at Basil, and studied divinity there, and having adopted a set of principles very different from the system of Protestants, he resolved to maintain and propagate them; for which purpose he wrote a treatise *De Iesu Christo Servatore*. In 1579 Socinus retired into Poland, and desired to be admitted into the communion of the Unitarians; but as he differed from them in some points, on which he refused to be silent, he met with a repulse. However, he did not cease to write in defence of their churches against those who attacked them. At length his book against James Paleologus furnished his enemies with a pretence to exasperate the king of Poland against him; but though the mere reading of it was sufficient to refute his accusers, Socinus thought proper to leave Cracow, after having resided there four years. He then lived under the protection of several Polish lords, and married a lady of a good family; but her death, which happened in 1587, so deeply afflicted him as to injure his health; and to complete his sorrow, he was deprived of his patrimony by the death of Francis de Medicis great duke of Florence. The consolation he found in seeing his sentiments at last approved by several ministers, was greatly interrupted in 1598; for he met with a thousand insults at Cracow, and was with great difficulty saved from the hands of the rabble. His house was plundered, and he lost his goods; but this loss was not so uneasy to him as that of some manuscripts, which he extremely regretted. To deliver himself from such dangers, he retired to a village about nine miles distant from Cracow, where he spent the remainder of his days at the house of Abraham Blonski, a Polish gentleman, and died there in 1604. All Faustus Socinus's works are contained in the two first volumes of the *Bibliotheca Fratrum Polonorum*.

SOCMANS, SOKEMANS, or *Socmen (Socmanni)*, are such tenants as hold their lands and tenements by socage tenure. See SOCAGE.

SOCOTORA, an island lying between Asia and Arabia Felix; about 50 miles in length, and 22 in breadth. It is particularly noted for its fine aloes, known by the name of *Socotrine* ALOES. The religion of the natives

natives is a mixture of Mahometanism and Paganism; but they are civil to strangers who call there in their passage to the East Indies. It abounds in fruit and cattle; and they have a king of their own, who is dependent on Arabia.

SOCRATES, the greatest of the ancient philosophers, was born at Alopece, a village near Athens, in the fourth year of the 77th olympiad. His parents were of low rank; his father Sophroniscus being a statuary, and his mother Phœnareta a midwife. Sophroniscus brought up his son, contrary to his inclination, in his own manual employment; in which Socrates, though his mind was continually aspiring after higher objects, was not unsuccessful, for whilst he was a young man, he is said to have formed statues of the habited Graces, which were allowed a place in the citadel of Athens. Upon the death of his father he was left in such straitened circumstances as laid him under the necessity of exercising that art to procure the means of subsistence, though he devoted, at the same time, all the leisure which he could command to the study of philosophy. His distress, however, was soon relieved by Crito, a wealthy Athenian; who, remarking his strong propensity to study, and admiring his ingenuous disposition and distinguished abilities, generously took him under his patronage, and intrusted him with the instruction of his children. The opportunities which Socrates by this means enjoyed of attending the public lectures of the most eminent philosophers, so far increased his thirst after wisdom, that he determined to relinquish his occupation, and every prospect of emolument which that might afford, in order to devote himself entirely to his favourite pursuits. Under Anaxagoras and Archelaus he prosecuted the study of nature in the usual manner of the philosophers of the age, and became well acquainted with their doctrines. Prodicus the sophist was his preceptor in eloquence, Evenus in poetry, Theodorus in geometry, and Damo in music. Aspasia, a woman no less celebrated for her intellectual than her personal accomplishments, whose house was frequented by the most celebrated characters, had also some share in the education of Socrates. Under such preceptors it cannot reasonably be doubted but that he became master of every kind of learning which the age in which he lived could afford; and being blessed with very uncommon talents by nature, he appeared in Athens, under the respectable characters of a good citizen and a true philosopher. Being called upon by his country to take arms in the long and severe struggle between Athens and Sparta, he signalized himself at the siege of Potidæa, both by his valour and by the hardiness with which he endured fatigue. During the severity of a Thracian winter, whilst others were clad in furs, he wore only his usual clothing, and walked barefoot upon the ice. In an engagement in which he saw ALCIBIADES falling down wounded, he advanced to defend him, and saved both him and his arms: and though the prize of valour was on this occasion unquestionably due to Socrates, he generously gave his vote that it might be bestowed upon Alcibiades, to encourage his rising merit. He served in other campaigns with distinguished bravery, and had the happiness on one occasion to save the life of Xenophon, by bearing him, when covered with wounds, out of the reach of the enemy.

It was not till Socrates was upwards of 60 years of age that he undertook to serve his country in any civil office, when he was chosen to represent his own district, in the senate of five hundred. In this office, though he at first exposed himself to some degree of ridicule from the want of experience in the forms of business, he soon convinced his colleagues that he was superior to them all in wisdom and integrity. Whilst they, intimidated by the clamours of the populace, passed an unjust sentence of condemnation upon the commanders, who, after the engagement at the Arginusian islands, had been prevented by a storm from paying funeral honours to the dead, Socrates stood forth singly in their defence, and to the last refused to give his suffrage against them, declaring that no force should compel him to act contrary to justice and the laws. Under the subsequent tyranny he never ceased to condemn the oppressive and cruel proceedings of the thirty tyrants; and when his boldness provoked their resentment, so that his life was in hazard, fearing neither treachery nor violence, he still continued to support with undaunted firmness the rights of his fellow citizens.

Having given these proofs of public virtue both in a military and civil capacity, he wished to do still more for his country. Observing with regret how much the opinions of the Athenian youth were misled, and their principles and taste corrupted by philosophers who spent all their time in refined speculations upon nature and the origin of things, and by sophists who taught in their schools the arts of false eloquence and deceitful reasoning; Socrates formed the wise and generous design of instituting a new and more useful method of instruction. He justly conceived the true end of philosophy to be, not to make an ostentatious display of superior learning and ability in subtle disputations or ingenious conjectures, but to free mankind from the dominion of pernicious prejudices; to correct their vices; to inspire them with the love of virtue; and thus conduct them in the path of wisdom to true felicity. He therefore assumed the character of a moral philosopher; and, looking upon the whole city of Athens as his school, and all who were disposed to lend him their attention as his pupils, he seized every occasion of communicating moral wisdom to his fellow citizens. He passed the greater part of his time in public; and the method of instruction of which he chiefly made use was, to propose a series of questions to the person with whom he conversed, in order to lead him to some unforeseen conclusion. He first gained the consent of his respondent to some obvious truths, and then obliged him to admit others from their relation or resemblance to those to which he had already assented. Without making use of any direct argument or persuasion, he chose to lead the person he meant to instruct, to deduce the truths of which he wished to convince him, as a necessary consequence from his own concessions. He commonly conducted these conferences with such address, as to conceal his design till the respondent had advanced too far to recede. On some occasions he made use of ironical language, that vain men might be caught in their own replies, and be obliged to confess their ignorance. He never assumed the air of a morose and rigid preceptor, but communicated useful instruction with all the ease and pleasantry of polite conversation. Though eminently furnished with every kind of learning, he preferred moral to speculative wisdom. Convinced that philosophy

Socrates. losophy is valuable, not as it furnishes questions for the schools, but as it provides men with a law of life, he censured his predecessors for spending all their time in abstruse researches into nature, and taking no pains to render themselves useful to mankind. His favourite maxim was, Whatever is above us doth not concern us. He estimated the value of knowledge by its utility, and recommended the study of geometry, astronomy, and other sciences, only so far as they admit of a practical application to the purposes of human life. His great object in all his conferences and discourses was, to lead men into an acquaintance with themselves; to convince them of their follies and vices; to inspire them with the love of virtue; and to furnish them with useful moral instructions. Cicero might therefore very justly say of Socrates, that he was the first who called down philosophy from heaven to earth, and introduced her into the public walks and domestic retirements of men, that she might instruct them concerning life and manners.

Through his whole life this good man discovered a mind superior to the attractions of wealth and power. Contrary to the general practice of the preceptors of his time, he instructed his pupils without receiving from them any gratuity. He frequently refused rich presents, which were offered him by Alcibiades and others, though importunately urged to accept them by his wife. The chief men of Athens were his stewards: they sent him in provisions, as they apprehended he wanted them; he took what his present wants required, and returned the rest. Observing the numerous articles of luxury which were exposed to sale in Athens, he exclaimed, "How many things are there which I do not want!" With Socrates, moderation supplied the place of wealth. In his clothing and food, he consulted only the demands of nature. He commonly appeared in a neat but plain cloak, with his feet uncovered. Though his table was only supplied with simple fare, he did not scruple to invite men of superior rank to partake of his meals; and when his wife, upon some such occasion, expressed her dissatisfaction on being no better provided, he desired her to give herself no concern; for if his guests were wise men, they would be contented with whatever they found at his table; if otherwise, they were unworthy of notice. Whilst others, says he, live to eat, wise men eat to live.

Though Socrates was exceedingly unfortunate in his domestic connection, he converted this infelicity into an occasion of exercising his virtues. Xantippe, concerning whose ill humour ancient writers relate many amusing tales, was certainly a woman of a high and unmanageable spirit. But Socrates, while he endeavoured to curb the violence of her temper, improved his own. When Alcibiades expressed his surprise that his friend could bear to live in the same house with so perverse and quarrelsome a companion, Socrates replied, that being daily inured to ill humour at home, he was the better prepared to encounter perverseness and injury abroad.

In the midst of domestic vexations and public disorders, Socrates retained such an unruffled serenity, that he was never seen either to leave his own house or to return home with a disturbed countenance. In acquiring this entire dominion over his passions and appetites, he had the greater merit, as it was not effected without a violent struggle against his natural propensities. Zopyrus, an eminent physiognomist, declared, that he discovered in the features of the philosopher evident traces of many vicious inclinations. The friends of Socrates who were present ridiculed the ignorance of this pretender to extraordinary sagacity. But Socrates himself ingenuously acknowledged his penetration, and confessed that he was in his natural disposition prone to vice, but that he had subdued his inclinations by the power of reason and philosophy.

Through the whole of his life Socrates gave himself up to the guidance of unbiassed reason, which is supposed by some to be all that he meant by the genius or *dæmon* from which he professed to receive instruction. But this opinion is inconsistent with the accounts given by his followers of that dæmon, and even with the language in which he spoke of it himself. Plato sometimes calls it his *guardian*, and Apuleius his *god;* and as Xenophon attests that it was the belief of his master that the gods occasionally communicate to men the knowledge of future events, it is by no means improbable that Socrates admitted, with the generality of his countrymen, the existence of those intermediate beings called *dæmons*, of one of which he might fancy himself the peculiar care.

It was one of the maxims of Socrates, "That a wise man will worship the gods according to the institutions of the state to which he belongs." Convinced of the weakness of the human understanding, and perceiving that the pride of philosophy had led his predecessors into futile speculations on the nature and origin of things, he judged it most consistent with true wisdom to speak with caution and reverence concerning the divine nature.

The wisdom and the virtues of this great man, whilst they procured him many followers, created him also many enemies. The Sophists *, whose knavery and ignorance he took every opportunity of exposing to public contempt, became inveterate in their enmity against so bold a reformer, and devised an expedient, by which they hoped to check the current of his popularity. They engaged Aristophanes, the first buffoon of the age, to write a comedy, in which Socrates should be the principal character. Aristophanes, pleased with so promising an occasion of displaying his low and malignant wit, undertook the task, and produced the comedy of *The Clouds*, still extant in his works. In this piece, Socrates is introduced hanging in a basket in the air, and thence pouring forth absurdity and profaneness. But the philosopher, showing in a crowded theatre that he was wholly unmoved by this ribaldry, the satire failed of its effect; and when Aristophanes attempted the year following to renew the piece with alterations and additions, the representation was so much discouraged, that he was obliged to discontinue it.

* See *Sophists*.

From this time Socrates continued for many years to pursue without interruption his laudable design of instructing and reforming his fellow-citizens. At length, however, when the inflexible integrity with which he had discharged the duty of a senator, and the firmness with which he had opposed every kind of political corruption and oppression, had greatly increased the number of his enemies, clandestine arts were employed to raise a general prejudice against him. The people were industriously reminded, that Critias, who had been one of the most cruel of the thirty tyrants, and Alcibiades, who

Socrates.

who had insulted religion, by defacing the public statues of Mercury, and performing a mock representation of the Eleusinian mysteries, had in their youth been disciples of Socrates; and the minds of the populace, being thus prepared, a direct accusation was preferred against him before the supreme court of judicature. His accusers were Anytus a leather-dresser, who had long entertained a personal enmity against Socrates, for reprehending his avarice, in depriving his sons of the benefits of learning, that they might pursue the gains of trade; Melitus, a young rhetorician, who was capable of undertaking any thing for the sake of gain; and Lycon, who was glad of any opportunity of displaying his talents. The accusation, which was delivered to the senate under the name of Melitus, was this: "Melitus, son of Melitus, of the tribe of Pythos, accuseth Socrates, son of Sophroniscus, of the tribe of Alopece. Socrates violates the laws, in not acknowledging the gods which the state acknowledges, and by introducing new divinities. He also violates the laws by corrupting the youth. Be his punishment DEATH."

This charge was delivered upon oath to the senate; and Crito a friend of Socrates became surety for his appearance on the day of trial. Anytus soon afterwards sent a private message to Socrates, assuring him that if he would desist from censuring his conduct, he would withdraw his accusation. But Socrates refused to comply with so degrading a condition; and with his usual spirit replied, "Whilst I live I will never disguise the truth, nor speak otherwise than my duty requires." The interval between the accusation and the trial he spent in philosophical conversations with his friends, choosing to discourse upon any other subject rather than his own situation.

When the day of trial arrived, his accusers appeared in the senate, and attempted to support their charge in three distinct speeches, which strongly marked their respective characters. Plato, who was a young man, and a zealous follower of Socrates, then rose up to address the judges in defence of his master; but whilst he was attempting to apologise for his youth, he was abruptly commanded by the court to sit down. Socrates, however, needed no advocate. Ascending the chair with all the serenity of conscious innocence, and with all the dignity of superior merit, he delivered, in a firm and manly tone, an unpremeditated defence of himself, which silenced his opponents, and ought to have convinced his judges. After tracing the progress of the conspiracy which had been raised against him to its true source, the jealousy and resentment of men whose ignorance he had exposed, and whose vices he had ridiculed and reproved, he distinctly replied to the several charges brought against him by Melitus. To prove that he had not been guilty of impiety towards the gods of his country, he appealed to his frequent practice of attending the public religious festivals. The crime of introducing new divinities, with which he was charged, chiefly as it seems on the ground of the admonitions which he professed to have received from an invisible power, he disclaimed, by pleading that it was no new thing for men to consult the gods and receive instructions from them. To refute the charge of his having been a corrupter of youth, he urged the example which he had uniformly exhibited of justice, moderation, and temperance; the moral spirit and tendency of his discourses: and the effect which had actually been produced by his doctrine upon the manners of the young. Then, disdaining to solicit the mercy of his judges, he called upon them for that justice which their office and their oath obliged them to administer; and professing his faith and confidence in God, resigned himself to their pleasure.

The judges, whose prejudices would not suffer them to pay due attention to this apology, or to examine with impartiality the merits of the cause, immediately declared him guilty of the crimes of which he stood accused. Socrates, in this stage of the trial, had a right to enter his plea against the punishment which the accusers demanded, and instead of the sentence of death, to propose some pecuniary amercement. But he at first peremptorily refused to make any proposal of this kind, imagining that it might be construed into an acknowledgement of guilt; and asserted, that his conduct merited from the state reward rather than punishment. At length, however, he was prevailed upon by his friends to offer upon their credit a fine of thirty *minæ*. The judges, notwithstanding, still remained inexorable: they proceeded, without farther delay, to pronounce sentence upon him: and he was condemned to be put to death by the poison of hemlock.

The sentence being passed, he was sent to prison: which, says Seneca, he entered with the same resolution and firmness with which he had opposed the thirty tyrants; and took away all ignominy from the place, which could not be a prison while he was there. He lay in fetters 30 days; and was constantly visited by Crito, Plato, and other friends, with whom he passed the time in dispute after his usual manner. Anxious to save so valuable a life, they urged him to attempt his escape, or at least to permit them to convey him away: and Crito went so far, as to assure him that, by his interest with the jailor, it might be easily accomplished, and to offer him a retreat in Thessaly; but Socrates rejected the proposal, as a criminal violation of the laws, and asked them, whether there was any place out of Attica which death could not reach.

At length the day arrived when the officers to whose care he was committed delivered to Socrates early in the morning the final order for his execution, and immediately, according to the law, set him at liberty from his bonds. His friends, who came thus early to the prison that they might have an opportunity of conversing with their master through the day, found his wife sitting by him with a child in her arms. Socrates, that the tranquillity of his last moments might not be disturbed by her unavailing lamentations, requested that she might be conducted home. With the most frantic expressions of grief she left the prison. An interesting conversation then passed between Socrates and his friends, which chiefly turned upon the immortality of the soul. In the course of this conversation, he expressed his disapprobation of the practice of suicide, and assured his friends that his chief support in his present situation was an expectation, though not unmixed with doubts, of a happy existence after death. "It would be inexcusable in me (said he) to despise death, if I were not persuaded that it will conduct me into the presence of the gods, who are the most righteous governors, and into the society of just and good men: but I derive confidence from the hope that something of man remains after death,

death, and that the condition of good men will then be much better than that of the bad." Crito afterwards asking him in what manner he wished to be buried? Socrates replied with a smile, "As you please, provided I do not escape out of your hands." Then, turning to the rest of his friends, he said, "Is it not strange, after all that I have said to convince you that I am going to the society of the happy, that Crito still thinks that this body, which will soon be a lifeless corpse, is Socrates? Let him dispose of my body as he pleases, but let him not at its interment mourn over it as if it were Socrates."

Towards the close of the day he retired into an adjoining apartment to bathe; his friends, in the mean time, expressing to one another their grief at the prospect of losing so excellent a father, and being left to pass the rest of their days in the solitary state of orphans. After a short interval, during which he gave some necessary instructions to his domestics, and took his last leave of his children, the attendant of the prison informed him that the time for drinking the poison was come. The executioner, though accustomed to such scenes, shed tears as he presented the fatal cup. Socrates received it without change of countenance or the least appearance of perturbation: then offering up a prayer to the gods that they would grant him a prosperous passage into the invisible world, with perfect composure he swallowed the poisonous draught. His friends around him burst into tears. Socrates alone remained unmoved. He upbraided their pusillanimity, and entreated them to exercise a manly constancy worthy of the friends of virtue. He continued walking till the chilling operation of the hemlock obliged him to lie down upon his bed. After remaining for a short time silent, he requested Crito (probably in order to refute a calumny which might prove injurious to his friends after his decease) not to neglect the offering of a cock which he had vowed to Esculapius. Then, covering himself with his cloak, he expired. Such was the fate of the virtuous Socrates! A story, says Cicero, which I never read without tears.

The friends and disciples of this illustrious teacher of wisdom were deeply afflicted by his death, and attended his funeral with every expression of grief. Apprehensive, however, for their own safety, they soon afterwards privately withdrew from the city, and took up their residence in distant places. Several of them visited the philosopher Euclid of Megara, by whom they were kindly received. No sooner was the unjust condemnation of Socrates known through Greece, than a general indignation was kindled in the minds of good men, who universally regretted that so distinguished an advocate for virtue should have fallen a sacrifice to jealousy and envy. The Athenians themselves, so remarkable for their caprice, who never knew the value of their great men till after their death, soon became sensible of the folly as well as criminality of putting to death the man who had been the chief ornament of their city and of the age, and turned their indignation against his accusers: Melitus was condemned to death; and Anytus, to escape a similar fate, went into voluntary exile. To give a farther proof of the sincerity of their regret, the Athenians for a while interrupted public business; decreed a general mourning; recalled the exiled friends of Socrates; and erected a statue to his memory in one of the most frequented parts of the city. His death happened in the first year of the 96th olympiad, and in the 70th year of his age.

Socrates left behind him nothing in writing; but his illustrious pupils Xenophon and Plato have in some measure supplied this defect. The Memoirs of Socrates, written by Xenophon, afford, however, a much more accurate idea of the opinions of Socrates, and of his manner of teaching, than the Dialogues of Plato, who everywhere mixes his own conceptions and diction with the ideas and language of his master. It is related, that when Socrates heard Plato recite his Lysis, he said, "How much does this young man make me say which I never conceived!"

His distinguishing character was that of a moral philosopher; and his doctrine concerning God and religion was rather practical than speculative. But he did not neglect to build the structure of religious faith upon the firm foundation of an appeal to natural appearances: He taught that the Supreme Being, though invisible, is clearly seen in his works: which at once demonstrate his existence and his wise and benevolent providence. He admitted, besides the one Supreme Deity, the existence of beings who possess a middle station between God and man, to whose immediate agency he ascribed the ordinary phenomena of nature, and whom he supposed to be particularly concerned in the management of human affairs. Hence he declared it to be the duty of every one, in the performance of religious rites, to follow the customs of his country. At the same time, he taught, that the merit of all religious offerings depends upon the character of the worshipper, and that the gods take pleasure in the sacrifices of none but the truly pious.

Concerning the human soul, the opinion of Socrates, according to Xenophon, was, that it is allied to the Divine Being, not by a participation of essence, but by a similarity of nature; that man excels all other animals in the faculty of reason; and that the existence of good men will be continued after death in a state in which they will receive the reward of their virtue. Although it appears that on this latter topic he was not wholly free from uncertainty, the consolation which he professed to derive from this source in the immediate prospect of death, leaves little room to doubt that he entertained a real expectation of immortality: and there is reason to believe that he was the only philosopher of ancient Greece whose principles admitted of such an expectation (see METAPHYSICS, Part III. Chap. iv.). Of his moral system, which was in a high degree pure, and founded on the surest basis, the reader will find a short view in our article MORAL PHILOSOPHY, N° 4.

SOCRATES was also the name of an ecclesiastical historian of the 5th century, born at Constantinople in the beginning of the reign of Theodosius: he professed the law and pleaded at the bar, whence he obtained the name of *Scholasticus*. He wrote an ecclesiastical history from the year 309, where Eusebius ended, down to 440; and wrote with great exactness and judgment. An edition of Eusebius and Socrates, in Greek and Latin, with notes by Reading, was published at London in 1720.

SODA, the name given by the French chemists to the mineral alkali, which is found native in many parts of the world: it is obtained also from common salt, and

from

from the ashes of the *kali*, a species of salsola. See CHEMISTRY *Index*, for an account of its properties and combinations: but long after that article was written, soda and potash were decomposed by means of galvanism; and the alkalies, hitherto considered as simple substances, appear, from the experiments of Mr Davy, who first made the discovery, to be compounds of oxygen and a metallic base. Mr Davy's conclusions have been controverted by some of the French chemists; and as the subject may perhaps in a few months receive some farther elucidation, we shall delay our account of the whole till we come to describe the apparatus by which the experiments are conducted. See *TROUGH, Galvanic*.

SODA is also a name for a heat in the stomach, or heart-burn. See MEDICINE, N° 275.

SODOM, formerly a town of Palestine in Asia, famous in Scripture for the wickedness of its inhabitants, and their destruction by fire from heaven on account of that wickedness. The place where it stood is now covered by the waters of the Dead sea, or the lake Asphaltites. See ASPHALTITES.

SODOMY, an unnatural crime, so called from the city of Sodom, which was destroyed by fire for the same. The Levitical law adjudged those guilty of this execrable crime to death; and the civil law assigns the same punishment to it. The law of England makes it felony. There is no statute in Scotland against sodomy; the libel of the crime is therefore founded on the divine law, and practice makes its punishment to be burned alive.

SODOR, a name always conjoined with Man, in mentioning the bishop of Man's diocese. Concerning the origin and application of this word, very different opinions have been formed by the learned. Buchanan (lib. i. cap. 34.) says, that before his time the name of *Sodor* was given to a town in the isle of Man. In Gough's edition of Camden's *Britannia* (vol. iii. p. 701.) it is said, that after the isle of Man was annexed to the crown of England, this appellation was given to a small island within musket-shot of Man, in which the cathedral stands, called by the Norwegians the *Holm*, and by the inhabitants the *Peel*. In support of this opinion, a charter is quoted A. D. 1505, in which Thomas earl of Derby and lord of Man confirms to Huan Hesketh bishop of Sodor all the lands, &c. anciently belonging to the bishops of Man. "Ecclesiam cathedralem sancti Germani in *Holm Sodor vel Pele* vocatam, ecclesiam sancti Patricii ibidem, et locum præfatum in quo ecclesiæ præfatæ sitæ sunt." The truth of either, or perhaps of both, these accounts might be allowed; but neither of them is sufficient to account for the constant conjunction of Sodor and Man, in charters, registers, and histories. If Sodor was a small town or island belonging to Man, it cannot be conceived why it is always mentioned before it, or rather why it should be mentioned at all in speaking of a bishop's diocese. To speak of the bishopric of Sodor and Man in this case would be as improper as it would be to call the bishopric of Durham the bishopric of Holy Island and Durham, or the bishopric of Darlington and Durham; the former being a small island and the latter a town belonging to the county and diocese of Durham. Neither of these accounts, therefore, gives a satisfactory account of the original conjunction of Sodor and Man.

The island of Iona was the place where the bishop of the Isles resided, the cathedral church of which, it is said, was dedicated to our Saviour, in Greek *Soter*, hence *Sotorenses*, which might be corrupted into *Sodorenses*, a name frequently given by Danish writers to the western isles of Scotland. That we may be the more disposed to accede to this Grecian etymology, the advocates for this opinion tell us, that the name *Icolumkill*, which is often applied to this island, is also of Greek extraction, being derived from *Columba*, "a pigeon;" a meaning that exactly corresponds to the Celtic word *Colum* and the Hebrew word *Iona*. We must confess, however, that we have very little faith in the conjectures of etymologists, and think that upon no occasion they alone can establish any fact, though when concurring with facts they certainly tend to confirm and explain them. It is only from historical facts that we can know to what Sodor was applied.

It appears from the history of the Orkneys, compiled by an old Icelandic writer, translated and enlarged by Torfæus, that the Æbudæ or Western isles of Scotland were divided into two clusters, Nordureys and Sudereys. The Nordureys, which were separated from the Sudereys by the point of Ardnamurchan, a promontory in Argyleshire, consisted of Muck, Egg, Rum, Canna, Skye, Rasay, Barra, South Uist, North Uist, Benbecula, and Lewis, including Harris, with a great number of small isles. The Sudereys were, Man, Arran, Bute, Cumra, Avon, Gid, Ila, Colonsay, Jura, Scarba, Mull, Iona, Tiree, Coll, Ulva, and other small islands. All these, when joined together, and subject to the same prince, made up the kingdom of Man and the Isles. In the Norwegian language, *Suder* and *Norder* signify southern and northern, and *ey* or *ay* an island. When the Æbudæ were under one monarch, the seat of empire was fixed in the Sudereys, and the Nordureys were governed by deputies; hence the former are much oftener mentioned in history than the latter; hence, too, the Sudereys often comprehend the Nordureys, as in our days Scotland is sometimes comprehended under England. Sudereys, or Suder, when anglicised, became Sodor; and all the Western isles of Scotland being included in one diocese under the Norwegian princes, the bishop appointed to superintend them was called the bishop of Man and the Isles, or the bishop of Sodor and Man. Since Man was conquered by Edward III. it has been separated from the other isles, and its bishops have exercised no jurisdiction over them. Should it now be asked, why then is the bishop of Man still called the bishop of Sodor and Man? we reply, that we have been able to discover no reason; but suppose the appellation to be continued in the same way, as the title king of France has been kept up by the kings of Great Britain, for several centuries after the English were entirely expelled from France.

SOFA, in the east, a kind of alcove raised half a foot above the floor of a chamber or other apartment; and used as the place of state, where visitors of distinction are received. Among the Turks the whole floor of their state-rooms is covered with a kind of tapestry, and on the window-side is raised a sofa or sopha, laid with a kind of mattress, covered with a carpet much richer than the other. On this carpet the Turks are seated, both men and women, like the tailors in England, cross-legged, leaning against the wall, which is bolstered

bolstered with velvet, satin, or other stuff suitable to the season. Here they eat their meals; only laying a skin over the carpet to serve as a tablecloth, and a round wooden board over all, covered with plates, &c.

SOFALA, or CEFALA, a kingdom of Africa, lying on the coast of Mosambique, near Zangnebar. It is bounded on the north by Monomotapa; on the east by the Mosambique sea; on the south by the kingdom of Sabia; and on the west by that of Manica. It contains mines of gold and iron, and a great number of elephants. It is governed by a king, tributary to the Portuguese, who built a fort at the principal town, which is of the same name, and of great importance for their trade to the East Indies. It is seated in a small island, near the mouth of a river. E. Long. 35. 40. S. Lat. 20. 20.

SOFFITA, or SOFFIT, in *Architecture*, any timber ceiling formed of cross beams of flying corniches, the square compartiments or pannels of which are enriched with sculpture, painting, or gilding; such are those in the palaces of Italy, and in the apartments of Luxembourg at Paris.

SOFFITA, or *Soffit*, is also used for the underside or face of an architrave; and more particularly for that of the corona or larmier, which the ancients called *lacunar*, the French *plafond*, and we usually the *drip*. It is enriched with compartiments of roses; and in the Doric order has 18 drops, disposed in three ranks, six in each, placed to the right of the guttæ, at the bottom of the triglyphs.

SOFI, or SOPHI. See SOPHI.

SOFTENING, in *Painting*, the mixing and diluting of colours with the brush or pencil.

SOHO, the name of a set of works, or manufactory of a variety of hardwares, belonging to the late Mr Boulton, situated on the borders of Staffordshire, within two miles of Birmingham; now so justly celebrated as to deserve a short historical detail.

About 30 years ago the premises consisted of a small mill and a few obscure dwellings. Mr Boulton, in conjunction with Mr Fothergill, then his partner, at an expence of 9000l. erected a handsome and extensive edifice, with a view of manufacturing metallic toys. The first productions consisted of buttons, buckles, watch-chains, trinkets, and such other articles as were peculiar to Birmingham. Novelty, taste, and variety, were however always conspicuous; and plated wares, known by the name of Sheffield plate, comprising a great variety of useful and ornamental articles, became another permanent subject of manufacture.

To open channels for the consumption of these commodities, all the northern part of Europe was explored by the mercantile partner Mr Fothergill. A wide and extensive correspondence was thus established, the undertaking became well known, and the manufacturer, by becoming his own merchant, eventually enjoyed a double profit.

Impelled by an ardent attachment to the arts, and by the patriotic ambition of forming his favourite Soho into a fruitful seminary of artists, the proprietor extended his views; and men of taste and talents were now sought for, and liberally patronised. A successful imitation of the French *or moulise* ornaments, consisting of vases, tripods, candelabra, &c. &c. extended the celebrity of the works. Services of plate and other works in silver, both massive and airy, were added, and an assay office was established in Birmingham.

Mr Watt, the ingenious improver of the steam-engine, was afterwards taken into partnership with Mr Boulton; and they carried on at Soho a manufactory of steam-engines, not less beneficial to the public than lucrative to themselves. This valuable machine, the nature and excellencies of which are described in another place (see STEAM-*Engine*), Mr Boulton proposed to apply to the operation of coining, and suitable apparatus was erected at a great expence, for the purpose of being employed by government to make a new copper-coinage for the kingdom. Artists of merit were engaged, and specimens of exquisite delicacy were exhibited; the works were also employed upon highly finished medals and private coins. To enumerate all the productions of this manufactory would be tedious (A).

In a national view, Mr Boulton's undertakings are highly valuable and important. By collecting around him artists of various descriptions, rival talents have been called forth, and by successive competition have been multiplied to an extent highly beneficial to the public. The manual arts partook of the benefit, and became proportionably improved.

A barren heath has been covered with plenty and population; and Mr Boulton's works, which in their infancy were little known and attended to, now cover several acres, give employment to more than 600 persons, and are said to be the first of their kind in Europe.

SOIL, the mould covering the surface of the earth, in which vegetables grow. It serves as a support for vegetables, and as a reservoir for receiving and communicating nourishment.

Soils are commonly double or triple compounds of the several reputed primitive earths, except the barytic. The magnesian likewise sparingly occurs. The more fertile soils afford also a small proportion of coally substance arising from putrefaction, and some traces of marine acid and gypsum. The vulgar division into clay, chalk, sand, and gravel, is well understood. Loam denotes any soil moderately adhesive; and, according to the ingredient that predominates, it receives the epithets of clayey, chalky, sandy, or gravelly. The intimate mixture of clay with the oxydes of iron is called *till*, and is of a hard consistence and a dark reddish colour. Soils are found by analysis to contain their earthy ingredients in very different proportions. According to M. Giobert, fertile mould in the vicinity of Turin, where the fall of rain amounts yearly to 40 inches, affords for each 100 parts, from 77 to 79 of silex, from 8 to 14 of argill, and from 5 to 12 of lime; besides about one-half of carbonic matter, and nearly an equal weight of gas, partly carbonic and partly hydrocarbonic. The same experimenter represents the composition of barren soils in similar situations to be from 42 to 88 per cent. of silex,

(A) It was at this place, in the year 1772, that Mr Eginton invented an expeditious method of copying pictures in oil; but we do not know how far this method has succeeded.

lex, from 20 to 30 of argill, and from 4 to 20 of lime. The celebrated Bergman found rich soils in the valleys of Sweden, where the annual quantity of rain is 24 inches, to contain, for each 100 parts, 56 of siliceous sand, 14 of argill, and 30 of lime. In the climate of Paris, where the average fall of rain is 20 inches, fertile mixtures, according to M. Tillet, vary from 46 to 52 per cent. of silex, and from 11 to 17 of argill, with 37 of lime. Mr Arthur Young discovered, that the value of fertile lands is nearly proportioned to the quantities of gas which equal weights of their soil afford by distillation, and Sir Humphrey Davy concludes that the fertility of soils is nearly in proportion to their power of absorbing moisture. See AGRICULTURE in this work, and in the SUPPLEMENT.

SOISSONS, an ancient, large, and considerable city of France, in the department of Aisne and late province of Soissonnois. It was the capital of a kingdom of the same name, under the first race of the French monarchs. It contained 8189 inhabitants in 1800, and is a bishop's see. The environs are charming, but the streets are narrow, and the houses ill-built. The fine cathedral has one of the most considerable chapters in the kingdom; and the bishop, when the archbishop of Rheims was absent, had a right to crown the king. The castle, though ancient, is not that in which the kings of the first race resided. Soissons is seated in a very pleasant and fertile valley, on the river Aisne, 30 miles west by north of Rheims, and 60 north-east of Paris. E. Long. 3. 24. N. Lat. 49. 23.

SOKE, or SOK. See SOCAGE.

SOKEMANS. See SOC and SOCAGE.

SOL, in *Music*, the fifth note of the gamut, *ut*, *re*, *mi*, *fa*, *sol*, *la*. See GAMUT.

SOL, or *Sou*, a French coin made up of copper mixed with a little silver, and is worth upwards of an English halfpenny, or the 23d part of an English shilling. The sol when first struck was equal in value to 12 deniers Tournois, whence it was also called *douzain*, a name it still retains, though its ancient value be changed; the sol having been since augmented by three deniers, and struck with a puncheon of a fleur-de-lis, to make it current for 15 deniers. Soon after the old sols were coined over again, and both old and new were indifferently made current for 15 deniers. In 1709, the value of the same sols was raised to 18 deniers. Towards the latter end of the reign of Louis XIV. the sol of 18 deniers was again lowered to 15; and by the late king it was reduced to the original value of 12. What it is at present posterity may perhaps discover.

The Dutch have also two kinds of sols: the one of silver, called *sols de gros*, and likewise *scheling*; the other of copper, called also the *stuyver*.

SOL, the *Sun*, in *Astronomy*, *Astrology*, &c. See ASTRONOMY, *passim*.

SOL, in *Chemistry*, is gold; thus called from an opinion that this metal is in a particular manner under the influence of the sun.

SOL, in *Heraldry*, denotes Or, the golden colour in the arms of sovereign princes.

SOLÆUS, or SOLEUS, in *Anatomy*, one of the extensor muscles of the foot, rising from the upper and hinder parts of the tibia and fibula.

SOLAN-GOOSE. See PELICANUS, ORNITHOLOGY *Index*.

SOLANDRA, a genus of plants belonging to the class of monadelphia, and to the order of polyandria; and in the natural system arranged under the 38th order, *Tricoccæ*. See BOTANY *Index*.

SOLANUM, a genus of the monogynia order, belonging to the pentandria class of plants; and in the natural method ranking under the 28th order, *Luridæ*. See BOTANY *Index*.

SOLAR, something belonging to the SUN.

SOLAR *Spots*. See ASTRONOMY *Index*.

SOLDAN. See SULTAN.

SOLDANELLA, a genus of plants belonging to the class of pentandria, and order of monogynia; and in the natural system arranged under the 21st order, *Preciæ*. See BOTANY *Index*.

SOLDER, SODDER, or *Soder*, a metallic or mineral composition used in soldering or joining together other metals.

Solders are made of gold, silver, copper, tin, bismuth, and lead; usually observing, that in the composition there be some of the metal that is to be soldered mixed with some higher and finer metals. Goldsmiths usually make four kinds of solder, viz. solder of eight, where to seven parts of silver there is one of brass or copper; solder of six, where only a sixth part is copper; solder of four, and solder of three. It is the mixture of copper in the solder that makes raised plate come always cheaper than flat.

As mixtures of gold with a little copper are found to melt with less heat than pure gold itself, these mixtures serve as solders for gold: two pieces of fine gold are soldered by gold that has a small admixture of copper; and gold alloyed with copper is soldered by such as is alloyed with more copper: the workmen add a little silver as well as copper, and vary the proportions of the two to one another, so as to make the colour of the solder correspond as nearly as may be to that of the piece. A mixture of gold and copper is also a solder for fine copper as well as for fine gold. Gold being particularly disposed to unite with iron, proves an excellent solder for the finer kinds of iron and steel instruments.

The solder used by plumbers is made of two pounds of lead to one of block-tin. Its goodness is tried by melting it, and pouring the bigness of a crown-piece on a table; for, if good, there will arise little bright shining stars therein. The solder for *copper* is made like that of the plumbers; only with copper and tin; and for very nice works, instead of tin, they sometimes use a quantity of silver. Solder for *tin* is made of two-thirds of tin and one of lead, or of equal parts of each; but where the work is any thing delicate, as in organ-pipes, where the juncture is scarce discernible, it is made of one part of bismuth and three parts of pewter. The pewterers use a kind of solder made with two parts of tin and one of bismuth; this composition melts with the least heat of any of the solders.

Silver solder is that which is made of two parts of silver and one of brass, and used in soldering those metals. Spelter solder is made of one part of brass and two of spelter or zinc, and is used by the braziers and coppersmiths for soldering brass, copper, and iron. This solder is improved by adding to each ounce of it one pennyweight of silver; but as it does not melt without a considerable degree of heat, it cannot be used when it it is inconvenient to heat the work red hot; in which case copper and brass are soldered with silver.

Though spelter solder be much cheaper than silver-solder, yet workmen in many cases prefer the latter. And Mr Boyle informs us, that he has found it to run with so moderate a heat, as not much to endanger the melting of the delicate parts of the work to be soldered; and if well made, this silver solder will lie even upon the ordinary kind itself; and so fill up those little cavities that may chance to be left in the first operation, which is not easily done without a solder more easily fusible than the first made use of. As to iron, it is sufficient that it be heated to a white heat, and the two extremities, in this state, be hammered together; by which means they become incorporated one with the other.

SOLDERING, the joining and fastening together of two pieces of the same metal, or of two different metals, by the fusion and application of some metallic composition on the extremities of the metals to be joined.

To solder upon silver, brass, or iron: Take silver, five pennyweights; brass, four pennyweights: melt them together for soft solder, which runs soonest. Take silver, five pennyweights; copper, three pennyweights: melt them together for hard solder. Beat the solder thin, and lay it on the place to be soldered, which must be first fitted and bound together with wire as occasion requires; then take borax in powder, and temper it like pap, and lay it upon the solder, letting it dry; then cover it with live coals, and blow, and it will run immediately; take it presently out of the fire, and it is done. It is to be observed, that if any thing is to be soldered in two places, which cannot well be done at one time, you must first solder with the harder solder, and then with the soft; for if it be first done with the soft, it will unsolder again before the other is fastened. Let it be observed, that if you would not have your solder run about the piece that is to be soldered, you must rub such places over with chalk.—In the soldering either of gold, silver, copper, or either of the metals above mentioned, there is generally used borax in powder, and sometimes rosin. As to iron, it is sufficient that it be heated red hot, and the two extremities thus hammered together, by which means they will become incorporated with each other. For the finer kinds of iron and steel instruments, however, gold proves an excellent solder. This metal will dissolve twice or thrice its weight of iron in a degree of heat very far less than that in which iron itself melts; hence if a small plate of gold is warped round the parts to be joined, and afterwards melted by a blow-pipe, it strongly unites the pieces together without any injury to the instrument, however delicate.

SOLDIER, a military man listed to serve a prince or state in consideration of a certain daily pay.

Soldier-Crab. See Cancer, Entomology *Index.*

Fresh-Water Soldier. See Stratiotes, Botany *Index.*

SOLE, in the manege, a sort of horn under a horse's foot, which is much more tender than the other horn that encompasses the foot, and by reason of its hardness is properly called the *horn* or *hoof.*

Sole. See Pleuronectes, Ichthyology *Index.*

SOLEA. See Sandal and Shoe.

SOLECISM, in *Grammar*, a false manner of speaking, contrary to the rules of grammar, either in respect of declension, conjugation, or syntax.—The word is Greek, σολοικισμος, derived from the *Soli*, a people of Attica, who being transplanted to Cilicia, lost the purity of their ancient tongue, and became ridiculous to the Athenians for the improprieties into which they fell.

SOLEMN, something performed with much pomp, ceremony, and expence. Thus we say, solemn feasts, solemn funerals, solemn games, &c.—In law, *solemn* signifies something authentic, or what is clothed in all its formalities.

SOLEN, Razor-sheath, or *Knife-handle Shell;* a genus belonging to the class of *vermes*, and order of *testacea.* See Conchology *Index.*

SOLEURE, a canton of Swisserland, the 11th in rank in the Helvetic confederacy, into which it was admitted in the year 1481. It stretches partly through the plain, and partly along the chains of the Jura. It contained in 1815 about 48,600 inhabitants, upon 385 square miles. The soil for the most part is exceedingly fertile in corn; and the districts within the Jura abound in excellent pastures. The trade of the town and canton is of little value, although they are commodiously situated for commerce. It is divided into 11 bailiwicks, the inhabitants of which are all Roman Catholics, except those of the bailiwick of Buckegberg, who profess the reformed religion. The sovereign power resides in the great council, which, comprising the senate or little council of 36, consists of 102 members, chosen by the senate in equal proportions from the 11 tribes or companies into which the ancient burghers are distributed.

A melancholy catastrophe took place in this canton on the 13th July 1813. The river Birse, swelled by the rains, overflowed its banks at Dornach, and undermined a house, which was thrown down and buried a number of persons in its ruins. An ancient tower, which was occupied as the prison, experienced a similar fate, fell on the bridge, broke it in the centre, and precipitated a great crowd of persons collected upon it into the torrent. By this accident 150 of the inhabitants lost their lives.

Soleure, an ancient and extremely neat town of Swisserland, capital of the canton of the same name. It contains about 4000 inhabitants, and is pleasantly seated on the Aar, which here expands into a noble river. Among the most remarkable objects of curiosity in this town is the new church of St Urs, which was begun in 1762 and finished in 1772; a noble edifice of a whitish grey stone or coarse marble, which admits a polish. This building cost at least 80,000l. a considerable sum for such a small republic, whose revenue scarcely exceeds 12,000l. a-year. Soleure is surrounded by regular stone fortifications, and is 20 miles north-north-east of Bern, 27 south-south-west of Basle, and 45 west of Zurich. E. Long. 7. 10. N. Lat. 47. 15.

SOLFAING, in *Music*, the naming or pronouncing the several notes of a song by the syllables *ut, re, mi, fa, sol,* &c. in learning to sing it.

Of the seven notes in the French scale *ut, re, mi, fa, sol, la, si,* only four are used among us in singing, as *mi, fa, sol, la*: their office is principally, in singing, that by applying them to every note of the scale, it may not only be pronounced with more ease, but chiefly that by them the tones and semitones of the natural scale may be better marked out and distinguished. This design is obtained by the four syllables *fa, sol, la, mi.* Thus

Thus from *fa* to *sol* is a tone, also from *sol* to *la*, and from *la* to *mi*, without distinguishing the greater or less tone; but from *la* to *fa*, also from *mi* to *fa*, is only a semitone. If then these be applied in this order, *fa*, *sol*, *la*, *fa*, *sol*, *la*, *mi*, *fa*, &c. they express the natural series from C; and if that be repeated to a second or third octave, we see by them how to express all the different orders of tones and semitones in the diatonic scale; and still above *mi* will stand *fa*, *sol*, *la*, and below it the same inverted *la*, *sol*, *fa*, and one *mi* is always distant from another an octave; which cannot be said of any of the rest, because after *mi* ascending come always *fa*, *sol*, *la*, which are repeated invertedly descending.

To conceive the use of this, it is to be remembered, that the first thing in learning to sing, is to make one raise a scale of notes by tones and semitones to an octave, and descend again by the same; and then to rise and fall by greater intervals at a leap, as thirds and fourths, &c. and to do all this by beginning at notes of different pitch. Then those notes are represented by lines and spaces, to which these syllables are applied, and the learners taught to name each line and space thereby, which makes what we call *solfaing*; the use whereof is, that while they are learning to tune the degrees and intervals of sound expressed by notes on a line or space, or learning a song to which no words are applied, they may not only do it the better by means of articulate sounds, but chiefly that by knowing the degrees and intervals expressed by those syllables, they may more readily know the places of the semitones, and the true distance of the notes. See the article SINGING.

SOLFATERRA, a mountain of Italy in the kingdom of Naples, and Terra di Lavoro. This mountain appears evidently to have been a volcano in ancient times; and the soil is yet so hot, that the workmen employed there in making alum need nothing else besides the heat of the ground for evaporating their liquids. Of this mountain we have the following account by Sir William Hamilton. "Near Astruni (another mountain, formerly a volcano likewise) rises the Solfaterra, which not only retains its cone and crater, but much of its former heat. In the plain within the crater, smoke issues from many parts, as also from its sides: here, by means of stones and tiles heaped over the crevices, through which the smoke passes, they collect in an awkward manner what they call *sale armoniaco*; and from the sand of the plain they extract sulphur and alum. This spot, well attended to, might certainly produce a good revenue, whereas I doubt if they have hitherto ever cleared 200l. a-year by it. The hollow sound produced by throwing a heavy stone on the plain of the crater of the Solfaterra, seems to indicate that it is supported by a sort of arched natural vault; and one is induced to think that there is a pool of water beneath this vault (which boils by the heat of a subterraneous fire still deeper), by the very moist steam that issues from the cracks in the plain of the Solfaterra, which, like that of boiling water, runs off a sword or knife, presented to it, in great drops. On the outside and at the foot of the cone of the Solfaterra, towards the lake of Agnano, water rushes out of the rocks so hot as to raise the quicksilver in Fahrenheit's thermometer to the degree of boiling water (A); a fact of which I was myself an eye-witness. This place, well worthy the observation of the curious, has been taken little notice of; it is called the *Pisciarelli*. The common people of Naples have great faith in the efficacy of this water; and make much use of it in all cutaneous disorders, as well as for another disorder that prevails here. It seems to be impregnated chiefly with sulphur and alum. When you approach your ear to the rocks of the Pisciarelli, from whence this water oozes, you hear a horrid boiling noise, which seems to proceed from the huge cauldron that may be supposed to be under the plain of the Solfaterra. On the other side of the Solfaterra, next the sea, there is a rock which has communicated with the sea, till part of it was cut away to make the road to Puzzole; this was undoubtedly a considerable lava, that ran from the Solfaterra when it was an active volcano. Under this rock of lava, which is more than 70 feet high, there is a stratum of pumice and ashes. This ancient lava is about a quarter of a mile broad; you meet with it abruptly before you come in sight of Puzzole, and it finishes as abruptly within about 100 paces of the town. The ancient name of the Solfaterra was *Forum Volcani*; a strong proof of its origin from subterraneous fire. The degree of heat that the Soltaferra has preserved for so many ages, seems to have calcined the stones upon its cone and in its crater, as they are very white and crumble easily in the hottest parts.

SOLICITOR, a person employed to take care of and manage suits depending in the courts of law or equity. Solicitors are within the statute to be sworn, and admitted by the judges, before they are allowed to practise in our courts, in like manner as attorneys.

There is also a great officer of the law, next to the attorney-general, who is styled the king's solicitor-general; who holds his office by patent during the king's pleasure, has the care and concern of managing the king's affairs, and has fees for pleading, besides other fees arising by patents, &c. He attends on the privy-council; and the attorney-general and he were anciently reckoned among the officers of the exchequer; they have their audience, and come within the bar in all other courts.

SOLID, in *Philosophy*, a body whose parts are so firmly connected together, as not easily to give way or slip from each other; in which sense *solid* stands opposed to *fluid*.

Geometricians define a solid to be the third species of magnitude, or that which has three dimensions, viz. length, breadth, and thickness or depth.

Solids are commonly divided into regular and irregular. The regular solids are those terminated by regular and

(A) "I have remarked, that after a great fall of rain, the degree of heat in this water is much less; which will account for what Padre Torre says (in his book, intitled *Histoire et Phenomenes du Vesuve*), that when he tried it in company with Monsieur de la Condamine, the degree of heat, upon Reaumur's thermometer, was 68°.

and equal planes, and are only five in number, viz. the tetrahedron, which consists of four equal triangles; the cube or hexahedron, of six equal squares; the octahedron, of eight equal triangles; the dodecahedron, of twelve; and the icosahedron, of twenty equal triangles.

The irregular solids are almost infinite, comprehending all such as do not come under the definition of regular solids; as the sphere, cylinder, cone, parallelogram, prism, parallelopiped, &c.

SOLIDS, in *Anatomy*, are the bones, ligaments, membranes, muscles, nerves and vessels, &c.

The solid parts of the body, though equally composed of vessels, are different with regard to their consistence; some being hard and others soft. The hard, as the bones and cartilages, give firmness and attitude to the body, and sustain the other parts: the soft parts, either alone or together with the hard, serve to execute the animal functions. See ANATOMY.

SOLIDAGO, a genus of plants belonging to the class of syngenesia, and to the order of polygamia superflua; and in the natural system ranging under the 49th order, *Compositæ*. See BOTANY *Index*.

SOLIDITY, that property of matter, or body, by which it excludes all other bodies from the place which itself possesses; and as it would be absurd to suppose that two bodies could possess one and the same place at the same time, it follows, that the softest bodies are equally solid with the hardest. See METAPHYSICS, N° 44, 173, &c.

Among geometricians, the solidity of a body denotes the quantity or space contained in it, and is called also its solid content.

The solidity of a cube, prism, cylinder, or parallelopiped is had by multiplying its basis into its height. The solidity of a pyramid or cone is had by multiplying either the whole base into a third part of the height, or the whole height into a third part of the base.

SOLILOQUY, a reasoning or discourse which a man holds with himself; or, more properly, according to Papias, it is a discourse by way of answer to a question that a man proposes to himself.

Soliloquies are become very common on the modern stage; yet nothing can be more inartificial, or more unnatural, than an actor's making long speeches to himself, to convey his intentions to the audience. Where such discoveries are necessary to be made, the poet should rather take care to give the dramatic persons such confidents as may necessarily share their inmost thoughts; by which means they will be more naturally conveyed to the audience; yet even this is a shift which an accurate poet would not have occasion for. The following lines of the duke of Buckingham concerning the use and abuse of soliloquies deserve attention:

Soliliquies had need be very few,
Extremely short, and spoke in passion too.
Our lovers talking to themselves, for want
Of others, make the pit their confidant:
Nor is the matter mended yet, if thus
They trust a friend, only to tell it us.

SOLIMAN II. emperor of the Turks, surnamed the *Magnificent*, was the only son of Selim I. whom he succeeded in 1520. He was educated in a manner very different from the Ottoman princes in general; for he was instructed in the maxims of politics and the secrets of government. He began his reign by restoring those persons their possessions whom his father had unjustly plundered. He re-established the authority of the tribunals, which was almost annihilated, and bestowed the government of provinces upon none but persons of wealth and probity: "I would have my viceroys (he used to say) resemble those rivers that fertilize the fields through which they pass, not those torrents which sweep every thing before them."

After concluding a truce with Ismael Sophy of Persia, and subduing Gozeli Bey, who had raised a rebellion in Syria, he turned his arms against Europe. Belgrade was taken in 1522, and Rhodes fell into his hands the year following, after an obstinate and enthusiastic defence. In 1526 he defeated and slew the king of Hungary in the famous battle of Mohatz. Three years after he conquered Buda, and immediately laid siege to Vienna itself. But after continuing 20 days before that city, and assaulting it 20 times, he was obliged to retreat with the loss of 80,000 men. Some time after he was defeated by the Persians, and disappointed in his hopes of taking Malta. He succeeded, however, in dispossessing the Genoese of Chio, an island which had belonged to that republic for more than 200 years.

He died at the age of 76, while he was besieging Sigeth, a town in Hungary, on the 30th August 1566.

He was a prince of the strictest probity, a lover of justice, and vigorous in the execution of it; but he tarnished all his glory by the cruelty of his disposition. After the battle of Mohatz he ordered 1500 prisoners, most of them gentlemen, to be ranged in a circle, and beheaded in presence of his whole army.

Soliman thought nothing impossible which he commanded: A general having received orders to throw a bridge over the Drave, wrote him, that it was impossible. The sultan sent him a long band of linen with these words written on it: "The emperor Soliman, thy master, orders thee to build a bridge over the Drave in spite of the difficulties thou mayest meet with. He informs thee at the same time, that if the bridge be not finished upon his arrival, he will hang thee with the very linen which informs thee of his will."

SOLIPUGA, or SOLIFUGA, in *Natural History*, the name given by the Romans to a small venomous insect of the spider-kind, called by the Greeks *heliocentros*; both words signifying an animal which stings most in the country and seasons where the sun is most hot. Solinus makes this creature peculiar to Sardinia; but this is contrary to all the accounts given us by the ancients. It is common in Africa and some parts of Europe. Almost all the hot countries produce this venomous little creature. It lies under the sand to seize other insects as they go by; and if it meet with any uncovered part of a man, produces a wound which proves very painful; it is said that the bite is absolutely mortal, but probably this is not true. Solinus writes the word *solifuga*, and so do many others, erroneously deriving the name from the notion that this animal flies from the sun's rays, and buries itself in the sand.

SOLIS, ANTONIO DE, an ingenious Spanish writer, of an ancient and illustrious family, born at Placenza in Old Castile, in 1610. He was intended for the law; but his inclination toward poetry prevailed, and he cultivated it with great success. Philip IV. of Spain

made

made him one of his secretaries; and after his death the queen-regent appointed him historiographer of the Indies, a place of great profit and honour: his History of the Conquest of Mexico shows that she could not have named a fitter person. He is better known by this history at least abroad, than by his poetry and dramatic writings, though in these he was also distinguished. He turned priest at 57 years of age, and died in 1686.

SOLITARY, that which is remote from the company or commerce of others of the same species.

SOLITARIES, a denomination of nuns of St Peter of Alcantara, instituted in 1676, the design of which was to imitate the severe penitent life of that saint. Thus they are to keep a continual silence, never to open their mouths to a stranger; to employ their time wholly in spiritual exercises, and leave their temporal concerns to a number of maids, who have a particular superior in a separate part of the monastery: they always go bare-footed, without sandals; gird themselves with a thick cord, and wear no linen.

SOLO, in the Italian music, is frequently used in pieces consisting of several parts, to mark those that are to perform alone; as *flauto solo, violino solo.* It is also used for sonatas composed for one violin, one German flute, or other instrument, and a bass; thus we say, *Corelli's solos*, *Geminiani's solos*, &c. When two or three parts play or sing separately from the grand chorus, they are called a *doi soli*, a *tre soli*, &c. Solo is sometimes denoted by *S.*

SOLOMON, the son of David king of Israel, renowned in Scripture for his wisdom, riches, and magnificent temple and other buildings. Towards the end of his life he sullied all his former glory by his apostasy from God; from which cause vengeance was denounced against his house and nation. He died about 975 B. C.

Solomon's Seal, a species of CONVALLARIA, which see, BOTANY *Index*.

SOLON, one of the seven wise men of Greece, was born at Salamis, of Athenian parents, who were descended from Codrus. His father leaving little patrimony, he had recourse to merchandise for his subsistence. He had, however, a greater thirst after knowledge and fame than after riches, and made his mercantile voyages subservient to the increase of his intellectual treasures. He very early cultivated the art of poetry, and applied himself to the study of moral and civil wisdom. When the Athenians, tired out with a long and troublesome war with the Megarensians, for the recovery of the isle of Salamis, prohibited any one, under pain of death, to propose the renewal of their claim to that island, Solon thinking the prohibition dishonourable to the state, and finding many of the younger citizens desirous to revive the war, feigned himself mad, and took care to have the report of his insanity spread through the city. In the mean time he composed an elegy adapted to the state of public affairs, which he committed to memory. Every thing being thus prepared, he sallied forth into the market-place with the kind of cap on his head which was commonly worn by sick persons, and, ascending the herald's stand, he delivered, to a numerous crowd, his lamentation for the desertion of Salamis. The verses were heard with general applause; and Pisistratus seconded his advice, and urged the people to renew the war. The decree was immediately repealed; the claim to Salamis was resumed; and the conduct of the war was committed to Solon and Pisistratus, who, by means of a stratagem, defeated the Megarensians, and recovered Salamis.

His popularity was extended through Greece in consequence of a successful alliance which he formed among the states in defence of the temple at Delphos against the Cirrhæans. When dissensions had arisen at Athens between the rich creditors and their poor debtors, Solon was created archon, with the united powers of supreme legislator and magistrate. He soon restored harmony between the rich and poor: He cancelled the debts which had proved the occasion of so much oppression; and ordained that in future no creditor should be allowed to seize the body of the debtor for his security: He made a new distribution of the people, instituted new courts of judicature, and framed a judicious code of laws, which afterwards became the basis of the laws of the twelve tables in Rome. Among his criminal laws are many wise and excellent regulations; but the code is necessarily defective with respect to those principles which must be derived from the knowledge of the true God, and of pure morality, as the certain foundations of national happiness. Two of them in particular were very exceptionable; the permission of a voluntary exile to persons that had been guilty of premeditated murder, and the appointment of a less severe punishment for a rape than for seduction. Those who wish to see accurately stated the comparative excellence of the laws of Moses, of Lycurgus, and Solon, may consult Prize Dissertations relative to Natural and Revealed Religion by Teyler's Theological Society, vol. ix.

The interview which Solon is said to have had with Crœsus king of Lydia; the solid remarks of the sage after surveying the monarch's wealth; the recollection of those remarks by Crœsus when doomed to die, and the noble conduct of Cyrus on that occasion, are known to every schoolboy. Solon died in the island of Cyprus about the 80th year of his age. Statues were erected to his memory both at Athens and Salamis. His thirst after knowledge continued to the last: "I grow old (said he) learning many things." Among the apophthegms and precepts which have been ascribed to Solon, are the following: Laws are like cobwebs, that entangle the weak, but are broken through by the strong. He who has learned to obey, will known how to command. In all things let reason be your guide. Diligently contemplate excellent things. In every thing that you do, consider the end.

SOLSTICE, in *Astronomy*, that time when the sun is in one of the solstitial points; that is, when he is at his greatest distance from the equator; thus called because he then appears to stand still, and not to change his distance from the equator for some time; an appearance owing to the obliquity of our sphere, and which those living under the equator are strangers to.

The solstices are two in each year; the æstival or summer solstice, and the hyemal or winter solstice. The summer solstice is when the sun seems to describe the tropic of cancer, which is on June 22. when he makes the longest day: the winter solstice is when the sun enters the first degree, or seems to describe the tropic of capricorn, which is on December 22. when he makes the shortest day. This is to be understood as in our northern hemisphere; for in the southern, the sun's entrance

trance into capricorn makes the summer solstice, and that into cancer the winter solstice. The two points of the ecliptic, wherein the sun's greatest ascent above the equator, and his descent below it, are terminated, are called the *solstitial points;* and a circle, supposed to pass through the poles of the world and these points, is called the *solstitial colure.* The summer solstitial point is in the beginning of the first degree of cancer; and is called the *æstival* or *summer point;* and the winter solstitial point is in the beginning of the first degree of capricorn, and is called the *winter point.* These two points are diametrically opposite to each other.

SOLUTION, in *Chemistry*, denotes an intimate union of solid with fluid bodies, so as to form a transparent liquor. See CHEMISTRY *passim.*

SOLVENT, that which dissolves a solid body into a transparent fluid.

SOLWAY MOSS. See *Moving Moss.*

SOMBRERO, the name of an uninhabited island in the West Indies in the form of a hat, whence the name is derived. It is also the name of one of the Nicobar islands in the East Indies.

Wonderful Plant of SOMBRERO, is a strange kind of sensitive plant growing in the East Indies, in sandy bays and in shallow water. It appears like a slender straight stick; but when you attempt to touch it, immediately withdraws itself into the sand. Mr Miller gives an account of it in his description of Sumatra. He says, the Malays call it *lolan lout*, that is, sea grass. He never could observe any tentacula; but, after many unsuccessful attempts, drew out a broken piece about a foot long. It was perfectly straight and uniform, and resembled a worm drawn over a knitting needle. When dry it appears like a coral.

Philosophical Transactions, vol. lxviii. p. 13.

SOMERS, JOHN, lord high chancellor of England, was born at Worcester in 1652. He was educated at Oxford, and afterwards entered himself at the Middle-Temple, where he studied the law with great vigour. In 1688 he was one of the counsel for the seven bishops at their trial, and argued with great learning and eloquence against the dispensing power. In the convention which met by the prince of Orange's summons, January 22. 1689, he represented Worcester; and was one of the managers for the House of Commons, at a conference with the House of Lords upon the word *abdicated.* Soon after the accession of King William and Queen Mary to the throne, he was appointed solicitor-general, and received the honour of knighthood. In 1692 he was made attorney-general, and in 1693 advanced to the post of lord keeper of the great seal of England. In 1695 he proposed an expedient to prevent the practice of clipping the coin. In 1697 he was created Lord Somers, baron of Evesham, and made lord high chancellor of England. In the beginning of 1700 he was removed from his post of lord chancellor, and the year after was impeached of high crimes and misdemeanors by the House of Commons, of which he was acquitted upon trial by the House of Lords. He then retired to a studious course of life, and was chosen president of the Royal Society. In 1706 he proposed a bill for the regulation of the law; and the same year was one of the principal managers for the union between England and Scotland. In 1708 he was made lord president of the council; from which post he was removed in 1710, upon the change of the ministry. In the latter end of Queen Anne's reign his lordship grew very infirm in his health; which is supposed to be the reason that he held no other post than a seat at the council-table, after the accession of King George I. He died of an apoplectic fit in 1716. Mr Addison has drawn his character very beautifully in the Freeholder.

SOMERSETSHIRE, a county of England, taking its name from Somerton, once the capital, between 50° and 51° 27′ north latitude, and between 1° 25′ and 2° 59′ west longitude. It is bounded on the west by Devonshire, on the south by Dorsetshire, on the north by Bristol channel or the Severn sea, on the north-east by a small part of Gloucestershire, and on the east by Wiltshire. It is one of the largest counties in England, extending in length from east to west about 68 miles; in breadth, from south to north, about 47; and 240 in circumference. It is divided into 42 hundreds, in which are 3 cities, 32 market-towns, 1700 villages, 385 parishes, of which 132 are vicarages, containing more than 1,000,000 of acres, and in 1811 there were 303,180 souls. It sends 18 members to parliament, viz. two for the county, two for Bristol, two for Bath, two for Wells, two for Taunton, two for Bridgewater, two for Ilchester, two for Milbourn-port, and two for Minehead.

The air of this county is very mild and wholesome, especially that of the hilly part. The soil in general is exceeding rich, so that single acres very commonly produce forty or fifty bushels of wheat, and there have been instances of some producing sixty of barley. As there is very fine pasture both for sheep and black cattle, it abounds in both, which are as large as those of Lincolnshire, and their flesh of a finer grain. In consequence of this abundance of black cattle, great quantities of cheese are made in it, of which that of Cheddar is thought equal to Parmesan. In the hilly parts are found coal, lead, copper, and lapis calaminaris. Wood thrives in it as well as in any county of the kingdom. It abounds also in pease, beans, beer, cyder, fruit, wild-fowl, and salmon; and its mineral waters are celebrated all over the world.

The riches of this county, both natural and acquired, exceed those of any other in the kingdom, Middlesex and Yorkshire excepted. The woollen manufacture in all its branches is carried on to a very great extent; and in some parts of the county great quantities of linen are made. If to these the produce of various other commodities in which it abounds is added, the amount of the whole must undoubtedly be very great. Its foreign trade must also be very extensive; it has a large trade for sea-coal, and possesses, besides other ports, that of Bristol, a town of the greatest trade in England, next to London and Liverpool.

Besides small streams, it is well watered and supplied with fish by the rivers Severn, Avon, Parrel, Froome, Ax, Torre, and Tone. Its greatest hills are Mendip, Pouldon, and Quantock, of which the first abounds in coal, lead, &c. The rivers Severn and Parrel breed very fine salmon. The chief town is Bristol. See SOMERSETSHIRE, SUPPLEMENT.

SOMERTON, an ancient town in Somersetshire, from whence the county derives its name. It is 123 miles from London; it has five streets, containing 251 houses, which are mostly built of the blue stone from the quarries in the neighbourhood. It is governed by constables, and has a hall for petty sessions. The market for corn is considerable, and it has several fairs for cattle. The church has, what is not very frequent, an *octangular* tower with six bells. It contained 1478 inhabitants in 1811. N. Lat. 51. 4. W. Long. 1. 53.

SOMME, a department in the north-west of France, comprising the greater part of the ancient Picardy. The soil yields corn, flax, hemp, legumes, and excellent pasturage, but no vines or maize. Sheep are pretty numerous. The manufactures are, especially those of woollens, among the most extensive in France. The territorial extent is 604,456 hectares, and the population in 1817 was 495,058. Amiens is the chief town.

SOMNAMBULI, persons who walk in their sleep. See SLEEPWALKERS.

SOMNER, WILLIAM, an eminent English antiquary, was born at Canterbury in 1606. His first treatise was The Antiquities of Canterbury, which he dedicated to Archbishop Laud. He then applied himself to the study of the Saxon language; and having made himself master of it, he perceived that the old glossary prefixed to Sir Roger Twisden's edition of the laws of King Henry I. printed in 1644, was faulty in many places; he therefore added to that edition notes and observations valuable for their learning, with a very useful glossary. His Treatise of Gavelkind was finished about 1648, though not published till 1660. Our author was zealously attached to King Charles I.; and in 1648 he published a poem on his sufferings and death. His skill in the Saxon tongue led him to inquire into most of the European languages ancient and modern. He assisted Dugdale and Dodsworth in compiling the *Monasticon Anglicanum*. His Saxon Dictionary was printed at Oxford in 1659. He died in 1669.

SON, an appellation given to a male child considered in the relation he bears to his parents. See PARENT and FILIAL *Piety*.

SONATA, in *Music*, a piece or composition, intended to be performed by instruments only; in which sense it stands opposed to *cantata*, or a piece designed for the voice. See CANTATA.

The sonata then, is properly a grand, free, humorous composition, diversified with a great variety of motions and expressions, extraordinary and bold strokes, figures, &c. And all this purely according to the fancy of the composer; who, without confining himself to any general rules of counterpoint, or to any fixed number or measure, gives a loose to his genius, and runs from one mode, measure, &c. to another, as he thinks fit. This species of composition had its rise about the middle of the 17th century; those who have most excelled in it were Bassani and Corelli. We have sonatas of 1, 2, 3, 4, 5, 6, 7, and even 8 parts, but usually they are performed by a single violin, or with two violins, and a thorough bass for the harpsichord; and frequently a more figured bass for the bass viol, &c.

There are a thousand different species of sonatas; but the Italians usually reduce them to two kinds. *Suonate de chiesa*, that is, sonatas proper for church music, which usually begin with a grave solemn motion, suitable to the dignity and sanctity of the place and the service, after which they strike into a brisker, gayer, and richer manner. These are what they more peculiarly call sonatas. *Suonate de camera*, or sonatas for the chamber, are properly serieses of several little pieces, for dancing, only composed to the same tune.

They usually begin with a prelude or little sonata, serving as an introduction to all the rest: afterwards come the allemand, pavane, courant, and other serious dances; then jigs, gavots, minutes, chacons, passecailles, and other gayer airs: the whole composed in the same tune or mode.

SONCHUS, SOW-THISTLE, in *Botany*, a genus of plants belonging to the class of *syngenesia*, and to the order of *polygamia æqualis*. There are 13 species; four of these are natives of Britain.—1. *Palustris*, marsh sow-thistle. The stem is erect, from six to ten feet high, branched and hairy towards the top: the leaves are firm, broad, half pinnated, serrated, and sharp-pointed; the lower ones sagittate at the base: the flowers are of a deep yellow, large, and dispersed on the tops of the branches: the calyx is rough. It is frequent in marshes, and flowers in July or August.—2. *Arvensis*, corn sow-thistle. The leaves are alternate, runcinate, and heart-shaped at the base; the root creeps under ground; the stem is three or four feet high, and branched at the top. It grows in corn-fields, and flowers in August.—3. *Oleraceus*, common sow-thistle. The stalk is succulent, pistular, and a cubit high or more; the leaves are broad, embracing the stem, generally deeply sinuated, smooth, or prickly at the edges; the flowers are of a pale yellow, numerous, in a kind of umbel, and terminal; the calyx is smooth. It is frequent in waste places and cultivated grounds.—4. *Alpinus*, blue-flowered sow-thistle. The stem is erect, purplish, branched, or simple, from three to six feet high: the leaves are large, smooth, and sinuated; the extreme segment large and triangular: the flowers are blue, and grow on hairy viscid pedicles, in long spikes: the calyx is brown. This species is found in Northumberland.

SONG, in *Poetry*, a little composition, consisting of easy and natural verses, set to a tune in order to be sung. See POETRY, N° 120.

SONG, in *Music*, is applied in general to a single piece of music, whether contrived for the voice or an instrument. See AIR.

SONG of Birds, is defined by the honourable Daines Barrington to be a succession of three or more different notes, which are continued without interruption, during the same interval, with a musical bar of four crotchets in an adagio movement, or whilst a pendulum swings four seconds.

It is affirmed, that the notes of birds are no more innate than language in man, and that they depend upon imitation, as far as their organs will enable them to imitate the sounds which they have frequent opportunities of hearing: and their adhering so steadily, even in a wild state, to the same song, is owing to the nestlings attending only to the instruction of the parent bird, whilst they disregard the notes of all others that may perhaps be singing round them.

Birds in a wild state do not commonly sing above 10 weeks in the year, whereas birds that have plenty of food in a cage sing the greatest part of the year; and we may add, that the female of no species of birds ever sings. This is a wise provision of nature, because her song would discover her nest. In the same manner, we may rationally account for her inferiority in plumage. The faculty of singing is confined to the cock birds; and accordingly Mr Hunter, in dissecting birds of several species, found the muscles of the larynx to be stronger

stronger in the nightingale than in any other bird of the same size; and in all those instances where he dissected both cock and hen, the same muscles were stronger in the cock. To the same purpose, it is an observation as ancient as the time of Pliny, that a capon does not crow.

Some have ascribed the singing of the cock-bird in the spring solely to the motive of pleasing his mate during incubation; others, who allow that it is partly for this end, believe it is partly owing also to another cause, viz. the great abundance of plants and insects in the spring, which, as well as seeds, are the proper food of singing birds at that time of the year.

Mr Barrington remarks, that there is no instance of any singing bird which exceeds our blackbird in size; and this, he supposes, may arise from the difficulty of its concealing itself, if it called the attention of its enemies, not only by its bulk, but by the proportionable loudness of its notes. This writer farther observes, that some passages of the song in a few kinds of birds correspond with the intervals of our musical scale, of which the cuckoo is a striking and known instance; but the greater part of their song cannot be reduced to a musical scale; partly, because the rapidity is often so great, and it is also so uncertain when they may stop, that we cannot reduce the passages to form a musical bar in any time whatsoever; partly also, because the pitch of most birds is considerably higher than the most shrill notes of those instruments which have the greatest compass; and principally, because the intervals used by birds are commonly so minute, that we cannot judge of them from the more gross intervals into which we divide our musical octave. This writer apprehends, that all birds sing in the same key; and in order to discover this key, he informs us, that the following notes have been observed in different birds, A, B flat, C, D, F, and G; and therefore E only is wanting to complete the scale: now these intervals, he says, can only be found in the key of F with a sharp third, or that of G with a flat third; and he supposes it to be the latter, because admitting that the first musical notes were learned from birds, those of the cuckoo, which have been most attended to, form a flat third, and most of our compositions are in a flat third, where music is simple, and consists merely of melody. As a farther evidence that birds sing always in the same key, it has been found by attending to a nightingale, as well as a robin which was educated under him, that the notes reducible to our intervals of the octave were always precisely the same.

Most people, who have not attended to the notes of birds, suppose, that every species sing exactly the same notes and passages: but this is by no means true; though it is admitted that there is a general resemblance. Thus the London bird-catchers prefer the song of the Kentish goldfinches, and Essex chaffinches; and some of the nightingale fanciers prefer a Surrey bird to those of Middlesex.

Of all singing birds, the song of the nightingale has been most universally admired: and its superiority (deduced from a cage-bird) consists in the following particulars; its tone is much more mellow than that of any other bird, though at the same time, by a proper exertion of its musical powers, it can be very brilliant. Another point of superiority is its continuance of song without a pause, which is sometimes no less than 20 seconds; and when respiration becomes necessary, it takes it with as much judgment as an opera singer. The sky-lark in this particular, as well as in compass and variety, is only second to the nightingale. The nightingale also sings (if the expression may be allowed) with superior judgement and taste. Mr Barrington has observed, that his nightingale, which was a very capital bird, began softly like the ancient orators, reserving its breath to swell certain notes, which by these means had a most astonishing effect. This writer adds, that the notes of birds, which are annually imported from Asia, Africa, and America, both singly and in concert, are not to be compared to those of European birds.

The following table, formed by Mr Barrington, agreeably to the idea of M. de Piles in estimating the merits of painters, is designed to exhibit the comparative merit of the British singing birds; in which 20 is supposed to be the point of absolute perfection.

SONNA, a book of Mahometan traditions, which the orthodox mussulmans are required to believe.

SONNERATIA, a genus of plants belonging to the class of *icosandria*, and to the order of *monogynia*. See Botany *Index*.

SONNET, in *Poetry*, a composition contained in 14 verses, viz. two stanzas or measures of four verses each, and two of three, the first eight verses being all in three rhimes.

SONNITES, among the Mahometans, an appellation given to the orthodox mussulmans or true believers; in opposition to the several heretical sects, particularly the Shiites, or followers of Ali.

SOOJU, or Soy. See Dolichos.

SOONTABURDAR, in the East Indies; an attendant, who carries a silver bludgeon in his hand about two or three feet long, and runs before the palanquin. He is inferior to the chubdar; the propriety of an Indian newaury requiring two soontaburdars for every chubdar in the train. The chubdar proclaims the approach of visitors, &c. He generally carries a large silver

ver staff about five feet long in his hands; and among the Nabobs he proclaims their praises aloud as he runs before their palanquins.

SOOT, a volatile matter arising from wood and other fuel along with the smoke; or rather, it is the smoke itself condensed and gathered to the sides of the chimney. Though once volatile, however, soot cannot be again resolved into vapour; but, if distilled by a strong fire, yields a volatile alkali and empyreumatic oil, a considerable quantity of fixed matter remaining at the bottom of the distilling vessel. If burnt in an open fire, it flames with a thick smoke, whence other soot is produced. It is used as a material for making sal ammoniac, and as a manure. See AMMONIA, *muriate of*, CHEMISTRY *Index*.

Soot-Black. See *Colour-Making*.

SOPHI, or SOFI, a title given to the emperor of Persia, importing as much as wise, sage, or philosopher.

The title is by some said to have taken its rise from a young shepherd named *Sophi*, who attained to the crown of Persia in 1370; others derive it from the *sophoi* or sages anciently called *magi*. Vossius gives a different account of the word: sophi in Arabic, he observes, signifies *wool;* and he adds, that it was applied by the Turks out of derision to the kings of Persia ever since Ishmael's time; because, according to their scheme of religion, he is to wear no other covering on his head but an ordinary red woollen stuff; whence the Persians are also called *hezelbaschs*, q. d. *red-heads.* But Bochart assures us, that sophi in the original Persian language, signifies one that is pure in his religion, and who prefers the service of God in all things: and derives it from an order of religious called by the same name. The sophis value themselves on their illustrious extraction. They are descended in a right line from Houssein, second son of Ali, Mahomet's cousin, and Fatima, Mahomet's daughter.

SOPHIS, or *Sofees*, a kind of order of religious among the Mahometans in Persia, answering to what are otherwise called *dervises*, and among the Arabs and Indians *faquirs*. Some will have them called sophis from a kind of coarse camblet which they wear, called *souf*, from the city Souf in Syria, where it is principally manufactured. The more eminent of those sophis are complimented with the title *schiek*, that is, *reverend*, much as in Romish countries the religious are called *reverend fathers*. Schiek Sophi, who laid the foundation of the grandeur of the royal house of Persia, was the founder, or rather the restorer of this order: Ishmael, who conquered Persia, was himself a sophi, and greatly valued himself on his being so. He chose all the guards of his person from among the religious of this order; and would have all the great lords of his court sophis. The king of Persia is still grandmaster of the order; and the lords continue to enter into it, though it be now fallen under some contempt.

SOPHISM, in *Logic*, a specious argument having the appearance of truth, but leading to falsehood. Sophisms are reduced by Aristotle into eight classes, an arrangement so just and comprehensive, that it is equally proper in present as in former times. 1. *Ignoratio elenchi*, in which the sophist seems to determine the question, while he does it only in appearance. Thus the question, "Whether the excess of wine be hurtful?" seems to be determined by proving, that wine revives the spirits and gives a man courage: but the principal point is here kept out of sight; for still it may be hurtful to health, to fortune, and reputation. 2. *Petitio principii*, a begging of the question, or taking for granted that which remains to be proved, as if any one should undertake to prove that the soul is extended through all the parts of the body, because it resides in every member. This is affirming the same thing in different words. 3. Reasoning in a circle; as when the Roman Catholics prove the Scriptures to be the word of God by the authority of the church, and the authority of the church from the Scriptures. 4. *Non causa pro causa*, or the assigning of a false cause to any effect. Thus the supposed principle, that nature abhors a vacuum, was applied to explain the rising of water in a pump before Galileo discovered that it was owing to the pressure of the atmosphere. In this way the vulgar ascribe accidents to divine vengeance, and the heresies and infidelity of modern times are said to be owing to learning. 5. *Fallacia accidentis*, in which the sophist represents what is merely accidental as essential to the nature of the subject. This is nearly allied to the former, and is committed by the Mahometans and Roman Catholics. The Mahometans forbid wine, because it is sometimes the occasion of drunkenness and quarrels; and the Roman Catholics prohibit the reading of the Bible, because it has sometimes promoted heresies. 6. By deducing an universal assertion from what is true only in particular circumstances, and the reverse: thus some men argue, "transcribers have committed many errors in copying the Scriptures, therefore they are not to be depended on." 7. By asserting any thing in a compound sense which is only true in a divided sense; so when the Scriptures assure us, that the worst of sinners may be saved, it does not mean that they shall be saved while they remain sinners, but that if they repent they may be saved. 8. By an abuse of the ambiguity of words. Thus Mr Hume reasons in his Essay on Miracles: "Experience is our only guide in reasoning concerning matters of fact; now we know from experience, that the laws of nature are fixed and invariable. On the other hand, testimony is variable and often false; therefore since our evidence for the reality of miracles rests solely on testimony which is variable, and our evidence for the uniformity of the laws of nature is invariable, miracles are not to be believed." The sophistry of this reasoning depends on the ambiguity of the word *experience*, which in the first proposition signifies the maxims which we form from our own observation and reflection; in the second it is confounded with testimony; for it is by the testimony of others, as well as our own observation, that we learn whether the laws of nature are variable or invariable. The Essay on Miracles may be recommended to those who wish to see more examples of sophistry; as we believe most of the eight species of sophisms which we have mentioned are well illustrated by examples in that essay.

SOPHIST, an appellation assumed in the early periods of Grecian history by those who devoted their time to the study of science. This appellation appearing too arrogant to Pythagoras, he declined it, and wished to be called a *philosopher;* declaring that, though he could not consider himself as a wise man, he was indeed a lover of wisdom. True wisdom and modesty are generally

generally united. The example of Pythagoras was followed by every man of eminence; while the name *sophist* was retained only by those who with a pomp of words made a magnificent display of wisdom upon a very slight foundation of knowledge. Those men taught an artificial structure of language, and a false method of reasoning, by which, in argument, the worse might be made to appear the better reason (see SOPHISM). In Athens they were long held in high repute, and supported, not only by contributions from their pupils, but by a regular salary from the state. They were among the bitterest enemies of the illustrious Socrates, because he embraced every opportunity of exposing to contempt and ridicule their vain pretensions to superior knowledge, and the pernicious influence of their doctrines upon the taste and morals of the Athenian youth.

SOPHISTICATION, the mixing of any thing with what is not genuine; a practice too common in the making up of medicines for sale; as also among vintners, distillers, and others, who are accused of sophisticating their wines, spirits, oils, &c. by mixing with them cheaper and coarser materials; and in many cases the cheat is carried on so artfully as to deceive the best judges.

SOPHOCLES, the celebrated Greek tragic poet, the son of Sophilus an Athenian, was born at Colonos, and educated with great attention. Superior vigour and address in the exercises of the palestra, and skill in music, were the great accomplishments of young men in the states of Greece. In these, Sophocles excelled; nor was he less distinguished by the beauty of his person. He was also instructed in the noblest of all sciences, civil polity and religion: from the first of these he derived an unshaken love of his country, which he served in some embassies, and in high military command with Pericles; from the latter he was impressed with a pious reverence for the gods, manifested by the inviolable integrity of his life. But his studies were early devoted to the tragic muse; the spirit of Eschylus lent a fire to his genius, and excited that noble emulation which led him to contend with, and sometimes to bear away the prize from, his great master. He wrote 43 tragedies, of which 7 only have escaped the ravages of time: and having testified his love of his country by refusing to leave it, though invited by many kings; and having enjoyed the uninterrupted esteem and affection of his fellow citizens, which neither the gallant actions and sublime genius of Eschylus, nor the tender spirit and philosophic virtue of Euripides, could secure to them, he died in the 91st year of his age, about 406 years before Christ. The burial-place of his ancestors was at Decelia, which the Lacedæmonians had at that time seized and fortified: by Lysander, the Spartan chief, permitted the Athenians to inter their deceased poet; and they paid him all the honours due to his love of his country, integrity of life, and high poetic excellence. Eschylus had at once seized the highest post of honour in the field of poetry, the true sublime; to that eminence his claim could not be disputed. Sophocles had a noble elevation of mind, but tempered with so fine a taste, and so chastened a judgment, that he never passed the bounds of propriety. Under his conduct the tragic muse appeared with the chaste dignity of some noble matron at a religious solemnity; harmony is in her voice, and grace in all her motions. From him the theatre received some additional embellishments; and the drama the introduction of a third speaker, which made it more active and interesting: but his distinguished excellence is in the judicious disposition of the fable, and so nice a connection and dependence of the parts on each other, that they all agree to make the event not only probable, but even necessary. This is peculiarly admirable in his "Oedipus King of Thebes;" and in this important point he is far superior to every other dramatic writer.

The ingratitude of the children of Sophocles is well known. They wished to become immediate masters of their father's possessions; and therefore tired of his long life, they accused him before the Areopagus of insanity. The only defence the poet made was to read his tragedy of Oedipus at Colonos, which he had lately finished; and then he asked his judges, whether the author of such a performance could be taxed with insanity! The father upon this was acquitted, and the children returned home covered with shame and confusion. The seven tragedies of Sophocles which still remain, together with the Greek Scholia which accompany them, have been translated into Latin by Johnson, and into English by Dr Franklin and Mr Potter.

SOPHORA, a genus of plants belonging to the class of decandria, and to the order of monogynia; and in the natural system arranged under the 32d order, *Papilionaceæ*. See BOTANY *Index*.

SOPORIFIC, or SOPORIFEROUS, a medicine that produces sleep. Such are opium, laudanum, the seed of poppies, &c. The word is formed from the Latin *sopor*, "sleep." The Greeks in place of it use the word *hypnotic*.

SORBONNE, or SORBON, the house or college of the faculty of theology established in the university of Paris. It was founded in 1252 by St Louis, or rather by Robert de Sorbon his confessor and almoner, first canon of Cambray, and afterwards of the church of Paris; who gave his own name to it, which he himself took from the village of Sorbon or Serbon, near Sens, where he was born. The foundation was laid in 1250; Queen Blanche, in the absence of her husband, furnishing him with a house which had formerly been the palace of Julian the apostate, of which some remains are still seen. Afterwards the king gave him all the houses he had in the same place, in exchange for some others. The college has been since magnificently rebuilt by the cardinal de Richelieu. The design of its institution was for the use of poor students in divinity. There are lodgings in it for 36 doctors, who are said to be of the *society of the Sorbonne*; those admitted into it without being doctors, are said to be of the *hospitality of the Sorbonne*. Six regent doctors formerly held lectures every day for an hour and a half each; three in the morning, and three in the afternoon.

SORBONNE, is also used in general for the whole faculty of theology at Paris; as the assemblies of the whole body are held in the house of the Sorbonne; and the bachelors of the other houses of the faculty, as the house of Navarre, &c. come hither to hold their *sorbonnique*, or act for being admitted doctor in divinity.

SORBUS, SERVICE-TREE, a genus of plants belonging to the class of icosandria, and to the order of trigynia. See BOTANY *Index*.—The *aucuparia*, mountain-ash, quicken-tree, quick-beam, or roan tree, rises with

Sorbus, Sorcery.

a straight upright stem and regular branching head, twenty or thirty feet high or more, covered with a smooth grayish brown bark; pinnated leaves of eight or ten pair of long, narrow, serrated folioles, and an odd one, smooth on both sides; and large umbellate clusters of white flowers at the sides and ends of the branches, succeeded by clusters of fine red berries, ripe in autumn and winter. There is a variety with yellow striped leaves. This species grows wild in many parts of this island, in mountainous places, woods, and hedge-rows, often growing to the size of timber; and is admitted into most ornamental plantations, for the beauty of its growth, foliage, flowers, and fruit; the latter, in particular, being produced in numerous red large bunches all over the tree, exhibit a fine appearance in autumn and winter, till devoured by the birds, especially the blackbird and thrush, which are so allured by this fruit as to flock from all parts and feed on it voraciously.—In the island of Jura the juice of the berries is employed as an acid for punch. It is probable that this tree was in high esteem with the Druids; for it is more abundant than any other tree in the neighbourhood of those Druidical circles of stones, so common in North Britain. It is still believed by some persons, that a branch of this tree can defend them from enchantment or witchcraft. Even the cattle are supposed to be preserved by it from danger. The dairy-maid drives them to the summer pastures with a rod of the roan-tree, and drives them home again with the same. In Strathspey, we are told, a hoop is made of the wood of this tree on the 1st of May, and all the sheep and lambs are made to pass through it.

The *domestica*, or cultivated service-tree, with eatable fruit, grows with an upright stem, branching 30 or 40 feet high or more, having a brownish bark, and the young shoots in summer covered with a mealy down; pinnated leaves of eight or ten pair of broadish deeply serrated lobes and an odd one, downy underneath; and, large umbellate clusters of white flowers at the sides and ends of the branches, succeeded by bunches of large, fleshy, edible red fruit, of various shapes and sizes. This tree is a native of the southern warm parts of Europe, where its fruit is used at table as a dessert, and it is cultivated here in many of our gardens, both as a fruit-tree and as an ornament to diversify hardy plantations.

SORCERY, or MAGIC; the power which some persons were formerly supposed to possess of commanding the devil and the infernal spirits by skill in charms and invocations, and of soothing them by fumigations. Sorcery is therefore to be distinguished from witchcraft; an art which was supposed to be practised, not by commanding evil spirits, but by compact with the devil. As an instance of the power of bad smells over dæmons or evil spirits, we may mention the flight of the evil spirit mentioned in Tobit into the remote parts of Egypt, produced, it is said, by the smell of the burnt liver of a fish. Lilly informs us, that one Evans having raised a spirit at the request of Lord Bothwell and Sir Kenelm Digby, and forgetting a fumigation, the spirit, vexed at the disappointment, pulled him without the circle, and carried him from his house in the Minories into a field near Battersea Causeway.

King James, in his *Dæmonologia*, has given a very full account of the art of sorcery. "Two principal things (says he) cannot well in that errand be wanted: holy water (whereby the devill mockes the papists), and some present of a living thing unto him. There are likewise certaine daies and houres that they observe in this purpose. These things being all ready and prepared, circles are made, triangular, quadrangular, round, double, or single, according to the forme of the apparition they crave. When the conjured spirit appeares, which will not be while after many circumstances, long prayers, and much muttering and murmurings of the conjurors, like a papist priest dispatching a hunting masse—how soone, I say, he appeares, if they have missed one jote of all their rites; or if any of their feete once slyd over the circle, through terror of his fearfull apparition, he paies himself at that time, in his owne hand, of that due debt which they ought him, and otherwise would have delaide longer to have paied him: I mean, he carries them with him, body and soule." How the conjurors made triangular or quadrangular circles, his majesty has not informed us, nor does he seem to imagine there was any difficulty in the matter. We are therefore led to suppose, that he learned his mathematics from the same system as Dr Sacheverell, who, in one of his speeches or sermons, made use of the following simile: "They concur like parallel lines, meeting in one common centre."

Another mode of consulting spirits was by the beryl, by means of a speculator or seer; who, to have a complete sight, ought to be a pure virgin, a youth who had not known woman, or at least a person of irreproachable life and purity of manners. The method of such consultation is this: The conjuror having repeated the necessary charms and adjurations, with the litany or invocation peculiar to the spirits or angels he wishes to call (for every one has his particular form), the seer looks into a crystal or beryl, wherein he will see the answer, represented either by types or figures; and sometimes, though very rarely, will hear the angels or spirits speak articulately. Their pronunciation is, as Lilly says, like the Irish, much in the throat. Lilly describes one of these beryls or crystals. It was, he says, as large as an orange, set in silver, with a cross at the top, and round about engraved the names of the angels Raphael, Gabriel, and Uriel. A delineation of another is engraved in the frontispiece to Aubery's Miscellanies.

These sorcerers or magicians do not always employ their art to do mischief; but, on the contrary, frequently exert it to cure diseases inflicted by witches; to discover thieves; recover stolen goods; to foretel future events, and the state of absent friends. On this account they are frequently called *white witches*. See MAGIC, WITCHCRAFT, &c.

Our forefathers were strong believers when they enacted, by statute 33 Hen. VIII. c. 8. all witchcraft and sorcery to be felony without benefit of clergy; and again, by statute 1 Jac. I. c. 12. that all persons invoking any evil spirit, or consulting, covenanting with, entertaining, employing, feeding, or rewarding any evil spirit; or taking up dead bodies from their graves to be used in any witchcraft, sorcery, charm, or enchantment; or killing or otherwise hurting any person by such infernal arts; should be guilty of felony without benefit of clergy, and suffer death. And if any person should attempt by sorcery to discover hidden treasure, or or to restore stolen goods, or to provoke unlawful love, or to hurt any man or beast, though the same were not effected, he or she should suffer imprisonment and pillory for the first offence, and death for the second. These acts continued in force till lately, to the terror of all ancient females in the kingdom; and many poor wretches were sacrificed thereby to the prejudice of their neighbours and their own illusions, not a few having by some means or other confessed the fact at the gallows. But all executions for this dubious crime are now at an end; our legislature having at length followed the wise example of Louis XIV. in France, who thought proper by an edict to restrain the tribunals of justice from receiving informations of witchcraft. And accordingly it is with us enacted, by statute 9 Geo. II. c. 5. that no prosecution shall for the future be carried on against any person for conjuration, witchcraft, sorcery, or inchantment: But the misdemeanor of persons pretending to use witchcraft, tell fortunes, or discover stolen goods, by skill in the occult sciences, is still deservedly punished with a year's imprisonment, and standing four times in the pillory.

SOREX, the SHREW, a genus of animals belonging to the class of *mammalia*, and order of *feræ*. See MAMMALIA *Index*.

SORITES, in *Logic*, a species of reasoning in which a great number of propositions are so linked together, that the predicate of the one becomes continually the subject of the next following, till at last a conclusion is formed by bringing together the subject of the first proposition and the predicate of the last. Such was that merry argument of Themistocles, to prove that his little son under ten years old governed the whole world. Thus: *My son governs his mother; his mother me; I the Athenians; the Athenians the Greeks; Greece commands Europe; Europe the whole world: therefore my son commands the whole world.* See LOGIC, N° 96, 97.

SORNING, in *Scots Law*. See LAW, N° clxxxvi. 30.

SORREL, in *Botany*, a species of the RUMEX, which grows in pastures and meadows, and is well known. The natives of Lapland boil large quantities of the leaves in water, and mix the juice when cold with the milk of the rein-deer, which they esteem an agreeable and wholesome food. The Dutch are said to cultivate this plant for its usefulness in the dyeing of woollen cloths black; and we know that by means of the common broad-leaved sorrel an excellent black colour is, in many places of Scotland, given to woollen stuffs without the aid of copperas. As this mode of dyeing does not in the smallest degree injure the texture of the cloth, which continues to the last soft and silky, without that hardness to the touch which it acquires when dyed black by means of copperas, our readers will probably thank us for the following receipt, with which we have been favoured by a learned physician:

Let the stuff to be dyed be well washed with soap and water, and afterwards completely dried. Then of the common broad-leaved sorrel boil as much as shall make an acid decoction of sufficient quantity to let the stuff to be dyed lie in it open and easy to be stirred. The greater quantity of sorrel that is used, the better will the colour be; and therefore if the pot or cauldron will not hold enough at once, when part has been sufficiently boiled, it must be taken out and wrung, and a fresh quantity be boiled in the same juice or decoction. When the liquor is made sufficiently acid, strain it from the sorrel through a sieve, put the cloth or yarn into it, and let it boil for two hours, stirring it frequently. If stockings be among the stuff to be dyed, it will be expedient, after they have been an hour in the boiling liquor, to turn them inside out, and at the end of the second hour let the whole be poured into a tub or any other vessel. The pot or cauldron must then be washed, and water put into it, with half a pound of logwood chips for every pound of dry yarn or cloth. The logwood and water should boil slowly for four hours; and then the cloth or yarn being wrung from the sour liquor, and put into the logwood decoction, the whole must be suffered to boil slowly for four hours, stockings, if there be any, being turned inside out at the end of two hours. Of this last decoction there must, as of the former, be enough to let the cloth lie open and easy to be stirred while boiling. At the end of the four hours the cloth must be taken out, and among the boiling liquor, first removed from the fire, must be poured a Scotch pint or half an English gallon of stale urine for every pound of dry cloth or other stuff to be dyed. When this compound liquor has been stirred and become cold, the cloth must be put into it and suffered to remain well covered for 12 hours, and then dried in the shade; it is then washed in cold water, and dried for use.

Wood-Sorrel. See OXALIS, BOTANY *Index*.

Sorrel-Colour, in the manege, is a reddish colour, generally thought to be a sign of a good horse.

SORRENTO, sea-port town of Naples; seated in a peninsula, on the bay of Naples, at the foot of a mountain of the same name, and 15 miles south-east of Naples. Sorrentum was famous in ancient times for its beautiful earthen vessels, particularly goblets and drinking cups; and claims the honour of being the birth-place of Torquato Tasso. E. Long. 14. 24. N. Lat. 40. 40.

SORTILEGE, (*Sortilegium*) a species of divination performed by means of *sortes* or lots.

The *sortes Prenestinæ*, famous in antiquity, consisted in putting a number of letters, or even whole words, into an urn; and then, after shaking them together, they were thrown on the ground; and whatever sentences could be made out of them, constituted the answer of the oracle. To this method of divination succeeded that which has been called the *sortes Homerianæ* and *sortes Virgilianæ*, a mode of inquiring into futurity, which undoubtedly took its rise from a general custom of the oracular priests of delivering their answers in verse; it subsisted a long time among the Greeks and Romans; and being from them adopted by the Christians, it was not till after a long succession of centuries that it became exploded. Among the Romans it consisted in opening some celebrated poet at random, and among the Christians the Scriptures, and drawing, from the first passage which presented itself to the eye, a prognostic of what would befal one's self or others, or direction for conduct when under any exigency. There is good evidence that this was none of the vulgar errors; the greatest persons, philosophers of the best repute, admitted this superstition. Socrates, when in prison, hearing this line of Homer,

Within three days I Phthia's shore shall see,

immediately said, within three days I shall be out of the world;

Sortilege.

world; gathering it from the double meaning of the word *Phthia*, which in Greek is both the name of a country and signifies corruption or death. This prediction, addressed to Æschines, was not easily forgotten, as it was verified.

When this superstition passed from Paganism into Christianity, the Christians had two methods of consulting the divine will from the Scriptures; the one, casually, to open the divine writings, and take their direction, as above mentioned; the other, to go to church with a purpose of receiving, as a declaration of the will of heaven, the words of the Scripture, which were singing at the instant of one's entrance.

This unwarrantable practice of inquiring into futurity prevailed very generally in England till the beginning of the 18th century; and sometimes the books of Scripture, and sometimes the poems of Virgil were consulted for oracular responses. One remarkable instance is that of King Charles I. who, being at Oxford during the civil wars, went one day to see the public library, where he was shown, among other books, a Virgil nobly printed and exquisitely bound. The lord Falkland, to divert the king, would have his majesty make a trial of his fortune by the *Sortes Virgilianæ*. Whereupon the king opening the book, the passage which happened to come up was this:

At, bello audacis populi vexatus et armis,
Finibus extorris, complexu avulsus Iuli,
Auxilium imploret; videatque indigna suorum
Funera: nec, cum se sub leges pacis iniquæ
Tradiderat, regno aut optata luce fruatur;
Sed cadat ante diem, mediaque inhumatus arena.
Æneid, lib. iv.

Yet let a race, untamed and haughty foes,
His peaceful entrance with dire arms oppose;
Oppressed with numbers in the unequal field,
His men discouraged, and himself expelled,
Let him for succour sue from place to place,
Torn from his subjects, and his son's embrace:
First let him see his friends in battle slain,
And their untimely fate lament in vain;
And when at length the cruel war shall cease,
On hard conditions may he buy his peace.
Nor let him then enjoy supreme command,
But fall untimely by some hostile hand,
And lie unburied on the barren sand.

Lord Falkland observing that the king was concerned at this accident, would likewise try his own fortune in the same manner, hoping he might fall upon some passage that would have no relation to his case, and thereby divert the king's thoughts from any impression which the other might have upon him; but the place he stumbled upon was as much suited to his destiny as the other had been to the king's; being the lamentation of Evander for the untimely death of his son Pallas*: for this lord's eldest son, a young man of an amiable character, had been slain in the first battle of Newbury.

* Æneid, lib. xi.

We have ourselves known several, whose devotion has not always been regulated by judgment, pursue this method of divination; and have generally observed, that the consequence has been despair or presumption. To such we beg leave to recommend one passage in Scripture which will never disappoint them: *Thou shalt not tempt the Lord thy God.*

Sortilege || Souffriere.

SOTERIA, in antiquity, sacrifices offered to the gods for delivering a person from danger; as also poetical pieces composed for the same purpose.

SOUBISE, a town of France, in the department of Lower Charente, and late territory of Saintonge. It is seated on the river Charente, 22 miles south of Rochelle, in W. Long. 1. 2. N. Lat. 45. 57.

SOUDAN, a kingdom of Africa, situated between 11° and 16° N. Lat. and 26° and 30° E. Long. See DAR FUR.

SOUGH, among miners, denotes a passage dug under ground, to convey off waters from mines. See MINE.

SOVEREIGN, in matters of government, is applied to the supreme magistrate or magistrates of an independent government or state; because their authority is only bounded by the laws of God and the laws of the state: such are kings, princes, &c. See PREROGATIVE, &c.

SOVEREIGN Power, or *Sovereignty*, is the power of making laws; for wherever that power resides, all others must conform to it, and be directed by it, whatever appearance the outward form and administration of the government may put on. For it is at any time in the option of the legislature to alter that form and administration by a new edict or rule, and to put the execution of the laws into whatever hands it pleases: and all the other powers of the state must obey the legislative power in the execution of their several functions, or else the constitution is at an end. In our constitution the law ascribes to the king the attribute of sovereignty: but that is to be understood in a qualified sense, i. e. as supreme magistrate, not as sole legislator; as the legislative power is vested in the king, lords, and commons, not in any of the three estates alone.

SOU. See SOL.

SOUFFRIERE, a small town, situated at the bottom of a bay, near the leeward extremity of the island of St Lucia. Of itself it is not entitled to much notice, but the adjacent ground is very remarkable. The declivities of the surrounding hills are cultivated, and afford sugar-cane of a good quality.

The extremity of the south side of Souffriere bays runs into two steep hills of a conical shape, and nearly perpendicular, reckoned the highest on the island, and known by the appellation of the *Sugar-Loaf Hills*. It is impossible to ascend them; for although it was once attempted by two negroes, it is said that they never returned. Passing the hills to the windward of Souffriere, a fine level country presents itself, extending from 15 to 20 miles from the back of the Sugar-Loaf Hills along the sea coast, being wholly cultivated, and divided into rich estates. It is intersected by numerous rivers of very clear water, which, by art, are made subservient to the purpose of sugar-making. The rains here are less frequent than on any other part of the island, and the wind blows from the sea, or nearly so.

There is a volcano in the vicinity of this town. After passing one or two small hills, the smell of sulphur is sensibly felt before any vestige of the place is perceived. The first thing discerned is a rivulet of black running water, sending forth streams nearly in a state of ebullition, from which the volcano soon comes into view, situated

Solfatara ‖ Sounding.

tuated in a hollow, and surrounded by hills on every side. There are many pits in the hollow, of a black and thick boiling matter, which appears to work with great force. Lava is ejected by slow degrees, and there is a large mass of it in the centre of the hollow, forming a sort of hill. The lava is said to be a sulphur mixed with calcareous earth and some saline body. Small quantities of alum have been found in a perfect state; and there is a rivulet of good water in the opening, at the north side of the hollow. When the bottom of it is stirred, the water is very hot, so much so as not to be touched. The liquid running from the pits is strongly impregnated with sulphur, and very much resembles the preparation sold in the shops, called *aqua sulphurata*.

SOUL, the principle of perception, memory, intelligence, and volition, in man; which, since the earliest era of philosophy, has furnished questions of difficult investigation, and materials of keen and important controversy (see METAPHYSICS, Part III. chap. ii. iii. iv. v.; and RESURRECTION, N° 42—48.). In the 4th volume of the memoirs of the Literary and Philosophical Society of Manchester, the reader will find a very valuable paper by Dr Ferrier, proving by evidence apparently complete, that every part of the brain has been injured without affecting the act of thought. An abridgement of that memoir would weaken its reasoning; which, built on matters of fact and experience, appears to us to have shaken the modern theory of the Materialists from its very foundation.

SOUL of Brutes. See BRUTES.

SOUND, in *Physics*, a term which expresses a simple idea; it is that primary information which we obtain of external things by means of the sense of hearing. See ACOUSTICS.

SOUND, in *Geography*, denotes in general any strait or inlet of the sea between two headlands. It is given by way of eminence to the strait between Sweden and Denmark, joining the German ocean to the Baltic, being about three miles over. See DENMARK, N° 32. and ELSINORE.

SOUND-Board, the principal part of an organ, and that which makes the whole machine play. It is a reservoir into which the wind, drawn in by the bellows, is conducted by a port-vent, and thence distributed into the pipes placed over the holes of its upper part. The wind enters them by valves, which open by pressing on the keys, after the registers are drawn, by which the air is prevented from going into any of the other pipes, besides those in which it is required.

SOUND-Board also denotes a thin broad board placed over the head of a public speaker, to enlarge or extend and strengthen his voice.

Sound-boards are found by experience to be of no use in theatres, as their distance from the speaker is too great to be impressed with sufficient force. But sound-boards over a pulpit have frequently a good effect, when the case is constructed of a proper thickness, and according to particular principles.

SOUND-Post, is a post placed in the inside of a violin, &c. as a prop between the back and belly of the instrument, and nearly under the bridge.

SOUNDING, the operation of trying the depth of the sea, and the nature of the bottom, by means of a plummet sunk from a ship to the bottom.

There are two plummets used for this purpose in navigation; one of which is called the *hand-lead*, weighing about 8 or 9 pounds; and the other the *deep-sea-lead*, which weighs from 25 to 30 pounds; and both are shaped like the frustum of a cone or pyramid. The former is used in shallow waters, and the latter at a great distance from the shore; particularly on approaching the land after a sea voyage. Accordingly the lines employed for this purpose are called the *deep-sea lead-line*, and the *hand lead-line*.

The hand lead-line, which is usually 20 fathoms in length, is marked at every two or three fathoms; so that the depth of the water may be ascertained either in the day or night. At the depth of two or three fathoms there are marks of black leather; at 5 fathoms, there is a white rag; at 7, a red rag; at 10, black leather; at 13, black leather; at 15, a white rag; and at 17, a red ditto.

Sounding with the hand lead, which is called *heaving the lead* by seamen, is generally performed by a man who stands in the main-chains to windward. Having the line quite ready to run out without interruption, he holds it nearly at the distance of a fathom from the plummet; and having swung the latter backwards and forwards three or four times, in order to acquire the greater velocity, he swings it round his head, and thence as far forward as is necessary; so that by the lead's sinking whilst the ship advances, the line may be almost perpendicular when it reaches the bottom. The person sounding then proclaims the depth of the water in a kind of song resembling the cries of hawkers in a city. Thus if the mark of five fathoms is close to the surface of the water, he calls, 'By the mark five!' and as there is no mark at four, six, eight, &c. he estimates those numbers, and calls, By the dip four,' &c. If he judges it to be a quarter or an half more than any particular number, he calls, 'And a quarter five! and a half four,' &c. If he conceives the depth to be three quarters more than a particular number, he calls it a quarter less than the next: thus, at four fathoms and three fourths he calls, 'A quarter less five! and so on.

The deep-sea-lead is marked with two knots at 20 fathoms, three at 30, and 4 at 40, and so on to the end. It is also marked with a single knot in the middle of each interval, as at 25, 35, 45 fathoms, &c. To use this lead more effectually at sea, or in deep water on the sea coast, it is usual previously to bring to the ship, in order to retard her course: the lead is then thrown as far as possible from the ship on the line of her drift, so that, as it sinks, the ship drives more perpendicularly over it. The pilot, feeling the lead strike the bottom, readily discovers the depth of the water by the mark on the line nearest its surface. The bottom of the lead being also well rubbed over with tallow, retains the distinguishing marks of the bottom, as shells, ooze, gravel, &c. which naturally adhere to it.

The depth of the water, and the nature of the ground, which is called the *soundings*, are carefully marked in the log-book, as well to determine the distance of the place from the shore, as to correct the observations of former pilots.

A machine for the same purpose has been invented by Mr Massey, of which the following description is given:

"The importance of obtaining true soundings at sea must

Sounding.

be admitted by every seamen; and it is rather singular, that no other method than the common lead has hitherto been brought into use; as its imperfections are very generally acknowledged.

" Many vessels have been lost, by depending upon the soundings taken in the usual way. The difficulty of obtaining the true perpendicular, and the uncertainty as to the exact moment when the lead strikes the bottom, upon which the accuracy of the result depends, must always prevent the possibility of obtaining the true depth, while the ship has any considerable way upon her. Indeed, it has been acknowledged by experienced seamen, during some experiments, made at various times, in the river Mersey, that they could not depend upon the common lead, when going five or six knots in the hour, in ten or twelve fathoms of water. When the depth is considerable, the vessel must be hove to, which is an operation attended with great loss of time, and sometimes considerable injury to the sails; and during a chase, this inconvenience must be particularly felt.

" True soundings may be taken with this machine in thirty fathoms water, without the trouble of heaving the vessel to, although she may be going at the rate of six miles in the hour. True soundings may also thus be obtained in very deep water, where it is not possible to take them by the common lead.

Plate cccexcvii. fig. 1.

" Fig. 1. represents the sounding machine. *a* is the sounding weight, containing a register, 1, 2, with two dials: the hand of the dial 1 makes one revolution when the weight has descended twenty fathoms, the other revolves once when the descent amounts to five hundred fathoms. A rotator, *b*, similar to that attached to the log, communicates with the wheel work of the dials 1, 2, by means of the rod *c*, on which there are three universal joints, 3, 4, and 5. This rod is supported during the descent of the weight, by the drop, *d*, at the end of which is a fork, 6, and a friction wheel, 7.

" When the machine is to be used, a sounding line is fastened to the ring, *e*; and one of the vanes of the rotator is slipped into the spring 8: the rotator will then be in the position indicated by the dotted lines, *x*. The indices must be set at 0, and the cover or lid, *f*, be shut. The machine must then be projected perpendicularly into the sea. As soon as it reaches the surface, the resistance of the water forces the dotted rotator, *x*, out of the spring 8, and it assumes its perpendicular direction as represented by the rotator *b*. As the machine descends, it is evident the rotator will revolve, and its motion be communicated freely past the friction wheel 7, and the universal joint 5, to the wheel work of the dials 1, 2, and thus indicate the space passed through in fathoms. When the machine has arrived at the bottom, the rotator, as it is no longer buoyed up by the reaction of the water, will fall to the bottom, quitting the fork of the drop *d*, which will also fall from its horizontal position, and in its descent, by means of the locking rod 9, prevent the rotator from revolving as the machine is drawn up. When at the bottom, the rotator will be in the position of the dotted lines *y*.

" This machine, simple in its construction, and scarcely more liable to accident than the common lead, ascertains, with the utmost precision, the perpendicular depth, by the mere act of descent through the water. No mistake can arise from that common source of error, the drift or lee-way of the ship during the time of descent; nor does an operation of such importance depend upon the uncertain sensation caused by the lead striking the bottom, on which the accuracy of the common log altogether depends, and which, it is well known, frequently and materially misleads the best seaman: for though a thousand fathoms of line were laid out, in the smallest depth of water, no inaccuracy could arise, as the perpendicular depth, at the point of heaving, would be registered on the index. The only inconvenience experienced would be the additional labour necessary for hauling in the excess of line. The most inexperienced person may use this machine, without risk of error, in the most turbulent sea, and during the night.

" The advantages already enumerated would render the sounding machine of great importance; but there are other properties of still more consequence.

" To heave a ship to, in order to obtain soundings, on a lee shore, in stormy weather, is a very disagreeable operation, attended with much trouble, and loss of way; also with considerable danger to the ship's sails; indeed, it would often, under such circumstances, be attended with great hazard to the safety of the ship. To avoid these unpleasant consequences, the master sometimes adopts a measure, which he conceives to be the less exceptionable alternative, by running on without sounding at all.

" To prove how much inconvenience and danger are avoided by Massey's lead, it is enough to state, that soundings may be taken in depth from 60 to 80 fathoms, while the ship is under way, at the rate of three miles an hour; and as the rate of sailing may be still materially reduced, without entirely stopping the vessel, or altering her course, so may soundings be had, to any depth required, while she is under way.

" In order more clearly to show the superiority of this machine, and make it apparent, that the quantity of stray-line veered out does not at all affect the truth of the result: suppose the common lead thrown from the mizen chains of the ship, which may be represented by the point *a* of the triangle *a b c*, (fig. 2.); and that the ship has moved forwards through the space equal to the line *b c*, while the lead has descended through the line *a c*; it is evident, that it is impossible, in this case, to ascertain the exact depth, as a quantity of line, equal to *a b*, would be paid out, whereas the true depth is equal only to the line *a c*, which is much less. But the case is very different when the patent sounding machine is used, as the operation ceases when it has reached the bottom; nor is the stray-line, *a b*, whatever its length, at all taken into the account. Fig. 2.

" It has been extremely difficult, and sometimes impossible, to obtain soundings in very deep water with the common lead, which may perhaps be thus accounted for. The common line which is used for sounding, though, if left to itself, it would sink in water, yet its descent would be much slower than that of the lead, separately; it consequently follows, that the lead must be so much impeded by carrying the line with it, that when it does reach the bottom, there will be scarcely any sensible check to enable the seaman to know the precise moment. Indeed, if he can ascertain even this to a certainty, he still cannot depend upon the truth of his soundings; for if there be the least drift or current, the line itself will assume a curve, similar to that of the line of a kite in the air. These two causes will always operate

rate against the perfection of the common mode of sounding.

"After so fully describing the principle of the patent sounding machine, it is scarcely necessary to prove that it is liable to neither of the foregoing objections; and it may be sufficient to say, that, as it will certainly find its way to the bottom, if a sufficient portion of stray-line be allowed to guard against its being checked in its progress, and the certainty of its having reached the bottom may be ascertained by the arming, there can be no doubt of the practicability of its obtaining soundings, in any depth, and no reasonable doubt of their correctness when obtained.

"From the construction of this machine, it might be imagined, that the rotator would impede its motion through the water, and that it could not descend so rapidly as the common lead; but during repeated trials, in thirteen fathoms water, in which the rotator was frequently detached, and the lead suffered to descend alone, there was no difference perceptible in the time of their descent, though an excellent quarter-second stop watch was used during the experiment, to detect any change. The following table shows how very uniformly the times of descent corresponded with the depths in fathoms, during a series of trials made on the river Mersey, with the patent lead, weighing 14 pounds.

"The manner of conducting these experiments was such as is deserving of perfect reliance. Two pilots, of well-known ability and experience, were employed: one threw the lead, and the other, the moment he found, by the slackening of the rope, that the weight had arrived at the bottom, cried 'stop,' to a third person who held the watch.

Time of descent.	Fathoms.	Time of descent.	Fathoms.
2 seconds	$2\frac{1}{2}$	$7\frac{1}{4}$ seconds	$11\frac{1}{2}$
$2\frac{1}{2}$ ——	3	$7\frac{1}{4}$ ——	$11\frac{1}{2}$
3 ——	4	$7\frac{1}{4}$ ——	$11\frac{1}{2}$
5 ——	8	$7\frac{1}{2}$ ——	12
$5\frac{1}{2}$ ——	$8\frac{1}{2}$	$7\frac{3}{4}$ ——	$12\frac{3}{4}$
6 ——	10	8 ——	13
6 ——	10	$8\frac{1}{4}$ ——	$13\frac{1}{2}$
7 ——	$11\frac{1}{4}$	6 ——	10

"Taken when under sail, at upwards of five knots in the hour.

"Several captains and masters in the navy have made trial of the log and sounding machine, and given very favourable reports of their performance; and it has been adopted by order of the Navy Board in the British navy *."

* Nich. Journ. xxi. 25

SOUP, a strong decoction of flesh or other substances.

Portable or dry soup is a kind of cake formed by boiling the gelatinous parts of animal substances till the watery parts are evaporated. This species of soup is chiefly used at sea, and has been found of great advantage. The following receipt will show how it is prepared.

Of calves feet take 4; leg of beef 12 lbs.; knuckle of veal 3 lbs.; and leg of mutton 10 lbs. These are to be boiled in a sufficient quantity of water, and the scum taken off as usual; after which the soup is to be separated from the meat by straining and pressure. The meat is then to be boiled a second time in other water; and the two decoctions, being added together, must be left to cool, in order that the fat may be exactly separated. The soup must then be clarified with five or six whites of eggs, and a sufficient quantity of common salt added. The liquor is then strained through flannel, and evaporated on the water-bath to the consistence of a very thick paste; after which is is spread rather thin upon a smooth stone, then cut into cakes, and lastly dried in a stove until it becomes brittle; these cakes are kept in well closed bottles. The same process may be used to make a portable soup of the flesh of poultry; and aromatic herbs may be used as a seasoning, if thought proper.

These tablets or cakes may be kept four or five years. When intended to be used, the quantity of half an ounce is put into a large glass of boiling water, which is to be covered, and set upon hot ashes for a quarter of an hour, or until the whole is entirely dissolved. It forms an excellent soup, and requires no addition but a small quantity of salt.

Sour-Gourd, or *African Calabash-tree*. See ADANSONIA, BOTANY *Index*.

SOUTH, DR ROBERT, an eminent divine, was the son of Mr William South a merchant of London, and was born at Hackney near that city in 1633. He studied at Westminster school, and afterwards in Christchurch college, Oxford. In 1654, he wrote a copy of Latin verses to congratulate Cromwell upon the peace concluded with the Dutch; and the next year a Latin poem, entitled *Musica Incantans*. In 1660 he was elected public orator of the university; and the next year became domestic chaplain to Edward earl of Clarendon, lord-high chancellor of England. In 1663 he was installed prebendary of Westminster, admitted to the degree of doctor of divinity, and had a sinecure bestowed on him in Wales by his patron the earl of Clarendon; after whose retirement into France in 1667 he became chaplain to the duke of York. In 1670 he was installen canon of Christ church in Oxford; and in 1676 attended as chaplain to Laurence Hyde, Esq. ambassador extraordinary to the king of Poland. In 1678 he was presented to the rectory of Islip in Oxfordshire; and in 1680 rebuilt the chancel of that church, as he afterwards did the rectory-house belonging to it. After the revolution he took the oath of allegiance to King William and Queen Mary, though he excused himself from accepting a great dignity in the church, vacated by the personal refusal of that oath. His health began to decline several years before his death, which happened in 1716. He was interred in Westminster Abbey, where a monument is erected to his memory. He published, 1. Animadversions on Dr Sherlock's Vindication of the Holy and Ever Blessed Trinity. 2. A Defence of his Animadversions. 3. Sermons, 8 vols 8vo. And after his decease were published his *Opera Posthuma Latina*, and his posthumous English works. Dr South was remarkable for his wit, which abounds in all his writings, and particularly in his sermons; but at the same time they equally abound in ill-humour, spleen, and satire. He was remarkable for being a time-server. During the life of Cromwell he was a staunch Presbyterian, and then railed against the Independents: at the Restoration

tion he exerted his pulpit-eloquence against the Presbyterians; and in the reign of Queen Anne, was a warm advocate for Sacheverel.

South, one of the four cardinal points from which the winds blow.

South Sea, or *Pacific Ocean*, is that vast body of water interposed between Asia and America. It does not, however, strictly speaking, reach quite to the continent of Asia, excepting to the northward of the peninsula of Malacca: for the water interposed between the eastern coast of Africa and the peninsula just mentioned has the name of the *Indian ocean*. The South sea then is bounded on one side by the western coast of America, through its whole extent, from the unknown regions in the north to the straits of Magellan and Terra del Fuego, where it communicates with the southern part of the Atlantic. On the other side, it is bounded by the coast of Asia, from the northern promontory of Tschnkotskoi Noss, to the peninsula of Malacca already mentioned. Thence it is bounded to the southward by the northern coasts of Borneo, Celebes, Macassar, New Guinea, New Holland, and the other islands in that quarter, which divide it from the Indian ocean. Then, washing the eastern coast of the great island of New Holland, it communicates with that vast body of water encompasing the whole southern part of the globe, and which has the general name of the *Southern ocean* all round. Thus does this vast ocean occupy almost the semicircumference of the globe, extending almost from one pole to the other, and about the equatorial parts extending almost 180° in longitude, or 12,500 of our miles.

The northern parts of the Pacific ocean are entirely destitute of land; not a single island having yet been discovered in it from the latitude of 40° north and upwards, excepting such as are very near the coast either of Asia or America; but in the southern part there are a great number.

Till very lately the South sea was in a great measure unknown. From the great extent of ice which covers the southern part of the globe, it was imagined that much more land existed there than in the northern regions: but that this could not be justly inferred merely from that circumstance, is plain from what has been advanced under the article America, N° 3—24.; and the southern continent, long known by the name o *Terra Australis*, has eluded the search of the most expert navigators sent out from Britain and France by royal authority. See Terra Australis.

South Sea Company. See Company.

SOUTHAMPTON, a sea-port town of Hampshire in England; is seated on an arm of the sea; is a place of good trade, and in 1801 contained nearly 8000 inhabitants. It is surrounded by walls and several watchtowers, and had a strong castle to defend the harbour, now in ruins. It is a corporation and a county of itself, with the title of an earldom, and sends two members to parliament. W. Long. 1. 24. N. Lat. 50. 54.

SOUTHERN, Thomas, an eminent dramatic writer, was born at Dublin in 1660, and received his education in the university there. He came young to London to study law; but instead of that devoted himself to poetry and the writing of plays. His Persian Prince, or Loyal Brother, was introduced in 1682, when the Tory interest was triumphant in England; and the character of the Loyal Brother being intended to compliment James duke of York, he rewarded the author when he came to the throne with a commission in the army. On the Revolution taking place, he retired to his studies, and wrote several plays, from which he is supposed to have derived a very handsome subsistence, being the first who raised the advantage of playwriting to a second and third night. The most finished of all his plays is Oroonoko, or the Royal Slave, which is built on a true story related in one of Mrs Behn's novels. Mr Southern died in 1746, in the 86th year his age; the latter part of which he spent in a peaceful serenity, having by his commission as a soldier, and the profits of his dramatic works, acquired a handsome fortnne; and being an exact economist, he improved what fortune he gained to the best advantage. He enjoyed the longest life of all our poets; and died the richest of them, a very few excepted. His plays are printed in two volumes 12mo.

SOY. See Dolichos.

SOZOMENUS, Hermias, an ecclesiastical historian of the 5th century, was born in Bethelia, a town of Palestine. He was educated for the law, and became a pleader at Constantinople. He wrote an Abridgement of Ecclesiastical History, in two books, from the ascension of our Saviour to the year 323. This compendium is lost; but a continuation of it in nine books, written at greater length, down to the year 440, is still extant. He seems to have copied Socrates, who wrote a history of the same period. The style of Sozomenus is perhaps more elegant; but in other respects he falls far short of that writer, displaying throughout his whole book an amazing credulity and a superstitious attachment to monks and the monastic life. The best edition of Sozomenus is that of Robert Stephen in 1544. He has been translated and published by Valesius, and republished with additional notes by Reading at London, 1720, in 3 vols folio.

SPA, a town of Germany, in the circle of Westphalia and bishopric of Liege, famous for its mineral water, lies in E. Long. 5. 50. N. Lat. 50. 30. about 21 miles south-east from Liege, and 7 south-west from Lomburg. It is situated at one end of a deep valley, on the banks of a small rivulet, and is surrounded on all sides by high mountains. The sides of these mountains next to Spa are rude and uncultivated, presenting a rugged appearance as if shattered by the convulsions of earthquakes; but as they are strewed with tall oaks and abundance of shrubs, the country around forms a wild, romantic, and beautiful landscape. The access to the town

Spa.

town is very beautiful. The road winds over the mountains till it descends to their bottom, when it runs along a smooth valley for a mile or a mile and a half.

The town consists of four streets in form of a cross, and contains about 400 inhabitants. Spa has no wealth to boast of. It can scarcely furnish the necessaries of life to its own inhabitants during the winter, and almost all the luxuries which are requisite for the great concourse of affluent visitors during the summer are carried from Liege by women. Its only source of wealth is its mineral waters. No sooner does the warm season commence, than crowds of valetudinarians arrive, as well as many other persons who are attracted solely by the love of amusement, and some from less honourable motives. The inhabitants, who spend seven or eight months of the year without seeing the face of a stranger, wait for the return of this period with impatience. The welcome sound of the carriages brings multitudes from the town, either to gratify their curiosity, or to offer their services in the hopes of securing your employment while you remain at Spa. Immediately after your arrival, your name and designation is added to the printed list of the annual visitors; for which you pay a stated sum to the booksellers, who have a patent for this purpose from the prince bishop of Liege. This list not only enables one to know at a glance whether any friends or acquaintance are residing there, but also to distinguish persons of rank and fashion from adventurers, who seldom have the effrontery to insert their names.

There are two different ways of accommodating the visitors at Spa with lodging and necessaries. People may either lodge at a hotel, where every thing is furnished them in a splendid and expensive style; or they may take up their residence in private lodgings, from which they may send for provisions to a cook's shop.

Among the people who visit Spa, there are many persons of the first rank and fashion in Europe. Perhaps indeed there is no place in Europe to which so many kings and princes resort; but it is also visited by many self-created nobility, who, under the titles of counts, barons, marquises, and knights, contrive by their address, and artifices, to prey upon the rich and unexperienced.

Spa.

The manners established at Spa are conducive both to health and amusement. Every body rises early in the morning, at six o'clock or before it, when a great many horses stand ready saddled for those who choose to drink the Sauveniere or Geronstere waters at a little distance from Spa. After this healthy exercise a part of the company generally breakfast together at Vauxhall, a magnificent and spacious building. At this place a number of card-tables are opened every forenoon, round which many persons assemble and play for stakes to a very considerable amount. A ball too is generally held once a week at Vauxhall, besides two balls at the assembly rooms near the Pouhon in the middle of the town.

The most remarkable waters at Spa are, 1. The Pouhon, situated in the middle of the town; 2. The Sauveniere, a mile and a half east from it; 3. Groisbeck, near to the Sauveniere; 4. Tonnelet, situated a little to the left of the road which leads to the Sauveniere; 5. Geronstere, two miles south from Spa; 6. Wartroz, near to the Tonnelet; 7. Sarts or Niveset, in the district of Sarts; 8. Chevron or Bru, in the principality of Slavelot; 9. Couve; 10. Beverse; 11. Sige; 12. Geremont. These four last are near Malmedy.

Dr Brownrigg was the first person who discovered that fixed air, or, as it is now generally called, *carbonic acid gas*, forms a principal ingredient in the composition of the Spa waters, and actually separated a quantity of this elastic fluid, by exposing it to different degrees of heat from 110° to 170° of Fahrenheit. From 20 ounces 7 drams and 14 grains apothecaries weight of the Pouhon water, he obtained 8 ounces 2 drams and 50 grains. Since June 1765, when Dr Brownrigg read a paper on this subject before the Royal Society of London, the waters of Spa have been often analysed, but perhaps by none with more accuracy than by Dr Ash, who published a book on the chemical and medicinal properties of these waters in 1788. We shall present the result of his analysis of the five principal springs in the following table:

Fountains.	Quantity of Water	Ounce measures of Gas.	Solid contents.	Aerated Lime.	Aerated Magnesia.	Aerated Mineral Alkali.	Aerated iron.	Selenite.	Aerated Vegetab. Alkali.
	Ounces.		Grains.						
Pouhon	33.	35.75	16.25	2.75	9.50	2.25	1.75	—	—
Geronstere	32.75	24.75	5.50	2.50	—	1.75	0.75	0.50	—
Sauveniere	32.50	33.50	3.75	1.50	—	0.75	0.50	—	1.
Groisbeck	32.25	35.50	5.25	1.50	—	1.	0.75	—	2.
Tonnelet	32.	40.75	2.00	0.25	—	0.75	1.	—	—

The Pouhon spring rises from the hill to the north of Spa, which consists of argillaceous schistus and ferrugineous slate. The other fountains rise from the surrounding hills to the south-east, south, west, and north-west of the town; and this ridge of mountains is formed of calcareous earths mixed with siliceous substances. The surface of the mountains is covered with woods, interspersed with large boggy swamps filled with mud and water. The Pouhon is considered as the principal spring at Spa, being impregnated with a greater quantity of iron than any of the rest, and containing more fixed air than any except the Tonnelet. It is from this spring that the Spa water for exportation is bottled; for which the demand is so great, that, according to the best information that Mr Thicknesse could obtain, the quantity exported amounts to 200,000 or 250,000 bottles annually. This exported water is inferior in its virtue to that which is drunk on the spot; for the vessels into which it is collected are injudiciously exposed to the sun, rain, wind, and dust, for several hours before they are corked, by which means a considerable part of its volatile ingredients must be evaporated; for it has been

Thicknesse's Journey through the Pais Bas.

Spa.

been found by experiment, that by exposing it to a gentle heat, air-bubbles ascend in great numbers. It is in its greatest perfection when collected in cold dry weather; it is then pellucid, colorless, and without smell, and almost as light as distilled water. It varies in its heat from 52° or 53° to 67° of Fahrenheit's thermometer.

The Geronstere is a much weaker chalybeate water than the Pouhon; and as it is exceedingly nauseous, and tastes and smells like rotten eggs, it certainly contains some hepatic gas. This is a circumstance which Dr Ash seems not to have attended to sufficiently. The Sauveniere water also, when newly taken from the well, smells a little of sulphur. The Groisbeck contains more alkali, and almost as much gas as the Pouhon, and has been celebrated for its good effects in the case of calculous concretions. The Tonnelet contains more gas than any of the rest. Dr Ash informs us, that in the neighbourhood of this well, the cellars, on any approaching change of weather, are found to contain much fixed air; and the best prognostic which they have of rain is the aversion which cats show to be carried into these cellars.

The Spa waters are diuretic, and sometimes purgative. They exhilarate the spirits with an influence much more benign than wine or spirituous liquors; and they are more cooling, and allay thirst more effectually, than common water. They are found beneficial in cases of weakness and relaxation, either partial or universal; in nervous disorders; in obstructions of the liver and spleen; in cases where the blood is too thin and putrescent; in cases of excessive discharges proceeding from weakness; in the gravel and stone; and in most cases where a strengthening remedy is wanted. But they are hurtful in confirmed obstructions attended with fever, where there is no free outlet to the matter, as in ulcerations of the lungs. They are also injurious to bilious and plethoric constitutions, when used before the body is cooled by proper evacuations.

Spa || Spahis.

SPACE. See METAPHYSICS, Part II. Chap. iv.

SPACE, in *Geometry*, denotes the area of any figure, or that which fills the interval or distance between the lines that terminate it.

SPADIX, in *Botany*, anciently signified the receptacle of the palms. It is now used to express every flower-stalk that is protruded out of a spatha or sheath.

The spadix of the palms is branched; that of all other plants simple. This last case admits of some variety; in *calla*, *dracontium*, and *pothos*, the florets cover it on all sides; in *arum*, they are disposed on the lower part only: and in *zostera* on one side. See BOTANY.

SPAGIRIC ART, a name given by old authors to that species of chemistry which works on metals, and is employed in the search of the philosopher's stone.

SPAHIS, horsemen in the Ottoman army, chiefly raised in Asia. The great strength of the grand seignior's army consists in the janisaries, who are the foot; and the spahis, who are the horse.

SPAIN.

Spain.

1 Situation and boundary.

THE kingdom of Spain, which occupies by far the greater portion of the south-western peninsula of Europe, is bounded on the north by the bay of Biscay and Pyrenean mountains, which separate it from France; on the east by the Mediterranean sea; on the south by the straits of Gibraltar, which divide it from the African kingdom of Morocco; and on the west, partly by the Atlantic ocean, but chiefly by the narrow kingdom of Portugal. This last is the only artificial boundary of the Spanish territory, and consists of ideal lines, except in three parts, where the river Minho to the north, and the Douro and the Chanca, till its junction with the Guadiana to the east, form rather more natural limits.

2 Extent.

From Cape Ortegal in N. Lat. 43° 44′, to the rock of Gibraltar, in N. Lat. 35° 57′, the continent of Spain extends through nearly 8° of latitude, while its extent from west to east, viz. from Cape Finisterre in Long. 9° 17′ W. from Greenwich to Cape Creus, or Croix, in Long. 3° 30′ E. from the same meridian, comprehends nearly 13° of longitude. In British miles, its length from north to south, viz. from Cape Penas to Gibraltar, may be estimated at 550 miles, while its medium breadth may be computed at 440. According to De Laborde, its superficial extent, exclusive of Portugal, is 25,137 square French leagues, or about 21,000 square English leagues.

Besides the continental part of Spain, this monarchy comprehends several islands in the Mediterranean, especially Majorca, Minorca, and Iviça; the Canary islands, and several places on the north-western coast of Africa; the Philippine and Ladrone islands; together with an immense territory both in North and South America, comprehending Mexico or New Spain, New Mexico, the island of Cuba, Porto Rico, &c. in North America, and in the southern part of that continent, the greatest portion of *Terra Firma*, Peru, Chili, almost the whole of Paraguay, with an extensive territory lying on the banks of the river Plate.

Spain.

3 Division.

The usual division of the Spanish continent is into fourteen provinces, viz. those of CATALONIA, ARAGON, and NAVARRE, on the confines of France; BISCAY, ASTURIAS, and GALLICIA, on the shores of the Atlantic; LEON and ESTREMADURA, on the side of Portugal; ANDALUSIA chiefly on the straits of Gibraltar; GRANADA, MURCIA, and VALENCIA, on the shores of the Mediterranean; OLD and NEW CASTILE in the centre.

The latest writer on the geography of Spain, De Laborde, reckons only 13 provinces, as he includes Granada under Andalusia. In the following table we have brought together the most important circumstances respecting each of these provinces, viz. the subdivisions, extent in square British miles, population at the end of the 18th century, and chief towns; and we have arranged the provinces in the order followed by Laborde.

Published by A. Constable & C.o Edinburgh 1819.

Provinces.	*Subdivisions.*	*Extent in square miles.*	*Population.*	*Chief Towns.*
Province of CATALONIA.	County of Roussillon ——— Cerdagne	10,400	814,412	BARCELONA, Tarragona, Urgel, Lerida, Gerona, Salsona, Vich, Tortosa, Figueras, &c.
Kingdom of VALENCIA.		7,800	932,150	VALENCIA, Alicant, Elche, Orihuela, Castellan, Alzira, Carcaxente, Gandia, Xaciva, Otiniente, Alcoy, Segorbe, &c.
Province of ESTREMADURA.		16,000	416,922	BADAJOZ, Placencia, Coria, Merida, Truxillo, Xera de los Cavalleros, Llerina, Almatona, Zafra, &c.
Province of ANDALUSIA.	Kingdom of Seville	12,600	754,293	SEVILLE, Xeres de la Frontera, Arcos, Cadiz, Real Ejo, Ayamonte, Nivela, &c.
	——— Granada	4,500	661,661	GRANADA, Malaga, Loxa, Santa Fé, *Antiquera*, Ronda, Guadix, Baza, &c.
	——— Cordova	1,080	236,016	CORDOVA, and Archidona, &c.
	——— Jaen	2,400	177,136	JAEN, Ubeda, Baeza, Anduxar, &c.
Kingdom of MURCIA.		8,812	337,686	MURCIA, Carthagena, Lorca, Chinchilla, Alba Cete, Villena, Almanza, &c.
Kingdom of ARAGON.		16,500	623,308	ZARAGOZA, Iaca, Barbastro, Huesca, Tarazona, Albarrazin, Teruel, &c.
Kingdom of NAVARRE.		2,287	287,382	PAMPELUNA, Tudela, &c.
Province of BISCAY.	Biscay Proper Alava Guipuzcoa	4,000	116,042 74,000 12,076	BILBOA, Vermijo, &c. VITTORIA, Trevino, Onate, &c. ST SEBASTIAN, Fuenaraba, Tolosa, Placentia, &c.
Principality of the ASTURIAS.	Oviedo Santillana	3,375 1,200	350,000	OVIEDO, Aviles, Luarca, Gijon, &c. SANTILLANA, San Vincente, Riva de Sella, &c.
Kingdom of GALLICIA.		11,500	1,350,000	SAN JAGO DE COMPOSTELLA, Bayona, Lugo, Orense, Mondonedo, Corunna, Vigo, &c.
Kingdom of LEON.	Leon Palencia Zamora Salamanca	10,750	665,432	LEON, Duero, Astorga, Salamanca, Zamora, &c.
Kingdom of OLD CASTILE.	Burgos Avila Segovia	10,800	1,190,180	BURGOS, Osma, Siguenza, Avila, Valladolid, Segovia, Calahorra, Soria, &c.
Kingdom of NEW CASTILE.	Toledo Cuença Lamanca	22,000	1,146,809	MADRID, Toledo, Aranjuez, Talavera della Reyna, &c. CUENÇA, Guete, Alacon, &c. OCANA, Hucles, Laguardia, Tarrazona, &c.
Kingdom of MAJORCA.	Islands of Majorca ——— Cabrera ——— Iviça	1,440 110	136,000	PALMA, Alcudia, &c. IVIÇA.
Island of MINORCA.		360	27,000	MAHON, Cittadella.
			10,308,505	

Some account of these provinces will be found under the articles ANDALUSIA, ARAGON, ASTURIAS, BISCAY, CASTILE, CATALONIA, ESTREMADURA, GALLICIA, GRANADA, LEON, MURCIA, NAVARRE, VALENCIA, IVICA, MAJORCA, and MINORCA; but for the best view of their present state, we must refer our readers to De Laborde's *View of Spain*, vols. i. ii. and iii. or to Playfair's *Geography*, vol. i.

In its general appearance, Spain presents a pleasing variety of hill and dale, mountain and valley. It must be regarded as a mountainous country, its plains being few in number and of small extent. The most remarkable of these occupies the centre of the kingdom, especially New Castile, which forms the most elevated tract of level country to be found in Europe, having a mean elevation of more than 300 fathoms above the level of the sea. The country is well wooded, and abounds with rivers; but these are often very deficient in water, and

4 Face of the country.

Spain, especially on its eastern coast, is remarkable for the dryness of its soil. Notwithstanding this aridity, however, most parts of the kingdom teem with fertility, and native verdure and high cultivation render the scenery delightful. Here and there, indeed, occurs a tract of desert utterly incapable of cultivation; but, in general, nature has done much more for the country than the labour of its inhabitants.

5 Soil. The soil is said to be in general light, and easily wrought; but on many parts of the eastern coast it is composed chiefly of a stiff loam or clay. The most fertile parts of the kingdom are in Valencia, on the coast of Granada, in the kingdom of Old Castile, and in several parts of those of New Castile and Leon. The soil of Catalonia is very discouraging, except in the valleys, and the same may be said of all the provinces bordering on the Pyrenees; the soil of Estremadura, though naturally good, has been so long abandoned to itself, that it has almost ceased to produce, and that of Andalusia has a very mixed character. The soil of Murcia is uncommonly arid; that of the Asturias cold; that of Gallicia extremely wet. In the neighbourhood of Carthagena there is an extensive tract, which is so covered with stones as to form a desert as sterile and untameable as any on the sandy plains of Africa or Arabia.

6 Mountains. We have said that Spain is a mountainous country. The chain of the Pyrenees, common to it and France, is by no means the most considerable in point either of elevation or extent; though that chain may be regarded as the common root or origin of all the rest. From the western corner of the Pyrenees a vast ridge branches off through Navarre, Biscay, Asturias and Gallicia, terminating only at Cape Finisterre, and Cape Ortegal. This ridge is the *Cantabrian* mountains, and is distinguished into several subordinate groups, denominated from the principal towns situated in their vicinity. Thus we have the mountains of Mondonedo in Gallicia. In general, these groups are called *Sierras*, from the jagged or *serrated* appearance of their tops; as the *Sierra de la Asturias*, *Sierra d'Avila*, &c. The subordinate mountains that extend from the Sierra of the Asturias in the north, to the Alpuxaras in the south, run in parallel lines; and the same direction prevails in the mountains of Saint Andero, which join the Pyrenees.

From the mountains of Biscay arises a main ridge, which, after proceeding a little to the south, divides into three or four branches. Of these the most northerly chain separates the provinces of Old Castile and New Castile, extending to the confines of Portugal, and called the mountains of Guadarrama. A second branch divides the principal part of New Castile from the province of La Mancha, running from the north-east to the south-west, as far as Badajos in Estremadura. The most remarkable part of this chain is the Sierra of Guadalupe. South of these runs the Sierra Morena, or Sable mountains, rendered classical by the inimitable pen of Cervantes. This is the last chain till we reach the Alpuxaras, that extend through the provinces of Granada and Andalusia.

Of these mountains there are two points, which, in elevation, exceed Mont Perdu, the highest of the Pyrenees, viz. the Pico de Venleta, in the Sierra Nevada, or snowy mountains of Granada, which is elevated more than 1781 fathoms above the level of the ocean, and the peak of Mulahasen, in the same chain, raised above 1824 fathoms, which is within 76 fathoms of the peak of Teneriffe.

7 Capes and promontories. The principal capes and promontories of the Spanish continent are, Cape Creus, Cape St Antoine, opposite the island of Iviça; Cape Palas, near Carthagena; Cape de Gatte, near Almeria, and the promontory on which stands the town of Gibraltar, all on the coast of the Mediterranean; and Cape Machicaco, Cape Penas, Cape Ortegal, the promontory of Ferrol, Cape Finisterre, and Cape Trafalgar, on the coasts of the Atlantic.

8 Bays and gulfs. The principal bays and gulfs on the coast of Spain, pursuing the same course, are the following; the bay of Valencia, the bay of Alicant, the gulf of Carthagena, the bay of Almeria, the bay of Gibraltar, the harbour of Cadiz, the bay of Corunna, commonly called the Groyne, and the bay of Biscay.

9 Rivers. The rivers of Spain are intimately connected with the mountains from which they derive their source, and between the chains of which they generally flow. The most important are, the Ebro, rising in the mountains of Santillana in the Asturias, and running in a south-eastern direction between the Castiles and Valencia on the one hand, and the provinces of Navarre, Aragon, and Catalonia, on the other, till it reaches the Mediterranean, at a small distance from Tortosa; the Xacar, rising in the Sierra of Cuença in New Castile, and flowing into the Mediterranean considerably to the southward of Valencia; the Segura, rising in a mountain of the same name, traversing the province of Murcia, and meeting the Mediterranean about midway in the capital of that province, and Alicant. These flow into the Mediterranean, and there are several other rivers of less note, which pour their waters into the same sea, and which we can merely enumerate. These are the Ter at Gerona, the Lobregate at Barcelona, and the Mijares, passing by Segorbe. The rivers which flow into the Atlantic are, the Guadalquiver, rising at the foot of Mount Segura, from the opposite side of which originates the river of the same name, flowing with a sluggish course through the province of Andalusia, and meeting the Atlantic a little to the north-west of Xeres; the Guadiana, rising among some lakes to the north-west of Alcaraz in New Castile, and passing between the Sierra Morena and the Sierra de Guadalupe, till, near Badajos, it enters the kingdom of Portugal, and runs nearly in a southerly direction, till it meets the Atlantic at Ayamonte; the Tagus, rising among the mountains of Albaraçin in New Castile, and running westerly till, at Alcantara, it becomes a river of Portugal; the Douro, rising in Old Castile near Soria, and passing by Valladolid and Zamora, near which it forms a part of the boundary of Portugal; the Minho, rising in the mountains of Gallicia, and running to the south-west, till it meets the Atlantic to the north of Camina. The only other river of any importance in this direction is the Lima, supposed to be the Lethe of the poets, which rises in Gallicia, and flows into the sea below Viara.

10 Lakes. If we except the series of small lakes from which we have said the river Guadiana takes its rise, there are, in Spain, few lakes that merit particular notice. The most remarkable of these is the lake of Albufera, in the province of Valencia. This lake begins near the village of Catarroija, about a league south of the city of Valencia, and extends nearly four leagues as far as Cullera. When it

it is full, it is about four leagues long, two in breadth, and six in circumference; but it is so shallow, that small boats can scarcely float in it. To supply the deficiency of water, an engine is employed, by which the neighbouring waters are drawn into the bed of the lake; and any superabundant water occasioned by heavy rains, is carried off into the sea by means of an artificial opening. This lake contains a great many fish, and numerous aquatic birds make it their haunt. On certain days in the year the inhabitants of Valencia make incursions hither to shoot the birds, and the surface of the lake is at these times covered with boats.

11 Forests.

Many parts of the kingdom of Spain abound in large tracts of wood. Extensive forests are found in Catalonia, the Asturias, Gallicia, and in the Sierra Morena. It is in the mountainous chains that the forests of Spain are most remarkable; and there are few of these heights, except in the snowy regions of the Sierra Nevada, but what are covered with wood almost to their summits.

12 Climate and seasons.

The climate of Spain is as delightful as that of any part of Europe; and though at certain seasons of the year the eastern coast is subject to excessive heat and drought, and the north-western to almost perpetual rains, the temperature is in general mild, and the air salubrious.

The climate of Spain has been admirably depicted by M. A. de Humboldt; and we shall here present to our readers the substance of his remarks, as they are related by De Laborde, in his View of Spain.

No country of Europe presents a configuration so singular as Spain. It is this extraordinary form which accounts for the dryness of the soil in the interior of the Castiles, for the power of evaporation, the want of rivers, and that difference of temperature which is observable between Madrid and Naples, two towns situated under the same degree of latitude.

The interior of Spain is, as we have seen, an elevated plane, which is higher than any of the same kind in Europe, occupying so large an extent of country. The mean height of the barometer at Madrid is 26 inches $2\frac{2}{3}$ lines. It is therefore $\frac{1}{11}$ lower than the mean height of the mercury at the level of the ocean. This is the difference of the pressure of the atmosphere that is experienced by all bodies exposed to the air at Madrid, and at Cadiz and Bourdeaux. At Madrid the barometer falls as low as 25 inches 6 lines, and sometimes even lower.

The following is a table of the variations in the height of the barometer during the first nine months of the year 1793.

Months.	Maximum.		Minimum.		Mean Height of the Mercury.	
1793.	Inches.	Lines.	Inches.	Lines.	Inches.	Lines.
January,	26	5.8	25	9.8	26	2.6
February,	26	5.3	25	6.2	26	1.6
March,	26	4.7	25	6.	25	11.6
April,	26	2.4	25	6.9	25	11.6
May,	26	4.6	25	10.5	26	0.8
June,	26	4.	25	11.8	26	1.6
July,	26	4.3	26	0.7	26	2.4
August,	26	3.2	25	11.5	26	1.4
September,	26	4.3	25	11.	26	1.7

From the mean height of the barometer at Madrid, we find that capital to be elevated $309\frac{6}{10}$ fathoms above the level of the ocean. Madrid, consequently, stands as high as the town of Inspruck, situated on one of the highest defiles of the Tyrol, while its elevation is 15 times greater than that of Paris, and three times greater than that of Geneva.

According to M. Thalacker, the mineralogist, who has taken several heights with the barometer in the environs of Madrid, the elevation of the king's palace at San Ildefonso is 593 fathoms, which is higher than the edge of the crater of Mount Vesuvius, and is, strictly speaking, in the regions of the clouds, which generally float from 550 to 600 fathoms high.

The height of the plain of the Castiles has an evident effect on its temperature. We are astonished at not finding oranges in the open air under the same latitude as that of Tarentum, part of Calabria, Thessaly, and Asia Minor; but the mean temperature of Madrid is very little superior to that of Marseilles, Paris, and Berlin, and is nearly the same with that of Genoa and Rome. The following table shews the mean temperature at Madrid and at Rome, during the first nine months of the years 1793 and 1807.

	At Madrid.			At Rome.		
Months.	Deg. of Fahrenheit.			Deg. of Fahrenheit.		
January,	39°	3		40°	11′	15″
February,	43	24		47	49	30
March,	47	54		50	15	45
April,	52	19	30″	54	34	30
May,	59	4	30	65	56	15
June,	72	32	15	72	30	
July,	77	13	30	79	15	
August,	81	34	30	79	15	
September,	65	45		72	34	30

Thus, the mean temperature at Madrid appears to be 59° of Fahrenheit, while that of the coasts of Spain, from the 41° to the 36° of Lat. is between $63\frac{1}{2}$° and 68° of Fahrenheit. In the former climate we find that orange trees will not flourish in perfection, while in the latter we see banana trees, heliconias, and even sugar-canes, growing in situations that are sheltered from the cold winds.

Spain presents few species of animals that are not found in the other parts of southern Europe. Among the quadrupeds, we may remark, as peculiar to Spain, the genet (*viverra genetta*). The bear is found in several parts of the great Pyrenean chain, especially on some of the mountains of Aragon, as well as those of Occar and Reynosa in Old Castile. Wolves are met with in all the higher and mountainous parts of the country, and wild boars on the mountains of Navarre, on the Pinar, and the Sierra de Carascoy, in the kingdom of Valencia. The roebuck is found on some of the mountains of Navarre, and the lynx and the ibex on those of Cuença in New Castile, in the valleys of Aure and Gistau, as well as in the Pyrenees. The glory of Spanish zoology is the horse, for which this kingdom has been famous in all ages. The Spanish horses 13 Animals.

Spain.

horses have probably originated from the Barbs of the north of Africa, supposed to be the immediate offspring of the Arabian breed. The Spanish mules are also excellent, and the ass is here no ignoble animal, though not equal to those of Arabia. There is little remarkable in the breed of cattle; but the Merino sheep have long been distinguished, and are perhaps superior to any in the world for the beauty of the fleece, if not for the delicacy of the mutton. The flocks of Merino sheep are sometimes extremely large, and Mr Townsend mentions one nobleman who possessed not fewer than 14,000. The whole number in the kingdom may be estimated at about 5,000,000. These animals were, by a special code, called the *Mesta*, authorised to travel from one province to another, according as the season presented the best pasturage in the mountains or the plains. The fleece of the Merino sheep is esteemed double in value to that of any other breed.

Of the birds more peculiarly found in Spain, the *vultur percnopterus*, the *cuculus glandarius*, *cuculus tridactyla*, *motacilla hispanica*, *hirundo mellia*, and *hirundo rupestris*, are the most remarkable.

Fresh-water fishes are very plentiful in the Spanish rivers; but those in most esteem are from the small river Tormes in Old Castile, where have been taken trout of 20 lbs. weight. The tench of the lakes near Tobar in New Castile, are remarkably fine and delicate, and are taken in great abundance every year, during the months of May and June. The fish taken on the coasts are much the same as those of the other countries bordering on the Mediterranean and the Atlantic. The tunny was formerly taken on the eastern coast, where it formed a particular branch of the fishery, but is now, we believe, little regarded.

Among the Spanish insects, the most remarkable are, the cantharides, (*meloë vesicatorius*), and the kermes insect (*coccus ilicis*). The latter insect is much cultivated as an article of dyeing, especially in the territory of Bujalance, and of Fernan Nunes in the kingdom of Cordova, as also in the vicinity of the town of De las Aguas, four leagues from Alicant, and near the river Henares, in New Castile. The evergreen oaks on which these animals feed, present in the spring, a most singular appearance, from the red *nidi* of the kermes, with which the leaves are covered.

14 Vegetables.

No country of Europe of the same extent, furnishes such an ample field for the researches of the botanist, as Spain; and indeed its botany constitutes a very important part of its natural history. The mountainous districts are clothed with the evergreen oak, the common oak, the chesnut, and in some places various species of pine; but their most useful production is the cork tree. The smaller heights produce the wild olive, the almond, the shumac, the laurel, the bay, the cypress, Canary and Portugal broom, the yellow jessamine, and the Provence rose. The vine, the palm tree, the orange, the lemon and the olive, are so nearly naturalized as to require but little cultivation; and the same may be said of the kali (*salsola soda*), which is produced in large quantities on the coasts, and furnishes the best kind of kelp, commonly called *barilla*, used in the manufacture of soap and glass. The plains and valleys are covered with many of those plants which form some of the greatest ornaments of our flower gardens, as the tulip, several species of iris, the pæony, the passion flower, the orange and martagon lily, the jonquil, several species of narcissus and hyacinth, and above all the rhododendron. The mountains, however, exhibit the greatest variety of botanical riches. Those most worthy of the visits and researches of the enterprising botanist, are, the Sierra de Guadalupe in Estremadura; the mountains of Moncayo in Aragon; of Pineda, Guadarrama, and Cuença, in New Castile; of Caroscoy, in the kingdom of Murcia; of Pena-Colosa, Mongi, Aytona, and Mariola, in the kingdom of Valencia, and the Pyrenees.

The sugar-cane was, before the discovery of the West India islands, one of the most important objects of Spanish cultivation, and numerous sugar mills were established along the coast of the Mediterranean, especially in the kingdom of Granada. At the conquest of that Moorish kingdom, not fewer than fourteen sugar plantations and two mills, were found within the province. Some sugar canes are still cultivated in the kingdom of Valencia, but the manufacture of sugar is discontinued, and the canes are used only for distillation. There is, we believe, still a manufactory for sugar from Spanish canes in Granada.

15 Minerals.

Spain has long been celebrated for the riches of its mineral kingdom, and it may still be considered as the Mexico and Peru of Europe. There are few metals which may not be found in this kingdom; and, till the discovery of America put the Spaniards in possession of mines which far surpass their own in produce, the gold and silver mines of Spain were thought to be nearly the richest in the world. At present, no gold mines are wrought, but grains of that metal are found disseminated in ferruginous quartz, forming a vein that passes through a mountain near the village of San Ildefonso in Old Castile. Spangles of gold are found intermixed with emery, in a mine near Alocer in Estremadura, and in the territory of Molena in Aragon; and this metal is occasionally found in the sand of two rivers; the Agneda, in the kingdom of Leon, which rises from the mountains of Xalamo, and the Tagus in New Castile, especially in the vicinity of Toledo.

Silver is much more abundant, but most of its mines have also been abandoned. We believe the only silver mine now in work is that of the Sierra de Guadalupe, near the village of Logrozen, where the silver is found mixed with micaceous schistus. The most remarkable silver mines formerly worked are those of Alrodoval del Campo; of Zalamea on the road to Alocer in Estremadura; of Almazaron near Carthagena; three in the Sierra Morena, about a league from Guadalcanal, in the kingdom of Seville, and another about two leagues from Linarez, in the kingdom of Jaen. This last mine was well known both to the Carthaginians and the Romans; while Spain was under the dominion of the former it belonged to Himilca, the wife of Asdrubal. After having been long abandoned, it was again wrought in the 17th century, when a vein of ore five feet in diameter was discovered; at present, however, it is no longer in a state of activity.

Mines of copper are found near Pampeluna in Navarre, near Salva Tierra in Alava; near Escarray, and at the foot of the mountains of Guadarrama in Old Castile; near Lorea in Murcia; near the Chartreuse of the Val de Christo in Valencia; in the Sierra de Guadalupe in Estremadura; in the mountains near Cordova; near Riotinto, and at la Canada de los Conejos in Seville; in pain in the district of Alhuladni in Granada, and near Linarez in the kingdom of Jaen.

There are numerous lead mines, especially near Tortosa in Catalonia; at Zoma, Benasques, and Plan in Aragon; near Logrosen and Alcoser in Estremadura; in the mountain Guadarrama in Old Castile; near los Alumbres and Lorca in Murcia; at Alcaniz and Constantia in Seville, and at the district of Linarez in Jaen.

The mines of iron are abundant, and need not be enumerated. Of antimony there are two mines, both in the district of La Mancha. One of these is at Alendia, near Almodovar; the other at the foot of the Sierra Morena. There is only one mine of cobalt, viz. in the province of Aragon, found in the valley of Geston. There are two mines of cinnabar in Valencia; one about two leagues from Alicant in the limestone mountains of Alcoray; the other between Valencia and San Felipe; and two others in the same province, that produce native mercury, but none of these are worked. The most abundant mine of mercury and cinnabar united is in the district of La Mancha, on the borders of Cordova. It is situated in a hill of sandstone which rests on slate. The whole length of the hill is traversed by two principal veins, both of which were wrought by the Romans. The whole of this mine was lately wrought by the agents of the king, and its produce was very abundant.

Plumbago is found in a thick vein intermixed with feldspar, about a league from the village of Real Monasterio, in the kingdom of Seville. Mines of sulphur occur, both in Aragon and Murcia; jet has been found in the district of Old Colmenar, in Old Castile; and there is good evidence of the presence of coal at several places in Catalonia, in the Asturias, New Castile, and Aragon; but it is said that no coal mines have as yet been opened.

The marbles of Spain are very numerous and valuable. A black marble, veined with white, is procured near Barcelona; many dendritic marbles occur near Tortosa. Near the town of Molina, in Aragon, is found a granular marble spotted with red, yellow, and white. At the village of Salinos, in the district of Guipuzcoa, is a beautiful blue pyritical marble, containing marine shells. From Monte Segarra, near Segorbia, in the province of Valencia, are procured several fine marbles, which were held in great estimation even by the Romans. The province of Granada, however, contains more valuable varieties of this beautiful mineral than all the rest of Spain; of these some of the principal are the following. A pure white statuary marble, of which the whole mountain of Filabra, near Almeria, is composed; a flesh-coloured marble from a mountain near Antiquera; an exquisitely beautiful wax-coloured alabaster, from the vicinity of the city of Granada; and a finely veined marble from the Sierra Nevada.

16 Mineral waters. Of the Spanish mineral waters the following are the most celebrated. The principal cold springs are, a hepatic water in the town of Buron, in Valencia; a carbonated water at Gerona, in Catalonia; a saline purgative water at Vacia-Madrid, three leagues from the capital, and another of a similar nature near Toledo.

The principal hot springs are, the baths of Abu-Zulena, at Javal-Cohol, near Baeza; a hepatic spring used for bathing near Alhama de Granada; another near Almeria, in the province of Granada, to which are attached both bathing and vapour baths: all these were discovered, or at least brought into general use, by the Moors. A very copious hot spring near Merida, in Estremadura, made use of by the Romans. The Calda de Bonar, in the neighbourhood of Leon, a spring of tepid water frequented by the Romans, and still exhibiting the ruins of baths and ancient inscriptions. A very hot spring near Orense, in Gallicia. A spring at Alhama, near Calataynd, in Aragon, formerly much frequented, but now in a state of neglect. The Fuente de Buzot, near Alicant, a saline spring of the temperature of 104° Fahrenheit. A very copious and hot spring at Archena, near Murcia, where still remain the ruins of Roman and Moorish baths. A hepatic spring near Arnedillo, in Old Castile.

17 Natural curiosities. Among the natural curiosities of Spain, we may particularize the mountain of Montserrat in Catalonia (see MONTSERRAT); the insulated hill of rock salt near the town of Cardona, in Catalonia (see GEOLOGY, N° 102); the subterranean lake contained within a cave, in the neighbourhood of the Cava Perella, in the island of Minorca; the stalactitic cave called St Michael's, on the west side of the rock of Gibraltar, and the river Guadiana, which appears and disappears several times in the course of its progress to the sea.

18 Spanish islands. The various groups of islands that are subject to Spain have long been distinguished by particular names. Thus *Majorca*, *Minorca*, *Cabrera* and *Dragonera*, were called by the ancients *Insulæ Baleares*, and are still named the *Balearic Isles*; while Iviça and *Feromentara* form a lesser group, denominated the *Pityuse Isles*. Of these islands, the latter were taken possession of by the Carthaginians nearly 700 years before the Christian era; and about 200 years after that enterprising people made themselves masters of the Balearic isles. After the fall of Carthage, all these islands long maintained a state of piratical independence, and only Majorca was ever completely subject to the Romans. In the time of Augustus we are told that the Balearic isles were so infested with rabbits, that the inhabitants sent deputies to Rome for assistance to destroy these formidable invaders of their plantations. In the year 426 of the Christian era, these islands came into the possession of the Vandals, from whom they were taken at the end of the 8th century by the African Moors. At the beginning of the 9th century they were seized on by a fleet sent into the Mediterranean by Charlemagne; but they were soon after reconquered by the Moors, who maintained the sovereignty in these islands till, in 1228, they were finally dispossessed by Don James grandson of Alphonso II. king of Aragon.

19 Names of Spain. Though Spain appears to have been known to the Phœnicians nearly 1000 years before the birth of Christ, it seems to have been little regarded by the Greeks till after the period when Herodotus composed his history. Some part of this country was probably the Tarshish of Scripture, from which the Phœnicians imported gold, silver, and other precious commodities into Judea. When the Greeks had established a colony at Marseilles, they must have been well acquainted with at least the northern part of this peninsula, to which they gave the names of Iberia and Celtiberia, from two nations who then inhabited the country, and of Hesperia, from its extreme situation in the west of the then known world. The name Hispania, from which its modern appellation is

Spain.

is derived, was bestowed on it by the Romans; but the etymology of this name is uncertain.

20 Original population.

The Aborigines of Spain were doubtless a Celtic tribe, which probably passed into this peninsula from the adjoining continent of Gaul, though at a very early period they appear to have been mixed with a colony of Mauritani, or Moors from the coast of Africa. The Celtic inhabitants, or Celtiberi, seem to have possessed the north-east of the peninsula, while the Mauritani occupied the southern and south-western districts.

21 Spain invaded by the Carthaginians. An. 240. B. C.

Nothing certain is known respecting the early state of Spain, till the commencement of the first Punic war between the Romans and the Carthaginians, in the middle of the third century before Christ. Not long before this date, probably at the beginning of the century, the latter people had possessed themselves of Catalonia, when their general Hamilcar Barcas is said to have founded the city of Barceno, the modern Barcelona. The Carthaginian colony, however, seems to have been rather a mercantile than a warlike settlement, and the Celtiberi were more the allies than the subjects of their African neighbours. Of the contests carried on between the Carthaginians and the Romans, till the final subjugation of the former, and the consequent occupation of all their territories by the Roman republic, we have given an account under the articles CARTHAGE and ROME. We shall here briefly consider the state of Spain at the time of its occupation by the Romans, and relate the events to which that occupation gave rise, and which are less connected with the more immediate transactions of the Punic wars.

22 State of Spain at the Roman conquest.

At the time of the Roman conquest, Spain, though prodigious quantities of silver had been carried out of it by the Carthaginians and Tyrians, was yet a very rich country. In the most ancient times, indeed, its riches are said to have exceeded what is related of the most wealthy country in America. Aristotle assures us, that when the Phenicians first arrived in Spain, they exchanged their naval commodities for such immense quantities of silver, that their ships could neither contain nor sustain its load, though they used it for ballast, and made their anchors and other implements of silver. When the Carthaginians first came to Spain, they found the quantity of silver nothing lessened, since the inhabitants at that time made all their utensils, and even mangers, of that precious metal. In the time of the Romans this amazing plenty was very much diminished; however, their gleanings were by no means despicable, since in the space of nine years they carried off 111,542 pounds of silver, and 4095 of gold, besides an immense quantity of coin and other things of value (A). The Spaniards were always remarkable for their bravery, and some of Hannibal's best troops were brought from thence; but as the Romans penetrated farther into the country than the Carthaginians had done, they met with nations whose love of liberty was equal to their valour, and whom the whole strength of their empire was scarcely able to subdue. Of these the most formidable were the Numantines, Cantabrians, and Asturians.

23 Successes of Viriathus against the Romans.

In the time of the third Punic war, one Viriathus, a celebrated hunter, and afterwards the captain of a gang of banditti, took upon him the command of some nations who had been in alliance with Carthage, and ventured to oppose the Roman power in that part of Spain called *Lusitania*, now Portugal. The prætor named *Vetilius*, who commanded in those parts marched against him with 10,000 men; but was defeated and killed, with the loss of 4000 of his troops. The Romans immediately dispatched another prætor with 10,000 foot and 1300 horse: but Viriathus having first cut off a detachment of 4000 of them, engaged the rest in a pitched battle; and having entirely defeated them, reduced great part of the country. Another prætor, who was sent with a new army, met with the same fate; so that, after the destruction of Carthage, the Romans thought proper to send a consul named *Quintus Fabius*, who defeated the Lusitanians in several battles, and regained two important places which had long been in the hands of the rebels. After the expiration of Fabius's consulate, Viriathus continued the war with his usual success, till the senate thought proper to send against him the consul Q. Cæcilius Metellus, an officer of great valour and experience. With him Viriathus did not choose to venture a pitched battle, but contented himself with acting on the defensive; in consequence of which the Romans recovered a great many cities, and the whole of Tarraconian Spain was obliged to submit to their yoke. The other consul, named *Servilianus*, did not meet with the same success; his army was defeated in the field, and his camp was nearly taken by Viriathus. Notwithstanding the good fortune of Metellus, however, he could not withstand the intrigues of his countrymen against him, and he was not allowed to finish the war he had begun with so much success. In resentment for this he took all imaginable pains to weaken the army under his command: he disbanded the flower of his troops, exhausted the magazines, let the elephants die, broke in pieces the arrows which had been provided for the Cretan archers, and threw them into a river. Yet, after all, the army which he gave up to his successor Q. Pompeius, consisting of 30,000 foot and 2000 horse, was sufficient to have crushed Viriathus if the general had known how to use it. But, instead of opposing Viriathus with success, the imprudent consul procured much more formidable enemies. The Termantines and Numantines, who had hitherto kept themselves independent, offered very advantageous terms of peace and alliance with Rome; but Pompeius insisted on their delivering up their arms. Upon this war was immediately commenced. The consul with great confidence invested Numantia; but being repulsed with considerable loss, he sat down before Termantia, where he was attended with still worse success. The very first day, the Termantines killed 700 of his legionaries; took a great convoy which was coming to the

(A) In this account we must allow something for the exaggerations of fabulous historians. There is no doubt, however, that Spain was at this time immensely rich, and if we may believe Strabo, there was then a mine near Carthage which yielded every day 25,000 drams of silver, or about 300,000l. per annum.

Spain. the Roman camp: and having defeated a considerable body of their horse, pushed them from post to post till they came to the edge of a precipice, where they all tumbled down, and were dashed to pieces. In the mean time Servilius, who had been continued in his command with the title of *proconsul*, managed matters so ill, that Viriathus surrounded him on all sides, and obliged him to sue for peace. The terms offered to the Romans were very moderate; being only that Viriathus should keep the country he at that time possessed, and the Romans remain masters of all the rest. This peace the proconsul was very glad to sign, and afterwards procured its ratification by the senate and people of Rome.

24 The Romans surrounded on all sides, and forced to conclude a peace with Viriathus.

The next year Q. Pompeius was continued in his command against the Numantines in Farther Spain, while Q. Servilius Cæpio, the new consul, had for his province Hither Spain, where Viriathus had established his new state. Pompeius undertook to reduce Numantia by turning aside the stream of the Durius, now the Douro, by which it was supplied with water; but, in attempting this, such numbers of his men were cut off, that, finding himself unable to contend with the enemy, he was glad to make peace with them on much worse terms than they had offered of their own accord. The peace, however, was ratified at Rome; but in the mean time Cæpio, desirous of showing his prowess against the renowned Viriathus, prevailed on the Romans to declare war against him without any provocation. As Cæpio commanded an army greatly superior to the Lusitanians, Viriathus thought proper to sue for peace; but finding that Cæpio would be satisfied with nothing less than a surrender at discretion, he resolved to stand his ground. In the mean time, the latter having bribed some of the intimate companions of Viriathus to murder him in his sleep, he by that infamous method put an end to a war which had lasted 14 years, very little to the honour of the republic.

25 Viriathus treacherously murdered.

After the death of Viriathus, the Romans with like treachery ordered their new consul Popilius to break the treaty with the Numantines. His infamous conduct met with the reward it deserved; the Numantines sallying out, put the whole Roman army to flight with such slaughter, that they were in no condition to act during the whole campaign. Mancinus, who succeeded Popilius, met with still worse success; his great army, consisting of 30,000 men, was utterly defeated by 4000 Numantines, and 20,000 of them killed in the pursuit. The remaining 10,000, with their general, were pent up by the Numantines in such a manner that they could neither advance nor retreat, and would certainly have been all put to the sword or made prisoners, had not the Numantines, with a generosity which their enemies never possessed, offered to let them depart upon condition that a treaty should be concluded with them upon very moderate terms. This the consul very willingly promised, but found himself unable to perform. On the contrary, the people not satisfied with declaring his treaty null and void, ordered him to be delivered up to the Numantines. The latter refused to accept him, unless he had along with him the 10,000 men whom they had relieved as before related. At last, after the consul had remained a whole day before the city, his successor Furius, thinking this a sufficient recompense to the Numantines for breaking the treaty, ordered him to be received again into the camp. However, Furius did not choose to engage with such a desperate and resolute enemy as the Numantines had showed themselves; and the war with them was discontinued till the year 133 B. C. when Scipio Æmilianus, the destroyer of Carthage, was sent against them. Against this renowned commander the Numantines with all their valour were not able to contend. Scipio, having with the utmost care introduced strict discipline among his troops, and reformed the abuses which his predecessors had suffered in their armies, by degrees brought the Romans to face their enemies, which at his arrival they had absolutely refused to do. Having then ravaged all the country round the town, it was soon blocked up on all sides, and the inhabitants began to feel the want of provisions. At last they resolved to make one desperate attempt for their liberty, and either to break through their enemies, or perish in the attempt. With this view they marched out in good order by two gates, and fell upon the works of the Romans with the utmost fury. The Romans, unable to stand this desperate shock, were on the point of yielding, when Scipio, hastening to the places attacked, with no fewer than 20,000 men, the unhappy Numantines were at last driven into the city, where they sustained for a little longer the miseries of famine. Finding at last, however, that it was altogether impossible to hold out, it was resolved by the majority to submit to the pleasure of the Roman commander. But this resolution was not universally approved. Many shut themselves up in their houses, and died of hunger, while even those who had agreed to surrender repented their offer, and setting fire to their houses, perished in the flames with their wives and children, so that not a single Numantine was left alive to grace the triumph of the conqueror of Carthage.

26 The Romans defeated by the Numantines.

27 Scipio Æmilianus sent against them. An. 133. B. C.

28 Miserable end of the people.

After the destruction of Numantia, the whole of Spain submitted to the Roman yoke; and nothing remarkable happened till the times of the Cimbri, when a prætorian army was cut off in Spain by the Lusitanians. From this time nothing remarkable occurs in the history of Spain till the civil war between Marius and Sylla. The latter having crushed the Marian faction, as related under the article ROME, proscribed all those that had sided against him, whom he could not immediately destroy. Among these was Sertorius, a man of consummate valour and experience in war. He had been appointed prætor of Spain by Marius; and upon the overthrow of Marius, retired to that province. Sylla no sooner heard of his arrival in that country, that he sent thither one Caius Annius with a powerful army to drive him out. As Sertorius had but few troops along with him, he dispatched one Julius Salinator with a body of 6000 men to guard the passes of the Pyrenees, and to prevent Annius from entering the country. But Salinator having been treacherously murdered by assassins hired by Annius for that purpose, he no longer met with any obstacle; and Sertorius was obliged to embark for the coast of Africa with 3000 men, being all he had now remaining. With these he landed in Mauritania; but as his men were straggling carelessly about, great numbers of them were cut off by the Barbarians. This new misfortune obliged Sertorius to re-embark for Spain; but finding the whole coast lined with the troops of Annius, he put to sea again, not knowing what course to steer. In this new voyage he met with a small fleet of Cilician pirates; and having prevailed with

29 Sertorius supports the Marian faction in Spain.

30 Is driven out, and undergoes many hardships.

with them to join him, he made a descent on the coast of Iviça, overpowered the garrison left there by Annius, and gained a considerable booty. On the news of this victory Annius set sail for Iviça, with a considerable squadron, having 5000 land forces on board. Sertorius, not intimidated by the superiority of the enemy, prepared to give them battle. But a violent storm arising, most of the ships were driven on shore and dashed to pieces, Sertorius himself with great difficulty escaping with the small remains of his fleet. For some time he continued in great danger, being prevented from putting to sea by the fury of the waves, and from landing, by the enemy; at last, the storm abating, he passed the straits of Gades, now Gibraltar, and landed near the mouth of the river Bætis. Here he met with some seamen newly arrived from the Atlantic or Fortunate Islands; and was so charmed with the account which they gave him of those happy regions, that he resolved to retire thither to spend the rest of his life in quiet and happiness. But having communicated this design to the Cilician pirates, they immediately abandoned him, and set sail for Africa, with an intention to assist one of the barbarous kings against his subjects who had rebelled. Upon this Sertorius sailed thither also, but took the opposite side; and having defeated the king named *Ascalis*, obliged him to shut himself up in the city of Tingis, now Tangier, which he closely besieged. But in the mean time Pacianus, who had been sent by Sylla to assist the king, advanced with a considerable army against Sertorius. Upon this the latter, leaving part of his forces before the city, marched with the rest to meet Pacianus, whose army, though greatly superior to his own in number, he entirely defeated; killed the general, and took all his forces prisoners.—The fame of this victory soon reached Spain; and the Lusitanians, being threatened with a new war from Annius, invited Sertorius to head their armies. With this request he readily complied, and soon became very formidable to the Romans. Titus Didius, governor of that part of Spain called *Bætica*, first entered the lists with him; but he being defeated, Sylla next dispatched Metellus, reckoned one of the best commanders in Rome, to stop the progress of this new enemy. But Metellus, notwithstanding all his experience, knew not how to act against Sertorius, who was continually changing his station, putting his army into new forms, and contriving new stratagems. On his arrival he sent for L. Domitius, then prætor of Hither Spain, to his assistance; but Sertorius being informed of his march, detached Hirtuleius, or Herculeius, his quæstor, against him, who gave him a total overthrow. Metellus then dispatched Lucius Lollius prætor of Narbonne Gaul against Hirtuleius; but he met with no better success, being utterly defeated, and his lieutenant-general killed.

31 Lands in Africa, and carries on a successful war in that country.

32 Returns to Spain, and defeats the Romans there.

33 Erects Lusitania into a republic.

The fame of these victories brought to the camp of Sertorius such a number of illustrious Roman citizens of the Marian faction, that he formed a design of erecting Lusitania into a republic in opposition to that of Rome. Sylla was continually sending fresh supplies to Metellus; but Sertorius with a handful of men, accustomed to range about the mountains, to endure hunger and thirst, and live exposed to the inclemencies of the weather, so harassed the Roman army, that Metellus himself began to be quite discouraged. At last, Sertorius hearing that Metellus had spoken disrespectfully of his courage, challenged his antagonist to end the war by single combat; but Metellus very prudently declined the combat, as being advanced in years; yet this refusal brought upon him the contempt of the unthinking multitude, upon which Metellus resolved to retrieve his reputation by some signal exploit; and therefore laid siege to Lacobriga, a considerable city in those parts. This he hoped to reduce in two days, as there was but one well in the place; but Sertorius having previously removed all those who could be of no service during the siege, and conveyed 6000 skins full of water into the city, Metellus continued a long time before it without making any impression. At last, his provisions being almost spent, he sent out Aquinas at the head of 6000 men to procure a new supply; but Sertorius falling unexpectedly upon them, cut in pieces or took the whole detachment; the commander himself being the only man who escaped to carry the news of the disaster: upon which Metellus was obliged to raise the siege with disgrace.

34 Obliges Metellus to raise the siege of Lacobriga.

35 Civilizes the Lusitanians.

And now Sertorius, having gained some intervals of ease in consequence of the many advantages he had obtained over the Romans, began to civilize his new subjects. Their savage and furious manner of fighting he changed for the regular order and discipline of a well-formed army; he bestowed liberally upon them gold and silver to adorn their arms, and by conversing familiarly with them, prevailed with them to lay aside their own dress for the Roman *toga*. He sent for all the children of the principal people, and placed them in the great city of Osca, now Huesca, in the kingdom of Aragon, where he appointed them masters to instruct them in the Roman and Greek learning, that they might, as he pretended, be capable of sharing with him the government of the republic. Thus he made them really hostages for the good behaviour of their parents; however, the latter were greatly pleased with the care he took of their children, and all Lusitania were in the highest degree attached to their new sovereign. This attachment he took care to heighten by the power of superstition; for having procured a young hind of a milk-white colour, he made it so tame that it followed him wherever he went; and Sertorius gave out to the ignorant multitude, that this hind was inspired by Diana, and revealed to him the designs of his enemies, of which he always took care to be well informed by the great number of spies whom he employed.

36 Pompey the Great sent against him.

While Sertorius was thus employed in establishing his authority, the republic of Rome, alarmed at his success, resolved to crush him at all events. Sylla was now dead, and all the eminent generals in Rome solicited this honourable though dangerous employment. After much debate a decree was passed in favour of Pompey the Great, but without recalling Metellus. In the mean time, the troops of one Perpenna, or Perperna, had in spite of all that their general could do, abandoned him, and taken the oath of allegiance to Sertorius. This was a most signal advantage to Sertorius; for Perpenna commanded an army of 33,000 men, and had come into Spain with a design to settle there as Sertorius had done; but as he was descended from one of the first families of Rome, he thought it below his dignity to serve under any general, however eminent he might be. But the troops of Perperna were of a different opinion; and therefore declaring that they would serve

serve none but a general who could defend himself, they to a man joined Sertorius; upon which Perperna himself, finding he could do no better, consented to serve also as a subaltern.

On the arrival of Pompey in Spain, several of the cities which had hitherto continued faithful to Sertorius began to waver: upon which the latter resolved, by some signal exploit, to convince them that Pompey

37 could no more screen them from his resentment than Metellus. With this view he laid siege to Lauron, now Lirias, a place of considerable strength. Pompey, not doubting but he should be able to raise the siege, marched quite up to the enemy's lines, and found means to inform the garrison that those who besieged them were themselves besieged, and would soon be obliged to retire with loss and disgrace. On hearing this message, "I will teach Sylla's disciple (said Sertorius), that it is the duty of a general to look behind as well as before him." Having thus spoken, he sent orders to a detachment of 6000 men, who lay concealed among the mountains, to come down and fall upon his rear if he

Sertorius besieges Lauron.

38 should offer to force the lines. Pompey, surprised at their sudden appearance, durst not stir out of his camp; and in the mean time the besieged, despairing of relief, surrendered at discretion; upon which Sertorius granted them their lives and liberty, but reduced their city to ashes.

Takes and burns it in the sight of Pompey.

While Sertorius was thus successfully contending with Pompey, his questor Hirtuleius was entirely defeated by Metellus, with the loss of 40,000 men; upon which Sertorius advanced with the utmost expedition to

39 the banks of the Sucro in Tarraconian Spain, with a design to attack Pompey before he could be joined by Metellus. Pompey, on his part, did not decline the combat: but, fearing that Metellus might share the glory of the victory, advanced with the greatest expedition. Sertorius put off the battle till towards the evening; Pompey, though he knew that the night would prove disadvantageous to him, whether vanquished or victorious, because his troops were unacquainted with the country, resolved to venture an engagement, especially as he feared that Metellus might arrive in the mean time, and rob him of part of the glory of conquering so great a commander. Pompey, who commanded his own right wing, soon obliged Perperna, who commanded Sertorius's left, to give way. Hereupon Sertorius himself, taking upon him the command of that wing, brought back the fugitives to the charge, and obliged Pompey to fly in his turn. In his flight he was overtaken by a gigantic African, who had already lifted up his hand to discharge a blow at him with his broadsword; but Pompey prevented him by cutting off his right hand at one blow. As he still continued his flight, he was wounded and thrown from his horse; so that he would certainly have been taken prisoner, had not the Africans who pursued him quarrelled about the rich furniture of his horse. This gave an opportunity to the general to make his escape; so that at length he reached his camp with much difficulty. But in the mean time Afranius, who commanded the left wing of the Roman army, had entirely defeated the wing which Sertorius had left, and even pursued them so close that he entered the camp along with them. Sertorius, returning suddenly, found the Romans busy in plundering the tents; when taking advantage of their situation, he drove them out with great slaughter, and retook the camp. Next day he offered battle a second time to Pompey: but Metellus then coming up with all his forces, he thought proper to decline an engagement with both commanders. In a few days, however, Pompey and Metellus agreed to attack the camp of Sertorius. The event was similar to that of the former battle; Metellus defeated Perperna, and Sertorius routed Pompey. Being then informed of Perperna's misfortune, he hastened to his relief; rallied the fugitives, and repulsed Metellus in his turn, wounded him with his lance, and would certainly have killed him, had not the Romans, ashamed to leave their general in distress, hastened to his assistance, and renewed the fight with great fury. At last Sertorius was obliged to quit the field, and retire to the mountains. Pompey and Metellus hastened to besiege him; but while they were forming their camp, Sertorius broke through their lines, and escaped into Lusitania. Here he soon raised such a powerful army, that the Roman generals, with their united forces, did not think proper to venture an engagement with him. They could not, however, resist the perpetual attacks of Sertorius, who now drove them from place to place, till he obliged them to separate; the one went into Gaul, and the other to the foot of the Pyrenees.

Defeats Pompey on the banks of the Sucro.

40 Pompey defeated a second time.

41 Pompey and Metellus driven from Spain by Sertorius.

Thus did this celebrated commander triumph over all the power of the Romans; and there is little doubt but he would have continued to make head against all the other generals whom the republic could have sent, had he not been assassinated at an entertainment by the infamous treachery of Perperna, in 73 B. C. after he had made head against the Roman forces for almost 10 years. Pompey was no sooner informed of his death, than, without waiting for any new succours, he marched against the traitor, whom he easily defeated and took prisoner; and having caused him to be executed, thus put an end, with very little glory, to a most dangerous war.

42 Sertorius treacherously murdered.

An 73. B. C.

Many of the Spanish nations, however, still continued to bear the Roman yoke with great impatience; and as the civil wars which took place first between Julius Cæsar and Pompey, and afterwards between Octavianus and Antony, diverted the attention of the republic from Spain, by the time that Augustus had become sole master of the Roman empire, they were again in a condition to assert their liberty. The CANTABRIANS and ASTURIANS were the most powerful and valiant nations at that time in Spain; but after incredible efforts, they were obliged to lay down their arms, or rather were almost exterminated by Agrippa, as related under these articles.

When the Romans first became masters of the western peninsula of Europe, to which, as we have said, they gave the name of Hispania, it was divided into two provinces, called *Citerior* and *Ulterior*, which were governed, sometimes by prætors, and sometimes by proconsuls. In the distribution of the empire by Augustus, *Hispania Citerior* contained the modern provinces of Gallicia, the Asturias, Biscay, Navarre, Leon, the two Castiles, Aragon, Catalonia, Murcia, and Valencia; and was denominated *Provincia Tarraconensis*, from the city of Tarragona in Catalonia, which was then the seat of government. *Hispania Ulterior* was subdivided into Bætica, including the provinces now called Granada

43 Spain under the Romans.

and

and Andalusia; and Lusitania, comprehending the greatest part of Estremadura, and the modern kingdom of Portugal. The province called *Tarraconensis* was then inhabited by the following tribes, viz. the *Ausetani*, occupying the sea-coast, at the north-east, between the Ter and the Lobregat, and having for their capital Germa; the *Ceretani*, inhabiting the district of Cerdana, at the foot of the Pyrenees, whose capital was *Julia*, the modern Llivia; the *Valetani*, occupying the sea coast between the rivers Ter and Lobregat, in the immediate neighbourhood of the *Ausetani*, and whose capital was Barcelona; the *Cosetani* to the left of the mouth of the Ebro, with Tarragona for their capital; the *Locetani*, on the left bank of the river *Sicoris;* the *Illergetes*, extending from that river to the small stream Gallego, which joins the Ebro near Zaragoza, whose capital was Lerida; the *Jacetani* in the northern extremity of Aragon, having their seat of government at Jaca; the *Vascones* in Navarre, and the *Varduii* in the modern Guipuzcoa. These nations occupied the southern and eastern parts of the province. The northern was possessed by the *Caristi*, the *Ostregones*, both in Biscay; the *Cantabri*, cantoned near the source of the Ebro, and along the bay of Biscay; the *Astures* in Asturias and part of Leon; the *Callæci* in Gallicia; the *Vacceni* along the Douro; the *Arebaci* in Old Castile; the *Celtiberi*, between the Ebro and the source of the Tagus, and many others of inferior note.

Lusitania was held by three principal tribes, the *Lusitani*, occupying the greater part of the province, and having for their capital the modern Lisbon; the *Vettones* and the *Celtici*.

Bætica was inhabited by the *Turdetani*, the *Turduli*, the *Bastitani*, and the *Bastuli*.

All these districts, with their principal towns, are minutely treated of by Dr Playfair, in the first volume of his geography.

44 State of Roman Spain.

When incorporated with the Roman empire, Spain partook of its tranquillity, and received in exchange for her liberty, at least wise laws and a mild government. If she could not prevent herself from falling under the dominion of the masters of the world, she was at least the most powerful, the richest, and the happiest province of their empire. Columella has left us an interesting account of her agriculture under the first emperors. The tradition of her ancient population is probably exaggerated, but the ruins of several towns prove it to have been considerable. It was increased by a great many Roman families after the conquest; several legions were established in Spain; 25 colonies were distributed in the most fertile parts of the country, and intermarried with the inhabitants. After a while the Spaniards, seeing in their masters only countrymen, were the first to solicit the rights of Roman citizens, by which they were completely consolidated. Some municipal towns went so far as to desire permission to take the title of colonies, though in the change they lost their independence, nearly in the same manner as certain proprietors of lands under the feudal system converted their domains into fiefs, in order to enjoy the honours attached to them. The government was, in general, milder in Spain than in the other Roman provinces. The administration was carried on in the towns by magistrates named by themselves, and the different provinces were under the superintendance of prætors, proconsuls, and legates or deputies, according to the different eras of the Roman empire; those in their respective departments took care of all the works of public utility, the aqueducts, baths, circuses, and highways, whose magnificent ruins are still existing; but they were principally employed in collecting the revenues of the state, which were singularly analogous to those of the present times. They principally arose from dues, fines, or alienations of property, and the produce of the mines. Spain at that time drew from her own mines the same riches she now draws from the new world, and they were distributed in nearly the same manner. One part belonged to the state, and the other to the inhabitants of the country, who paid a certain duty on the metals which they procured from the mines. Their returns went on increasing, and depended entirely on the number of hands which could be devoted to work in the mines. An employment, so laborious, however, which required a numerous population, tended to diminish that population by the excessive fatigues which it occasioned. Agriculture also suffered by the accumulation of estates in the hands of a few wealthy landholders. By the little attention paid to it by the proprietors, and by the defects inseparable from the system of cultivation by means of slaves, commerce and industry languished; and Spain, after having shared in the splendour of the Roman empire, was beginning to participate in its decline, when a new calamity, by completing her ruin, prepared her regeneration.

This calamity was the irruption of the northern hordes, which soon involved Spain in the general attack. This province was invaded first by the Franks, who in the third century had entered Gaul with a formidable force.

45 Spain invaded by the Franks. A. D. 260.

The Rhine, though dignified by the title of Safeguard of the Provinces, was an imperfect barrier against the daring spirit of enterprise with which the Franks were actuated. Their rapid devastations stretched from the river to the foot of the Pyrenees; nor were they stopped by those mountains. Spain, which had never dreaded, was unable to resist the inroads of the Germans. During 12 years, the greatest part of the reign of Gallienus, that opulent country was the theatre of unequal and destructive hostilities. Tarragona, the flourishing capital of a peaceful province, was sacked and almost destroyed; and so late as the days of Orosius, who wrote in the 5th century, wretched cottages, scattered amidst the ruins of magnificent cities, still recorded the rage of the barbarians. When the exhausted country no longer supplied a variety of plunder, the Franks seized on some vessels, and retreated to Mauritania.

46 By the Suevi, Vandals, &c. An. 409.

The situation of Spain, separated, on all sides, from the enemies of Rome, by the sea, by the mountains, and by intermediate provinces, had secured the long tranquillity of that remote and sequestered country; and we may observe, as a sure symptom of domestic happiness, that, in a period of 400 years, Spain furnished very few materials to the history of the Roman empire. The footsteps of the Barbarians, who, in the reign of Gallienus, had penetrated beyond the Pyrenees, were soon obliterated by the return of peace; and in the 4th century of the Christian era, the cities of Emerita or Merida, of Corduba, Seville, Bracara, and Tarragona, were numbered with the most illustrious of the Roman world. The

Spain. The various plenty of the animal, the vegetable, and the mineral kingdoms, was improved and manufactured by the skill of an industrious people; and the peculiar advantages of naval stores contributed to support an extensive and profitable trade. The arts and sciences flourished under the protection of the emperors; and if the character of the Spaniards was enfeebled by peace and servitude, the hostile approach of the Germans, who had spread terror and desolation from the Rhine to the Pyrenees, seemed to rekindle some sparks of military ardour. As long as the defence of the mountains was intrusted to the hardy and faithful militia of the country, they successfully repelled the frequent attempts of the Barbarians. But no sooner had the national troops been compelled to resign their post to the Honorian bands, in the service of Constantine, than the gates of Spain were treacherously betrayed to the public enemy, about ten months before the sack of Rome by the Goths. The consciousness of guilt, and the thirst of rapine, prompted the mercenary guards of the Pyrenees to desert their station; to invite the arms of the Suevi, the Vandals, and the Alani; and to swell the torrent which was poured with irresistible violence from the frontiers of Gaul to the sea of Africa. The misfortunes of Spain may be described in the language of its most eloquent historian, who has concisely expressed the passionate, and perhaps exaggerated, declamations of contemporary writers. "The irruption of these nations was followed by the most dreadful calamities; as the Barbarians exercised their indiscriminate cruelty on the fortunes of the Romans and the Spaniards; and ravaged with equal fury the cities and the open country. The progress of famine reduced the miserable inhabitants to feed on the flesh of their fellow-creatures; and even the wild beasts, who multiplied, without controul, in the desert, were exasperated, by the taste of blood, and the impatience of hunger, boldly to attack and devour their human prey. Pestilence soon appeared, the inseparable companion of famine; a large proportion of the people was swept away; and the groans of the dying excited only the envy of their surviving friends. At length the Barbarians satiated with carnage and rapine, and afflicted by the contagious evil which they themselves had introduced, fixed their permanent seats in the depopulated country. The ancient Gallicia, whose limits included the kingdom of Old Castile, was divided between the Suevi and the Vandals; the Alani were scattered over the provinces of Carthagena and Lusitania, and from the Mediterranean to the Atlantic ocean; and the fruitful territory of Bætica was allotted to the Silingi, another branch of the Vandalic nation. After regulating this partition, the conquerors contracted with their new subjects some reciprocal engagements of protection and obedience: the lands were again cultivated; and the towns and villages were again occupied by a captive people. The greatest part of the Spaniards was even disposed to prefer this new condition of poverty and barbarism, to the severe oppressions of the Roman government; yet there were many who still asserted their native freedom, and who refused, more especially in the mountains of Gallicia, to submit to the barbarian yoke *."

* Mariana de reb. Hispan. lib. v.

An. 41[illegible]. The important present of the heads of Jovinus and Sebastian, had approved the friendship of Adolphus, and restored Gaul to the obedience of his brother Honorius. Peace was incompatible with the situation and temper of the King of the Goths. He readily accepted the proposal of turning his victorious arms against the barbarians of Spain; the troops of Constantius intercepted his communication with the sea-ports of Gaul, and gently pressed his march towards the Pyrenees. He passed the mountains, and surprised, in the name of the emperor, the city of Barcelona. The fondness of Adolphus for his Roman bride, Placidia, was not abated by time or possession; and the birth of a son, surnamed, from his illustrious grandsire, Theodosius, appeared to fix him for ever in the interest of the republic. The loss of that infant, whose remains were deposited in a silver coffin in one of the churches near Barcelona, afflicted his parents; but the grief of the Gothic king was suspended by the labours of the field: and the course of his victories was soon interrupted by domestic treason. He had imprudently received into his service one of the followers of Sarus; a barbarian of a daring spirit, but of a diminutive stature; whose secret desire of revenging the death of his beloved patron, was continually irritated by the sarcasms of his insolent master. Adolphus was assassinated in the palace of Barcelona; the laws of the succession were violated by a tumultuous faction; and a stranger to the royal race, Singeric, the brother of Sarus himself, was seated on the Gothic throne. The first act of his reign was the inhuman murder of the six children of Adolphus, the issue of a former marriage, whom he tore, without pity, from the feeble arms of a venerable bishop. The unfortunate Placidia, instead of the respectful compassion, which she might have excited in the most savage breasts, was treated with cruel and wanton insult. The daughter of the emperor Theodosius, confounded among a crowd of vulgar captives, was compelled to march on foot above 12 miles, before the horse of a barbarian, the assassin of a husband whom Placidia loved and lamented. An. 415.

47 Conquered by the Goths. An. 415.—418.

But Placidia soon obtained the pleasure of revenge; and the view of her ignominious sufferings might rouse an indignant people against the tyrant, who was assassinated on the seventh day of his usurpation. After the death of Singeric, the free choice of the nation bestowed the Gothic sceptre on Wallia, whose warlike and ambitious temper appeared, in the beginning of his reign, extremely hostile to the republic. He marched, in arms, from Barcelona to the shores of the Atlantic ocean, which the ancients revered and dreaded as the boundary of the world. But when he reached the southern promontory of Spain, and, from the rock now covered by the fortress of Gibraltar, contemplated the neighbouring and fertile coast of Africa, Wallia resumed the designs of conquest, which had been interrupted by the death of Alaric. The winds and waves disappointed the enterprises of the Goths; and the minds of a superstitious people were deeply affected by the repeated disasters of storms and shipwrecks. In this disposition, the successor of Adolphus no longer refused to listen to a Roman ambassador, whose proposals were enforced by the real, or supposed, approach of a numerous army, under the conduct of the brave Constantius. A solemn treaty was stipulated and observed: Placidia was honourably restored to her brother; 600,000 measures of wheat were delivered to the hungry Goths; and Wallia engaged to draw his sword in the service of the empire. A bloody war was instantly excited among the barbarians of Spain; and the contending princes are said to have

Spain. have addressed their letters, their ambassadors, and their hostages, to the throne of the western emperor, exhorting him to remain a tranquil spectator of their contest; the events of which must be favourable to the Romans, by the mutual slaughter of their common enemies. The Spanish war was obstinately supported, during three campaigns, with desperate valour and various success; and the martial achievements of Wallia diffused through the empire the superior renown of the Gothic hero. He exterminated the Silingi, who had irretrievably ruined the elegant plenty of the province of Bætica. He slew in battle the king of the Alani; and the remains of those Scythian wanderers, who escaped from the field, instead of choosing a new leader humbly sought a refuge under the standard of the Vandals, with whom they were ever afterwards confounded. The Vandals themselves, and the Suevi, yielded to the efforts of the invincible Goths. The promiscuous multitude of barbarians, whose retreat had been intercepted, were driven into the mountains of Gallicia, where they still continued in a narrow compass, and on a barren soil, to exercise their domestic and implacable hostilities. In the pride of victory, Wallia was faithful to his engagements; he restored his Spanish conquests to the obedience of Honorius; and the tyranny of the imperial officers soon reduced an oppressed people to regret the time of their barbarian servitude. While the event of the war was still doubtful, the first advantages obtained by the arms of Wallia, had encouraged the court of Ravenna to decree the honours of a triumph to their feeble sovereign. He entered Rome like the ancient conquerors of nations, and if the monuments of servile corruption had not long since met with the fate which they deserved, we should probably find that a crowd of poets, and orators, of magistrates and bishops, applauded the fortune, the wisdom, and the invincible courage of the emperor Honorius.

An. 428. After the retreat of the Goths, the authority of Honorius had obtained a precarious establishment in Spain; except only in the province of Gallicia, where the Suevi and the Vandals had fortified their camps, in mutual discord, and hostile independence. The Vandals prevailed; and their adversaries were besieged in the Nervascan hills, between Leon and Oviedo, till the approach of Count Asterius compelled, or rather provoked, the victorious barbarians to remove the scene of the war to the plains of Bætica. The rapid progress of the Vandals soon required a more effectual opposition; and the master-general Costinus marched against them with a numerous army of Romans and Goths. Vanquished in battle by an inferior enemy, Costinus fled with dishonour to Tarragona; and this memorable defeat, which has been represented as the punishment, was most probably the effect, of his rash presumption. Seville and Carthagena became the reward, or rather the prey, of the ferocious conquerors; and the vessels which they found in the harbour of Carthagena, might easily transport them to the isles of Majorca and Minorca, where the Spanish fugitives, as in a secure recess, had vainly concealed their families and their fortunes. The experience of navigation, and perhaps the prospect of Africa, encouraged the Vandals to accept the invitation which they received from Count Boniface; and the death of Gonderic served only to forward and animate the bold enterprise. In the room of a prince, not conspicuous for any superior powers of the mind or body, they acquired his bastard brother, the terrible Genseric; a name which, in the destruction of the Roman empire, has deserved an equal rank with the names of Alaric and Attila. Almost in the moment of his departure he was informed, that Hermanric, king of the Suevi, had presumed to ravage the Spanish territories, which he was resolved to abandon. Impatient of the insult, Genseric pursued the hasty retreat of the Suevi as far as Merida; precipitated the king and his army into the river Anas, and calmly returned to the sea shore, to embark his victorious troops. The vessels which transported the Vandals over the modern straits of Gibraltar, a channel only twelve miles in breadth, were furnished by the Spaniards, who anxiously wished their departure; and by the African general, who had implored their formidable assistance.

When Theodoric king of the Visigoths encouraged Avitus to assume the purple, he offered his person and his force, as a faithful soldier of the republic. The exploits of Theodoric soon convinced the world, that he had not degenerated from the warlike virtues of his ancestors. After the establishment of the Goths in Aquitain, and the passage of the Vandals into Africa, the Suevi who had fixed their kingdom in Gallicia, aspired to the conquest of Spain, and threatened to extinguish the feeble remains of the Roman dominion. The provincials of Carthagena and Tarragona, afflicted by an hostile invasion, represented their injuries and their apprehensions. Count Fronto was dispatched, in the name of the emperor Avitus, with advantageous offers of peace and alliance; and Theodoric interposed his weighty mediation, to declare that, unless his brother-in-law, the king of the Suevi, immediately retired, he should be obliged to arm in the cause of justice and of Rome. "Tell him," replied the haughty Rechiarius, "that I despise his friendship and his arms; but that I shall soon try, whether he will dare to expect my arrival under the walls of Thoulouse." Such a challenge urged Theodoric to prevent the bold designs of his enemy: He passed the Pyrenees at the head of the Visigoths; the Franks and Burgundians served under his standard; and though he professed himself the dutiful servant of Avitus, he privately stipulated, for himself and his successors, the absolute possession of his Spanish conquests. The two armies, or rather the two nations, encountered each other on the banks of the river Urbicus, about 12 miles from Astorga; and the decisive victory of the Goths appeared for a while to have extirpated the name and kingdom of the Suevi. From the field of battle Theodoric advanced to Braga, their metropolis, which still retained the splendid vestiges of its ancient commerce and dignity. His entrance was not polluted with blood, and the Goths respected the chastity of their female captives, more especially of the consecrated virgins; but the greatest part of the clergy and people were made slaves, and even the churches and altars were confounded in the universal pillage. The unfortunate king of the Suevi had escaped to one of the ports of the ocean; but the obstinacy of the winds opposed his flight: he was delivered to his implacable rival; and Rechiarius, who neither desired nor expected mercy, received, with manly constancy, the death which he would probably have inflicted. After this bloody sacrifice to policy or resentment, Theodoric carried his victorious

An. 456.

Spain.

victorious arms as far as Merida, the principal town of Lusitania, without meeting any resistance, except from the miraculous powers of St Eulalia; but he was stopped in the full career of success, and recalled from Spain, before he could provide for the security of his conquests. In his retreat towards the Pyrenees, he revenged his disappointment on the country through which he passed; and in the sack of Pallentia and Astorga, he shewed himself a faithful ally, as well as a cruel enemy.

48
Introduction of Christianity,
A. 586.—589.

Recared was the first Catholic king of Spain. He had imbibed the faith of his unfortunate brother, and he supported it with more prudence and success. Instead of revolting against his father, Recared patiently expected the hour of his death. Instead of condemning his memory, he piously supposed, that the dying monarch had abjured the errors of Arianism, and recommended to his son the conversion of the Gothic nation. To accomplish that salutary end, Recared convened an assembly of the Arian clergy and nobles, declared himself a Catholic, and exhorted them to imitate the example of their prince. The laborious interpretation of doubtful texts, or the curious pursuit of metaphysical arguments, would have excited endless controversy; and the monarch discreetly proposed to his illiterate audience, two substantial and visible arguments, the testimony of Earth and of Heaven. The *Earth* had submitted to the Nicene synod; the Romans, the Barbarians, and the inhabitants of Spain, unanimously professed the same orthodox creed; and the Visigoths resisted, almost alone, the consent of the Christian world. A superstitious age was prepared to reverence, as the testimony of *Heaven*, the preternatural cures which were performed by the skill or virtue of the Catholic clergy; the baptismal fonts of Osset in Bætica, which were spontaneously replenished each year, on the vigil of Easter; and the miraculous shrine of St Martin of Tours, which had already converted the Suevic prince and people of Gallicia. The Catholic king encountered some difficulties on this important change of the national religion. A conspiracy, secretly fomented by the queen-dowager, was formed against his life; and two counts excited a dangerous revolt in the Narbonnese Gaul. But Recared disarmed the conspirators, defeated the rebels, and executed severe justice; which the Arians, in their turn, might brand with the reproach of persecution. Eight bishops, whose names betray their Barbaric origin, abjured their errors; and all the books of Arian theology were reduced to ashes, with the house in which they had been purposely collected. The whole body of the Visigoths and Suevi were allured or driven into the pale of the Catholic communion; the faith, at least, of the rising generation, was fervent and sincere; and the devout liberality of the Barbarians enriched the churches and monasteries of Spain. Seventy bishops assembled in the council of Toledo, received the submission of their conquerors; and the zeal of the Spaniards improved the Nicene creed, by declaring the procession of the Holy Ghost from the Son, as well as from the Father; a weighty point of doctrine, which produced, long afterwards, the schism of the Greek and Latin churches. The royal proselyte immediately saluted and consulted Pope Gregory, surnamed the Great, a learned and holy prelate, whose reign was distinguished by the conversion of heretics and infidels. The ambassadors of Recared respectfully offered on the threshold of the Vatican his rich present of gold and gems: they accepted, as a lucrative exchange, the hairs of St John the Baptist; a cross, which inclosed a small piece of the true wood; and a key, that contained some particles of iron which had been scraped from the chains of St Peter*.

* Gibbon's *Rome*, 4to, vol. iii. p. 549.

49
Legislative assemblies of the Goths in Spain.

After their conversion from idolatry or heresy, the Franks and the Visigoths were disposed to embrace, with equal submission, the inherent evils, and the accidental benefits of superstition. But the prelates of France, long before the extinction of the Merovingian race, had degenerated into fighting and hunting barbarians. They disdained the use of synods, forgot the laws of temperance and chastity, and preferred the indulgence of private ambition and luxury, to the greatest interest of the sacerdotal profession. The bishops of Spain respected themselves, and were respected by the public: their indissoluble union disguised their vices, and confirmed their authority; and the regular discipline of the church introduced peace, order, and stability into the government of the state. From the reign of Recared, the first Catholic king, to that of Witiza, the immediate predecessor of the unfortunate Roderic, sixteen national councils were successively convened. The six metropolitans, Toledo, Seville, Merida, Braga, Tarragona and Narbonne, presided according to their respective seniority; the assembly was composed of their suffragan bishops, who appeared in person, or by their proxies; and a place was assigned to the most holy, or opulent, of the Spanish abbots. During the first three days of the convocation, as long as they agitated the ecclesiastical questions of doctrine and discipline, the profane laity was excluded from their debates; which were conducted, however, with decent solemnity. But, on the morning of the fourth day, the doors were thrown open for the entrance of the great officers of the palace, the dukes and counts of the provinces, the judges of the cities, and the Gothic nobles; and the decrees of Heaven were ratified by the consent of the people. The same rules were observed in the provincial assemblies, the annual synods, which were empowered to hear complaints, and to redress grievances; and a legal government was supported by the prevailing influence of the Spanish clergy. The bishops who, in each revolution, were prepared to flatter the victorious, and to insult the prostrate, laboured, with diligence and success, to kindle the flames of persecution, and to exalt the mitre above the crown. Yet the national councils of Toledo, in which the free spirit of the Barbarians was tempered and guided by episcopal policy, have established some prudent laws for the benefit of the king and people. The vacancy of the throne was supplied by the choice of the bishops and palatines; and after the failure of the line of Alaric, the regal dignity was still limited to the pure and noble blood of the Goths. The clergy, who anointed their lawful prince, always recommended, and sometimes practised, the duty of allegiance; and the spiritual censures were denounced on the heads of the impious subjects, who should resist his authority, conspire against his life, or violate, by an indecent union, the chastity even of his widow. But the monarch himself, when he ascended the throne, was bound by a reciprocal oath to God and his people, that he would faithfully execute his important trust. The real or imaginary faults of his administration were subject to the

Spain.

the controul of a powerful aristocracy; and the bishops and palatines were guarded by a fundamental privilege that they should not be degraded, imprisoned, tortured, nor punished with death, exile, or confiscation, unless by the free and public judgment of their peers.

50 Code of the Visigoths.

One of these legislative councils of Toledo, examined and ratified the code of laws which had been compiled by a succession of Gothic kings, from the fierce Euric, to the devout Egica. As long as the Visigoths themselves were satisfied with the rude customs of their ancestors, they indulged their subjects of Aquitaine and Spain in the enjoyment of the Roman law. Their gradual improvements in arts, in policy, and at length in religion, encouraged them to imitate, and to supersede, these foreign institutions, and to compose a code of civil and criminal jurisprudence, for the use of a great and united people. The same obligations, and the same privileges, were communicated to the nations of the Spanish monarchy; and the conquerors, insensibly renouncing the Teutonic idiom, submitted to the restraints of equity, and exalted the Romans to the participation of freedom. The merit of this impartial policy was enhanced by the situation of Spain, under the reign of the Visigoths. The provincials were long separated from their Arian masters, by the irreconcileable difference of religion. After the conversion of Recared had removed the prejudices of the Catholics, the coasts, both of the ocean and Mediterranean, were still possessed by the Eastern emperors, who secretly excited a discontented people to reject the yoke of the barbarians, and to assert the name and dignity of Roman citizens. The allegiance of doubtful subjects is indeed most effectually secured by their own persuasion, that they hazard more in a revolt, than they can hope to obtain by a revolution; but it has appeared so natural to oppress those whom we hate and fear, that the contrary system well deserves the praise of wisdom and moderation.

The Gothic princes continued to reign over a considerable part of Spain till the beginning of the 8th century, when their empire was overthrown by the Saracens. During this period, they had entirely expelled

51 The Gothic kingdom overthrown by the Saracens.

the eastern emperors from what they possessed in Spain, and even made considerable conquests in Barbary; but towards the end of the 7th century the Saracens overran all that part of the world with a rapidity which nothing could resist; and having soon possessed themselves of the Gothic dominions in Barbary, they made a descent upon Spain about the year 711 or 712. The king of the Goths at that time was called *Roderic*, and by his bad conduct had occasioned great disaffection among his subjects. He therefore determined to put all to the issue of a battle, knowing that he could not depend upon the fidelity of his own people if he allowed the enemy time to tamper with them. The two armies met in a plain near Xeres in Andalusia. The Goths began the attack with great fury; but though they fought like men in despair, they were at last defeated with excessive slaughter, and their king himself was supposed to have perished in the battle, being never more heard of.

An. 711.

By this battle the Moors in a short time rendered themselves masters of almost all Spain. The poor remains of the Goths were obliged to retire into the mountainous parts of Asturias, Burgos, and Biscay: the inhabitants of Aragon, Catalonia, and Navarre, though they might have made a considerable stand against the enemy, chose for the most part to retire into France. In 718, however, the power of the Goths began again to revive under Don Pelagio or Pelayo, a prince of the royal blood, who headed those that had retired to the mountains after the fatal battle of Xeres. The place where he first laid the foundation of his government was in the Asturias, in the province of Liebana, about nine leagues in length and four in breadth. This is the most inland part of the country, full of mountains enormously high, and so much fortified by nature, that its inhabitants are capable of resisting almost any number of invaders. Alakor the Saracen governor was no sooner informed of this revival of the Gothic kingdom, than he sent a powerful army, under the command of one Alchaman, to crush Don Pelagio before he had time to establish his power. The king, though his forces were sufficiently numerous (every one of his subjects arrived at man's estate being a soldier), did not think proper to venture a general engagement in the open field; but taking post with part of them himself in a cavern in a very high mountain, he concealed the rest among precipices, giving orders to them to fall upon the enemy as soon as they should perceive him attacked by them. These orders were punctually executed, though indeed Don Pelagio himself had repulsed his enemies, but not without a miracle, as the Spanish historians pretend. The slaughter was dreadful; for the troops who lay in ambuscade joining the rest, and rolling down huge stones from the mountains upon the Moors (the name by which the Saracens were known in Spain), no fewer than 124,000 of those unhappy people perished in one day. The remainder fled till they were stopped by a river, and beginning to coast it, part of a mountain suddenly fell down, stopped up the channel of the river, and either crushed or drowned, by the sudden rising of the water, almost every one of that vast army.

Spain.

52 The power of the Goths revives under Pelagio.

An. 718.

53 He gives the Saracens a dreadful overthrow.

The Moors were not so much disheartened by this disaster, but that they made a second attempt against Don Pelagio. Their success was as bad as ever, the greatest part of their army being cut in pieces or taken; in consequence of which, they lost all the Asturias, and never dared to enter the lists with Pelagio afterwards. Indeed, their bad success had in a great measure taken from them the desire of conquering a country where little or nothing was to be gained; and therefore they rather directed their force against France, where they hoped for more plunder. Into this country they poured in prodigious multitudes; but were utterly defeated, in 732, by Charles Martel, with the loss of 300,000 men, as the historians of those times pretend.

54 Another army cut in pieces or taken.

The subsequent history of Spain is rendered so confused by the numerous kingdoms that were established either by the Christians or the Moors, that some chronological guide is necessary to make it intelligible. Before pursuing the thread of the narration, we shall lay before our readers the following chronological table of the cotemporary monarchs from Pelagio to Ferdinand VII.

1788	Charles IV.
1808	Ferdinand VII.

An. 737. Don Pelagio died in 737; and soon after his death such intestine divisions broke out among the Moors, as greatly favoured the increase of the Christian power. In 745 Don Alonso the Catholic, son-in-law to Pelagio, in conjunction with his brother Froila passed the mountains, and fell upon the northern part of Gallicia; and meeting with little resistance, he recovered almost the whole of that province in a single campaign. Next year he invaded the plains of Leon and Castile; and before the Moors could assemble any force to oppose him, he reduced Astorgas, Leon, Saldagna, Montes de Oca, Amaya, Alava, and all the country at the foot of the mountains. The year following he pushed his conquests as far as the borders of Portugal, and the next campaign ravaged the country as far as Castile. Being sensible, however, that he was yet unable to defend the flat country which he had conquered, he laid the whole of it waste, obliged the Christians to retire to the mountains, and carried off all the Moors for slaves. Thus secured by a desert frontier, he met with no interruption for some years; during which time, as his kingdom advanced in strength, he allowed his subjects gradually to occupy part of the flat country, and to rebuild Leon and Astorgas, which he had demolished. He died in 758, and was succeeded by his son Don Froila. In his time Abdoulrahman, the khaliff's viceroy in Spain, threw off the yoke, and rendered himself independent, fixing the seat of his government at Cordova. Thus the intestine divisions among the Moors were composed; yet their success seems to have been little better than before; for, soon after, Froila encountered the Moors with such success, that 54,000 of them were killed on the spot, and their general taken prisoner. Soon after he built the city of Oviedo, which he made the

55 Conquests of the Christians. An. 755.

56 The Saracens in Spain throw off the yoke of the khaliffs. An. 758.

the capital of his dominions, in order to be in a better condition to defend the flat country, which he now determined to people.

57 History of the kingdom of Navarre. An 850.

In the year 850, the power of the Saracens received another blow by the rise of the kingdom of Navarre. This kingdom, we are told, took its origin from an accidental meeting of gentlemen, to the number of 600, at the tomb of an hermit named *John*, who had died among the Pyrenees. At this place, where they had met on account of the supposed sanctity of the deceased, they took occasion to converse on the cruelty of the Moors, the miseries to which the country was exposed, and the glory that would result from throwing off their yoke; which, they supposed, might easily be done, by reason of the strength of their country. On mature deliberation, the project was approved; one Don Garcias Ximenes was appointed king, as being of illustrious birth, and looked upon as a person of great abilities. He recovered Ainsa, one of the principal towns of the country, out of the hands of the infidels, and his successor Don Garcias Inigas extended his territories as far as Biscay: however, the Moors still possessed Portugal, Murcia, Andalusia, Valencia, Granada, Tortosa, with the interior part of the country as far as the mountains of Castile and Zaragoza. Their internal dissensions, which revived after the death of Abdoulrahman, contributed greatly to reduce the power of the infidels in general.

58 Conquests of Charles the Great.

In 778, Charles the Great being invited by some discontented Moorish governors, entered Spain with two great armies; one passing through Catalonia, and the other through Navarre, where he pushed his conquests as far as the Ebro. On his return he was attacked and defeated by the Moors; though this did not hinder him from keeping possession of all those places he had already reduced. At this time he seems to have been master of Navarre: however, in 831 Count Azner, revolting from Pepin son to the emperor Louis, asserted the independency of Navarre; but the sovereigns did not assume the title of kings till the time of Don Garcias, who began to reign in 857.

An. 921.

In the mean time, the kingdom founded by Don Pelagio, now called the kingdom of *Leon* and *Oviedo*, continued to increase rapidly in strength, and many advantages were gained over the Moors, who having two enemies to contend with, lost ground every day. In 921, however, they gained a great victory over the united forces of Navarre and Leon, by which the whole force of the Christians in Spain must have been entirely broken, had not the victors conducted their affairs so wretchedly, that they suffered themselves to be almost entirely cut in pieces by the remains of the Christian army. In short, the Christians became at length so terrible to the Moors, that it is probable they could not long have kept their footing in Spain, had not a great general, named *Mohammed Ebn Amir Almanzor*, appeared, in 979, to support their sinking cause.

59 Exploits of Almanzor a Saracen general. An. 979.

This man was visir to the king of Cordova, and being exceedingly provoked against the Christians on account of what his countrymen had suffered from them, made war with the most implacable fury. He took the city of Leon, murdered the inhabitants, and reduced the houses to ashes. Barcelona shared the same fate; Castile was reduced to a desert; Gallicia and Portugal ravaged; and he is said to have overcome the Christians in fifty different engagements. At last, having taken and demolished the city of Compostella, and carried off in triumph the gates of the church of St James, a flux happened to break out among his troops, which the superstitious Christians supposed to be a divine judgment on account of his sacrilege. Taking it for granted, therefore, that the Moors were now entirely destitute of all heavenly aid, they fell upon them with such fury in the next engagement, that all the valour and conduct of Almanzor could not prevent a defeat. Overcome with shame and despair at this misfortune, he desired his followers to shift for themselves, while he himself retired to Medina Cœli, and put an end to his life by abstinence in the year 998.

60 He is defeated, and starves himself to death. An. 998.

61 Rise of the kingdom of Castile. An. 1037.

During this period a new Christian principality appeared in Spain, namely that of Castile, which is now divided into the Old and New Castile. The Old Castile was recovered long before that called the *New*. It was separated from the kingdom of Leon on one side by some little rivers; on the other, it was bounded by the Asturias, Biscay, and the province of Rioja. On the south it had the mountains of Segovia and Avila; thus lying in the middle between the Christian kingdom of Leon and Oviedo, and the Moorish kingdom of Cordova. Hence this district soon became an object of contention between the kings of Leon and those of Cordova; and as the former were generally victorious, some of the principal Castilian nobility retained their independence under the protection of the Christian kings, even when the power of the Moors was at its greatest height. In 884, we first hear of Don Rodriguez assuming the title of *count of Castile*, though it does not appear that either his territory or title were given him by the king of Leon. Nevertheless, this monarch having taken upon him to punish some of the Castilian lords as rebels, the inhabitants made a formal renunciation of their allegiance, and set up a new kind of government. The supreme power was now vested in two persons of quality styled *judges*; however, this method did not long continue to give satisfaction, and the sovereignty was once more vested in a single person. By degrees Castile fell entirely under the power of the kings of Leon and Oviedo; and, in 1037, Don Sancho bestowed it on his eldest son Don Ferdinand, with the title of *king*; and thus the territories of Castile were first firmly united to those of Leon and Oviedo, and the sovereigns were thenceforth styled *kings of Leon and Castile*.

62 Rise of Aragon. An. 1035.

Besides all these, another Christian kingdom was set up in Spain about the beginning of the 11th century. This was the kingdom of Aragon. The inhabitants were very brave, and lovers of liberty, so that it is probable they had in some degree maintained their independence, even when the power of the Moors was greatest. The history of Aragon, however, during its infancy, is much less known than that of any of the others hitherto mentioned. We are only assured, that about the year 1035, Don Sancho, surnamed the *Great*, king of Navarre, erected Aragon into a kingdom in favour of his son Don Ramiro, and afterwards it became very powerful.

63 State of Spain in the beginning of the 11th century.

At this time, then, we may imagine the continent of Spain divided into two unequal parts by a straight line drawn from east to west, from the coasts of Valencia to a little below the mouth of the Douro. The country north of this belonged to the Christians, who, as yet, had the smallest and least valuable

Spain.

able share, and all the rest to the Moors. In point of wealth and real power, both by land and sea, the Moors were much superior; but their continual dissensions greatly weakened them, and every day facilitated the progress of the Christians. Indeed, had either of the parties been united, the other must soon have yielded; for though the Christians did not make war upon each other constantly as the Moors did, their mutual feuds were yet sufficient to have ruined them, had their adversaries made the proper use of the advantages thus afforded them. But among the Moors almost every city was a kingdom; and as these petty sovereignties supported one another very indifferently, they fell a prey one after another to their enemies. In 1080, the king of Toledo was engaged in a war with the king of Seville, another Moorish potentate; which being observed by Alphonso king of Castile, he also invaded his territories; and in four years made himself master of the city of Toledo, with all the places of importance in its neighbourhood; from thenceforth making Toledo the capital of his dominions. In a short time the whole province of New Castile submitted; and Madrid, the present capital of Spain, fell into the hands of the Christians, being at that time but a small place.

64 Toledo and Madrid taken by the Christians. An. 1080.

The Moors were so much alarmed at these conquests, that they not only entered into a general confederacy against the Christians, but invited to their assistance Mahomet Ben Joseph the sovereign of Barbary. He accordingly came, attended by an incredible multitude; but was utterly defeated by the Christians in the defiles of the Black Mountain, or Sierra Morena, on the borders of Andalusia. This victory happened on the 16th of July 1212, and the anniversary is still celebrated at Toledo. This victory was not improved; the Christian army immediately dispersed themselves, while the Moors of Andalusia were strengthened by the remains of the African army; yet, instead of being taught, by their past misfortunes, to unite among themselves, their dissensions became worse than ever, and the conquests of the Christians became daily more rapid. In 1236, Don Ferdinand of Castile and Leon took the celebrated city of Cordova, the residence of the first Moorish kings; at the same time that James I. of Aragon dispossessed them of the island of Majorca, and drove them out of Valencia. Two years after, Ferdinand made himself master of Murcia, and took the city of Seville; and in 1303 Ferdinand IV. reduced Gibraltar.

65 A signal victory gained over the Moors. An. 1212.

An. 1236.

In the time of Edward III. we find England, for the first time, interfering in the affairs of Spain, on the following occasion. In the year 1284 the kingdom of Navarre had been united to that of France by the marriage of Donna Joanna queen of Navarre with Philip the Fair of France. In 1328, however, the kingdoms were again separated, though the sovereigns of Navarre were still related to those of France. In 1350, Charles, surnamed the *Wicked*, ascended the throne of Navarre, and married the daughter of John king of France. Notwithstanding this alliance, and that he himself was related to the royal family of France, he secretly entered into a negociation with England against the French monarch, and even drew into his schemes the dauphin Charles, afterwards surnamed *the Wise*. The young prince, however, was soon after made fully sensible of the danger and folly of the connections into which he had entered; and, by way of atonement, promised to sacrifice his associates. Accordingly he invited the king of Navarre, and some of the principal nobility of the same party, to a feast at Rouen, where he betrayed them to his father. The most obnoxious were executed, and the king of Navarre was thrown into prison. In this extremity, the party of the king of Navarre had recourse to England. The prince of Wales, surnamed *the Black Prince*, invaded France, defeated King John at Poictiers, and took him prisoner*; which unfortunate event produced the most violent disturbances in that kingdom. The dauphin, now about 19 years of age, naturally assumed the royal power during his father's captivity: but possessed neither experience nor authority sufficient to remedy the prevailing evils. In order to obtain supplies, he assembled the states of the kingdom: but that assembly, instead of supporting his administration, laid hold of the present opportunity to demand limitations of the prince's power, the punishment of past malversations, and the liberty of the king of Navarre. Marcel, provost of the merchants of Paris, and first magistrate of that city, put himself at the head of the unruly populace, and pushed them to commit the most criminal outrages against the royal authority. They detained the dauphin in a kind of captivity, murdered in his presence Robert de Clermont and John de Conflans, mareschals of France; threatened all the other ministers with the like fate; and when Charles, who had been obliged to temporize and dissemble, made his escape from their hands, they levied war against him, and openly rebelled. The other cities of the kingdom, in imitation of the capital, shook off the dauphin's authority, took the government into their own hands, and spread the contagion into every province.

66 England interferes in the Spanish affairs.

67 The king of Navarre imprisoned by John king of France.

* See *France*, N° 44.

Amidst these disorders, the king of Navarre made his escape from prison, and presented a dangerous leader to the furious malecontents. He revived his pretensions to the crown of France: but in all his operations he acted more like a leader of banditti than one who aspired to be the head of a regular government, and who was engaged by his station to endeavour the re-establishment of order in the community. All the French, therefore, who wished to restore peace to their country, turned their eyes towards the dauphin; who, though not remarkable for his military talents, daily gained by his prudence and vigilance the ascendant over his enemies. Marcel, the seditious provost of Paris, was slain in attempting to deliver that city to the king of Navarre. The capital immediately returned to its duty: the most considerable bodies of the mutinous peasants were dispersed or put to the sword; some bands of military robbers underwent the same fate; and France began once more to assume the appearance of civil government.

68 Escapes, and heads the French malecontents.

John was succeeded in the throne of France by his son Charles V. a prince educated in the school of adversity, and well qualified, by his prudence and experience, to repair the losses which the kingdom had sustained from the errors of his predecessors. Contrary to the practice of all the great princes of those times, who held nothing in estimation but military courage, he seems to have laid it down as a maxim, never to appear at the head of his armies; and he was the first Eurpean monarch that showed the advantage of policy and foresight over a rash and precipitate valour.

Before Charles could think of counterbalancing so great

Spain.

great a power as England, it was necessary for him to remedy the many disorders to which his own kingdom was exposed. He accordingly turned his arms against the king of Navarre, the great disturber of France during that age; and he defeated that prince, and reduced him to terms, by the valour and conduct of Bertrand du Gnesclin, one of the most accomplished captains of those times, whom Charles had the discernment to choose as the instrnment of his victories. He also settled the affairs of Britanny, by acknowledging the title of Mountfort, and receiving homage for his dominions. But much was yet to be done. On the conclusion of the peace of Bretigni, the many military adventurers who had followed the fortunes of Edward, being dispersed into the several provinces, and possessed of strong holds, refused to lay down their arms, or relinquish a course of life to which they were now accustomed, and by which alone they could earn a subistence. They associated themselves with the banditti, who were already inured to the habits of rapine and violence; and, under the name of *companies* and *companions*, became a terror to all the peaceable inhabitants. Some English and Gascon gentlemen of character were not ashamed to take the command of these ruffians, whose number amounted to near 40,000, and who bore the appearance of regular armies rather than bands of robbers. As Charles was not able by power to redress so enormous a grievance, he was led by necessity, as well as by the turn of his character, to correct it by policy; to discover some method of discharging into foreign countries this dangerous and intestine evil; and an occasion now offered.

69 Is defeated, and obliged to submit to hte terms prescribed by Charles V. of France.

70 Account of the banditti called *companies* or *companions*.

71 Reign of Pedro the Cruel, king of Castile.

Alphonso XI. king of Castile, who took the city of Algezira from the Moors, after a famous siege of two years, during which artillery are said first to have been used by the besieged, had been succeeded by his son Pedro I. surnamed *the Cruel;* a prince equally perfidious, debauched, and bloody. He began his reign with the murder of his father's mistress, Leonora de Gusman: his nobles fell every day the victims of his severity: he put to death his cousin and one of his natural brothers, from groundless jealousy; and he caused his queen Blanche de Bourbon, of the blood of France, to be thrown into prison, and afterwards poisoned, that he might enjoy in quiet the embraces of Mary de Padella, with whom he was violently enamoured.

Henry count of Trastamara, the king's natural brother, alarmed at the fate of his family, and dreading his own, took arms against the tyrant; but having failed in the attempt, he fled to France, where he found the minds of men much inflamed against Pedro, on account of the murder of the French princess. He asked permission of Charles to enlist the *companies* in his service, and to lead them to Castile against his brother. The French king, charmed with the project, employed du Guesclin in negociating with the leaders of these banditti. The treaty was soon concluded; and du Guesclin having completed his levies, led the army first to Avignon, where the pope then resided, and demanded, sword in hand, absolution for his ruffian soldiers, who had been excommunicated, and the sum of 200,000 livres for their subsistence. The first was readily promised him, but some difficulty being made with regard to the second, du Guesclin replied, "My fellows, I believe, may make a shift to do without your absolution, but the money is absolutely necessary." His holiness then extorted from the inhabitants of the city and its neighbourhood the sum of 100,000 livres, and offered it to du Guesclin. "It is not my purpose (cried that generous warrior) to oppress the innocent people. The pope and his cardinals can spare me double the sum from their own pockets. I therefore insist, that this money be restored to the owners; and if I hear they are defrauded of it, I will myself return from the other side of the Pyrenees, and oblige you to make them restitution." The pope found the necessity of submitting, and paid from his own treasury the sum demanded.

72 The Companies employed against him

73 He is driven out, but assisted by the Black Prince.

A body of experienced and hardy soldiers, conducted by so able a general, easily prevailed over the king of Castile, whose subjects were ready to join the enemy against their oppressor. Pedro fled from his dominions, took shelter in Guienne, and craved the protection of the prince of Wales, whom his father had invested with the sovereignty of the ceded provinces, under the title of the *principality of Aquitaine*. The prince promised his assistance to the dethroned monarch; and having obtained his father's consent, he levied an army, and set out on his enterprise.

The first loss which Henry of Trastamara suffered from the interposition of the prince of Wales, was the recalling of the companies from his service; and so much reverence did they pay to the name of Edward, that great numbers of them immediately withdrew from Spain, and enlisted under his standard. Henry, however, beloved by his new subjects, and supported by the king of Aragon, was able to meet the enemy with an army of 100,000 men, three times the number of those commanded by the Black Prince: yet du Guesclin, and all his experienced officers, advised him to delay a decisive action; so high was their opinion of the valour and conduct of the English hero! But Henry, trusting to his numbers, ventured to give Edward battle on the banks of the Ebro, between Najara and Navarette; where the French and Spaniards were defeated, with the loss of above 20,000 men, and du Guesclin and other officers of distinction taken prisoners. All Castile submitted to the victor; Pedro was restored to the throne, and Edward returned to Guienne with his usual glory; having not only overcome the greatest general of his age, but restrained the most blood-thirsty tyrant from executing vengeance on his prisoners.

74 The Spaniards defeated, and Pedro restored.

This gallant warrior had soon reason to repent of his connection with a man like Pedro, lost to all sense of virtue and honour. The ungrateful monster refused the stipulated pay to the English forces. Edward abandoned him: he treated his subjects with the utmost barbarity; their animosity was roused against him; and du Guesclin having obtained his ransom, returned to Castile with the count of Trastamara, and some forces levied anew in France. They were joined by the Spanish malecontents; and having no longer the Black Prince to encounter, they gained a complete victory over Pedro in the neighbourhood of Toledo. The tyrant now took refuge in a castle, where he was soon after besieged by the victors, and taken prisoner in endeavouring to make his escape. He was conducted to his brother Henry; against whom he is said to have rushed in a transport of rage, disarmed as he was. Henry slew him with his own

75 Is again driven out, defeated, and put to death.

own hand, in resentment of his cruelties; and, though a bastard, was placed on the throne of Castile, which he transmitted to his posterity.

There is little doubt that the character of Pedro has been greatly misrepresented, and that what is considered by most historians as tyranny and wanton cruelty, was only an inflexible regard to justice, necessary perhaps, in those days of anarchy and rebellion. Perhaps that unfortunate monarch owes to the hatred of those he meant to reduce to order, much of the obloquy which has been so plentifully bestowed upon him by historians, who have painted him to us as a tyrant so bloody, so wicked, as almost to exceed the bounds of probability. In Andalusia, where he fixed his residence and seemed most to delight, his memory is not held in the same abhorrence. The Sevillian writers speak of him very differently; and instead of his usual appellation of *Pedro el cruel*, distinguish him by that of *el justiciero*. It is certain that his bastard-brother and murderer, Henry of Trastamara, was guilty of crimes fully as atrocious as any of those imputed to Don Pedro; but as he destroyed him, his family and adherents, the friends of the new spurious race of monarchs were left at full liberty to blacken the characters of the adverse party, without the fear of being called to an account for calumny, or even contradicted. Truth is now out of our reach; and for want of proper proofs to the contrary, we must sit down contented with what history has left us; and allow Don Pedro to have been one of the most inhuman butchers that ever disgraced a throne.

After the death of Pedro the Cruel, nothing remarkable happened in Spain for almost a whole century; but the debaucheries of Henry IV. of Castile roused the resentment of his nobles, and produced a most singular insurrection, which led to the aggrandizement of the Spanish monarchy.

76 Reign of Henry the Impotent. An. 1450.

This prince, surnamed the *Impotent*, though continually surrounded with women, began his unhappy reign in 1450. He was totally enervated by his pleasures; and every thing in his court conspired to set the Castilians an example of the most abject flattery and most abandoned licentiousness. The queen, a daughter of Portugal, lived as openly with her parasites and her gallants as the king did with his minions and his mistresses. Pleasure was the only object, and effeminacy the only recommendation to favour: the affairs of the state went every day into disorder; till the nobility, with the archbishop of Toledo at their head, combining against the weak and flagitious administration of Henry, arrogated to themselves, as one of the privileges of their order, the right of trying and passing sentence on their sovereign, which they executed in a manner unprecedented in history.

77 He is formally deposed.

All the malecontent nobility were summoned to meet at Avila: a spacious theatre was erected in a plain without the walls of the town: an image, representing the king, was seated on a throne, clad in royal robes, with a crown on its head, a sceptre in its hand, and the sword of justice by its side. The accusation against Henry was read, and the sentence of deposition pronounced, in presence of a numerous assembly. At the close of the first article of the charge, the archbishop of Toledo advanced, and tore the crown from the head of the image; at the close of the second, the Conde de Placentia snatched the sword of justice from its side; at the close of the third, the Conde de Benavente wrested the sceptre from his hand; and at the close of the last, Don Diego Lopez de Stuniga tumbled it headlong from the throne. At the same instant, Don Alphonso, Henry's brother, a boy of about twelve years of age, was proclaimed king of Castile and Leon in his stead.

This extraordinary proceeding was followed by a civil war, which did not cease till some time after the death of the young prince, on whom the nobles had bestowed the kingdom. The archbishop and his party then continued to carry on war in the name of Isabella the king's sister, to whom they gave the title of *Infanta*; and Henry could not extricate himself out of these troubles, nor remain quiet upon his throne till he had signed one of the most humiliating treaties ever extorted from a sovereign; he acknowledged his sister Isabella the only lawful heiress of his kingdom, in prejudice to the rights of his reputed daughter Joan, whom the malecontents affirmed to be the offspring of an adulterous commerce between the queen and Don la Cueva.

78 Is obliged to acknowledge his sister Isabella to be heiress to the kingdom.

The grand object of the malecontent party now was the marriage of the princess Isabella, upon which, it was evident, the security of the crown and the happiness of the people must in a great measure depend. The alliance was sought by several princes: the king of Portugal offered her his hand; the king of France demanded her for his brother, and the king of Aragon for his son Ferdinand. The malecontents very wisely preferred the Aragonian prince, and Isabella prudently made the same choice: articles were drawn up; and they were privately married by the archbishop of Toledo.

79 She is married to Ferdinand of Aragon.

Henry was enraged at this alliance, which he foresaw would utterly ruin his authority, by furnishing his rebellious subjects with the support of a powerful neighbouring prince. He disinherited his sister, and established the rights of his daughter. A furious civil war desolated the kingdom. The names of Joan and Isabella resounded from every quarter, and were everywhere the summons to arms. But peace was at length brought about. Henry was reconciled to his sister and Ferdinand; though it does not appear that he ever renewed Isabella's right to the succession: for he affirmed in his last moments, that he believed Joan to be his own daughter. The queen swore to the same effect; and Henry left a testamentary deed, transmitting the crown to this princess, who was proclaimed queen of Castile at Placentia. But the superior fortune and superior arms of Ferdinand and Isabella prevailed: the king of Portugal was obliged to abandon his niece and intended bride, after many ineffectual struggles, and several years of war. Joan retired into a convent; and the death of Ferdinand's father, which happened about this time, added the kingdoms of Aragon and Sicily to those of Leon and Castile.

80 Union of the kingdom of Aragon and Sicily with Leon and Castile. An. 1474.

81 Administration of Ferdinand and Isabella.

Ferdinand and Isabella were persons of great prudence, and, as sovereigns, highly worthy of imitation: but they do not seem to have merited all the praises bestowed upon them by the Spanish historians. They did not live like man and wife, having all things in common under the direction of the husband; but like two princes in close alliance; they neither loved nor hated each other; were seldom in company together; had each a separate council; and were frequently jealous of one another in the administration. But they

were

were inseparably united in their common interests; always acting upon the same principles, and forwarding the same ends. Their first object was the regulation of their government, which the civil wars had thrown into the greatest disorder. Rapine, outrage, and murder were become so common, as not only to interrupt commerce, but in a great measure to suspend all intercourse between one place and another. These evils the joint sovereigns suppressed by their wise policy, at the same time that they extended the royal prerogative.

82 Institution of the Holy Brotherhood. About the middle of the 13th century, the cities in the kingdom of Aragon, and after their example those in Castile, had formed themselves into an association, distinguished by the name of the *Holy Brotherhood*. They exacted a certain contribution from each of the associated towns; they levied a considerable body of troops, in order to protect travellers and pursue criminals; and they appointed judges, who opened courts in various parts of the kingdom. Whoever was guilty of murder, robbery, or any act that violated the public peace, and was seized by the troops of the Brotherhood, was carried before their judges; who, without paying any regard to the exclusive jurisdiction which the lord of the place might claim, who was generally the author or abettor of the injustice, tried, and condemned the criminals. The nobles often murmured against the salutary institution; they complained of it as an encroachment on one of their most valuable privileges, and endeavoured to get it abolished. But Ferdinand and Isabella, sensible of the beneficial effects of the Brotherhood, not only in regard to the police of their kingdom, but in its tendency to abridge, and by degrees annihilate, the territorial jurisdiction of the nobility, countenanced the institution upon every occasion, and supported it with the whole force of royal authority; by which means the prompt and impartial administration of justice was restored, and with it tranquillity and order returned.

83 and of the Inquisition. But at the same time that their Catholic majesties (for such was the title they now bore) were giving vigour to their civil government, and securing their subjects from violence and oppression, an intemperate zeal led them to establish an ecclesiastical tribunal, equally contrary to the natural rights of humanity and the mild spirit of the gospel. This was the court of inquisition; which decides upon the honour, fortune, and even the life, of the unhappy wretch who happens to fall under the suspicion of heresy, or a contempt of any thing prescribed by the church, without his knowing, being confronted with his accusers, or permitted either defence or appeal. Six thousand persons were burnt by order of this sanguinary tribunal within four years after the appointment of Torquemada, the first inquisitor-general; and upwards of 100,000 felt its fury. The same furious and blinded zeal which led to the depopulation of Spain, led also to its aggrandizement.

84 Conquest of Granada. An. 1492. The kingdom of Granada now alone remained of all the Mahometan possessions in Spain. Princes equally zealous and ambitious were naturally disposed to turn their eyes to that fertile territory, and to think of increasing their hereditary dominions, by expelling the enemies of Christianity, and extending its doctrines. Every thing conspired to favour their project: the Moorish kingdom was a prey to civil wars; when Ferdinand, having obtained the bull of Sixtus IV. authorizing a crusade, put himself at the head of his troops, and entered Granada. He continued the war with rapid success: Isabella attended him in several expeditions; and they were both in great danger at the siege of Malaga; an important city, which was defended with great courage, and taken in 1487. Baza was reduced in 1489, after the loss of 20,000 men. Gaudix and Almeria were delivered up to them by the Moorish king Alzagel, who had first dethroned his brother Alboacen, and afterwards been chased from his capital by his nephew Abdali. That prince engaged in the service of Ferdinand and Isabella; who, after reducing every other place of eminence, undertook the siege of Granada. Abdali made a gallant defence; but all communication with the country being cut off, and all hopes of relief at an end, he capitulated, after a siege of eight months, on condition that he should enjoy the revenue of certain places in the fertile mountains of Alpuxarras; that the inhabitants should retain the undisturbed possession of their houses, goods, and inheritances; the use of their laws, and the free exercise of their religion (B). Thus ended the empire of the Arabs in Spain, after it had continued about 800 years. They introduced the arts and sciences into Europe at a time when it was lost in darkness; they possessed many of the luxuries of life, when they were not even known among the neighbouring nations; and they seem to have given birth to that romantic gallantry which so eminently prevailed in the ages of chivalry, and which, blending itself with the veneration of the northern nations for the softer sex, still particularly distinguishes ancient from modern manners. But the Moors, notwithstanding these advantages, and the eulogies bestowed upon them by some writers, appear always to have been destitute of the essential qualities of a polished people, humanity, generosity, and mutual sympathy.

The overthrow of the last Moorish kingdom was soon followed by the expulsion of the Saracens from Spain. This expulsion did not entirely take place till the 17th century. Vast numbers of the Moors, indeed, oppressed by their conquerors, abandoned a country where they could not reside with comfort and with freedom. From the reign of Ferdinand of Castile, to that of Philip III. of Spain, more than 3,000,000 of those people quitted Spain, and carried with them, not only a great part of their acquired wealth, but that industry and love of labour which are the foundation of national prosperity. 85

Prosperous state of Spain under the Moorish dominion. The state of Spain has never been so flourishing at any period of its civilization, as during the period when it was chiefly possessed by the Moors. The first Saracen invaders, and the twenty successive lieutenants of the caliphs of Damascus, were attended by a numerous train of civil and military followers, who preferred a distant

(B) The particulars of the conquest of Granada are involved in much obscurity. If we were to credit the narrative of Giles Perez, as related by Mr Swinburne, the circumstances which led to that conquest were of a most romantic nature. See Swinburne's Travels, Letter xxi.

distant fortune to narrow circumstances at home; the private and public interest was promoted by the establishment of faithful colonies, and the cities of Spain were proud to commemorate the tribe or the country of their eastern progenitors. Ten years after the conquest, a map of the province was presented to the caliph, shewing the seas, the rivers, and the harbours, the inhabitants and cities, the climate, the soil, and the mineral productions of the earth. In the space of two centuries the gifts of nature were improved by agriculture, the manufactures, and the commerce of an industrious people; though the effects of their diligence have been magnified by the idleness of their fancy. The first of the Ommiades who reigned in Spain solicited the support of the Christians; and in his edict of peace and protection, he contents himself with a modest imposition of 10,000 ounces of gold, 10,000 pounds of silver, 10,000 horses, as many mules, 1000 cuirasses, with an equal number of helmets and lances. The most powerful of his successors derived from the same kingdom the annual tribute of 12,045,000 dinars or pieces of gold, about 6,000,000l. of sterling money; a sum which, in the 10th century, most probably surpassed the united revenues of the Christian monarchs. His royal seat of Cordova contained 600 mosques, 900 baths, and 200,000 houses; he gave laws to 80 cities of the first, to 300 of the second and third order; and the fertile banks of the Guadalquiver were adorned with 12,000 villages and hamlets. The Arabs might exaggerate the truth; but they created, and they describe, the most prosperous era of the riches, the cultivation, and the populousness of Spain (c)

6 Jews expelled from Spain.

The conquest of Granada was followed by the expulsion, or rather the pillage and banishment, of the Jews, who had engrossed all the wealth and commerce of Spain. The inquisition exhausted its rage against these unhappy people, many of whom pretended to embrace Christianity, in order to preserve their property. About the same time their Catholic majesties concluded an alliance with the emperor Maximilian, and a treaty of marriage for their daughter Joan with his son Philip, archduke of Austria, and sovereign of the Netherlands. About this time also the contract was concluded with Christopher Columbus for the discovery of new countries; and the counties of Roussillon and Cerdagne were agreed to be restored by Charles VIII. of France, before his expedition into Italy. The discovery of America was soon followed by extensive conquests in that quarter, as is related under the articles Mexico, Peru, Chili, &c. which tended to raise the Spanish monarchy above any other in Europe.

87 Discovery of America, &c.

88 Accession of Chas. V. An. 1516.

On the death of Isabella, which happened in 1506, Philip archduke of Austria came to Castile in order to take possession of that kingdom as heir to his mother-in-law; but he dying in a short time after, his son Charles V. afterwards emperor of Germany, became heir to the crown of Spain. His father at his death left the king of France governor to the young prince, and Ferdinand at his death left Cardinal Ximenes sole regent of Castile, till the arrival of his grandson. This man, whose character is no less singular and illustrious, who united the abilities of a great statesman with the abject devotion of a superstitious monk, and the magnificence of a prime minister with the severity of a mendicant, maintained order and tranquillity in Spain, notwithstanding the discontents of a turbulent and high-spirited nobility. When they disputed his right to the regency, he coolly showed them the testament of Ferdinand, and the ratification of that deed by Charles; but these not satisfying them, and argument proving ineffectual, he led them insensibly towards a balcony, whence they had a view of a large body of troops under arms, and

(c) Abdoulrahman III. monarch of Cordova, surpassed all his predecessors in splendour, riches, and expence; and his subjects vied with each other in profusion and magnificence. Some idea may be entertained of the opulence and grandeur of the Moors of Cordova in the 10th century, by perusing the following enumeration of the presents made to Abdoulrahman by Abumelik his grand vizier, on his appointment to that office. We are told that the minister caused to be brought before the throne, and laid at the feet of his master,

400 lbs. of virgin gold.
Ingots of silver to the value of 420,000 sequins.
400 lbs. of lignum aloes, one piece weighing 140 lbs.
500 oz. of ambergris.
300 oz. of camphor.
30 pieces of gold tissue, so rich that none but the caliph could wear it.
10 suits of Khorassan sables.
100 suits of fur of a less valuable sort.
48 sets of gold and silk long trappings for horses.
4000 lbs. of silk.
30 Persian carpets.
800 iron coats-of-mail for war horses.
1000 shields.
100,000 arrows.
15 led horses of Arabia, as richly caparisoned as those on which the caliph was wont to ride.
100 horses of an inferior price.
20 mules with all their accoutrements.
40 young men, and 20 girls of exquisite beauty, and most sumptuously apparelled. This display of riches was accompanied with a most flattering poem, composed by the minister in praise of his sovereign, who in return for his homage, assigned him a pension of 100,000 pieces of gold, about 50,000l. sterling.

Spain.

and a formidable train of artillery. "Behold (said the cardinal) the powers which I have received from his Catholic majesty: by these I govern Castile; and will govern it, till the king, your master and mine, shall come to take possession of his kingdom." A declaration so bold and determined silenced all opposition; and Ximenes maintained his authority till the arrival of Charles in 1517.

89 Disgrace and death of Cardinal Ximenes.

The young king was received with universal acclamations of joy; but Ximenes found little cause to rejoice. He was seized with a violent disorder, supposed to be the effect of poison; and when he recovered, Charles, prejudiced against him by the Spanish grandees and his Flemish courtiers, slighted his advice, and allowed him every day to sink into neglect. The cardinal did not bear this treatment with his usual fortitude of spirit. He expected a more grateful return from a prince to whom he delivered a kingdom more flourishing than it had been in any former age, and authority more extensive and better established than the most illustrious of his ancestors had ever possessed. Conscious of his own integrity and merit, he could not therefore refrain from giving vent, at times, to indignation and complaint. He lamented the fate of his country, and foretold the calamities to which it would be exposed from the insolence, the rapaciousness, and the ignorance of strangers. But in the mean time he received a letter from the king, dismissing him from his councils, under pretence of easing his age of that burden which he had so long and so ably sustained. This letter proved fatal to the minister; for he expired in a few hours after reading it.

90 Maximilian attempts to get Charles elected emperor.

While Charles was taking possession of the throne of Spain, in consequence of the death of one grandfather, another was endeavouring to obtain for him the imperial crown. With this view Maximilian assembled a diet at Augsburg, where he cultivated the favour of the electors by many acts of beneficence, in order to engage them to choose that young prince as his successor. But Maximilian himself never having been crowned by the pope, a ceremony deemed essential in that age, as well as in the preceding, he was considered only as king of the Romans, or emperor elect; and no example occurring in history of any person being chosen successor to a king of the Romans, the Germans, always tenacious of their forms, obstinately refused to confer upon Charles a dignity for which their constitution knew no name.

But though Maximilian could not prevail upon the German electors to choose his grandson of Spain king of the Romans, he had disposed their minds in favour of that prince; and other circumstances, on the death of the emperor, conspired to the exaltation of Charles. The imperial crown had so long continued in the Austrian line, that it began to be considered as hereditary in that family; and Germany, torn by religious disputes, stood in need of a powerful emperor, not only to preserve its own internal tranquillity, but also to protect it against the victorious arms of the Turks, who under Selim I. threatened the liberties of Europe. This fierce and rapid conqueror had already subdued the Mamelukes, and made himself master of Egypt and Syria. The power of Charles appeared necessary to oppose that of Selim. The extensive dominions of the house of Austria, which gave him an interest in the preservation of Germany; the rich sovereignty of the Netherlands and Franche Compté; the entire possession of the great and warlike kingdom of Spain, together with that of Naples and Sicily, all united to hold him up to the first dignity among Christian princes; and the new world seemed only to be called into existence that its treasures might enable him to defend Christendom against the infidels. Such was the language of his partisans.

91 Francis I. aspires to the same dignity.

Francis I. however, no sooner received intelligence of the death of Maximilian, than he declared himself a candidate for the empire; and with no less confidence of success than Charles. He trusted to his superior years and experience; his great reputation in arms; and it was farther urged in his favour, that the impetuosity of the French cavalry, added to the firmness of the German infantry, would prove irresistible, and not only be sufficient, under a warlike emperor, to set limits to the ambition of Selim, but to break entirely the Ottoman power, and prevent it from ever becoming dangerous again to Germany.

Both claims were plausible. The dominions of Francis were less extensive, but more united than those of Charles. His subjects were numerous, active, brave, lovers of glory, and lovers of their king. These were strong arguments in favour of his power, so necessary at this juncture: but he had no natural interest in the Germanic body; and the electors, hearing so much of military force on each side, became more alarmed for their own privileges than the common safety. They determined to reject both candidates, and offered the imperial crown to Frederic, surnamed the *Wise*, duke of Saxony. But he, undazzled by the splendour of an object courted with so much eagerness, by two mighty monarchs, rejected it with a magnanimity no less singular than great.

92 Speech of Frederic duke of Saxony in favour of Charles.

"In times of tranquillity (said Frederic), we wish for an emperor who has no power to invade our liberties; times of danger demand one who is able to secure our safety. The Turkish armies, led by a warlike and victorious monarch, are now assembling: they are ready to pour in upon Germany with a violence unknown in former ages. New conjunctures call for new expedients. The imperial sceptre must be committed to some hand more powerful than mine or that of any other German prince. We possess neither dominions, nor revenues, nor authority, which enable us to encounter such a formidable enemy. Recourse must be had, in this exigency, to one of the rival monarchs. Each of them can bring into the field forces sufficient for our defence. But as the king of Spain is of German extraction, as he is a member and prince of the empire by the territories which descend to him from his grandfather, and as his dominions stretch along that frontier which lies most exposed to the enemy, his claim, in my opinion, is preferable to that of a stranger to our language, to our blood, and to our country." Charles was elected in consequence of this speech in the year 1520.

93 He is elected in consequence of this speech. An. 1520.

The two candidates had hitherto conducted their rivalship with emulation, but without enmity. They had even mingled in their competition many expressions of friendship and regard. Francis in particular declared with his usual vivacity, that his brother Charles and he were fairly and openly suitors to the same mistress: "The most assiduous and fortunate (added he) will win her; and the other must rest contented." But the preference was no sooner given to his rival, than Francis discovered

Spain.

discovered all the passions natural to disappointed ambition. He could not suppress his chagrin and indignation at being baulked in his favourite pursuit, and rejected, in the face of all Europe, for a youth yet unknown to fame. The spirit of Charles resented such contempt; and from this jealousy, as much as from opposition of interests, arose that emulation between those two great monarchs which involved them in almost perpetual hostilities, and kept their whole age in constant agitation.

94 ...utual ...red takes ...ce between ...rles and ...ncis.

Charles and Francis had many interfering claims in Italy; and the latter thought himself bound in honour to restore the king of Navarre to his dominions, unjustly seized by the crown of Spain. They immediately began to negociate; and as Henry VIII. of England was the third prince of the age in power and in dignity, his friendship was eagerly courted by each of the rivals. He was the natural guardian of the liberties of Europe. Sensible of the consequence which his situation gave him, and proud of his pre-eminence, Henry knew it to be his interest to keep the balance even between the contending powers, and to restrain both, by not joining entirely with either: but he was seldom able to reduce his ideas to practice. Vanity and resentment were the great springs of all his undertakings; and his neighbours by touching these, found an easy way to draw him into their measures, and force him upon many rash and inconsiderate enterprises.

95 ...h court ... friendship of Henry VIII. of England.

All the impolitic steps in Henry's government must not, however, be imputed to himself; many of them were occasioned by the ambition and avarice of his prime minister and favourite Cardinal Wolsey. This man, who, by his talents and accomplishments, had risen from one of the lowest conditions in life to the highest employments both in church and state, enjoyed a greater degree of power and dignity than any English subject ever possessed, and governed the haughty, presumptuous, and untractable spirit of Henry, with absolute authority. Francis was equally well acquainted with the character of Henry and of his minister. He had successfully flattered Wolsey's pride, by honouring him with particular marks of his confidence, and bestowing upon him the appellations of *Father*, *Tutor*, and *Governor*; and he had obtained the restitution of Tournay, by adding a pension to those respectful titles. He now solicited an interview with the king of England near Calais; in hopes of being able, by familiar conversation, to attach him to his friendship and interest, while he gratified the cardinal's vanity, by affording him an opportunity of displaying his magnificence in the presence of two courts, and of discovering to the two nations his influence over their monarchs. Charles dreaded the effects of this projected interview between two gallant princes, whose hearts were no less susceptible of friendship than their manners were of inspiring it. Finding it impossible, however, to prevent a visit, in which the vanity of all parties was so much concerned, he endeavoured to defeat its purpose, and to pre-occupy the favour of the English monarch, and of his minister, by an act of complaisance still more flattering and more uncommon. Relying wholly upon Henry's generosity for his safety, he landed at Dover, in his way from Spain to the Low Countries. The king of England, who was on his way to France, charmed with such an instance of confidence, hastened to receive his royal guest; and Charles, during his short stay, had the address not only to give Henry favourable impressions of his character and intentions, but to detach Wolsey entirely from the interest of Francis. The tiara had attracted the eye of that ambitious prelate; and as the emperor knew that the papacy was the sole point of elevation, beyond his present greatness, at which he could aspire, he made him an offer of his interest on the first vacancy.

9... Charl... vi-sits H...y in Eng...nd.

98 Henry visits Francis in France.

The day of Charles's departure, Henry went over to Calais with his whole court, in order to meet Francis. Their interview was in an open plain between Guisnes and Ardres; where the two kings and their attendants displayed their magnificence with such emulation and profuse expence, as procured it the name of the *Field of the Cloth of Gold*. Here Henry erected a spacious house of wood and canvas, framed in London, on which, under the figure of an English archer, was the following motto, "He prevails whom I favour;" alluding to his own political situation, as holding in his hands the balance of power among the potentates of Europe. Feats of chivalry, however, parties of gallantry, and such exercises as were in that age reckoned manly or elegant, rather than serious business, occupied the two courts during the time that they continued together, which was 18 days.

After taking leave of this scene of dissipation, the king of England paid a visit to the emperor and Margaret of Savoy at Gravelines, and engaged them to go along with him to Calais; where the artful and politic Charles completed the impression which he had begun to make on Henry and his favourite, and effaced all the friendship to which the frank and generous nature of Francis had given birth. He renewed his assurances of assisting Wolsey in obtaining the papacy; and he put him in present possession of the revenues belonging to the sees of Badajoz and Palencia in Spain. He flattered Henry's pride, by convincing him of his own importance, and of the justness of the motto which he had chosen; offering to submit to his sole arbitration any difference that might arise between him and Francis.

99 Charles invested with the imperial crown at Aix-la-Chapelle.

This important point being secured, Charles repaired to Aix-la-Chapelle, where he was solemnly invested with the crown and sceptre of Charlemagne, in presence of a more splendid and numerous assembly than had appeared on any former inauguration. About the same time Solyman the Magnificent, one of the most accomplished, enterprising, and victorious of the Turkish princes, and a constant and formidable rival to the emperor, ascended the Ottoman throne.

The first act of Charles's administration was to appoint a diet of the empire, to be held at Worms, in order to concert with the princes proper measures for checking the progress of "those new and dangerous opinions which threatened to disturb the peace of Germany, and to overturn the religion of their ancestors." The opinions propagated by Luther and his followers were here meant. But all his efforts for that purpose were insufficient, as is related under the articles LUTHER and REFORMATION.

100 War between Francis and Charles. An. 1521.

In 1521, the Spaniards, dissatisfied with the departure of their sovereign, whose election to the empire they foresaw would interfere with the administration of his own kingdom, and incensed at the avarice of the Flemings, to whom the direction of public affairs had

been

Spain. been committed since the death of Cardinal Ximenes, several grandees, in order to shake off this oppression, entered into an association, to which they gave the name of the *Sancta Juncta;* and the sword was appealed to as the means of redress. This seemed to Francis a favourable juncture for reinstating the family of John d'Albert in the kingdom of Navarre. Charles was at a distance from that part of his dominions, and the troops usually stationed there had been called away to quell the commotions in Spain. A French army, under Andrew de Foix, speedily conquered Navarre; but that young and inexperienced nobleman, pushed on by military ardour, ventured to enter Castile. The Spaniards, though divided among themselves, united against a foreign enemy, routed his forces, took him prisoner, and recovered Navarre in a shorter time than he had spent in subduing it.

Hostilities thus begun in one quarter, between the rival monarchs, soon spread to another. The king of France encouraged the duke of Bouillon to make war against the emperor, and to invade Luxembourg. Charles, after humbling the duke, attempted to enter France; but was repelled and worsted before Mezieres by the famous Chevalier Bayard, distinguished among his cotemporaries by the appellation of *The Knight without fear and without reproach;* and who united the talents of a great general to the punctilious honour and romantic gallantry of the heroes of chivalry. Francis broke into the Low Countries, where, by an excess of caution, an error not natural to him, he lost an opportunity of cutting off the whole imperial army; and, what was of still more consequence, he disgusted the constable Bourbon, by giving the command of the van to the duke of Alençon.

During these operations in the field, an unsuccessful congress was held at Calais, under the mediation of Henry VIII. It served only to exasperate the parties which it was intended to reconcile. A league was soon after concluded, by the intrigues of Wolsey, between the Pope, Henry, and Charles, against France. Leo had already entered into a separate league with the emperor, and the French were fast losing ground in Italy.

The insolence and exactions of Mareshal de Lautrec, governor of Milan, had totally alienated the affections of the Milanese from France. They resolved to expel the troops of that nation, and put themselves under the government of Francis Sforza, brother to Maximilian their late duke. In this resolution they were encouraged by the pope, who excommunicated Lautrec, and

101 Rapid conquests of Charles.

took into his pay a considerable body of Swiss. The papal army, commanded by Prosper Colonna, an experienced general, was joined by supplies from Germany and Naples; while Lautrec, neglected by his court, and deserted by the Swiss in its pay, was unable to make head against the enemy. The city of Milan was betrayed by the inhabitants to the confederates; Parma and Placentia were united to the ecclesiastical state; and of their conquests in Lombardy, only the town of Cremona, the castle of Milan, and a few inconsiderable forts, remained in the hands of the French.

Leo X. received the accounts of this rapid success with such transports of joy, as are said to have brought on a fever, which occasioned his death. The spirit of the confederacy was broken, and its operation suspended by this accident. The Swiss were recalled; some other mercenaries disbanded for want of pay; and only the Spaniards, and a few Germans in the emperor's service, remained to defend the duchy of Milan. But Lautrec, who with the remnant of his army had taken shelter in the Venetian territories, destitute both of men and money, was unable to improve this favourable opportunity as he wished. All his efforts were rendered ineffectual by the vigilance and ability of Colonna and his associates.

Meantime much discord prevailed in the conclave. Wolsey's name, notwithstanding all the emperor's magnificent promises, was scarcely mentioned there. Julio de Medici, Leo's nephew, thought himself sure of the election; when, by an unexpected turn of fortune, Cardinal Adrian of Utrecht, Charles's preceptor, who at that time governed Spain in the emperor's name, was unanimously raised to the papacy, to the astonishment of all Europe and the great disgust of the Italians.

Francis, roused by the rising consequence of his rival, resolved to exert himself with fresh vigour, in order to wrest from him his late conquests in Lombardy. Lautrec received a supply of money, and a reinforcement of 10,000 Swiss. With this reinforcement he was enabled once more to act offensively, and even to advance within a few miles of the city of Milan; when money again failing him, and the Swiss growing mutinous, he was obliged to attack the imperialists in their camp at Bicocca, where he was repulsed with great slaughter, having lost his bravest officers and best troops. Such of the Swiss as survived set out immediately for their own country; and Lautrec, despairing of being able to keep the field, retired into France. Genoa, which still remained subject to Francis, and made it easy to execute any scheme for the recovery of Milan, was soon after taken by Colonna: the authority of the emperor and his faction was everywhere established in Italy. The citadel of Cremona was the sole fortress which remained in the hands of the French. 102 Francis invades Italy.

The affliction of Francis for such a succession of misfortunes was augmented by the unexpected arrival of an English herald, who in the name of his sovereign declared war against France. The courage of this excellent prince, however, did not forsake him; though his treasury was exhausted by expensive pleasures, no less than by hostile enterprises, he assembled a considerable army, and put his kingdom in a posture of defence for resisting this new enemy, without abandoning any of the schemes which he was forming against the emperor. He was surprised, but not alarmed, at such a denunciation.

Meanwhile Charles, willing to draw as much advantage as possible from so powerful an ally, paid a second visit to the court of England in his way to Spain, where his presence was become necessary. His success exceeded his most sanguine expectations. He not only gained the entire friendship of Henry, who publicly ratified the treaty of Bruges; but disarmed the resentment of Wolsey, by assuring him of the papacy on Adrian's death; an event seemingly not distant, by reason of his age and infirmities. In consequence of these negociations an English army invaded France, under the command of the earl of Surrey; who, at the end of the campaign, was obliged to retire, with his forces greatly reduced, 103 Charles visits England a second time.

reduced, without being able to make himself master of one place within the French frontier. Charles was more fortunate in Spain: he soon quelled the tumults which had there arisen in his absence.

While the Christian princes were thus wasting each other's strength, Solyman the Magnificent entered Hungary, and made himself master of Belgrade, reckoned the chief barrier of that kingdom against the Turkish power. Encouraged by this success, he turned his victorious arms against the island of Rhodes, at that time the seat of the knights of St John of Jerusalem;

104 Rhodes taken by Solyman.

and though every prince in that age acknowledged Rhodes to be the great bulwark of Christendom in the east, so violent was their animosity against each other, that they suffered Solyman without disturbance to carry on his operations against that city and island. Lisle Adam, the grand master, made a gallant defence; but, after incredible efforts of courage, patience, and military conduct, during a siege of six months, he was obliged to surrender the place, having obtained an honourable capitulation from the sultan, who admired and respected his heroic qualities (see RHODES and MALTA). Charles and Francis were equally ashamed of having occasioned such a loss to Christendom by their contests; and the emperor, by way of reparation, granted to the knights of St John the small island of Malta, where they fixed their residence, and continued long to retain their ancient spirit, though much diminished in power and splendour.

Adrian VI. though the creature of the emperor, and devoted to his interest, endeavoured to assume the impartiality which became the common father of Christendom, and laboured to reconcile the contending princes, that they might unite in a league against Solyman, whose conquest of Rhodes rendered him more formidable than ever to Europe. The Italian states were no less desirous of peace than the pope: and so much regard was paid by the hostile powers to the exhortations of his holiness, and to a bull which he issued, requiring all Christian princes to consent to a truce for three years, that the imperial, the French, and the English ambassadors at Rome, were empowered to treat of that matter; but while they wasted their time in fruitless negociations, their masters were continuing their preparations for war; and other negociations soon took place. The confederacy against France became more formidable than ever.

105 A powerful confederacy against France.

The Venetians, who had hitherto adhered to the French interest, formed engagements with the emperor for securing Francis Sforza in the possession of the duchy of Milan; and the pope, from a persuasion that the ambition of the French monarch was the only obstacle to peace, acceded to the same alliance. The Florentines, the dukes of Ferrara and Mantua, and all the Italian powers, followed this example. Francis was left without a single ally, to resist the efforts of a multitude of enemies, whose armies everywhere threatened, and whose territories encompassed his dominions. The emperor in person menaced France with an invasion on the side of Guienne; the forces of England and the Netherlands hovered over Picardy, and a numerous body of Germans was preparing to ravage Burgundy.

The dread of so many and such powerful adversaries, it was thought, would have obliged Francis to keep wholly on the defensive, or at least have prevented him from entertaining any thoughts of marching into Italy. But before his enemies were able to strike a blow, Francis had assembled a great army, with which he hoped to disconcert all the emperor's schemes, by marching it in person into Italy: and this bold measure, the more formidable because unexpected, could scarcely have failed of the desired effect, had it been immediately carried into execution. But the discovery of a domestic conspiracy, which threatened the destruction of his kingdom, obliged Francis to stop short at Lyons.

106 Francis marches towards Italy, but is obliged to return by a domestic conspiracy.

Charles duke of Bourbon, lord high constable of France, was a prince of the most shining merit: his great talents equally fitted him for the council or the field, while his eminent services to the crown entitled him to its first favour. But unhappily Louisa duchess of Angouleme, the king's mother, had contracted a violent aversion against the house of Bourbon, and had taught her son, over whom she had acquired an absolute ascendant, to view all the constable's actions with a jealous eye. After repeated affronts he retired from court, and began to listen to the advances of the emperor's ministers. Meantime the duchess of Bourbon died; and as the constable was no less amiable than accomplished, the duchess of Angouleme, still susceptible of the tender passions, formed the scheme of marrying him. But Bourbon, who might have expected every thing to which an ambitious mind can aspire, from the doating fondness of a woman who governed her son and the kingdom, incapable of imitating Louisa in her sudden transition from hate to love, or of meanly counterfeiting a passion for one who had so long pursued him with unprovoked malice, rejected the match with disdain, and turned the proposal into ridicule. At once despised and insulted by the man whom love only could have made her cease to persecute, Louisa was filled with all the rage of disappointed woman; she resolved to ruin, since she could not marry Bourbon. For this purpose she commenced an iniquitous suit against him; and by the chicanery of Chancellor du Prat, the constable was stripped of his whole family estate. Driven to despair by so many injuries, he entered into a secret correspondence with the emperor and the king of England; and he proposed, as soon as Francis should have crossed the Alps, to raise an insurrection among his numerous vassals, and introduce foreign enemies into the heart of France.

Happily Francis got intimation of this conspiracy before he left the kingdom; but not being sufficiently convinced of the constable's guilt, he suffered so dangerous a foe to escape; and Bourbon entering into the emperor's service, employed all the force of his enterprising genius, and his great talents for war, to the prejudice of his prince and his native country.

In consequence of the discovery of this plot, and the escape of the powerful conspirator, Francis relinquished his intention of leading his army in person into Italy. He was ignorant how far the infection had spread among his subjects, and afraid that his absence might encourage them to make some desperate attempt in favour of a man so much beloved. He did not, however, abandon his design on the Milanese, but sent forward an army of 30,000 men, under the command of Admiral Bonnivet.

107 A French army enters Italy.

Colonna, who was entrusted with the defence of that duchy, was in no condition to resist such a force; and the city of Milan, on which the whole territory depends, Spain. pends, must have fallen into the hands of the French, had not Bonnivet, who possessed none of the talents of a general, wasted his time in frivolous enterprises, till the inhabitants recovered from their consternation. The imperial army was reinforced. Colonna died; and Lannoy, viceroy of Naples, succeeded him in the command: but the chief direction of military operations was committed to Bourbon and the marquis de Pescara, the greatest generals of their age. Bonnivet, destitute of troops to oppose this new army, and still more of the talents which could render him a match for its leaders, after various movements and encounters, was reduced

108 Defeated at Biagrassa. to the necessity of attempting a retreat into France. He was followed by the imperial generals, and routed at Biagrassa, where the famous Chevalier Bayard was killed.

The emperor and his allies were less successful in their attempts upon France. They were baffled in every quarter: and Francis, though stripped of his Italian dominions, might still have enjoyed in safety the glory of having defended his native kingdom against one half of Europe, and have bid defiance to all his enemies; but understanding that the king of England, discouraged by his former fruitless enterprises, and disgust-

109 Francis determines to enter Italy in person. ed with the emperor, was making no preparations for any attempt on Picardy, his ancient ardour seized him for the conquest of Milan, and he determined, notwithstanding the advanced season, to march into Italy.

The French army no sooner appeared in Piedmont, than the whole Milanese was thrown into consternation. The capital opened its gates. The forces of the emperor and Sforza retired to Lodi: and had Francis been so fortunate as to pursue them, they must have abandoned that post, and been totally dispersed; but his evil genius led him to besiege Pavia, a town of consider-

110 Is defeated and taken prisoner at Pavia. An. 1524. able strength, well garrisoned, and defended by Antonio de Leyva, one of the bravest officers in the Spanish service; before which place he was defeated and taken prisoner on the twenty-fourth day of February 1524.

The captivity of Francis filled all Europe with alarm. Almost the whole French army was cut off; Milan was immediately abandoned; and in a few weeks not a Frenchman was left in Italy. The power of the emperor, and still more his ambition, became an object of universal terror; and resolutions were everywhere taken to set bounds to it. Meanwhile Francis, deeply impressed with a sense of his misfortune, wrote to his mother Louisa, whom he had left regent of the kingdom, the following short but expressive letter: "All, Madam,

111 Hypocritical conduct of Charles. is lost but honour." The same courier that carried this letter, carried also dispatches to Charles; who received the news of the signal and unexpected success which had crowned his arms with the most hypocritical moderation. He would not suffer any public rejoicings to be made on account of it; and said, he only valued it, as it would prove the occasion of restoring peace to Christendom. Louisa, however, did not trust to those appearances; if she could not preserve what was yet left, she determined at least that nothing should be lost through her negligence or weakness. Instead of giving herself up to such lamentations as were natural to a woman so remarkable for maternal tenderness, she discovered all the foresight, and exerted all the activity, of a consummate politician. She took every possible measure for putting the kingdom in a posture of defence, while she employed all her address to appease the resentment and to gain the friendship of England; and a ray of comfort from that quarter soon broke in upon the French affairs.

Though Henry VIII. had not entered into the war against France from any concerted political views, he had always retained some imperfect idea of that balance of power which it was necessary to maintain between Charles and Francis; and the preservation of which he boasted to be his peculiar office. By his alliance with the emperor, he hoped to recover some part of those territories on the continent which had belonged to his ancestors; and therefore willingly contributed to give him the ascendency above his rival; but having never dreamt of any event so decisive and fatal as the victory at Pavia, which seemed not only to have broken, but to have annihilated the power of Francis, he now became sensible of his own danger, as well as that of all Europe, from the loss of a proper counterpoise to the power of 112

Charles. Instead of taking advantage of the distressed France assisted by Henry VIII. condition of France, Henry therefore determined to assist her in her present calamities. Some disgusts also had taken place between him and Charles, and still more between Charles and Wolsey. The elevation of the cardinal of Medici to St Peter's chair, on the death of Adrian, under the name of Clement VII. had made the English minister sensible of the insincerity of the emperor's promises, while it extinguished all his hopes of the papacy; and he resolved on revenge. Charles, too, had so ill supported the appearance of moderation which he assumed, when first informed of his good fortune, that he had already changed his usual style to Henry; and instead of writing to him with his own hand, and subscribing himself "your affectionate son and cousin," he dictated his letters to a secretary, and simple subscribed himself "Charles." Influenced by all these motives, together with the glory of raising a fallen enemy, Henry listened to the flattering submissions of Louisa; entered into a defensive alliance with her as regent of France, and engaged to use his best offices in order to procure the deliverance of her son from a state of captivity. 113

Meanwhile Francis was rigorously confined; and se- Francis severely used by his conqueror. vere conditions being proposed to him as the price of his liberty, he drew his dagger, and, pointing it at his breast, cried, "'Twere better that a king should die thus!" His hand was withheld: and flattering himself, when he grew cool, that such propositions could not come directly from Charles, he desired that he might be removed to Spain, where the emperor then resided. His request was complied with; but he languished long before he obtained a sight of his conqueror. At last he was favoured with a visit; and the emperor dreading a general combination against him, or that Francis, as he threatened, might, in the obstinacy of his heart, resign his crown to the dauphin, agreed to abate somewhat of his former demands. A treaty was accordingly concluded at Madrid; in consequence of which Francis obtained his liberty. The chief article in this treaty was, that Burgundy should be restored to Charles as the rightful inheritance of his ancestors, and 114

that Francis's two eldest sons should be immediately de- Is at last released. livered up as hostages for the performance of the conditions stipulated. The exchange of the captive monarch

Spain.

narch for his children was made on the borders between France and Spain. The moment that Francis entered his own dominions, he mounted a Turkish horse, and putting it to its speed, waved his hand, and cried aloud several times, "I am yet a king! I am yet a king!"

115 [fuses to] [cute the] [ditions] [is re-] [se.]

Francis never meant to execute the treaty of Madrid: he had even left a protest in the hands of notaries before he signed it, that his consent should be considered as an involuntary deed, and be deemed null and void. Accordingly, as soon as he arrived in France, he assembled the states of Burgundy, who protested against the article relative to their province; and Francis coldly replied to the imperial ambassadors, who urged the immediate execution of the treaty, that he would religiously perform the articles relative to himself, but in those affecting the French monarchy, he must be directed by the sense of the nation. He made the highest acknowledgments to the king of England for his friendly interposition, and offered to be entirely guided by his counsels. Charles and his ministers saw that they were over-reached in those very arts of negociation in which they so much excelled, while the Italian states observed with pleasure, that Francis was resolved not to execute a treaty which they considered as dangerous to the liberties of Europe. Clement absolved him from the oath which he had taken at Madrid; and the kings of France and England, the pope, the Swiss, the Venetians, the Florentines, and the duke of Milan, entered into an alliance, to which they gave the name of the *Holy League*, because his Holiness was at the head of it, in order to oblige the emperor to deliver up Francis's two sons on the payment of a reasonable ransom, and to re-establish Sforza in the quiet possession of the Milanese.

In consequence of this league, the confederate army took the field, and Italy once more became the scene of war. But Francis, who it was thought would have infused spirit and vigour into the whole body, had gone through such a scene of distress, that he was become diffident of himself, distrustful of his fortune, and desirous of tranquillity. He flattered himself, that the dread alone of such a confederacy would induce Charles to listen to what was equitable, and therefore neglected to send due reinforcements to his allies in Italy. Meantime the duke of Bourbon, who commanded the Imperialists, had made himself master of the whole Milanese, of which the emperor had promised him the investiture; and his troops beginning to mutiny for want of pay, he led them to Rome, and promised to enrich them with the spoils of that city. He was as good as his word; for though he himself was slain in planting a scaling ladder against the walls, his soldiers, rather enraged than discouraged by his death, mounted to the assault with the utmost ardour, animated by the greatness of the prize, and, entering the city sword in hand, plundered it for several days.

1[16] Rome [ta]ken b[y] the imper[ial]ists.

11[7] and m[ost] cruelly plunde[red].

Never did Rome in any age suffer so many calamities, not even from the Barbarians, by whom she was often subdued, the Huns, Vandals, or Goths, as now from the subjects of a Christian and Catholic monarch. Whatever was respectable in modesty, or sacred in religion, seemed only the more to provoke the rage of the soldiery. Virgins suffered violation in the arms of their parents, and upon those altars to which they had fled for safety. Venerable prelates, after enduring every indignity and every torture, were thrown into dungeons, and menaced with the most cruel death, in order to make them reveal their secret treasures. Clement himself, who had neglected to make his escape in time, was taken prisoner, and found that the sacredness of his character could neither procure him liberty nor respect. He was confined till he should pay an enormous ransom imposed by the victorious army, and surrender to the emperor all the places of strength belonging to the church.

118 The pope confined.

119 Shameful hypocrisy of Charles.

Charles received the news of this extraordinary event with equal surprise and pleasure; but in order to conceal his joy from his Spanish subjects, who were filled with horror at the insult offered to the sovereign pontiff, and to lessen the indignation of the rest of Europe, he expressed the most profound sorrow for the success of his arms. He put himself and his court into mourning; stopped the rejoicings for the birth of his son Philip, and ordered prayers to be put up in all the churches of Spain for the recovery of the pope's liberty, which he could immediately have procured by a letter to his generals.

The concern expressed by Henry and Francis for the calamity of their ally was more sincere. Alarmed at the progress of the imperial arms, they had, even before the taking of Rome, entered into a closer alliance, and agreed to invade the Low Countries with a powerful army; but no sooner did they hear of the pope's captivity, than they changed, by a new treaty, the scene of the projected war from the Netherlands to Italy, and resolved to take the most vigorous measures for restoring him to liberty. Henry, however, contributed only money. A French army entered Italy, under the command of Marshal Lautrec; Clement obtained his freedom; and war was for a time carried on by the confederates with success; but the death of Lautrec, and the revolt of Andrew Doria, a Genoese admiral in the service of France, entirely changed the face of affairs. The French army was utterly ruined; and Francis, discouraged and almost exhausted by so many unsuccessful enterprises, began to think of peace, and of obtaining the release of his sons by concessions, not by the terror of his arms.

120 A French army enters Italy, but is utterly ruined.

At the same time Charles, notwithstanding the advantages he had gained, had many reasons to wish for an accommodation. Sultan Solyman having overrun Hungary, was ready to break in upon the Austrian territories with the whole force of the East; and the progress of the Reformation in Germany threatened the tranquillity of the empire. In consequence of this situation of affairs, though pride made both parties conceal or dissemble their real sentiments, two ladies were permitted to restore peace to Europe. Margaret of Austria, Charles's aunt, and Louisa, Francis's mother, met in 1529 at Cambray, and settled the terms of accommodation between the French king and the emperor. Francis agreed to pay two millions of crowns as the ransom of his two sons, to resign the sovereignty of Flanders and Artois, and to forego all his Italian claims; and Charles ceased to demand the restitution of Burgundy.

121 Peace concluded at Cambray.

All the steps of this negociation had been communicated to the king of England; and Henry was, on that occasion, so generous to his friend and ally Francis, that he sent him an acquittal of near six hundred thousand crowns, in order to enable him to fulfil his agreement

with

Spain.

with Charles. But Francis's Italian confederates were less satisfied with the treaty of Cambray. They were almost wholly abandoned to the will of the emperor; and seemed to have no other means of security left but his equity and moderation. Of these, from his past conduct, they had not formed the most advantageous idea. But Charles's present circumstances, more especially in regard to the Turks, obliged him to behave with a generosity inconsistent with his character. The Florentines alone, whom he reduced under the dominion of the family of Medici, had reason to complain of his severity. Sforza obtained the investiture of Milan and his pardon: and every other power experienced the lenity of the conqueror.

122 Charles goes into Germany.

After having received the imperial crown from the hands of the pope at Bologna, Charles proceeded on his journey to Germany, where his presence was become highly necessary; for although the conduct and valour of his brother Ferdinand, on whom he had conferred the hereditary dominions of the house of Austria, and who had been elected king of Hungary, had obliged Solyman to retire with infamy and loss, his return was to be feared, and the disorders of religion were daily increasing; an account of which, and of the emperor's transactions with the Protestants, is given under the article REFORMATION.

123 He undertakes an expedition against the states of Barbary. An. 1541.

Charles having exerted himself as much as he could against the reformers, undertook his first expedition against the piratical states of Africa. Barbary, or that part of the African continent lying along the coast of the Mediterranean sea, was then nearly in the same condition which it is at present. Morocco, Algiers, and Tunis, were its principal states; and the two last were nests of pirates. Barbarossa, a famous corsair, had succeeded his brother in the kingdom of Algiers, which he had formerly assisted him to usurp. He regulated with much prudence the interior police of his kingdom, carried on his piracies with great vigour, and extended his conquests on the continent of Africa; but perceiving that the natives submitted to his government with impatience, and fearing that his continual depredations would one day draw upon him a general combination of the Christian powers, he put his dominions under the protection of the grand seignior. Solyman, flattered by such an act of submission, and charmed with the boldness of the man, offered him the command of the Turkish fleet. Proud of this distinction, Barbarossa repaired to Constantinople, and made use of his influence with the sultan to extend his own dominion. Partly by force, partly by treachery, he usurped the kingdom of Tunis; and being now possessed of greater power, he carried on his depredations against the Christian states with more destructive violence than ever.

Daily complaints of the piracies and ravages committed by the galleys of Barbarossa were brought to the emperor by his subjects, both in Spain and Italy: and all Christendom seemed to look up to him, as its greatest and most fortunate prince, for relief from this new and odious species of oppression. At the same time Muley-Hascen, the exiled king of Tunis, finding none of the African princes able or willing to support him in recovering his throne, applied to Charles for assistance against the usurper. Equally desirous of delivering his dominions from the dangerous neighbourhood of Barbarossa, of appearing as the protector of an unfortunate prince, and of acquiring the glory annexed in that age to every expedition against the Mahometans, the emperor readily concluded a treaty with Muley Hasceu, and set sail for Tunis with a formidable armament. The Goletta, a sea-port town, fortified with 300 pieces of cannon, was taken, together with all Barbarossa's fleet: he was defeated in a pitched battle, and 10,000 Christian slaves, having knocked off their fetters, and made themselves masters of the citadel, Tunis was preparing to surrender. But while Charles was deliberating on the conditions, his troops, fearing that they would be deprived of the booty which they had expected, broke suddenly into the town, and pillaged and massacred without distinction. Thirty thousand persons perished by the sword, and 10,000 were made prisoners. The sceptre was restored to Muley Hascen, on condition that he should acknowledge himself a vassal of the crown of Spain, put into the emperor's hands all the fortified sea ports in the kingdom of Tunis, and pay annually 12,000 crowns for the subsistence of the Spanish garrison in the Goletta. These points being settled, and 20,000 Christian slaves freed from bondage either by arms or by treaty, Charles returned to Europe, where his presence was become necessary; while Barbarossa, who had retired to Bona, recovered new strength, and again became the tyrant of the ocean.

124 Tunis taken, and the inhabitants cruelly massacred.

125 Francis attempts in vain to revive his pretensions to Italy.

The king of France took advantage of the emperor's absence to revive his pretensions in Italy. The treaty of Cambray had repressed but not extinguished the flames of discord. Francis in particular, who waited only for a favourable opportunity of recovering the territories and reputation which he had lost, continued to negociate against his rival with different courts. But all his negociations were disconcerted by unforeseen accidents. The death of Clement VII. (whom he had gained by marrying his son the duke of Orleans, afterwards Henry II. to Catharine of Medici, the niece of that pontiff), deprived him of all the support which he hoped to receive from the court of Rome. The king of England, occupied with domestic cares and projects, declined engaging in the affairs of the continent; and the Protestant princes, associated by the league of Smalkalde, to whom Francis had also applied, and who seemed disposed at first to listen to him, filled with indignation and resentment at the cruelty with which some of their reformed brethren had been treated in France, refused to have any connection with the enemy of their religion.

Francis was neither cruel nor bigotted: he was too indolent to concern himself about religious disputes; but his principles becoming suspected, at a time when the emperor was gaining immortal glory by his expedition against the infidels, he found it necessary to vindicate himself by some extraordinary demonstration of reverence for the established faith. The indiscreet zeal of some Protestant converts furnished him with the occasion. They had affixed to the gates of the Louvre and other public places papers containing indecent reflections on the rites of the Romish church. Six of the persons concerned in this rash action were seized; and the king, pretending to be struck with horror at their blasphemies, appointed a solemn procession, in order to avert the wrath of heaven. The holy sacrament was carried through the city of Paris in great pomp: Francis walked uncovered before it, bearing a torch in his hand;

126 His barbarity to the Protestants.

Spain. hand; the princes of the blood supported the canopy over it; the nobles walked behind. In presence of this numerous assembly, the king declared, that if one of his hands were infected with heresy, he would cut it off with the other; "and I would sacrifice (added he) even my own children, if found guilty of that crime." As an awful proof of his sincerity, the six unhappy persons who had been seized were publicly burnt, before the procession was finished, and in the most cruel manner. They were fixed upon a machine which descended into the flames, and retired alternately, until they expired.—No wonder that the Protestant princes were incensed at such barbarity!

127 [Francis] makes an army march towards Italy.

Francis, though unsupported by any ally, commanded his army to advance towards the frontiers of Italy, under pretence of chastising the duke of Milan for a breach of the law of nations, in putting to death his ambassador. The operations of war, however, soon took a new direction. Instead of marching directly to the Milanese, Francis commenced hostilities against the duke of Savoy, with whom he had cause to be dissatisfied, and on whom he had some claims; and before the end of the campaign, this feeble prince saw himself stripped of all his dominions, except the province of Piedmont. To complete his misfortunes, the city of Geneva, the sovereignty of which he claimed, and where the reformed opinions had already got footing, threw off his yoke; and its revolt drew along with it the loss of the adjacent territory. Geneva was then an imperial city, and till lately remained entirely free *.

128 Geneva throws off the yoke of the duke of Savoy.

* See Geneva.

In this extremity the duke of Savoy saw no resource but in the emperor's protection; and as his misfortunes were chiefly occasioned by his attachment to the imperial interest, he had a title to immediate assistance. But Charles, who was just returned from his African expedition, was not able to lend him the necessary support. His treasury was entirely drained, and he was obliged to disband his army till he could raise new supplies. Mean time the death of Sforza duke of Milan entirely changed the nature of the war, and afforded the emperor full leisure to prepare for action. The French monarch's pretext for taking up arms was at once cut off; but as the duke died without issue, all Francis's rights to the duchy of Milan, which he had yielded only to Sforza and his descendants, returned to him in full force. He instantly renewed his claim to it; and if he had ordered his army immediately to advance, he might have made himself master of it. But he unfortunately wasted his time in fruitless negociations, while his more politic rival took possession of the duchy as a vacant fief of the empire; and though Charles seemed still to admit the equity of Francis's claim, he delayed granting the investiture under various pretences, and as secretly taking every possible measure to prevent him from regaining footing in Italy.

129 Charles takes possession of Milan.

During the time gained in this manner, Charles had recruited his finances, and of course his armies; and finding himself in a condition for war, he at last threw off the mask under which he had so long concealed his designs from the court of France. Entering Rome with great pomp, he pronounced before the pope and cardinals, assembled in full consistory, a violent invective against Francis, by way of reply to his propositions concerning the investiture of Milan. Yet Francis, by an unaccountable fatality, continued to negotiate, as if it had been still possible to terminate their differences in an amicable manner; and Charles, finding him so eager to run into the snare, favoured the deception, and, by seeming to listen to his proposals, gained yet more time for the execution of his ambitious projects.

130 Weakness of Francis.

If misfortunes had rendered Francis too diffident, success had made Charles too sanguine. He presumed on nothing less than the subversion of the French monarchy; nay, he considered it as a certain event. Having chased the forces of his rival out of Piedmont and Savoy, he pushed forward at the head of 50,000 men, contrary to the advice of his most experienced ministers and generals, to invade the southern provinces of France; while two other armies were ordered to enter it, the one on the side of Picardy, the other on the side of Champagne. He thought it impossible that Francis could resist so many unexpected attacks on such different quarters; but he found himself mistaken.

131 Charles attempts to subvert the French monarchy,

The French monarch fixed on the most effectual plan for defeating the invasion of a powerful enemy; and he prudently persevered in following it, though contrary to his own natural temper and to the genius of his people. He determined to remain altogether upon the defensive, and to deprive the enemy of subsistence by laying waste the country before them. The execution of this plan was committed to the mareschal Montmorency its author, a man happily fitted for such a trust by the inflexible severity of his disposition. He made choice of a strong camp, under the walls of Avignon, at the confluence of the Rhone and Durance, where he assembled a considerable army; while the king, with another body of troops, encamped at Valence, higher up the Rhone. Marseilles and Arles were the only towns he thought it necessary to defend; and each of these he furnished with a numerous garrison of his best troops. The inhabitants of the other towns were compelled to abandon their habitations: the fortifications of such places as might have afforded shelter to the enemy were thrown down; corn, forage, and provisions of every kind, were carried off or destroyed; the mills and ovens were ruined, and the wells filled up or rendered useless.

132 But is disappointed in his designs.

This devastation extended from the Alps to Marseilles, and from the sea to the confines of Dauphiny; so that the emperor, when he arrived with the van of his army on the confines of Provence, instead of that rich and populous country which he expected to enter, beheld nothing but one vast and desert solitude. He did not, however, despair of success, though he saw that he would have many difficulties to encounter; and as an encouragement to his officers, he made them liberal promises of lands and honours in France. But all the land which any of them obtained was a grave, and their master lost much honour by this rash and presumptuous enterprise. After unsuccessfully investing Marseilles and Arles, after attempting in vain to draw Montmorency from his camp at Avignon, and not daring to attack it, Charles having spent two inglorious months in Provence, and lost one half of his troops by disease or by famine, was under the necessity of ordering a retreat; and though he was some time in motion before the enemy suspected his intention, it was conducted with so much precipitation and disorder, as to deserve the name of a flight, since the light troops of France turned it into a perfect rout. The invasion of Picardy

Spain.

Picardy was not more successful: the imperial forces were obliged to retire without effecting any conquest of importance.

Charles had no sooner conducted the shattered remains of his army to the frontiers of Milan, than he set out for Genoa; and unwilling to expose himself to the scorn of the Italians after such a reverse of fortune, he embarked directly for Spain.

133 Violent animosity between him and Francis.

Meanwhile Francis gave himself up to that vain resentment which had formerly disgraced the prosperity of his rival. They had frequently, in the course of their quarrels, given each other the lie, and mutual challenges had been sent; which, though productive of no serious consequences between the parties, had a powerful tendency to encourage the pernicious practice of duelling. Charles, in his invective pronounced at Rome, had publicly accused Francis of perfidy and breach of faith; Francis now exceeded Charles in the indecency of his accusations. The dauphin dying suddenly, his death was imputed to poison: Montecuculi his cup-bearer was put to the rack; and that unhappy nobleman, in the agonies of torture, accused the emperor's generals Gonzaga and de Leyva, of instigating him to the detestable act. The emperor himself was suspected; nay, this extorted confession, and some obscure hints, were considered as incontestable proofs of his guilt; though it was evident to all mankind, that neither Charles nor his generals could have any inducement to perpetrate such a crime, as Francis was still in the vigour of life himself, and had two sons besides the dauphin, grown up to a good age.

But the incensed monarch's resentment did not stop here. Francis was not satisfied with endeavouring to blacken the character of his rival by an ambiguous testimony which led to the most injurious suspicions, and upon which the most cruel constructions had been put; he was willing to add rebellion to murder. For this purpose he went to the parliament of Paris; where being seated with the usual solemnities, the advocate-general appeared, and accused Charles of Austria (so he affected to call the emperor) of having violated the treaty of Cambray, by which he was freed from the homage due to the crown of France for the counties of Artois and Flanders; adding, that this treaty being now void, he was still to be considered as a vassal of France, and consequently had been guilty of rebellion in taking arms against his sovereign. The charge was

134 Charles summoned to appear at Paris.

sustained, and Charles was summoned to appear before the parliament of Paris at a day fixed. The term expired; and no person appearing in the emperor's name, the parliament gave judgment, that Charles of Austria had forfeited, by rebellion and contumacy, the counties of Flanders and Artois, and declared these fiefs reunited to the crown of France.

Francis, soon after this vain display of his animosity, marched into the Low Countries, as if he had intended to execute the sentence pronounced by his parliament; but a suspension of arms took place, through the interposition of the queens of France and Hungary, before any thing of consequence was effected: and this cessation of hostilities was followed by a truce concluded at Nice, through the mediation of the reigning pontiff Paul III. of the family of Farnese, a man of a venerable character and pacific disposition.

Each of these rival princes had strong reasons to incline them to peace. The finances of both were exhausted; and the emperor, the more powerful of the two, was deeply impressed with the dread of the Turkish

135 Francis leagues with the Turks.

arms, which Francis had drawn upon him by a league with Solyman. In consequence of this league, Barbarossa with a great fleet appeared on the coast of Naples; filled that kingdom with consternation; landed without resistance near Taranto; obliged Castro, a place of some strength, to surrender; plundered the adjacent country; and was taking measures for securing and extending his conquests, when the unexpected arrival of Doria, the famous Genoese admiral, together with the pope's galleys and a squadron of the Venetian fleet, made it prudent for him to retire. The sultan's forces also invaded Hungary, where Mahmet the Turkish general, after gaining several inferior advantages, defeated the Germans in a great battle at Essek on the Drave. Happily for Charles and Europe it was not in Francis's power at this juncture either to join the Turks or assemble an army strong enough to penetrate into the Milanese. The emperor, however, was sensible that he could not long resist the efforts of two such powerful confederates, nor expect that the same fortunate circumstances would concur a second time in his favour; he therefore thought it necessary, both for his safety

136 A truce concluded.

and reputation, to give his consent to a truce: and Francis chose rather to run the risk of disobliging his new ally the sultan, than to draw on his head the indignation, and perhaps the arms of all Christendom, by obstinately obstructing the re-establishment of tranquillity, and contributing to the aggrandizement of the Infidels.

These considerations inclined the contending monarchs to listen to the arguments of the holy father; but he found it impossible to bring about a final accommodation between them, each inflexibly persisted in asserting his own claims. Nor could he prevail on them to see one another, though both came to the place of rendezvous: so great was the remains of distrust and rancour, or such

137 Interview between Francis and Charles.

the difficulty of adjusting the ceremonial! Yet, improbable as it may seem, a few days after signing the truce, the emperor, in his passage to Barcelona, being driven on the coast of Provence, Francis invited him to come ashore; frankly visited him on board his galley, and was received and entertained with the warmest demonstrations of esteem and affection. Charles, with an equal degree of confidence, paid the king next day a visit at Aignes-mortes; where these two hostile rivals and vindictive enemies, who had accused each other of every kind of baseness, conversing together with all the cordiality of brothers, seemed to vie with each other in expressions of respect and friendship.

138 Advantage gained by the pope from this pacification.

Besides the glory of having restored tranquillity to Europe, the pope gained a point of much consequence to his family. He obtained for his grandson, Margaret of Austria, the emperor's natural daughter, formerly wife of Alexander de Medici, whom Charles had raised to the supreme power in Florence. Laurencin de Medici, the kinsman and intimate companion of Alexander, had assassinated him by one of the blackest treasons recorded in history. Under pretence of having secured him an assignation with a lady of the highest rank and great beauty, he drew him into a secret apartment of his house, and there stabbed him as he lay carelessly on a couch, expecting the embrace of the lovely fair, whom he had often

Spain.

often solicited in vain. Laurenein, however, did not reap the fruits of his crime; for though some of his countrymen extolled him as a third Brutus, and endeavoured to seize this occasion for recovering their liberties, the government of Florence passed into the hands of Cosmo II. another kinsman of Alexander. Cosmo was desirous of marrying the widow of his predecessor; but the emperor chose rather to oblige the pope, by bestowing his daughter upon Octavio Farnese, son of the duke of Parma.

139 [Ch]arles [dist]ressed.

Charles had soon farther cause to be sensible of his obligations to the holy father for bringing about the treaty of Nice. His troops everywhere mutinied for want of pay, and the ability of his generals only could have prevented a total revolt. He had depended, as his chief resource for dicharging the arrears due to his soldiers, upon the subsidies which he expected from his Castilian subjects. For this purpose he assembled the Cortes of Castile at Toledo; and having represented to them the great expence of his military operations, he proposed to levy such supplies as the present exigency of affairs demanded, by a general excise on commodities; but the Spaniards, who already felt themselves oppressed by a load of taxes unknown to their ancestors, and who had often complained that their country was drained of its wealth and inhabitants, in order to prosecute quarrels in which they had no interest, determined not to add voluntarily to their own burdens. The nobles, in particular, inveighed with great vehemence against the imposition proposed, as an encroachment on the valuable and distinguished privilege of their order, that of being exempted from the payment of any tax. After employing arguments and promises in vain, Charles dismissed the assembly with indignation; and from that period neither the nobles nor the prelates have been called to the Cortes, on pretence that such as pay no part of the public taxes should not claim a vote in laying them on. These assemblies have since consisted merely of the procurators or representatives of 18 cities, two from each; in all 36 members, who are absolutely at the devotion of the crown.

[1]40 The Spaniards refuse to assist him with money.

[14]1 Inhabitants of Ghent rebel.

The citizens of Ghent, still more bold, broke out not long after into open rebellion against the emperor's government, on account of a tax which they judged contrary to their ancient privileges, and a decision of the council of Mechlin in favour of the imperial authority. Enraged at an unjust imposition, and rendered desperate on seeing their rights betrayed by that very court which was bound to protect them, they flew to arms, seized several of the emperor's officers, and drove such of the nobility as resided among them out of the city. Sensible, however, of their inability to support what their zeal had prompted them to undertake, and desirous of securing a protector against the formidable forces with which they might expect soon to be attacked, they offered to acknowledge the king of France as their sovereign, to put him into immediate possession of their city, and to assist him in recovering those provinces in the Netherlands which had anciently belonged to his crown. True policy directed Francis to comply with this proposal. The counties of Flanders and Artois were more valuable than the duchy of Milan, for which he had so long contended; and their situation in regard to France made it more easy to conquer or to defend them. But Francis over-rated the Milanese. He had lived in friendship with the emperor ever since their interview at Aigues-mortes, and Charles had promised him the investiture of that duchy. Forgetting, therefore, all his past injuries, and the deceitful promises by which he had been so often duped, the credulous, generous Francis, not only rejected the propositions of the citizens of Ghent, but communicated to the emperor his whole negociation with the malecontents.

Spain.

142 Extreme credulity of Francis.

Judging of Charles's heart by his own, Francis hoped by this seemingly disinterested proceeding to obtain at once the investiture of Milan; and the emperor, well acquainted with the weakness of his rival, flattered him in this apprehension, for his own selfish purposes. His presence being necessary in the Netherlands, he demanded a passage through France. It was immediately granted him; and Charles, to whom every moment was precious, set out, notwithstanding the remonstrances of his council and the fears of his Spanish subjects, with a small but splendid train of 100 persons. He was met on the frontiers of France by the dauphin and the duke of Orleans, who offered to go into Spain, and remain there as hostages, till he should reach his own dominions; but Charles replied, that the king's honour was sufficient for his safety, and prosecuted his journey without any other security. The king entertained him with the utmost magnificence at Paris, and the two young princes did not take leave of him till he entered the Low Countries; yet he still found means to evade his promise, and Francis continued to believe him sincere.

143 He allows Charles to pass through his dominions.

144 Severity of Charles to the city of Ghent.

The citizens of Ghent, alarmed at the approach of the emperor, who was joined by three armies, sent ambassadors to implore his mercy, and offered to throw open their gates. Charles only condescended to reply, "That he would appear among them as a sovereign and a judge, with the sceptre and the sword." He accordingly entered the place of his nativity on the anniversary of his birth; and instead of that lenity which might have been expected, exhibited an awful example of his severity. Twenty-six of the principal citizens were put to death: a greater number was banished: the city was declared to have forfeited its privileges; a new system of laws and political administration was prescribed; and a large fine was imposed on the inhabitants, in order to defray the expence of erecting a citadel, together with an annual tax for the support of a garrison. They were not only despoiled of their ancient immunities, but made to pay, like conquered people, for the means of perpetuating their own slavery.

145 His base treatment of Francis.

Having thus re-established his authority in the Low Countries, and being now under no necessity of continuing that scene of falsehood and dissimulation with which he had amused the French monarch, Charles began gradually to throw aside the veil under which he had concealed his intentions with respect to the Milanese, and at last peremptorily refused to give up a territory of such value, or voluntarily to make such a liberal addition to the strength of an enemy by diminishing his own power. He even denied that he had ever made any promise which could bind him to an action so foolish, and so contrary to his own interest.

This transaction exposed the king of France to as much scorn as it did the emperor to censure. The credulous simplicity of Francis seemed to merit no other return, after experiencing so often the duplicity and artifices of his rival. He remonstrated, however, and exclaimed

Spain.

claimed as if this had been the first circumstance in which the emperor had deceived him. The insult offered to his understanding affected him even more sensibly than the injury done to his interest; and he discovered such resentment as made it obvious that he would seize on the first opportunity of revenge, and that a new war would soon desolate the European continent.

146
He is obliged to make concessions to the Protestants.

Meanwhile Charles was obliged to turn his attention towards the affairs of Germany. The Protestants having in vain demanded a general council, pressed him earnestly to appoint a conference between a select number of divines of each party, in order to examine the points in dispute. For this purpose a diet was assembled at Ratisbon: and such a conference, notwithstanding the opposition of the pope, was held with great solemnity in the presence of the emperor. But the divines chosen to manage the controversy, though men of learning and moderation, were only able to settle a few speculative opinions, all points relative to worship and jurisdiction serving to inflame the minds of the disputants. Charles, therefore, finding his endeavours to bring about an accommodation ineffectual, and being impatient to close the diet, prevailed on a majority of the members to approve of the following edict of recess; viz. that the articles concerning which the divines had agreed, should be held as points decided; that those about which they had differed, should be referred to the determination of a general council, or if that could not be obtained, to a national synod: and should it prove impracticable also to assemble a synod of Germany, that a general diet of the empire should be called within 18 months, in order to give final judgment on the whole controversy; that, in the mean time, no innovations should be attempted, nor any endeavours employed to gain proselytes.

This diet gave great offence to the pope. The bare mention of allowing a diet, composed chiefly of laymen, to pass judgment in regard to articles of faith, appeared to him no less criminal and profane than the worst of those heresies which the emperor seemed so zealous to suppress. The Protestants also were dissatisfied with it, as it considerably abridged the liberty which they at that time enjoyed. They murmured loudly against it; and Charles, unwilling to leave any seeds of discontent in the empire, granted them a private declaration, exempting them from whatever they thought injurious or oppressive in the recess, and ascertaining to them the full possession of all their former privileges.

The situation of the emperor's affairs at this juncture made these extraordinary concessions necessary. He foresaw a rupture with France to be unavoidable, and he was alarmed at the rapid progress of the Turks in Hungary. A great revolution had happened in that kingdom. John Zapol Scæpus, by the assistance of Solyman, had wrested from the king of the Romans a considerable part of the country. John died, and left an infant son. Ferdinand attempted to take advantage of the minority, in order to repossess himself of the whole kingdom; but his ambition was disappointed by the activity and address of George Martinuzzi, bishop of Waradin, who shared the regency with the queen. Sensible that he was unable to oppose the king of the Romans in the field, Martinuzzi satisfied himself with holding out the fortified towns, all of which he provided with every thing necessary for defence; and at the same time he sent ambassadors to Solyman, beseeching him to extend towards the son that imperial protection which had so generously maintained the father on his throne. Ferdinand used his utmost endeavours to thwart this negociation, and even meanly offered to hold the Hungarian crown on the same ignominious condition by which John had held it, that of paying tribute to the Porte. But the sultan saw such advantages from espousing the interest of the young king, that he instantly marched into Hungary; and the Germans, having formed the siege of Buda, were defeated with great slaughter before that city. Solyman, however, instead of becoming the protector of the infant sovereign whom he had relieved, made use of this success to extend his own dominions: he sent the queen and her son into Transylvania, which province he allotted them, and added Hungary to the Ottoman empire.

Happily for the Protestants, Charles received intelligence of this revolution soon after the diet at Ratisbon; and by the concessions which he made them, he obtained such liberal supplies, both of men and money, as left him under little anxiety about the security of Germany. He therefore hastened to join his fleet and army in Italy, in order to carry into execution a great and favourite enterprise which he had concerted against Algiers: though it would certainly have been more consistent with his dignity to have conducted the whole force of the empire against Solyman, the common enemy of Christendom, who was ready to enter his Austrian dominions. But many reasons induced Charles to prefer the African expedition: he wanted strength, or at least money, to combat the Turks in so distant a country as Hungary; and the glory which he had formerly acquired in Barbary led him to hope for the like success, while the cries of his Spanish subjects roused him to take vengeance on their ravagers. But the unfortunate event of this expedition has already been related under the article ALGIERS, N° 14—20.

147
Undertakes an unsuccessful expedition against Algiers.

148
War between Francis and Charles.

The loss which the emperor suffered in this calamitous expedition encouraged the king of France to begin hostilities, on which he had been for some time resolved; and an action dishonourable to civil society furnished him with too good a pretext for taking arms. The marquis del Guasto, governor of the Milanese, having got intelligence of the motions and destination of two ambassadors, Rincon and Fergoso, whom Francis had dispatched, the one to the Ottoman Porte, the other to the republic of Venice; knowing how much his master wished to discover the intentions of the French monarch, and of what consequence it was to retard the execution of his measures, he employed some soldiers belonging to the garrison of Pavia to lie in wait for these ambassadors as they sailed down the Po, who murdered them and most of their attendants, and seized their papers. Francis immediately demanded reparation for this barbarous outrage; and as Charles endeavoured to put him off with an evasive answer, he appealed to all the courts of Europe, setting forth the heinousness of the injury, the iniquity of the emperor in disregarding his just request, and the necessity of vengeance. But Charles, who was a more profound negociator, defeated in a great measure the effects of these representations: he secured the fidelity of the Protestant princes in Germany, by granting them new concessions; and he engaged the king of England to espouse his cause, under pretence

Spain. pretence of defending Europe against the Infidels; while Francis was only able to form an alliance with the kings of Denmark and Sweden (who for the first time interested themselves in the quarrels of the more potent monarchs of the south), and to renew his treaty with Solyman, which drew on him the indignation of Christendom.

But the activity of Francis supplied all the defects of his negociation. Five armies were soon ready to take the field, under different generals, and with different destinations. Nor was Charles wanting in his preparations. He and Henry a second time made an ideal division of the kingdom of France. But as the hostilities which followed terminated in nothing decisive, and were distinguished by no remarkable event, except the battle of Cerisoles (gained by Count d'Enguien over the imperialists, and in which 10,000 of the emperor's best troops fell) at last Francis and Charles, mutually tired

49 Peace concluded at Crespy. of harassing each other, concluded at Crespy a treaty of peace, in which the king of England was not mentioned; and from being implacable enemies, became once more, to appearance, cordial friends, and even allies by the ties of blood.

The chief articles of this treaty were, that all the conquests which either party had made since the truce of Nice should be restored; that the emperor should give in marriage to the duke of Orleans, either his own eldest daughter, with the Low Countries, or the second daughter of his brother Ferdinand, with the investiture of the Milanese; that Francis should renounce all pretensions to the kingdom of Naples, as well as to the sovereignty of Flanders and Artois, and Charles give up his claim to the duchy of Burgundy; and that both should unite in making war against the Turks.

The emperor was chiefly induced to grant conditions so advantageous to France, by a desire of humbling the Protestant princes in Germany. With the papal jurisdiction, he foresaw they would endeavour to throw off the imperial authority; and he determined to make his zeal for the former a pretence for enforcing and extending the latter. However, the death of the duke of Orleans before the consummation of his marriage, disentangled the emperor from the most troublesome stipulation in the treaty of Crespy; and the French monarch, being still engaged in hostilities with England, was unable to obtain any reparation for the loss which he suffered by this unforeseen event. These hostilities, like those between Charles and Francis, terminated in nothing decisive. Equally tired of a struggle attended with no glory or advantage to either, the contending princes concluded, at Campe, near Ardres, a treaty of peace; in which it was stipulated, that France should pay the arrears due by former treaties to England. But these arrears did not exceed one-third of the sums expended by Henry on his military operations; and Francis being in no condition to discharge them, Boulogne (a chargeable pledge) was left in the hands of the English as a security for the debt.

150 Charles obliged to conclude a disadvantageous peace with the Turks and Protestants. In consequence of the emperor's resolution to humble the Protestant princes, he concluded a dishonourable peace with the Porte, stipulating that his brother Ferdinand should pay tribute for that part of Hungary which he still possessed; while the sultan enjoyed the imperial and undisturbed possession of all the rest. At the same time he entered into a league with Pope Paul III. for the extirpation of heresy; but in reality with a view to oppress the liberties of Germany. Here, however, his ambition met with a severe check; for though he was successful at first, he was obliged in 1552 to conclude a peace with the Protestants on their own terms; as has been related under the article REFORMATION, N° 26—32.

By the peace concluded on this occasion the emperor lost Metz, Toul, and Verdun, which had formed the barrier of the empire on that quarter; and therefore soon after put himself at the head of an army, in order to recover these three bishoprics. In order to conceal the destination of his army, he gave out, that he intended to lead it into Hungary, to second Maurice in his operations against the Infidels; and as that pretext failed him, when he began to advance towards the Rhine, he propagated a report that he was marching first to chastise Albert of Brandenburg, who had refused to be included in the treaty of Passau, and whose cruel exactions in that part of Germany called loudly for redress. 151 Attempts to recover some of his provinces.

The French, however, were not deceived by these arts. Henry immediately guessed the true object of Charles's armament, and resolved to defend his conquest with vigour. The defence of Metz, against which it was foreseen the whole weight of the war would be turned, was committed to Francis of Lorraine, duke of Guise, who possessed in an eminent degree all the qualities that render men great in military command. He repaired with joy to the dangerous station; and many of the French nobility, and even princes of the blood, eager to distinguish themselves under such a leader, entered Metz as volunteers. The city was of great extent, ill fortified, and the suburbs large. For all these defects the duke endeavoured to provide a remedy. He repaired the old fortifications with all possible expedition, labouring with his own hands; the officers imitated his example; and the soldiers, thus encouraged, cheerfully submitted to the most severe toils; he erected new works, and he levelled the suburbs with the ground. At the same time he filled the magazines with provisions and military stores, compelled all useless persons to leave the place, and laid waste the neighbouring country; yet such were his popular talents, as well as his arts of acquiring an ascendant over the minds of men, that the citizens not only refrained from murmuring, but seconded him with no less ardour than the soldiers in all his operations—in the ruin of their estates, and in the havoc of their public and private buildings. 152 Is obliged to raise the siege of Metz.

Meanwhile the emperor continued his march towards Lorraine, at the head of 60,000 men. On his approach Albert of Brandenburg, whose army did not exceed 20,000, withdrew into that principality as if he intended to join the French king; and Charles, notwithstanding the advanced season, it being towards the end of October, laid siege to Metz, contrary to the advice of his most experienced officers.

The attention of both the besiegers and the besieged was turned for some time towards the motions of Albert, who still hovered in the neighbourhood, undetermined which side to take, though resolved to sell his service. Charles at last came up to his price, and he joined the imperial army. The emperor now flattered himself that nothing could resist his force; but he found himself deceived. After a siege of almost 60 days, during

Spain.

ring which he had attempted all that was thought possible for art or valour to effect, and had lost upwards of 30,000 men by the inclemency of the weather, diseases, or the sword of the enemy, he was obliged to abandon the enterprise.

153 Miserable condition of his army.

When the French sallied out to attack the enemy's rear, the imperial camp was filled with the sick and wounded, with the dead and the dying. All the roads by which the army retired were strewed with the same miserable objects; who, having made an effort beyond their strength to escape, and not being able to proceed, were left to perish without assistance. Happily that, and all the kind offices which their friends had not the power to perform, they received from their enemies. The duke of Guise ordered them all to be taken care of, and supplied with every necessary; he appointed physicians to attend, and direct what treatment was proper for the sick and wounded, and what refreshments for the feeble; and such as recovered he sent home, under an escort of soldiers, and with money to bear their charges. By these acts of humanity, less common in that age, the duke of Guise completed that heroic character which he had justly acquired by his brave and successful defence of Metz.

154 His further misfortunes.

The emperor's misfortunes were not confined to Germany. During his residence at Villach, he had been obliged to borrow 200,000 crowns of Cosmo de Medici; and so low was his credit, that he was obliged to put Cosmo in possession of the principality of Piombino as a security for that inconsiderable sum; by which means he lost the footing he had hitherto maintained in Tuscany. Much about the same time he lost Sienna. The citizens, who had long enjoyed a republican government, rose against the Spanish garrison, which they had admitted as a check upon the tyranny of the nobility, but which they found was meant to enslave them; forgetting their domestic animosities, they recalled the exiled nobles; they demolished the citadel, and put themselves under the protection of France.

To these unfortunate events one still more fatal had almost succeeded. The severe administration of the viceroy of Naples had filled that kingdom with murmuring and dissatisfaction. The prince of Salerno, the head of the malecontents, fled to the court of France. The French monarch, after the example of his father, applied to the grand signior; and Solyman, at that time highly incensed against the house of Austria on account of the proceedings in Hungary, sent a powerful fleet into the Mediterranean, under the command of the corsair Dragut, an officer trained up under Barbarossa, and scarcely inferior to his master in courage, talents, or in good fortune. Dragut appeared on the coast of Calabria at the time appointed; but not being joined by the French fleet according to concert, he returned to Constantinople, after plundering and burning several places, and filling Naples with consternation.

155 Is successful in the Low Countries.

Highly mortified by so many disasters, Charles retired into the Low Countries, breathing vengeance against France: and here the war was carried on with considerable vigour. Impatient to efface the stain which his military reputation had received before Metz, Charles laid siege to Terouane; and the fortifications being in disrepair, that important place was carried by assault. Hesdin also was invested, and carried in the same manner. The king of France was too late in assembling his forces to afford relief to either of these places; and the emperor afterwards cautiously avoided an engagement.

156 But not so in other places.

The imperial arms were less successful in Italy. The viceroy of Naples failed in an attempt to recover Sienna; and the French not only established themselves more firmly in Tuscany, but conquered part of the island of Corsica. Nor did the affairs of the house of Austria go on better in Hungary during the course of this year. Isabella and her son appeared once more in Transylvania, at a time when the people were ready for revolt, in order to revenge the death of Martinuzzi, whose loss they had severely felt. Some noblemen of eminence declared in favour of the young king; and the bashaw of Belgrade, by Solyman's order, espousing his cause, in opposition to Ferdinand, Castaldo, the Austrian general, was obliged to abandon Transylvania to Isabella and the Turks.

157 Marriage between Philip of Spain and Mary of England. An. 1554.

In order to counterbalance those and other losses, the emperor, in 1554, concerted a marriage between his son Philip and Mary of England, in hopes of adding that kingdom to his other dominions. Meanwhile the war between Henry and Charles was carried on with various success in the Low Countries, and in Italy much to the disadvantage of France. The French, under the command of Strozzi, were defeated in the battle of Merciano; Sienna was reduced by Medicino, the Florentine general, after a siege of ten months; and the gallant Siennese were subjected to the Spanish yoke. Much about the same time a plot was formed by the Franciscans, but happily discovered before it could be carried into execution, to betray Metz to the Imperialists. The father guardian, and twenty other monks, received sentence of death on account of this conspiracy; but the guardian, before the time appointed for his execution, was murdered by his incensed accomplices, whom he had seduced; and six of the youngest were pardoned.

While war thus raged in Italy and the Low Countries, Germany enjoyed such profound tranquillity, as afforded the diet full leisure to confirm and perfect the plan of religious pacification agreed upon at Passau, and referred to the consideration of the next meeting of the Germanic body. During the negociation of this treaty, an event happened which astonished all Europe, and confounded the reasonings of the wisest politicians.

158 Charles resigns his dominions to his son Philip. An. 1556.

The emperor Charles V. though no more than 56, an age when objects of ambition operate with full force on the mind, and are generally pursued with the greatest ardour, had for some time formed the resolution of resigning his hereditary dominions to his son Philip. He now determined to put it into execution. Various have been the opinions of historians concerning a resolution so singular and unexpected; but the most probable seem to be, the disappointments which Charles had met with in his ambitious hopes, and the daily decline of his health. He had early in life been attacked with the gout; and the fits were now become so frequent and severe, that not only the vigour of his constitution was broken, but the faculties of his mind were sensibly impaired. He therefore judged it more decent to conceal his infirmities in some solitude, than to expose them any longer to the public eye; and as he was unwilling to

Spain. to forfeit the fame, or lose the acquisitions of his better years, by attempting to guide the reins of government when he was no longer able to hold them with steadiness, he determined to seek in the tranquillity of retirement, that happiness which he had in vain pursued amidst the tumults of war and the intrigues of state.

In consequence of this resolution, Charles, who had already ceded to his son Philip the kingdom of Naples and the duchy of Milan, assembled the states of the Low Countries at Brussels; and seating himself for the last time in the chair of state, he explained to his subjects the reasons of his resignation, and solemnly devolved his authority upon Philip. He recounted with dignity, but without ostentation, all the great things which he had undertaken and performed since the commencement of his administration. "I have dedicated (observed he) from the 17th year of my age, all my thoughts and attention to public objects, reserving no portion of my time for the indulgence of ease, and very little for the enjoyment of private pleasure. Either in a pacific or hostile manner, I have visited Germany nine times, Spain six times, France four times, Italy seven times, the Low Countries ten times, England twice, Africa as often; and while my health permitted me to discharge the duty of a sovereign, and the vigour of my constitution was equal in any degree to the arduous office of governing such extensive dominions, I never shunned labour, nor repined under fatigue; but now, when my health is broken, and my vigour exhausted by the rage of an incurable distemper, my growing infirmities admonish me to retire; nor am I so fond of reigning, as to retain the sceptre in an impotent hand, which is no longer able to protect my subjects. Instead of a sovereign worn out with diseases (continued he), and scarce half alive, I give you one in the prime of life, already accustomed to govern, and who adds to the vigour of youth all the attention and sagacity of maturer years." Then turning towards Philip, who fell on his knees, and kissed his father's hand, "It is in your power (said Charles), by a wise and virtuous administration, to justify the extraordinary proof which I give this day of my paternal affection, and to demonstrate that you are worthy of the extraordinary confidence which I repose in you. Preserve (added he) an inviolable regard for religion; maintain the Catholic faith in its purity; let the laws of your country be sacred in your eyes; encroach not on the rights of your people; and if the time should ever come when you shall wish to enjoy the tranquillity of private life, may you have a son to whom you can resign your sceptre with as much satisfaction as I give up mine to you." A few weeks after, he resigned to Philip the sovereignty of Spain and America; reserving nothing to himself out of all these vast possessions but an annual pension of 100,000 crowns.

Charles was now impatient to embark for Spain, where he had fixed on a place of retreat; but by the advice of his physicians, he put off his voyage for some months, on account of the severity of the season; and, by yielding to their judgment, he had the satisfaction before he left the Low Countries of taking a considerable step towards a peace with France. This he ardently longed for; not only on his son's account, whose administration he wished to commence in quietness, but that he might have the glory, when quitting the world, of restoring to Europe that tranquillity which his ambition had banished out of it almost from the time that he assumed the reins of government.

Spain.

The great bar to such a pacification, on the part of France, was the treaty which Henry had concluded with the Pope; and the emperor's claims were too numerous to hope for adjusting them suddenly. A truce of five years was therefore proposed by Charles; during which term, without discussing their respective pretensions, each should retain what was in his possession; and Henry, through the persuasion of the constable Montmorency, who represented the imprudence of sacrificing the true interests of his kingdom to the rash engagements that he had come under with Paul, authorised his ambassadors to sign at Vaucelles a treaty, which would insure to him for so considerable a period the important conquest which he had made on the German frontier, together with the greater part of the duke of Savoy's dominions.

159 A truce of five years concluded with France.

The Pope, when informed of this transaction, was no less filled with terror and astonishment than rage and indignation. But he took equal care to conceal his fear and his anger. He affected to approve highly of the truce; and he offered his mediation, as the common father of Christendom, in order to bring about a definitive peace. Under this pretext, he appointed Cardinal Rebibo his nuncio to the court of Brussels, and his nephew Cardinal Caraffa to that of Paris. The public instructions of both were the same; but Caraffa, besides these, received a private commission, to spare neither intreaties, promises, nor bribes, in order to induce the French monarch to renounce the truce and renew his engagements with the holy see. He flattered Henry with the conquest of Naples; he gained by his address the Guises, the queen, and even the famous Diana of Poictiers, duchess of Valentinois, the king's mistress; and they easily swayed the king himself, who already leaned to that side towards which they wished to incline him. All Montmorency's prudent remonstrances were disregarded; the nuncio (by powers from Rome) absolved Henry from his oath of truce; and that weak prince signed a new treaty with the Pope; which rekindled with fresh violence the flames of war, both in Italy and the Low Countries.

160 Quarrel betwixt the pope and King Philip.

No sooner was Paul made acquainted with the success of this negociation than he proceeded to the most indecent extremities against Philip. He ordered the Spanish ambassador to be imprisoned; he excommunicated the Colonnas, because of their attachment to the imperial house; and he considered Philip as guilty of high treason, and to have forfeited his right to the kingdom of Naples, which he was supposed to hold of the holy see, for afterward affording them a retreat in his dominions.

Alarmed at a quarrel with the Pope, whom he had been taught to regard with the most superstitious veneration, as the vicegerent of Christ and the common father of Christendom, Philip tried every gentle method before he made use of force. He even consulted some Spanish divines on the lawfulness of taking arms against a person so sacred. They decided in his favour; and Paul continuing inexorable, the duke of Alva, to whom the

the negociations as well as the war had been committed, entered the ecclesiastical state at the head of 10,000 veterans, and carried terror to the gates of Rome.

The haughty pontiff, though still inflexible and undaunted himself, was forced to give way to the fears of the cardinals, and a truce was concluded for 40 days. Mean time the duke of Guise arriving with a supply of 20,000 French troops, Paul became more arrogant than ever, and banished all thoughts from his mind but those of war and revenge. The duke of Guise, however, who had precipitated his country into this war, chiefly from a desire of gaining a field where he might display his own talents, was able to perform nothing in Italy worthy of his former fame. He was obliged to abandon the siege of Civetella; he could not bring the duke of Alva to a general engagement; his army perished by diseases; and the Pope neglected to furnish the necessary reinforcements. He begged to be recalled; and France stood in need of his abilities.

Philip, though willing to have avoided a rupture, was no sooner informed that Henry had violated the truce of Vaucelles, than he determined to act with such vigour, as should convince Europe that his father had not erred in resigning to him the reins of government. He immediately assembled in the Low Countries a body of 50,000 men, and obtained a supply of 10,000 from England, which he had engaged in his quarrel; and as he was not ambitious of military fame, he gave the command of his army to Emanuel Philibert duke of Savoy, one of the greatest generals of that warlike age.

The duke of Savoy kept the enemy for some time in suspense with regard to his destination; at last he seemed to threaten Champagne; towards which the French drew all their troops; then turning suddenly to the right, he advanced by rapid marches into Picardy, and laid siege to St Quintin. It was deemed in those times a town of considerable strength; but the fortifications had been much neglected, and the garrison did not amount to a fifth part of the number requisite for its defence: it must therefore have surrendered in a few days, if the admiral de Coligny had not taken the gallant resolution of throwing himself into it with such a body of men as could be collected on a sudden. This he effected in spite of the enemy, breaking through their main body. The place, however, was closely invested; and the constable Montmorency, anxious to extricate his nephew out of that perilous situation, in which his zeal for the public had engaged him, as well as to save a town of such importance, rashly advanced to its relief with forces one half inferior to those of the enemy. His army was cut in pieces, and he himself made prisoner.

161 The French entirely defeated at St Quintin. An. 1557.

The cautious temper of Philip on this occasion saved France from devastation, if not ruin. The duke of Savoy proposed to overlook all inferior objects, and march speedily to Paris, which, in its present consternation, he could not have failed to make himself master of; but Philip, afraid of the consequences of such a bold enterprise, desired him to continue the seige of St Quintin, in order to secure a safe retreat in case of any disastrous event. The town, long and gallantly defended by Coligny, was at last taken by storm; but not till France was in a state of defence.

Philip was now sensible that he had lost an opportunity which could never be recalled, of distressing his enemy, and contented himself with reducing Horn and Catelet; which petty towns, together with St Quintin, were the sole fruits of one of the most decisive victories gained in the 16th century. The Catholic king, however, continued in high exultation on account of his success; and as all his passions were tinged with superstition, he vowed to build a church, a monastery, and a palace, in honour of St Lawrence, on the day sacred to whose memory the battle of St Quintin had been fought. He accordingly laid the foundation of an edifice, in which all these were included, and which he continued to forward at a vast expence, for 22 years. The same principle which dictated the vow directed the building. It was so formed as to resemble a gridiron—on which culinary instrument, according to the legendary tale, St Lawrence had suffered martyrdom. Such is the origin of the famous Escurial near Madrid, the royal residence of the kings of Spain.

The first account of that fatal blow which France had received at St Quintin, was carried to Rome by the courier whom Henry had sent to recal the duke of Guise. Paul remonstrated warmly against the departure of the French army; but Guise's orders were peremptory. The arrogant pontiff therefore found it necessary to accommodate his conduct to the exigency of his affairs, and to employ the mediation of the Venetians, and of Cosmo de Medici, in order to obtain peace. The first overtures of this nature were eagerly listened to by the Catholic king, who still doubted the justice of his cause, and considered it as his greatest misfortune to be obliged to contend with the Pope. Paul agreed to renounce his league with France; and Philip stipulated on his part, that the duke of Alva should repair in person to Rome, and after asking pardon of the holy father in his own name and in that of his master, for having invaded the patrimony of the church, should receive absolution from that crime. Thus Paul, through the superstitious timidity of Philip, finished an unpropitious war not only without any detriment to the apostolic see, but saw his conqueror humbled at his feet: and so excessive was the veneration of the Spaniards in that age for the papal character, that the duke of Alva, the proudest man perhaps of his time, and accustomed from his infancy to converse with princes, acknowledged, that when he approached Paul, he was so much overawed, that his voice failed, and his presence of mind forsook him.

162 Peace concluded.

But though this war, which at its commencement threatened mighty revolutions, was terminated without occasioning any alteration in those states which were its immediate object, it produced effects of considerable consequence in other parts of Italy. In order to detach Octavio Farnese, duke of Parma from the French interest, Philip restored to him the city of Placentia and its territory, which had been seized by Charles V. and he granted to Cosmo de Medici the investiture of Sienna, as an equivalent for the sums due to him. By these treaties, the balance of power among the Italian states was poised with more equality, and rendered less variable than it had been since it received the first violent shock from the invasion of Charles VIII. and Italy henceforth ceased to be the theatre on which the monarchs of Spain, France, and Germany, contended for fame and dominion. Their hostilities, excited by new objects, stained other regions of Europe with blood, and

163 Consequences of the war in Italy.

Spain.

and made other states feel, in their turn, the miseries of war.

164 The French success in the Low Countries.

The duke of Guise, who left Rome the same day that his adversary the duke of Alva made his humiliating submission to the Pope, was received in France as the guardian angel of the kingdom. He was appointed lieutenant-general in chief, with a jurisdiction almost unlimited; and, eager to justify the extraordinary confidence which the king had reposed in him, as well as to perform something suitable to the high expectations of his countrymen, he undertook in winter the siege of Calais. Having taken that place, he next invested Thionville in the duchy of Luxembourg, one of the strongest towns on the frontiers of the Netherlands; and forced it to capitulate after a siege of three weeks. But the advantages on this quarter were more than balanced by an event which happened in another part of the Low Countries. The mareschal de Termes, governor of Calais, who had penetrated into Flanders and taken Dunkirk, was totally routed near Gravelines, and taken prisoner by Count Egmont. This disaster obliged the duke of Guise to relinquish all his other schemes, and hasten towards the frontiers of Picardy, that he might there oppose the progress of the enemy.

The eyes of all France were now turned towards the duke of Guise, as the only general on whose arms victory always attended, and in whose conduct as well as good fortune they could confide in every danger. His strength was nearly equal to the duke of Savoy's, each commanding about 40,000 men. They encamped at the distance of a few leagues from one another; and the French and Spanish monarchs having joined their respective armies, it was expected that, after the vicissitudes of war, a decisive battle would at last determine which of the rivals should take the ascendency for the future in the affairs of Europe. But both monarchs, as if by agreement, stood on the defensive; neither of them discovering any inclination, though each had it in his power, to rest the decision of a point of such importance on the issue of a single battle.

165 Peace concluded between Henry and Philip.

During this state of inaction, peace began to be mentioned in each camp, and both Henry and Philip discovered an equal disposition to listen to any overture that tended to re-establish it. The private inclinations of both kings concurred with their political interests and the wishes of their people. Philip languished to return to Spain, the place of his nativity, and peace only could enable him, either with decency or safety, to quit the Low Countries. Henry was now desirous of being freed from the avocations of war, that he might have leisure to turn the whole force of his government towards suppressing the opinions of the reformers which were spreading with such rapidity in Paris and the other great towns, that they began to grow formidable to the established church. Court intrigues conspired with these public and avowed motives to hasten the negociation, and the abbey of Cercamp was fixed on as the place of congress.

While Philip and Henry were making these advances towards a treaty which restored tranquillity to Europe, Charles V. whose ambition had so long disturbed it, but who had been for some time dead to the world,

166 Death of Charles V.

ended his days in the monastery of St Justus in Estremadura, which he had chosen as the place of his retreat, as is particularly related under the article CHARLES V.

After the death of Charles, the kingdom of Spain soon lost great part of its consequence. Though Charles had used all his interest to get his son Philip elected emperor of Germany, he had been totally disappointed; and thus the grandeur of Philip II. never equalled that of his father. His dominions were also considerably abridged by his tyrannical behaviour in the Netherlands. In consequence of this, the United Provinces revolted;

167 Revolt of the United Provinces.

and after a long and bloody war obtained their liberty *. In this quarrel Elizabeth of England took part against Philip, which brought on a war with Spain. The great loss he sustained in these wars exhausted the kingdom both of men and money, notwithstanding the great sums imported from America. Indeed the discovery of that country has much impoverished, instead of enriching Spain; for thus the inhabitants have been rendered lazy and averse to every kind of manufacture or traffic, which only can be a durable source of riches and strength to any nation. The ruin of the kingdom in this respect, however, was completed by Philip III. who, at the instigation of the inquisition, and by the advice of his prime minister the duke of Lerma, expelled from the kingdom all the Morescoes or Moors, descendants of the ancients conquerors of Spain. Thirty days only were allowed them to prepare for their departure, and it was death to remain beyond that time. The reason for this barbarous decree was, that these people were still Mahometans in their hearts, though they conformed externally to the rites of Christianity, and thus might corrupt the true faith. The Morescoes, however, chose themselves a king, and attempted to oppose the royal mandate; but, being almost entirely unprovided with arms, they were soon obliged to submit, and were all banished the kingdom. By this violent and impolitic measure, Spain lost almost a million of industrious inhabitants; and as the kingdom was already depopulated by bloody wars, by repeated emigrations to America, and enervated by luxury, it now sank into a state of languor from which it has never recovered.

* See *United Provinces*.

168 Expulsion of the Moors, and its bad consequences to Spain.

169 Philip IV. An. 1621.

The reign of Philip IV. the successor of Philip III. commenced in 1621. He had not been long seated on the throne before the expiration of the 12 years truce which Philip III. had concluded with the United Provinces, again involved Spain in the calamities of war. The renewed contest was carried on with vigour by both the contending powers, till in the year 1648 the Spanish monarch was compelled to sign the treaty of Munster, by which the United Provinces were declared free and independent. From this period the power of the Spanish monarchy began to decline, as it had already been severely shaken by the loss of Portugal.

170 Final loss of the United Provinces.

171 Revolt of Portugal. An. 1640.

This event took place in 1640, when the Portuguese finally threw off the Spanish yoke, and that country remained an independent kingdom, till the power of Bonaparte compelled its lawful monarch to abandon his European territories. Philip IV. also prosecuted an unsuccessful war with France. This war was terminated in 1659, and Philip died about six years after.

172 Charles II. An. 1665.

The new monarch, Charles II. was only four years old when he succeeded to the throne. He was of a feeble constitution, and a weak capacity. The war which had been occasioned by the revolt of Portugal, continued till the year 1668, when a peace was concluded, and the independence of that kingdom was acknowledged. Hostilities had been renewed with France,

but

Spain. but greatly to the disadvantage of the Spaniards, who lost some of the richest and best fortified towns which they still possessed in Flanders. The peace of Nimeguen between France and Spain was signed in the year 1678. Charles II. died in 1700, and with him ended the male line of the house of Austria; a dynasty to which Spain owes less than to any other race of its monarchs.

Historians have been fond of representing the dominion of the Austrian princes in Spain as productive of the greatest glory and advantage to that kingdom. The reign of Charles V. may indeed be said to have been a glorious reign; but little of its glory belonged to Spain, and the emperor certainly neglected her interests in advancing those of his more favoured territories. The picture given by the Spanish historians of the state of Spain at the accession and during the reign of Philip II. fully evinces how little that kingdom had profited by the change in the line of its succession. Agriculture was neglected; commerce was fettered by enormous duties, and the people were held in the chains of ignorance and superstition.

173 Accession of the House of Bourbon. An. 1700.

Charles II. was succeeded by Philip V. duke of Anjou, and grandson to Louis XIV. of France, who had been nominated heir to the Spanish throne by the late monarch. The transactions of the war which was soon declared against France and Spain, by England, Holland, and the empire, assisted by Savoy, Portugal, and Prussia, have been already related under the article BRITAIN, from N° 345 to N° 371. The treaty of Utrecht, which terminated the differences between the principal contending powers, was signed in 1713, and in 1715 a permanent peace was concluded between Spain and Portugal. Hostilities, however, still continued with Savoy and Sardinia, and in 1715 the island of Sardinia was taken by a Spanish fleet, and the year following another fleet belonging to the same nation invaded Sicily, but was defeated by the British admiral Byng. By a new treaty in 1720, Sardinia was given to the duke of Savoy, and Sicily to the emperor; and by the treaty of Seville, concluded in 1729, the duchies of Tuscany, Parma, and Placentia, were ceded to Spain. In 1731, the Spanish king invaded Naples, took possession of that kingdom, and conferred it on his son Don Carlos, in consequence of which war was declared between Spain and the empire in 1733. At the end of that year the palace of Madrid was consumed by fire, and all the archives relating to the Indies perished in the flames.

In 1739, hostilities were renewed between Spain and Britain, (see BRITAIN, N° 403); but the only successes acquired by the latter power were the capture of Porto Bello by Admiral Vernon, and that of the Manilla galleon by Commodore Anson. After a long and turbulent reign, Philip V. died in 1746.

174 Ferdinand VI. An. 1746.

Ferdinand VI. a mild, prudent, and beneficent prince, reformed abuses in the administration of justice, and management of the finances. He revived commerce, established manufactures, and promoted the prosperity of his kingdom. In April A. D. 1755, Quito in South America was destroyed by an earthquake.

175 Charles III. An. 1759.

Charles III. succeeded Ferdinand in 1759. The famous family compact was concluded at Versailles, A. D. 1761, among the four kings of the house of Bourbon. The English, alarmed by the naval preparations of Spain, declared war in 1762 (see BRITAIN, N° 450), and took Havannah in the island of Cuba, and Manilla in the East Indies. Notwithstanding this success, peace was hastily concluded at Fountainbleau, in November, by which the Havannah was restored. In 1767 the Jesuits were expelled from Spain. An unsuccessful expedition was concerted against Algiers, A. D. 1775, the particulars of which are related in M. Swinburne's Travels, letter v. In the war between Great Britain and her American colonies, Spain, by the intrigues of the French court, was prevailed on to take up arms in support of the latter. At the conclusion of that calamitous war, Great Britain, in a treaty with Spain, ceded to this power, East and West Florida, and the island of Minorca. Charles died in 1788, and was succeeded by his second son Charles Anthony prince of Asturias, the eldest having been declared incapable of inheriting the crown.

176 Charles IV. An. 1788.

Charles IV. had not been long seated on the throne before the portentous revolution in France involved Europe in a general scene of political and military contest. The king of Spain joined the general confederacy against the new republic, and in consequence was numbered among the objects of its resentment, by a declaration of war in 1793. The military operations of Spain, however, were extremely languid; and after two campaigns, in which she might be said to carry on rather a defensive than offensive war, against the republican armies (see FRANCE, N° 411), she was compelled to conclude a treaty of peace, which was signed at Basil on the 22d July 1795. By this treaty the French republic restored to the king of Spain all the conquests which she had made from him since the commencement of hostilities, and received in exchange all right and property in the Spanish part of St Domingo.

177 Engages in the confederation against France. An. 1793.

178 War between Spain and Britain. An. 1796.

This treaty was soon followed by a rupture with Great Britain. On 5th October 1796, the court of Spain published a manifesto against this country, to which the court of London made a spirited reply; and about the same time was published a treaty of offensive and defensive alliance, which had been concluded about two months before, between the king of Spain and the French republic. In the war which followed between Spain and Great Britain, his Catholic majesty could boast of but little honour or success; and the French republic gained little from its new ally, but the contributions of money, which she from time to time compelled him to advance. On the 14th of February 1797, a Spanish fleet of 27 sail of the line was defeated by Sir John Jervis off Cape St Vincent (see FRANCE, N° 482); and four of the Spanish line of battle ships were left in the hands of the victors. From this time till the temporary termination of hostilities by the peace of Amiens in 1802, there is nothing remarkable in the transactions of Spain. An. 1797.

On the renewal of the war in 1803, Spain was again compelled, by the overbearing power of France, to take an active part against Great Britain, and fitted out a formidable fleet, which was united to a considerable naval force of the new-made emperor of the French. The Spanish declaration of war against Britain is dated at Madrid on the 12th of December 1804; and on the 21st of October 1805, the combined fleets of France and Spain were nearly annihilated by Lord Nelson's decisive victory off Cape Trafalgar. An. 1803. An. 1805.

After this terrible blow to the naval power of Spain, nothing

179 Revolution in favour of prince Asturias. 1808.

nothing of importance took place till 1808, when the designs of Bonaparte against the independence of Spain, which had been long suspected, were openly avowed, in consequence of a domestic dispute, probably fomented by the emissaries of France, which took place between Charles IV. and the prince of Asturias. During the winter of 1807-8 the public mind in Spain had been greatly agitated. Some accused the prince of the Peace, Don Manuel Godoy, (who had long held the helm of state, and was the richest and most powerful subject in the kingdom), of having concerted with the queen to destroy the prince of Asturias. Others accused the prince of Asturias of being at the head of a party to dethrone his father. Solemn councils and long proceedings, followed up by exiles and violent acts, far from calming opinions, served to agitate them still more.

In March 1808, several disturbances happened at Aranjuez. These disturbances were excited by a report that the royal family were about to quit Spain and emigrate to America. In consequence of this report, the populace of the neighbouring villages repaired in crowds to Aranjuez, where they found the attendants of the court packing up the baggage of the royal household; and understood that relays of horses were stationed on the road to Seville, and that every thing was prepared for the departure of the royal fugitives, who were to take shipping at that port. It was suspected that Don Manuel Godoy, or, as he has commonly been called, the prince of the Peace, was the chief instigator of this unpopular measure; and the fury of the people was directed chiefly against that nobleman, whose palace they attacked on the 18th of March. He, however, found means to escape for the present, but was afterwards arrested in a garret of his own house. In the mean time the king issued two decrees with a view to allay the popular ferment; but as this still continued, he on the 19th took the extraordinary resolution of abdicating the throne in favour of the prince of Asturias. This resolution was made known by a royal decree, in which Charles declared that, as his natural infirmities no longer permitted him to support the weight of government, and the re-establishment of his health required a change of climate, he had after the most mature deliberation resolved to abdicate his crown in favour of his heir the prince of Asturias; and this resolution he declared to be the result of his own free will.

180 Ferdinand VII.

The new sovereign was accordingly proclaimed by the title of Ferdinand VII. and issued an edict confiscating the effects of Don Manuel Godoy, and announcing the appointment of the duke of Infantado, a nobleman deservedly popular for his talents and virtues, to the presidency of Castile and the command of the royal guards.

These disturbances have commonly been attributed to the machinations of the French emperor, who had gain a complete ascendency over the weak Charles; and had rendered the prince of the Peace entirely subservient to the views which he had formed on the independence and the liberties of Spain. How far this supposition is correct, it is impossible for us at this time to determine; but it is rendered probable by the active measures taken about this time by Napoleon to awe by a French force the Spanish nation. Murat the grand duke of Berg was at this time on his march towards the capital with a body of French troops; and his march was hastened by the information which he had received of the tumults at Aranjuez. This general caused it to be intimated to Ferdinand, that the emperor of the French was on his journey to Spain, and advised him to meet his master on the road. In the mean time he was tampering with the self-deposed monarch, whom he assured of the assistance of Bonaparte in reinstating him on the throne. Charles accordingly addressed a letter to Bonaparte, in which he contradicts the assertion of his decree of the 19th; and declares that his abdication was a measure of compulsion; and throws himself on the protection of that great monarch, his friend and ally, from whom alone he and his subjects can hope to derive tranquillity and happiness.

181 Designs of Bonaparte on the independence of Spain.

It appears to have been the design of Murat to draw out of Spain the whole of the royal family, and in this design he completely succeeded. Ferdinand set out to meet Bonaparte, accompanied by the French general Savary, and had advanced as far as Vittoria, where he was left by Savary, and where he found himself surrounded by French troops. He was compelled to remain at Vittoria, until Savary, who had proceeded to Bayonne, where Bonaparte then was, should return and intimate to him the pleasure of his master. When the general returned, he brought with him a letter from Napoleon to Ferdinand. In this letter, which is addressed to Ferdinand as prince of Asturias, and not as king of Spain, Bonaparte assured the prince, that the sole object of his journey into Spain was to make such reforms in that kingdom as would be agreeable to the public feelings. Without pretending to judge respecting the late revolution, he cautions Ferdinand against the danger to be apprehended from sovereigns permitting their subjects to take justice into their own hands. After insinuating his own power over the royal family of Spain, and adverting to the tumults that had taken place, in which some of his troops had fallen, he makes use of the following expression, "a few of my soldiers may be murdered; but the subjugation of Spain shall be the consequence of it."

Ferdinand confounded at the conduct of the French emperor, and alarmed for his own personal safety, was compelled to proceed on his journey. When he arrived at Bayonne he was received by the prince of Neufchatel and Duroc, and was conducted to a place by no means suited to his rank or his character as ally of Bonaparte. He however dined with the emperor; but after he had retired, General Savary brought a message from his master, intimating his determination that the present royal family of Spain should give up to him all right and title to the crown of that kingdom, and that they should be succeeded by a branch of his own family. Astonished at this intimation, Ferdinand sent his prime minister Cevallos, to canvas the matter with M. Champagny, the confidential secretary of Napoleon. The conference was held in an apartment adjoining the cabinet of the emperor, and, as it appeared, within his hearing: for when Cevallos was arguing with great warmth and strength of reasoning on the injustice and even impolicy of the proposed measures, both he and Champagny were ordered into the emperor's presence; and the former was reviled in the grossest terms, branded with the appellation of a traitor, accused of having maintained that the recognition of Bonaparte was not necessary to the validity of his master's title to the throne of Spain, and of

having

Spain.

having affirmed that if the French dared to attack the independence of the Spanish monarchy, three hundred thousand men would rise to defend it and repel the invaders. After Napolean had thus indulged the violence of his temper, he entered in a harsh and arrogant style on a discussion of the points in dispute between his secretary and Cevallos; and finding that he could neither convince nor silence the Spanish minister, he abruptly concluded with the following peremptory declaration: "I have a system of policy of my own; you ought to adopt more liberal ideas, to be less susceptible on the point of honour, and not sacrifice the prosperity of Spain to the interest of the House of Bourbon." From this time the destiny of the Spanish royal family was fixed. Ferdinand the monarch of the people's choice was already a captive, and not many days elapsed before the rest of the royal family was in the same situation. On the first of May, Ferdinand had made a conditional renunciation of his crown in favour of his father, and on the fifth of the same month Bonaparte had a long conversation with Charles the Fourth and his queen. Ferdinand was called in by his father, to hear, in the presence of him and the queen, the disgusting and humiliating expressions which were uttered by the French emperor, expressions of such a nature, that Cevallos says, he dares not record them. All the parties were seated except Ferdinand; he was ordered by his father to make an absolute renunciation of the crown, on pain of being treated as an usurper and a conspirator against the right of his parents. With this requisition Ferdinand complied, and thus completed the abdication of his family; for it appeared that on the preceding day Charles had executed the deed of resignation, which transferred to the emperor of the French his title to the crown of Spain, on consideration of receiving during his life an annuity of eighty millions of reals, of a dowry to his queen of two millions of reals, and to the infantes of Spain the annual sum of four hundred thousand livres.

Thus had Bonaparte effected the transference of the Spanish nation from the Bourbon dynasty to his own family, so far at least as that transference could be effected by the formal renunciation in his favour of the royal family, and by a strong but suspicious recommendation from them to the Spanish nation to receive their new sovereign, whoever he should be, with submission and obedience. Filled as the annals of mankind are with examples of treachery, perfidy, and violence, it would be difficult to point out a deed which in every part of its performance, in its own nature, or in the character of the means by which it was effected, bears such strong marks of unjust and lawless tyranny.

It was soon understood that Napolean designed the crown of Spain for his brother Joseph, who had some time before been placed on the throne of Naples. In an address to the Spanish nation, which Bonaparte published immediately after the abdication of Charles and Ferdinand, he informed them that he did not mean to reign over them in person, but that he would give them a sovereign every way resembling himself. In the beginning of June Joseph Bonaparte arrived in the neighbourhood of Bayonne, where he was received by a deputation of the grandees of Spain and from the council of Castile, and presented with a congratulatory address, written in the most fulsome style of adulation, on his accession to the Spanish throne.

But though the nomination of Joseph Bonaparte was easily effected, it was not so easy to place him on the throne in opposition to the almost unanimous will of the Spanish nation. Ferdinand the Seventh was the darling of the people; and his accession to the crown had been hailed by them, both as placing them under the dominion of a beloved monarch, and as releasing them from the tyranny of Godoy, who was an object of almost universal detestation. They had hitherto submitted with patience to the influence and power of France, hopeless of rescuing themselves while Charles possessed the throne, and while the prince of the Peace directed his councils; but the accession of Ferdinand, and the consequent disgrace of the favourite, had led them to hope that they should now find a sovereign willing to direct and assist their efforts to regain their independence. Under these expectations, a great part of the nation had come forward to offer their assistance in supporting the claims of the new monarch. The province of Catalonia, the most industrious and the most warlike of the Spanish nation, particularly distinguished itself by the promptitude and extent of its offers. Soon after Ferdinand had ascended the throne, the captain-general of Catalonia, relying on the well-known resources and dispositions of the inhabitants, had come forward with an offer of a military force of above a hundred thousand men; and other provinces would have followed this example, but Ferdinand had discouraged these military preparations, and appeared willing to submit quietly to French bondage.

Spain. 182 Opposed by a general insurrection of the Spaniards.

The spirit which had animated the Spaniards thus boldly to support their favourite sovereign, was not of a nature to be chilled and repressed by his timidity or example. The hatred which they had conceived against the French daily found fresh sources of nourishment. They saw Ferdinand, who had rejected their proffered services lest he should expose himself to the suspicion or displeasure of Bonaparte, enticed by deceit, or compelled by violence, to relinquish his kingdom and commit himself to the power of his enemy. They anticipated the consequences, and prepared to resist them with vigour and unanimity. The renunciation of the royal family in favour of Bonaparte was no sooner known in Spain, than the northern provinces burst into open insurrection. Asturias and Gallicia set the glorious example; and it was soon followed by almost every part of Spain, not immediately occupied or overawed by the armies of France.

One of the first steps taken by the leaders of the insurrection was, to assemble the juntas or general assemblies of the provinces. When these were organized, they issued proclamations, calling on the Spaniards to rise in defence of their sovereign, and in the assertion of their own independence. Besides these proclamations from the provincial juntas, addresses were published in almost every province by the leaders of the popular cause; in particular, the province of Aragon was addressed by Palafox, a name celebrated in the annals of the Spanish revolution, in a bold and spirited manifesto. The junta of Seville, which assembled on the 27th of May, formed itself into a supreme junta of government, caused Ferdinand to be proclaimed king of Spain, took possession of the military stores, and issued an order for all males from 16 to 45, who had not children, to enroll themselves in the national armies.

It was natural that, when entering on so determined an

Spain.

183 Peace and alliance with Britain.

an opposition to the measures of Bonaparte, the Spaniards should turn their eyes towards that nation, by whom alone the ambitious views of that potentate had been successfully combated. A peace and alliance with Britain was evidently not only a measure of policy, but would afford them the most effectual assistance in the formidable struggle in which they were about to engage. Accordingly, deputies were dispatched to Great Britain from several of the provinces, to solicit the aid and friendship of that country, and to concert measures with the British ministry for executing the plans which had been contrived for freeing the kingdom from the French yoke. The junta of Seville issued a declaration of war with France, and declared the Spanish nation on terms of peace and amity with Britain. The Spanish deputies were empowered to solicit supplies of arms, ammunition, clothing and money; but it was thought that a supply of British troops would be unnecessary, the Spanish patriots considering themselves as fully equal to the defence of their country. The cause of the Spanish patriots was eagerly embraced by the court of London, and by the British nation at large, and the most active measures were quickly taken to send them effectual aid.

184 Statement of the French and Spanish forces.

While these preparations were making on the part of the Spaniards, the French forces were collecting in great numbers, both on the frontiers, and in the neighbourhood of the capital. Above 25,000 men, under the command of Bessieres and Lassoles, threatened the provinces of Asturias and Biscay, or occupied the plains of Castile. Ten thousand men were shut up in the citadel of Barcelona; and, to relieve them a strong body of French troops had marched from the frontiers, and laid siege to Zaragoza. A considerable body under General Moncey attacked the city of Valencia; while the grand duke of Berg, after having detached General Dupont at the head of 20,000 men, to quiet the insurrection of the southern provinces, held Madrid with about 15,000 troops. Junot, with about 25,000 men, had entered Portugal, and taken possession of the capital. The whole French force at this time in Spain cannot be computed at less than 100,000 men. These were opposed by a very numerous, but undisciplined force, commanded by generals of acknowledged bravery, but differing widely from each other in experience and military prudence. General Palafox commanded in Aragon; General Castanos in the southern provinces; and General Blake in the north.

185 Successes of the Spanish patriots.

The first exertions of the Spanish patriots were eminently successful, though they have been greatly exaggerated in the newspapers published under authority of the juntas. The harbour of Cadiz, which contained a numerous and well-appointed fleet, was under the command of the marquis de Solano, a man notoriously attached to the French interest; and here lay a French fleet, consisting of five ships of the line and a frigate. One of the first efforts of the patriots was, to obtain possession both of Cadiz and the French fleet, and in this they completely succeeded. Solano was arrested and put to death, and Don Morla was appointed in his room. In the beginning of June the French fleet was summoned to surrender, and on the admiral's refusal, was furiously attacked by the batteries on shore, and obliged to capitulate. The force detached by Murat, under Dupont, was attacked near Baylen on the 22d July by Major-general Reding, second in command under Castanos, and after having been defeated, was compelled to surrender at discretion. The French force besieging Zaragoza, was repeatedly attacked by General Palafox, and suffered considerable losses, while that city held out with the most heroic bravery. Perhaps there are few instances in the annals of modern warfare, in which such persevering and successful courage has been displayed, as by the defenders of Zaragoza. All the means of attack which were in possession of the French, directed by the skill with which their long experience and success had supplied them, were made use of. The inhabitants were obliged continually to be upon their guard, and to be prepared to resist the most unexpected and secret, as well as the most open and violent assaults. The city was frequently bombarded in the middle of the night, at the same time that the gates were attempted to be forced under cover of the shells. More than once the French got into some parts of the town; but they were received with so much coolness and bravery, that they were never able to preserve what they had with so much difficulty and loss acquired. The women vied with their husbands, sons, and brothers, in the display of patriotism and contempt of danger: regardless of the fire of the enemy, they rushed into the very middle of the battle, administering support and refreshment to the exhausted and wounded, and animating, by their exhortations and example, all ranks to such a display of firmness and bravery as long secured this important city. When it is recollected, that the attacks of the French were numerous and varied, that they were constantly repeated with fresh, and generally with increasing forces, and that the sole defence of the city rested with its spirited inhabitants and the army of Palafox; some idea may be formed of the difficulties they must have undergone and surmounted, and of the glory to which they are so justly entitled. The patriots had gained possession of most of the sea ports in the bay of Biscay, and headed by the bishop of St Andero, repulsed the French in several attacks. The French force under General Moncey was also repulsed before Valencia, and the patriots were equally successful in several other quarters; so that by the end of July there did not remain above 40,000 French forces within the Spanish territory.

186 Arrival and flight of Joseph Bonaparte.

In the mean time preparations were making at Madrid for the reception of the new sovereign Joseph; and Murat, under pretence of ill health, quitted the capital, to give way to the brother of his master. Joseph Bonaparte arrived at Madrid in the latter end of July, with a guard of 10,000 men; but soon after his arrival the news of the defeat and capitulation of Dupont reached Madrid, and threw the new court into the utmost consternation. They understood that the victorious army of Castanos was on its march towards the capital; and if he did not speedily retire from so dangerous a position, King Joseph dreaded either falling into the hands of the conqueror of Dupont, or of being intercepted in his retreat by the army of General Blake. In this situation he found himself under the necessity of quitting the capital which he had so lately entered, and before the end of the month he had reached Burgos in his precipitate flight towards the frontiers. Thus, within the space of two months, did the people of Spain behold their country almost entirely freed from the presence of the French; and this glorious and happy issue had been brought about by their own intrepidity. At a time when their situation was the most dispiriting and forlorn;

Spain.

lorn; when their king had been compelled to forsake them, and to make over his right to the throne to a foreign potentate; when they beheld scarcely any troops surrounding them on all sides, but those of that potentate, they rose in arms, and opposed themselves, unskilled as they were in war, and totally unprepared for it, to a man before whom the mightiest empires in Europe had fallen.

187 Reverses.

The successes of the Spanish arms, though brilliant and important, were but transient. The leaders of the insurrection appear to have been bnt ill calculated to oppose the system of tactics which had been so often practised with success by the conqneror of Marengo, of Jena, and of Austerlitz. Though the conquests of Austria and Prussia had been effected by the same system which the French were now pursuing in Spain, the military men of this kingdom were incapable of analyzing them, or of adopting effectual measures of opposition or defence. In a series of about 30 bulletins, published from the French army of Spain, comprehending from the beginning of November 1808 to the middle of January 1809, we read of nothing but the rapid movements and successes of the French, and the defeat and annihilation of the best appointed armies of the insurgents. In Gallicia, General Blake, after having withstood the duke of Dantzic (Marshal Ney), in several encounters, was at length defeated, and his army dispersed. A division of the army of Estremadura, under Count Belvider, which had marched from Madrid to support the city of Burgos, was attacked and defeated by a division of the French army under the dukes of Istria and Dalmatia; while the army of General Castanos was in a great measure dispersed, after a severe conflict on the heights of Tudela. According to the French account, the army of Castanos consisted of 45,000 men. It was opposed by the duke of Montebello, and entirely defeated, with the loss of nearly 4000 killed, and 5000 taken prisoners.

In the meantime Bonaparte had entered Spain, and taken the command of the French army. He advanced by rapid marches towards Madrid, and at the end of November his advanced guard reached the important pass of Somosierra. This pass was defended by a body of 13,000 Spaniards, with sixteen pieces of cannon. They were attacked by the French under the duke of Belluno, and after making a considerable stand, were entirely defeated. On the 2d of December Bonaparte arrived in the neighbourhood of Madrid, and on the 5th he was master of that capital.

188 British expeditions in support of the Spanish patriots.

While the Spanish patriots were thus pursuing their plan of opposition to French tyranny with various success, the British cabinet were fitting out formidable expeditions to the coasts of Spain and Portugal. The result of the expedition under Sir Harry Burrard and Sir Arthur Wellesley, the battle of Vimiera, the convention of Cintra, and the consequent evacuation of Portugal by the French, in the month of August 1808, have been already noticed under Portugal, N° 49 and 50. After these transactions, the greater part of the British army under the command of Lieutenant-general Sir John Moore, proceeded on their march to the frontiers of Spain. The progress and operations of this army will be detailed afterwards. About the middle of the same month, a body of 13,000 British troops, under the command of Sir David Baird, arrived at Corunna, and proceeded through the interior of the country, intending to join Sir John Moore in the neighbourhood of Madrid. A brigade of 10,000 men under General Hope, reached that capital, and established themselves at the Escurial; but on the approach of Bonaparte, were under the necessity of retiring.

189 March of Sir John Moore to Sahagun.

Experience has shown that in their military campaigns on the continent, British forces have to contend with numerous difficulties, surmountable only by the utmost prudence and viligance on the part of the commanding officers, and by a considerable degree of skill and foresight on that of the projectors of such undertakings. Never perhaps were these difficulties more severely felt than in the march of Sir John Moore from Portugal to the centre of the Spanish territory. It was found that in whatever direction he might prosecute his march, he would encounter either bad roads or scanty supplies of provisions. In particular, the difficulty of transporting the artillery over the Portuguese mountains was extreme; and the Portuguese at Lisbon were either egregiously ignorant of the state of the roads which led through their own country to the Spanish frontiers, or were unwilling to communicate the information which they really possessed. Under these circumstances it was found necessary to divide the British army; and it was determined to send forward one division consisting of 6000 men under the command of Lieutenant-General Hope, which was directed to march by Elvas, to enter Spain by Badajos, and to proceed along the Madrid road by way of Espinar. Another division, consisting of two brigades under General Paget, was detached by way of Elvas and Alcantara, where it was to pass the Tagus. Two brigades under General Beresford moved through Portugal by way of Coimbra and Almeyda towards Salamanca, while three brigades under General Fraser marched towards the frontiers of Spain by Abrantes and Almeyda.

Burgos had been recommended by the Spanish government as the point of union for the British troops, and Madrid and Valladolid were appointed for magazines. The British had been led to expect that they would find between 60,000 and 70,000 Spaniards assembled under General Blake and the marquis de la Romana in the provinces of Asturias and Gallicia, and that a much greater number was ready to co-operate with them under the command of Castanos on the front and left of the principal French position. The Spaniards had been represented as unanimous in their enthusiasm for the cause of liberty, and as ready to treat the British troops as the saviours of their country. How far this information was correct, will be seen presently.

In marching through the Portuguese territory, the troops first encountered difficulties which they were not prepared to expect. The contractor at Lisbon, who had agreed to supply the divisions with rations on the march, failed in his contract, and excessive inconvenience was experienced from the want of money. The divisions under Generals Fraser and Beresford were obliged to halt, and it was some time before they could again set forward. The proceedings of the central junta, on which all the movements both of the British and Spanish armies chiefly depended, were languid, tardy, and irresolute; and before the British troops could assemble in any force in Spain, the principal armies of the patriots had been defeated and dispersed in almost every

every quarter. On the 8th of November Sir John Moore reached Almeyda. The weather was at this time extremely unfavourable, and the troops were exposed to almost incessant rain. They entered Spain on the 11th of November, and on the 13th Sir John arrived with his advanced guard at Salamanca, where he halted, intending to assemble there all the troops which were on their march through Portugal. While he remained at Salamanca, he was informed that a considerable French force had assembled and taken possession of Valladolid, at the distance of only twenty leagues, by which one of the places that had been intended for magazines was lost. At this time Sir John had with him only three brigades of infantry without artillery, and it would be at least ten days before the whole of the divisions could come up. He was thus exposed to almost an immediate attack by the French without any effectual support from the boasted patriotism of the Spaniards.

The situation of affairs in Spain had now become extremely critical; and every account sent to Sir John Moore by men of sound judgment, was filled with convincing proofs that the Spanish government had concealed from their ally the very desperate state of their affairs. General Hope, by a long and tiresome march, had reached the neighbourhood of Madrid, whence he wrote a letter to Sir John, stating that every branch was affected by the disjointed and inefficient construction of the government. On the 28th of November Sir John was advertised of the late defeat and dispersion of Castanos, and of the little probability there was of his being able to march forward, so as to effect any thing of advantage. He therefore determined to fall back, though this determination was evidently in opposition to the wishes and advice of his officers. Fresh dispatches, however, from the seat of government, diminishing the losses which had been sustained by the patriots, and exaggerating the ardour with which the people were actuated, induced him to delay his retreat, especially as he had now a complete, though small corps, with cavalry and artillery, and could, by a movement to the left, easily effect a junction with Sir David Baird, while the division under General Hope had, by rapid marches, arrived in the neighbourhood of Salamanca.

In addition to the misrepresentations by which the commanders of the British forces, and the British envoy at Aranjuez, had been deceived, they had now to contend with two designing men, who, it soon appeared, were in the French interest. These were Don Morla, the late governor of Cadiz, and a M. Charmilly. By the machinations of these men, Mr Frere was led to advise, and Sir John Moore strongly incited to undertake, bringing the whole of the British force to the neighbourhood of Madrid, where they would soon have been completely within the power of the enemy. Though by these arts Sir John was effectually misled, he did not suffer himself to be drawn into so dangerous a snare. He, however, advanced beyond Salamanca, and sent forward the reserve and General Beresford's brigade towards Toro on the Douro, where they were to unite with the cavalry under Lord Paget, who had advanced thither from Astorga. On December 12th, Lord Paget, with the principal part of the cavalry, marched from Toro to Tordesillas, while the brigade under General Stewart moved from Arivolo. In the vicinity of Tordesillas, near the village of Rueda, the British forces were first opposed by the French, a small party of whom were attacked and defeated.

While Sir John Moore was at Toro, he received intelligence that the duke of Dalmatia was at Saldana with a considerable body of French troops, that Junot, duke of Abrantes, was marching with another towards Burgos, and that a third under the duke of Treviso was destined for Zaragoza. He was very desirous that the first of these generals should advance to meet him, and with this view he had come forward to Toro, which he reached on the 16th of December. He had hoped for effectual assistance from the corps commanded by the marquis de la Romana, but he soon found that this general could render him no support. He had now resolved to threaten the communication between France and Madrid; and, if a favourable opportunity offered, to attack the duke of Dalmatia's corps, or any of the covering divisions that should present themselves. He foresaw that this would necessarily draw upon him a large French force, and of course would prove an important diversion in favour of the Spaniards; who would by this means have the opportunity of collecting in the south, and restoring their affairs. The army was now near the French position. The cavalry under Lord Paget were pushed so forward, that their patrols reached as far as Valladolid, and had frequent successful skirmishes with the enemy. Colonel Otway met a detachment of French cavalry, charged them, and made the whole prisoners.

On the 18th of December, Sir John's head-quarters were at Castro Nuevo, and Sir David Baird's at Benevente, on the road to join him. On the 20th Sir John reached Majorga, where he was joined by Sir David Baird. The united British army now amounted to rather fewer than 26,000 men, of whom about 2000 were cavalry. The weather was extremely cold, and the ground covered with deep snow. Still the exertions of the troops were indefatigable, and the cavalry in particular attacked and defeated a considerable body of French horse. On the 21st the army reached Sahagun, where Sir John established his head-quarters, and determined to halt for some time, to refresh his troops, after the fatigues which they had undergone.

Sir John had now arived within a very short distance from Saldana, where the duke of Dalmatia was posted, with the flower of the French army; and preparations were made for an attack, which was waited for with all the ardour and impatience which distinguish British troops. In the mean time, however, repeated couriers arrived at head-quarters, the bearers of unpleasant intelligence. Certain information was received, that a strong French reinforcement had arrived at Carrion, a little to the right of Sahagun, that the French corps, which was marching to the south, had halted at Talavera, and that the enemy were advancing from Madrid in considerable force. Sir John now saw that his motions had been watched by Bonaparte, and that all the arts of this experienced general had been preparing to entrap him. To advance was madness; to retreat, almost in the face of an enemy, was a measure of the utmost danger, but it was the only alternative.

190

On the 24th of December Sir John began silently and secretly to prepare for his retreat, and to provide, as far as possible, for the defence of those parts of the country. His retreat.

Spain. country which were still held by the patriots. With this latter view, he directed Sir David Baird to take the route towards Valencia de Don Juan, while the rest of the army was to proceed by Castro Gonzalo. By this division the magazines and stores which had been deposited at Benevente and Zamora, were also effectually secured.

According to the arrangement made, General Fraser, followed by General Hope, marched with their divisions on the 24th December to Valderos and Majorga, and Sir David Baird proceeded with his to Valencia. To conceal this movement, Lord Paget was ordered to push on strong patrols of cavalry close to the advanced posts of the enemy. The reserve, with two light corps, did not retire from Sagahun till the morning of the 25th, following General Hope. Lord Paget was ordered to remain with the cavalry until evening, and then follow the reserve. These last were accompanied by Sir John. The retreat commenced in this deliberate manner. On the 26th of December, Sir David Baird reached the Eslar, and passed the ferry with less difficulty than was expected. He took post, according to his orders, at Valencia, and wrote to the marquis of Romana, urging him to blow up the bridge of Mansilla. The other divisions of infantry proceeded unmolested to Castro Gonzalo. On the 24th the advanced guard of Bonaparte's army marched from Tordesillas, 120 miles from Madrid, and strong detachments of cavalry had been pushed forward to Villalpando and Majorga. On the 26th, Lord Paget fell in with one of those detachments at the latter place. His lordship immediately ordered Colonel Leigh, with two squadrons of the 10th hussars, to attack this corps, which had halted on the summit of a steep hill. One of Colonel Leigh's squadrons was kept in reserve; the other rode briskly up the hill; on approaching the top, where the ground was rugged, the colonel judiciously reined-in to refresh the horses, though exposed to a severe fire from the enemy. When he had nearly gained the summit, and the horses had recovered their breath, he charged boldly and overthrew the enemy; many of whom were killed and wounded, and above 100 surrendered prisoners. Nothing could exceed the coolness and gallantry displayed by the British cavalry on this occasion. The 18th dragoons had signalized themselves in several former skirmishes; they were successful in six different attacks. Captain Jones, when at Palencia, had even ventured to charge 100 French dragoons with only 30 British; 14 of the enemy were killed, and six taken prisoners. The cavalry, the horse-artillery, and a light corps, remained on the night of the 26th, at Castro Gonzalo; and the divisions under Generals Hope and Fraser marched to Benevente. On the 27th, the rear-guard crossed the Eslar, and followed the same route, after completely blowing up the bridge.

We shall not attempt any farther detail of this dangerous and calamitous retreat, in which our army suffered extremely, from the fatigues of constant marching, from the badness of the weather, and even from the brutality of the Spaniards, in whose cause they had embarked. Before they reached Astorga, it was found necessary to divide the army. A body of 3000 men, under Brigadier-general Crawford, was detached on the road to Orense towards Vigo, while the main body, under the command of Sir John Moore, marched by Astorga and Lugo, on the road to Corunna. They left Astorga on the 30th of December, and on the 11th of January came in sight of Corunna. The army had now reached the sea port from which they were to embark, but adverse winds had detained the transports, or the whole of the troops would have been speedily and safely on board. Only a few ships lay in the harbour, and in these some sick men and a few stragglers, under pretence of sickness, had immediately embarked. Spain. An. 1809.

191 Closely followed by the French.

During the whole march from Sahagun to Corunna, the British army was closely followed by the French, under Bonaparte and the duke of Dalmatia; and the two armies were often so near each other, that the French patrols fell in, during the night, with the cavalry piquets of the British. The duke of Dalmatia had joined Bonaparte at Astorga, and had increased his force to nearly 70,000 men, while the whole force of the British did not exceed 26,000. When Sir John's army reached Lugo, it was found that three divisions of the French were arranged in front, and it was thought advisable, on the 8th of January, to offer the enemy battle. This offer, however, the French thought proper to decline, and the duke of Dalmatia stirred not from his post. When the army reached Corunna, the French were far in the rear, and it was hoped that the transports might arrive before the enemy could come up.

The retreat of the British, considering the circumstances under which it was effected, was a brilliant and successful achievement. Two hundred and fifty miles of country had been traversed in 11 days, during the worst season of the year, through bad roads, over mountains, defiles, and rivers, and in almost daily contact with an enemy nearly three times their numbers. Though often engaged, the rear-guard of the British had never been beaten, nor even thrown into confusion. Many losses had indeed been sustained, in baggage, artillery, and horses, and many stragglers had fallen into the hands of the enemy; but neither Napoleon nor the duke of Dalmatia could boast of a single military trophy taken from the retreating army. The greatest danger was still to be incurred; the position of Corunna was found to be extremely unfavourable; the transports had not arrived, and the enemy began to appear upon the heights. The situation of the army was by most of the officers thought so desperate, that they advised the general to propose terms to the duke of Dalmatia, that they might be suffered to embark unmolested; but this advice Sir John, without hesitation, rejected.

On the 12th of January, the French were seen moving in considerable force on the opposite side of the river Mero. They took up a position near the village of Perillo, on the left flank of the British, and occupied the houses along the river. In the mean time Sir John was incessantly occupied in preparing for the defence of his post, and in making every arrangement for the embarkation of the troops.

192 Position of the army.

On the 13th, Sir David Baird marched out of Corunna with his division, and took post on a rising ground, where he determined to remain all night. A division under General Hope was sent to occupy a hill on the left, which commanded the road to Betanzos, forming a semicircle with Sir David Baird's division on the right. General Fraser's division was drawn up near the road to Vigo, about half a mile from Corunna, and communicated

communicated with that under Sir David Baird, by means of the rifle corps attached to the latter, which formed a chain across the valley. The reserve under Major-general Paget occupied a village on the Betanzos road, about half a mile from the rear of General Hope. The higher grounds on the rear and flanks of the British were possessed by the French, a situation which gave the latter a considerable advantage.

193 Battle of Corunna.

On the 16th, the French were observed to be getting under arms, and this was immediately succeeded by a rapid and determined attack on the division under Sir David Baird, which formed the right wing, and was the weakest part of the line. The first effort of the enemy was met by Sir John Moore and Sir David Baird at the head of the 42d regiment, and the brigade under Lord William Bentinck. The village on the right became an object of obstinate contest, but the enemy was at last repelled. While leading on his division to support this position, Sir David had his arm shattered with a grape shot. Not long after, while Sir John Moore was riding from post to post, everywhere encouraging his troops, and pointing out the most advantageous opportunities for attack or defence, his conspicuous situation had exposed him to the fire of the enemy. A cannon-ball struck his left shoulder, and beat him to the ground. He raised himself, and sat up with an unaltered countenance, looking intently at the Highlanders, who were warmly engaged. Captain Hardinge threw himself from his horse, and took him by the hand; then, observing his anxiety, he told him the 42d were advancing, upon which his countenance immediately brightened. His friend Colonel Graham now dismounted to assist him; and, from the composure of his features, entertained hopes that he was not even wounded; but observing the horrid laceration and effusion of blood, he rode off for surgeons. The general was carried from the field on a blanket, by a sergeant of the 42d, and some soldiers.

The enemy finding himself foiled in every attempt to force the right of the position, endeavoured by numbers to turn it. A judicious and well timed movement, which was made by Major-general Paget, with the reserve, which corps had moved out of its cantonments to support the right of the army, by a vigorous attack, defeated this intention. His efforts were, however, more forcibly directed towards the centre, where they were again successfully resisted by the brigade under Major-general Manningham, forming the left of Sir David Baird's division, and a part of that under Major-general Leith, forming the right of the division under General Hope. Finding his efforts unavailing on the right and centre, he seemed determined to render the attack on the left more serious, and had succeeded in obtaining possession of the village through which the great road to Madrid passes, and which was situated in front of that part of the line. From this point, however, he was soon expelled with considerable loss, by a gallant attack of some companies of the 2d battalion of the 14th regiment under Lieutenant-colonel Nicholls. Before five in the evening, the British had not only successfully repelled every attack made upon the position, but had gained ground in almost all points. At six the firing ceased.

Notwithstanding this advantage, General Hope did not, on reviewing all circumstances, conceive that he should be warranted in departing from what he knew was the previous and fixed determination of the late commander of the forces, to withdraw the army on the evening of the 16th, for the purpose of embarkation. The troops quitted their position about 10 at night, with a degree of order that did them credit.

By the unremitted exertion of the captains of the royal navy, who had been entrusted with the service of embarking the army, and in consequence of the arrangements made by the agents for transports, the whole of the forces were embarked with an expedition which has been seldom equalled.

Notwithstanding the ill success which had thus attended the expedition under Sir John Moore, the spirit of patriotism which appeared still to actuate the southern provinces of Spain, and the hope that the common cause might there be supported to greater advantage, induced the British ministry to send another military force to the western peninsula of Europe, to co-operate with the patriots who still continued in arms. Accordingly a body of about 15,000 forces, under the command of Sir Arthur Wellesley, whose bravery and good conduct in the battle of Vimiera had recommended him, in a particular manner, both to the ministry and the nation, was dispatched towards the coast of Portugal, where Marshal Beresford still maintained a British force; while General Hill, with about 5000 infantry, and 400 cavalry, sailed from Ireland with the same destination. General Hill arrived at Lisbon on the 4th of April, and soon after Sir Arthur landed with the main body. On the 7th of April the army moved forward towards the Douro, and crossed that river during the night of the 11th, a little above Oporto. Here they fell in with a French detachment from the army of the duke of Dalmatia, which they routed and put to flight, after a short but well-contested action. After this action the duke of Dalmatia found it necessary to retreat. 194 Second expedition under Sir Arthur Wellesley.

Sir Arthur Wellesley, after having remained for some time in the Portuguese territory, to refresh his men after the fatigues which they had undergone, advanced into Spain, and effected a junction with General Cuesta, who then commanded a considerable part of the remains of the patriotic army. In the latter end of July, the allied army had advanced to Talavera de la Reyna, in the neighbourhood of which they were encountered by a formidable French force, consisting of a corps commanded by Marshal Victor, another under General Sebastiani, the guards of Joseph Bonaparte, amounting to 8000 men, and the garrison of Madrid. This large force was commanded by Joseph Bonaparte in person, assisted by Marshals Jourdan and Victor, and General Sebastiani. On the 27th of July, an attack was made by the French army on that of the allies, who had taken up their position at Talavera. The attack was vigorous, but was repelled with great spirit and success, though not without considerable loss on the part of the British. The defeat of this attempt was followed about noon of the 28th by a general attack of the enemy's whole force, on the whole of that part of the position which was occupied by the British army. The general attack began by the march of several columns of infantry into the valley, with a view to attack the height occupied by Major-general Hill. These columns were immediately charged by the 1st German light dragoons, and 23d dragoons, under the command of General Anson, and supported by General Fane's brigade 195 Battle of Talavera.

Spain.

gade of heavy artillery; and although the 23d dragoons suffered considerable loss, the charge had the effect of preventing the execution of that part of the enemy's plan. At the same time, an attack directed upon Brigadier-general Alexander Campbell's position in the centre of the combined armies, was most successfully repulsed, and the allies were left in possession of the enemy's cannon.

An attack was also made at the same time on Lieutenant-general Sherbrooke's division, which was on the left and centre of the first line of the British army. This attack was most gallantly repulsed by a charge with bayonets, by the whole division; but the brigade of guards which were on the right, having advanced too far, were exposed on their left flank to the fire of the enemy's battery, and of their retiring columns; and the division was obliged to retire towards the original position, under cover of the second line of General Cotton's brigade of cavalry, which had moved from the centre, and the 1st battalion 48th regiment. This regiment was removed from its original position on the heights, as soon as the advance of the guards was perceived, and formed in the plain; it advanced upon the enemy, and covered the formation of Lieutenant-general Sherbrooke's division. Shortly after the repulse of this general attack, in which apparently all the enemy's troops were employed, he commenced his retreat across the Alberche, which was conducted in the most regular manner, and effected during the night, leaving in the hands of the British 20 pieces of cannon, ammunition, tumbrils, and some prisoners.—Though the French were defeated in this engagement, and, according to Sir Arthur Wellesley's account, must have lost at least 10,000 men, the loss of the British was very great. By the official returns it is stated to exceed 5000.

The victory, however, was not of that decisive kind to enable the British general to engage in vigorous offensive operations, as the French were continually receiving reinforcements: and Soult, Ney, and Mortier, having formed a junction shortly afterwards, he found it necessary to retire towards Badajos. In the north-east of Spain, the French had been closely occupied from the beginning of July in besieging the strong town of Gerona. It made an obstinate defence, and though the garrison was sorely pressed by famine, it held out till the 11th December. Its capture was considered a national misfortune by the Spaniards, and along with other losses, induced the junta to issue a proclamation for convoking the cortes.

In the month of February 1810, Lord Wellington left Badajos, and advanced into the province of Beira. Notwithstanding this, the French were in such force as to enter upon the siege of Ciudad Rodrigo in June, which surrendered on the 4th July; Almeida also yielded to their army a short time after. Lord Wellington now retired to Busaco, in the face of a superior force. The position he had chosen was strong; but the enemy, confiding in their numbers, attacked him. The French divisions on the right advanced to the top of the ridge, from which they were immediately driven by the bayonet. On the left they were equally unsuccessful; they left 2000 killed on the field. The loss of this battle, however did not prevent Massena from advancing to Coimbra; while Lord Wellington, not prepared for this movement, withdrew to Torres Vedras, a strong natural position, rendered still stronger by fortifications. Here he was joined by large reinforcements; and Massena, after remaining in front of the position till he had exhausted the neighbouring country, was obliged to commence his retreat on the 14th November. In this retreat he suffered severely from famine and desertion. While these things were passing in the west, the dissensions and misconduct of the supreme junta, left the south of Spain an easy prey to the French. The boasted line of defence at the Sierra Morena was forced without a struggle; and Seville, with all Andalusia, fell into the hands of the invaders. Cadiz however was secured by a British force, and resisted all the efforts of the enemy. The Spaniards, irritated by the inactivity of the supreme junta, called loudly for a change; and the junta at length resigned their functions to a regency, consisting of five persons, of whom General Castanos was placed at the head of the military department.

196 Assembling of the Cortes.

The cortes, on which the hopes of the Spaniards were so anxiously fixed, assembled at Cadiz on the 24th September. This body consisted of 208 members, elected from 32 provinces. Each parish nominated an elector, and these electors met in the chief town, and chose deputies in the proportion of one deputy for every 50,000 inhabitants. The Spanish colonies in America were also to send deputies. The pay of a deputy was six dollars a-day. This body possessed a strong national spirit, and, had they met earlier, might have roused their countrymen to greater exertions. But the Spanish affairs were now in too desperate a state to be retrieved by the cortes. It was indeed a striking, and almost a ludicrous circumstance, to see this assembly issuing decrees, and exercising all the empty formalities of supreme power, while they could not set a foot on the mainland of Spain, and the enemy's cannon were thundering in their ears. One of their first acts was to declare the press free for political, though not for religious discussion, and to appoint a commission to draw up a constitution. This constitution was not finally settled and promulgated till the 19th March 1812. It confers very extensive powers on the cortes, but chiefly grounded on the practices of that body in the ancient times of Spanish history. The members were to be elected for two years. They were to have the power of ratifying treaties, fixing taxes, and, what was of much importance, the power of appointing a permanent committee of their members to observe and controul the conduct of the executive government, during the vacation of their sessions; and this committee was authorised to convoke the cortes independently of the king. In October 1810 the cortes appointed a new regency, consisting of three members, Generals Blake, Ciscar, and Agar. Exertions were made to improve and augment the forces: but experience had now shewn the folly of opposing the French in large armies; and they therefore carried on hostilities in small corps, and by guerilla parties, who harassed the enemy in all his movements, and intercepted his supplies. Blake in Murcia, Ballasteros in Andalusia, and O'Donnel in Catalonia, kept considerable corps on foot, and gained some advantages over the French. Mina, a guerilla leader in the mountains of Guadalaxara, peculiarly distinguished himself in the desultory sort of warfare, for which the country is so well adapted.

In

ain. In the end of February 1811, about 4000 British troops under General Graham, with 7000 Spaniards
97 under General Pena, were embarked at Cadiz, and
B e of landed at Algesiras, with the view of joining the Spa-
B sa. nish forces at St Roque, and making an attack on the rear of the French, to compel them to raise the blockade of Cadiz. The united corps advanced to Barrosa on the 5th March. Here the British general was compelled, by an unexpected movement of the enemy, to attack a force about twice that of his own army. The victory was brilliant and decisive. The French were overthrown with the bayonet, with the loss of 3000 or 4000 killed or made prisoners. The British loss was 1243. Strong complaints were made of the conduct of the Spanish general, who made no exertions to support the British in their attack, or to improve the victory when it was gained.

In Estremadura the French obtained possession of Badajos. In the province of Salamanca Marshal Massena made a bloody but unsuccessful attack on the position of Fuentes d'Honor, and shortly after retired beyond the Agueda; in consequence of which Almeida was evacuated, and fell into the hands of the allies. With the view of relieving Badajos, which the allies were now besieging, Soult advanced from Seville; but Marshal
18 Beresford, apprised of his object, suspended the siege,
Batt of and met him at Albuera on the 16th of May. Here a
Albu . bloody and obstinate but undecisive battle was fought, which ended in Marshal Soult, who was the assailant, re-occupying his original position, and the next day retreating to Seville. The force under Marshal Beresford, which made a very gallant resistance, suffered a heavy loss. The French loss was estimated at 9000 men. Shortly after, however, the allies found it necessary to raise the siege of Badajos as well as Ciudad Rodrigo; the former after two unsuccessful assaults. In the east of Spain, the French took Tarragona by storm, sacked the town, and massacred a vast number of the inhabitants in cold blood. This conquest gave them the entire command of the coast of Catalonia.

On the 8th January 1812 Valencia surrendered to Marshal Suchet, with a garrison of 18,000 men; but this loss was balanced by the capture of Ciudad Rodrigo on the 19th January, and of Badajos on the 6th April, by the allies. Both these towns were carried by storm, at a great expence of blood; the loss of the British and Portuguese, in the siege of Badajos, was 4850 men. Bonaparte had now entered on his Russian campaign, and the great number of troops he had withdrawn from Spain, cramped the operations of his armies in that country. The Spaniards resumed their activity; and in July the British army advanced northwards to meet the French, who crossed the Douro under Marshal Marmont. On the 22d July the British general
199 found a favourable opportunity for attacking the enemy
Battle Salaman. near Salamanca. Marmont, though not expecting an attack, made an able and obstinate defence; but at length the rout became general, and darkness alone saved the French army from still greater destruction. About 7000 were made prisoners; and the number killed was much greater. The British and Portuguese loss amounted to 6500 men in killed and wounded.

This brilliant victory had a favourable effect on the state of the campaign in every part of Spain. In the end of August the French raised the siege of Cadiz, and began to withdraw their troops from the south of the peninsula. Bilboa and some other towns in the north were evacuated. Joseph Bonaparte left Madrid, which was occupied by two divisions of the British army on the 12th August. The arrival of reinforcements, however, enabled Souham, who succeeded Marmont, to advance again, and relieve the castle of Burgos, which Lord Wellington had made several fruitless attempts to storm. From this period the French continued to concentrate their troops. They reoccupied Madrid, and held it till June 1813, when they began to prepare for the evacuation of the country. In their retreat northwards the British came up with them at Vittoria, and gained a splendid victory. Never was success more complete. The victors, besides a vast number of prisoners, took 151 pieces of cannon, 415 ammunition waggons, with all the baggage of the French army. The British loss amounted to 700 killed, and 4000 wounded. Jourdan, who commanded the French in this battle, was replaced by Soult, who made an able and persevering defence, but could not long arrest the British army in its career of conquest. On the 31st July St Sebastian was taken by a very daring assault by the troops under General Graham, though with the loss of 2300 in killed and wounded. The check which the British troops, under Lord William Bentinck, received in Catalonia, produced little effect. Napoleon's power was now declining rapidly; and the battle of Leipsic, fought on the 18th October, shook his empire to its foundations. But even before this the British and Spanish army had entered France. After driving the French from a strong position at Sarre, the allies established themselves in the French territory, but waited for the cessation of the heavy rains before they advanced.

The cortes, in the meantime, was agitated by fierce party contests. It had displaced the members of the regency several times, and appointed new ones; and amidst these repeated changes, the government could not acquire any stability. A new subject had occurred to perplex its proceedings. Though the American colonies had felt a warm interest in the fortunes of the mother country at the beginning of the present contest; yet, when they saw the French in possession of the capital, and apparently masters of the whole peninsula, it was natural they should think of providing for their own security. Accordingly, in 1810, simultaneous movements were made in La Plata, in Venezuela, and in Mexico. In the latter country the revolutionary attempt was put down; but in the other two the authority of the parent state was thrown off almost without a struggle. Though the cortes endeavoured to attach the Americans to their cause, by allowing them to elect deputies to that body, it was soon found, that this privilege was entirely illusory, and that no disposition existed to remedy the gross abuses under which they suffered. The cortes tried to temporize, but the colonists saw through their intentions, while they, at the same time, despised their feebleness. The consequence has been the entire loss of Buenos Ayres to Spain, while the long resistance of the independents in Chili and Venezuela will certainly lead at last to the same result. In January 1814, the cortes held its first sittings in Madrid,

On the 23d February 1814, the allied army crossed the

Spain.

the Adour, and on the 27th defeated the French at Orthes. Bourdeaux was occupied on the 12th March; and the brilliant victory obtained by the duke of Wellington at Thoulouse on the 10th April, put an end to the war. The next day intelligence was received of the deposition of Napoleon, which led to an armistice, and the armistice to a peace. Ferdinand, now liberated, returned to Spain, and made his public entry into Madrid on the 13th May 1814. Nothing could exceed the enthusiastic joy with which he was received by all ranks. One of his first acts was to disavow the constitution promulgated by the cortes, and to declare that body an illegal assembly; and so little was freedom understood among the people, that these acts were, to all appearance, extremely popular. Not satisfied with this, he threw the most distinguished members both of the cortes and the regency into prison; and, about two months after his return, he issued a decree re-establishing the inquisition. The monstrous ingratitude of this worthless prince has driven several of those heroic men who sustained his cause against the French, to take up arms against him. Mina made an attempt in November 1814, and Porlier, in 1815, but, from the apathy of the people, both failed. The former escaped into France, the latter was taken and executed. Several other movements of the same kind proved equally unsuccessful.

It was plain, however, to discerning persons, that some great change was at hand. The incorrigible folly, as well as wickedness of Ferdinand's conduct, disgusted even the friends of monarchy, and discontent continued to spread rapidly among the body of the people. Every month brought forth a new list of proscriptions, and among the sufferers were included almost every man whom the nation had reason to esteem and honour. The extreme disorder of the finances increased the difficulties of the court; and repeated changes of ministers showed that the royal councils were in a state of extreme embarrassment and constant fluctuation. At length, on the 1st January 1820, a body of troops stationed near Cadiz, partly irritated by want of pay, and partly actuated by the spirit of discontent which was spreading through the country, proclaimed the constitution of the cortes. Other troops brought to reduce them to obedience, instead of acting against them, espoused their cause. Colonel Quiroga, the leader of the insurrection, published a spirited address to the nation in the name of the army, setting forth the calamities which Spain had suffered from arbitrary power, and calling on the people to support the generous effort of the army. From the want of a periodical press, however, it was some time before the nature and objects of the revolutionary movement were widely known. Seville and other towns in Andalusia were the first to declare in favour of the army: these were followed by Barcelona and other places in Catalonia, where the patriotic spirit has always been very strong. At length the popular cause began to show its head in Madrid; and Ferdinand finding that all his means of resistance were exhausted, issued a proclamation on the 6th of March, promising to convoke the cortes. The people of Madrid, however, justly suspicious of Ferdinand's intentions, were not satisfied with this concession; and demanded the immediate establishment of the constitution of 1812. Accordingly, on the 9th a junta was formed to conduct public measures till the cortes should meet; and in presence of this junta Ferdinand took an oath to maintain the constitution. This great revolution had nearly been accomplished without bloodshed, when an unhappy catastrophe occurred in Cadiz on the 10th March. The inhabitants of this city had met to celebrate, by public rejoicings, the establishment of the constitution, when, owing to some treachery, which has never been fully explained, they were assailed by a regiment of soldiers, and massacred without mercy. No less than 436 persons were killed in this affair, and a vast number were wounded.

Spain

The cortes met on the 9th July. All persons confined for state crimes had previously been liberated, and the opening of this representative body excited the most lively satisfaction in the kingdom. Its labours did not disappoint the public expectations. During the first session it abolished the inquisition, reduced a vast number of monasteries, and applied the funds arising from their suppression to the public service. It made new regulations for improving the administration of justice, abolished many useless offices, put an end to the monstrous abuse of entails, and introduced order and economy into the finances. Quiroga, Riego, and other leaders of the revolution, received promotion in the army, and votes of thanks for their services. In short, the cortes conducted its plans with a wise moderation, neither sparing abuses on the one hand, nor yielding to a rash spirit of innovation on the other.

From the reports laid before the cortes by the different ministers, it appeared that all the departments of the government were in the utmost disorder. The army was stated to consist of 87,779 infantry, including militia; and of 6338 cavalry: requiring an annual expence of 352,607,000 reals, or 3,500,000l. sterling. A great proportion of the officers had been for years on half pay, though in active service. Both infantry and cavalry were miserably clothed, and very badly armed and equipped. Since 1815 no less than 42,177 men had been sent out to America. The troops in Cuba, including militia, amounted to 10,995 men; those in North America to 41,036 infantry and cavalry. And the whole force in the colonies, including the Philippine islands, amounted to 96,578 men and 8419 horses. The budget for the financial year, commencing 1st July, was fixed as follows:

	Reals.
The king's household	45,090,000
Ministry for foreign affairs	12,000,000
The interior	8,410,375
The colonies	1,368,235
Justice	11,131,110
Finance	173,351,669
War	355,450,915
Marine	96,000,000
Total	702,802,304
Total revenues	530,394,271
Deficit	172,408,033

It was fixed, that the army in time of peace should consist of 66,828 men; viz. of 48,353 infantry, 12,475 cavalry, 5000 artillery, and 1000 sappers. In a period

Spain.

riod of war this force is to be increased to 124,579 men. The three Swiss regiments were suppressed.

The following is a view of the principal articles of the Spanish constitution.

Art. 2. The Spanish nation is free and independent, and is not, nor can be, the patrimony of any person or family.

3. The sovereignty resides essentially in the nation, and the right of enacting its fundamental laws belongs exclusively to it by this same principle.

27. The cortes consists in the union of all the deputies that represent the nation, nominated by the citizens, in manner as herein-after stated.

28. The basis of national representation is the population.

31. For every 70,000 souls there shall be one deputy to the cortes; any odd number exceeding 35,000 shall name a deputy for themselves. St Domingo names a deputy; and the ultra-marine population, viz. that of North and South America, elects deputies in the same proportion as that of Old Spain.

104. The cortes to assemble every year in the capital of the kingdom, with power (by Art. 105.) to remove to any place not more distant from Madrid than 12 leagues.

108. The session to begin on the 1st of March, and continue three months.

109. The deputies shall be renewed entirely every two years.

110. A member is not eligible to two successive parliaments.

117. The deputies swear to preserve the Roman catholic religion, to protect the political constitution, and to conduct themselves faithfully to the nation. N. B. All reference to the king is omitted in this oath.

The powers and duties of the cortes are—

1. To propose and decree the laws, and to interpret and alter them on necessary occasions.

2. To take an oath to the king, to the prince of Asturias, and to the regency, as is pointed out in their places.

3. To determine any doubt of fact or right that may occur in order of the succession to the crown.

4. To elect a regency or regent of the kingdom, when the constitution requires it, and to point out the limits within which the regency or the regent must exercise the royal authority.

6. To nominate a guardian to the king minor, when the constitution requires it.

7. To approve, previous to ratification, the treaties of offensive alliance, of subsidies, and the particulars of commerce.

8. To permit or refuse the admission of foreign troops into the kingdom.

9. To decree the creation and suppression of offices in the tribunals established by the constitution, and also the creation or abolition of public offices.

10. To fix every year, on the proposal of the king, the land and sea forces, determining the establishment in time of peace, and its augmentation in time of war.

11. To issue ordinances to the army, the fleet, and to the national militia, in all their branches.

12. To fix the expences of the public administration.

13. To establish annually the taxes.

19. To determine the value, the weight, the standard, the figure, and description of money.

22. To establish a general plan of public instruction in the whole monarchy, and approve that which is intended for the education of the prince of Asturias.

24. To protect the political liberty of the press.

25. To render real and effective the responsibility of the secretaries of state, and other persons in public employ.

26. Lastly, It belongs to the cortes to grant or refuse its consent in all those cases and acts which the constitution points out as necessary.

The king enjoys the following powers under art. 171. He watches over the prompt and perfect administration of justice throughout the kingdom; declares war and ratifies peace, subject to the approval of the cortes; nominates magistrates; presents to ecclesiastical dignities; is the fountain of honour; has the command of the army both by sea and land; regulates all diplomatic and commercial relations with other states; appoints ambassadors, ministers, and consuls; can pardon criminals, except in certain cases; proposes to the cortes such projects of laws as he may think necessary, but it is for the cortes to deliberate or not upon such propositions: has the power of appointing ministers. The king cannot, under any pretence, prevent the convocation of the cortes; nor when assembled can he suspend or dissolve them, nor in any manner interfere with their sittings or deliberations; and all persons who shall advise him to act contrary to this article shall be deemed traitors to the country. The king cannot leave the kingdom without the consent of the cortes; nor can he, without their consent, form any offensive treaty; nor private treaty of commerce with any foreign power; nor furnish subsidies to a foreign power; nor impose any taxes or duties: nor can he of his own authority deprive any individual of personal liberty, or of property, without due course of law. Before he contracts marriage, he shall communicate his intention to the cortes, for the purpose of obtaining their consent, without which *he shall be considered to have abdicated his throne.*—Should a law have passed the cortes, and fail on three successive applications to obtain the royal consent; on the third refusal, the sanction of the king shall be supposed to have been obtained, and the law shall be in full force. A permanent committee is to be nominated before the close of each session, and to continue sitting in vigilant attention to the proceedings of the government, until the next assembly of the cortes. This committee has the prerogative of summoning an extraordinary meeting of the cortes, when the crown shall become vacant, or the king incompetent, or when his majesty may be desirous of convoking them.

202 Population of Spain.

At the close of the 14th century, the population of Spain is stated by most Spanish writers to have been 21,700,000; but this is evidently a gross exaggeration.

According to the table of the provinces, collected chiefly from De Laborde, it amounted, at the end of the 18th century, to 10,308,505; and the latest writers

ers do not suppose the population at present to exceed this amount.

Of the number above stated, the clergy are reckoned at least 147,722: viz. of secular clergy, 60,240; of monks, 49,270; of nuns and friars, 22,337, and of subaltern ministers of the church, 15,875. The numbers of the clergy have indeed diminished by more than 27,000 during the last 30 years of the 18th century, as in the year 1768 they amounted to 176,057.

203 Number of towns, villages, &c. According to a calculation in the year 1776, the cities, towns, villages, and hamlets, amounted to 84,459, and public edifices and temples to 30,496.

204 Coins. The money of Spain is either real or imaginary, the former serving for the purposes of exchange, the latter for keeping accounts and transacting business. Both these are common through the whole kingdom; but several kinds of both are to be found in the different provinces.

Two kinds of real money, both in gold and silver, are distinguished in Spain; the old, that is, such as were coined before the year 1772, and those coined subsequent to that period. None of the former are uniform, but consist of small pieces of different sizes unequally cut, and their currency is only by weight. The latter uniformly bear the head of the sovereign on the obverse, and on the reverse side the arms of Spain; the ancient gold coins are more intrinsically valuable than the modern. The last only will be here described.

Modern Gold Coins.

Coins.	Value in sterling money.
Durito Escudo chico de oro Veniento de oro	4s. 2d. (E)
Escudo de oro Doblon senzillo	8s. 4d.
Doblon de oro	16s. 8d.
Doblon de quatre Medio doblon de a ocho Media onza de oro	1l. 13s. 4d.
Doblon de ocho Ouza de oro	3l. 6s. 8d.

Modern Silver Coins.

Coins.	Value in sterling money.
Real Real de vellon Medio real de plata	2½d.
Real de plata Media pecata	5d.
Pecata Real de a dos	10d.
Escudo Medio duro	2s. 1d.
Duro Pesoduro Real de à ocho	4s. 2d.

205 Weights and measures. The Spanish weights and measures vary considerably in different parts of the kingdom, as almost every province has both peculiar to itself. The pound generally consists of 16 ounces in that part of the kingdom formerly belonging to the crown of Castile, and of 12 ounces in those annexed to the crown of Aragon; viz. in Aragon, in the kingdom of Valencia, and in Catalonia; but the ounce is not the same. We shall here only particularize the weights of Castile.

206 In the Castiles they reckon by charges, quintals, arobas, arreldes, pounds, ounces, and drams. The following table gives the proportional value of the Castilian weights.

		lb.	oz.
The charge contains	3 quintals	300	0
—— quintal	4 arobas	100	0
—— aroba	25 pounds	25	0
—— arrelde	4 pounds	4	0
—— pound	16 ounces	1	0
—— ounce	16 drams		1
—— dram	30 grains		$\frac{1}{16}$
—— grain			$\frac{1}{480}$

The measures are still more complicated than the weights; and especially the measures of capacity will require to be considered rather more in detail. We shall, as usual, distinguish them into long measure, superficial or land measure, and measures of capacity.

Long measure.—The standard lineal measure in Spain is the royal foot, consisting of 153$\frac{41}{100}$ lines; and bearing to the English foot the proportion of about 153 to 144, or of 17 to 16. This foot, however, is not in general use, almost every province having its own foot, which is generally rather less than the royal foot. Thus, the foot in Castile is 8 lines less, and that of Valencia about 9½ lines less than the standard. 207

Of royal feet 100 are equivalent to 102 feet 7 inches of Catalonia, to 107 feet of Valencia, to 115 feet 10 inches and 4 lines of Castile.

One hundred feet of Catalonia are equal to 92 feet 2 inches 3 lines of the royal foot, to 97 feet 5½ lines of Valencia, and 104 feet 11 inches 11 lines of Castile.

In Valencia 100 feet are equivalent to 93 feet 4 inches 10 lines of the royal foot, to 98 feet 9 inches of Catalonia; and 107 feet 2 inches 6 lines of Castile.

In Castile, 100 feet are equal to 86 feet 1 inch 5 lines of the royal foot; to 93 feet 4 inches 9½ lines of Valencia; and 92 feet 2 inches 3 lines of Catalonia.

Land measure.—Land in the provinces belonging to the crown of Castile is measured by *ungadas*, *fanegas*, *estadales*, *brasses*, *varas*, *pas*, and *aranzadas*. Of these the ungada contains 50 fanegas, about 204$\frac{5}{10}$ feet; the fanega 400 estadales = about 4$\frac{8}{100}$ feet; the estadale two brasses = about ten feet; the brass two varas, or about 5 feet 1 inch 4 lines; the pas about 1$\frac{2}{3}$ of a vara, and the aranzada about 73 varas. This last is only used for measuring vineyards. 208

Measures of Capacity.—Corn is measured in the provinces belonging to the crown of Castile by *cahizas*, *fanegas*, *celemines*, and *quartillos*; and in Biscay the same measures are used, with the exception of the cahiza. The cahiza contains 12 fanegas, and is = about 1½ lb. French; the fanega contains 12 celemines = 124 lb.; the celemine 4 quartillos = 10lb. 5⅓ ounces, and the quartillo = 2 lb. 7¼ ounces. 209

In Catalonia grain is measured by *salmas*, *charges*, *quarteras*, *cortans*, and *picotis*. The salma contains 2 charges or 6 quintals = 546 lb.; the charge contains 2 quarteras or 3 quintals = 273 lb.; and the quartera 12 cortans or ½ quintal = 136 lb. 8 oz.: the cortan contains 4 picotis or 13 lb. of 12 oz. = 11 lb. 6 oz.; and the picoti 3¼ lb. of 12 oz. = 2 lb. 13¼ oz.

Wine in New Castile is measured by moyos, an imaginary

Spain.

ginary measure, cantaras, azumbres, quartillos, and sextarios. The moyo contains 16 cantaras, the cantara 1-2 azumbres, the azumbre 4 quartillos, each equal to 1 lb. At Cadiz wine is measured by tonneaux, arobas, azumbres, and quartillos. The tonneaux contains 30 arobas, the aroba 8 azumbres, the asumbre 4 quartillos, each of which is equal to 1 lb. 1 oz. At Seville the measures for wine are cantaras, azumbres, and quartillos. The cantara contains 8 azumbres, the aroba the same, the azumbre 4 quartillos, each of which is equal to 17 ounces. In Valencia these measures are, botas or tonneaux, charges, arobas, or cantaras, and azumbres or cuentas; and in Catalonia, pipes, charges, quintals, arobas, quarteros, and quartos, of which the pipe contains 4 charges, the charge 3 quintals, the quintal 4 arobas, the aroba 22 quarteros, the quartero 4 quartos, and the quarto is equal to nearly 3 ounces of Catalonian measure.

21 Laws.

The laws of Spain, which for a long time varied greatly in the different states of the monarchy, are at present reduced to a considerable degree of uniformity. Navarre and Biscay have retained their ancient laws and constitution; but the revolution which took place in Spain at the beginning of the 18 century, enabled Philip V. to introduce into Catalonia and the kingdoms of Aragon and Valencia the laws of Castile; which, excepting a few alterations, rendered necessary by local peculiarities, still continue in full effect.

The laws of Castile, which are thus become those of almost all Spain, are contained in the codes known by the titles of the *Fuero juzgo*, *Ley de las siete partidas*, *Ordenamiento real*, *Fuero real*, and *Recepilacion;* of these the last is a collection of occasional edicts of the kings of Spain, and enjoys the highest authority.

The Roman law has no validity in Spain; and though it may be studied by a few lawyers, as containing first principles universally applicable, yet it is never quoted in the courts, and is expressly excepted against by some of the old laws of Castile.

211 Administration of Justice.

The conducting of a law suit in Spain is subject to very complicated forms; whence necessarily results a slowness of progress. The whole business is carried on by writers, a peculiar branch of the legal profession. In the superior tribunals, the management of causes is in like manner committed to a kind of subaltern magistrates, called reporters (*relatores*), who contrive to render their own department a situation of much greater emolument than that of the judge.

In all the branches of civil, military, ecclesiastical, and judicial administration, in Spain, is evident a spirit of mildness and paternal indulgence, which often degenerates into great abuse. By multiplying courts for the administration of justice, and by establishing the long series of appeals from jurisdiction to jurisdiction, in order that each case may be heard and re-heard, and receive an equitable sentence, the still more important advantages of prompt decision are sacrificed, and a door is opened for chicane.

It is universally acknowledged that the courts of exception are far too numerous; they enfeeble the authority of the established judges, and withdraw a number of individuals from the superintendance of magistrates who reside among them, and are readily accessible, to consign them to the care of distant and dilatory tribunals.

A considerable degree of jealousy and opposition also subsists among many of the tribunals; hence they mutually weaken each other's authority, and the clients are consigned over from court to court; so that lawsuits become intolerably protracted, and a family is held in suspense for two or three generations. The consequence of this is, that the rich wear out those of inferior fortune.

Even the ordinary and regular forms of civil process are slow and complicated. The husbandman is called from his labour, the merchant from his commercial concerns, the artist from his work, and all from their domestic affairs. Nearly an equal tardiness takes place in criminal processes, so that witnesses die, and means of proof are lost, while the guilty often escape unpunished; and those who have been formerly acquitted, are still subject to a long detention in prison, whence they are at length dismissed without indemnity, and irretrievably ruined.

In consequence of the great number of courts, the facility of appeal from one to the other, and the tediousness of law suits; the multitude of judges, advocates, writers, and other subordinate officers employed in the administration of justice, is prodigious. The number of persons employed in the different law establishments has been estimated at 100,000, which is nearly an hundredth part of the population of the country; and the very last general enumeration of the inhabitants of Spain makes the number of advocates amount to 5675, and of writers ts 9351; besides the judges and their secretaries, the attorneys and their clerks, and the innumerable host of alguazils and inferior officers.

Another serious inconvenience in the administration of Spanish law, is the necessity of reposing entire and blind confidence in a class of subaltern officers of the courts, called writers. This appears to be a branch of the profession wholly peculiar to Spain; the writer exercising at the same time the functions of secretary, solicitor, notifier, registrar, and being the sole medium of communication between the client and the judge.

It is not customary in Spain to allow either of the parties concerned any copy of the documents requisite for carrying on a suit, except by the express order of the judge. All the writings on both sides are collected together and bound up into a volume, which remains statedly in the profession of the writer, who intrusts it for a certain time to the attorneys of the parties for the instruction of advocates. The writer, to whose care the documents of any suit are committed, also registers the decrees and sentences of the judges on the case, and notifies to the parties concerned, each step of the process, by reading to them the proper instrument; without, however, allowing them to have a copy of it.

The union of so many important functions in the same person, necessarily affords various opportunities for dishonesty; and the chance of being imposed upon is still further increased by an unwise regulation which obliges the defendent, in any action, to choose the same writer as is employed by the plaintiff.

It may be remarked that scarcely any other persons are under equal temptations to dishonesty, on account of the almost total impunity that they enjoy in consequence of the following regulation. In all those districts where there are either a corregidor and superior alcade, or two superior alcades; each of these officers has an independent tribunal for the decision of law suits; and the right of pronouncing sentence in any particular case belongs to

Spain.

to him of the two at whose tribunal the first application was made. Now the established salaries of these officers are so small, that the largest part of their emoluments arises from their fees; this portion of their income depends wholly on the writers, who have the power of instituting suits in which of the two courts they please. The natural consequence is, that the judges are induced to overlook and pass by in silence those malpractices of the writers which, they cannot prevent without incurring a serious personal loss. Finally, the authority of the writers is irrefragably established by the entire controul that they execute over all causes. They alone receive the declarations and personal answers for the parties concerned; they alone receive the depositions of the witnesses on each side; put what questions to them they please; and record the answers without the interposition, and even in the absence, of the judges.

Another serious defect in the administration of justice in Spain, is, that the party condemned, however clearly unjust may have been his demand, or however weak may have been his defence, is scarcely ever obliged to pay his adversary's costs of suit; whence it perpetually happens, that the expences of gaining a just cause are much greater than the loss of submitting to an unjust demand; hence also it is in the power of a rich villain to oppress and ruin all those who are unable to support the expences of a law suit; which in Spain are enormous, and perhaps the more so, because the established charges are very light.

212 Religion.

The religion of Spain is the Roman Catholic; which, in this country and Portugal, has been carried to a pitch of fanaticism unknown to the Italian states, or even in the papal territory. The inquisition has, in these unhappy kingdoms, been invested with exorbitant power, and has produced the most ruinous effects; having been formerly conducted with a spirit totally the reverse of the mildness and charity of Christianity. This evil has been recently subdued in a considerable degree; but one fanatic reign would suffice to revive it. A yet greater evil, which has sprung from fanaticism, is the destruction of morals; for the monks being extremely numerous, and human passions ever the same, those ascetics atone for the want of marriage by the practice of adultery; and the husbands, from dread of the inquisition, are constrained to connive at this enormous abuse. The conscience is seared by the practice of absolution, and the mind becomes reconciled to the strangest of all phenomena, theoretic piety and practical vice united in bonds almost indissoluble.

According to the returns made to the government, the Spanish clergy then stood as follows.

Parochial clergy, called curas	16,689
Assistants, called tenientes curas	5,771
Sacristans or sextons	10,873
Acolitos to assist at the altar	5,503
Ordinados de patrimonio, having a patrimony of three rials per day	13,244
Ordinados de menores, with inferior ecclesiastical orders	10,774
Beneficiados, or canons of cathedrals, and other beneficiaries	23,692
Monks	61,617
Carry forward	148,163
Brought over	148,163
Nuns	32,500
Beatas	1,130
Syndics to collect for the mendicants	4,217
Inquisitors	2,705
	188,625

The archbishoprics before the late revolution were eight in number; and the bishoprics 46. The most opulent see was that of Toledo, supposed to yield annually about 90,000l. The Mozarabic Missal, composed by St Isidora for the Gothic church, after the conversion from Arianism to the Catholic faith, continued to be used in Spain till the Moors were subdued, when the Roman form was introduced.

213 Present state of the Spanish clergy.

The Spanish clergy, in proportion to the population of the country, is less numerous than was the clergy of France prior to the revolution; even their wealth is less considerable, but better administered; and their contribution to the public revenue is much greater. As to the general conduct of the Spanish church, and its influence on the state, we may remark that after all the perverted and malicious industry that has been exerted in the examination of this question, the result has turned out highly favourable to the superior orders of the Spanish clergy, who are for the most part, free from those irregularities which are charged on the clergy of other countries. The conspicuous situations in the Spanish church are by no means considered as the patrimony of the rich and noble, but, as the well-merited reward of irreproachable conduct. Whatever may be the rank of an ecclesiastic in the sacerdotal hierarchy, he never habitually absents himself from his proper place of residence, where he expends the revenue of his benefice in alms or public works. From the period of the reconquest of Spain from the Moors, most of the public establishments owe their foundation to the clergy, by whom also whole towns have been rebuilt and raised from their ruins. The most beautiful aqueducts, fountains, and public walks in the cities, have been constructed at the expence of their bishops; from them also the poor have received the most effectual relief in times of scarcity, epidemic disease, and war. The bishop of Orense converted his episcopal palace into an almshouse, where were lodged and supported 300 French ecclesiastics, condemned to transportation during the furies of the revolution; the prelate himself took his place at their table, and refused to partake of any indulgence that he could not also procure for his guests. Cardinal Orenzana, archbishop of Toledo, converted the alcazar of that city into an establishment wherein are received 200 children, and 700 poor persons of all ages. The bishop of Cordova, during the scarcity of 1804, and for a long time afterwards, made a daily distribution of 1200 rations of bread to the poor inhabitants of his diocese. The aqueduct which conveys water to the city of Tarragona is the work of their archbishop, who has thus conferred upon the place the inappreciable benefits of cleanliness and health; to both of which it was long a stranger. Similar instances of public merit may be found in almost every diocese.

With regard to the religious orders, their conduct is certainly less exemplary, though by no means meriting the reproaches that have been so liberally cast upon them.

Spain. them. The reforms that have taken place at various periods have stopped the progress of the abuses introduced by length of time; and as the numbers of the monks have diminished, their pernicious influence on public opinion has proportionably declined. Some progress has been made in the desirable policy of uniting the different orders of the same rule into a single order; and from the present prohibition to receive novices, it is probable that several orders are about to be totally suppressed.

213 Language and literature.

The Spanish language is one of the great southern dialects which spring from the Roman; but many of the words become difficult to the French or Italian student, because they are derived from the Arabic used by the Moors. The speech is grave, sonorous, and of exquisite melody, containing much of the flow and formal manner of the orientals.

The Spanish language is, in some respects, very rich; it abounds in compound words, in superlatives, derivatives, augmentatives, diminutives, and frequentative verbs; it has many quite synonymous words, and others which well express the different shades of meaning. In the technical terms of arts and sciences it is, however, extremely poor; a few of these it has borrowed from the Latin, and almost all the rest from the French.

On the whole, the Spanish is one of the finest of the European languages. It is dignified, harmonious, energetic, and expressive; and abounds in grand and sonorous expressions, which unite into measured periods, whose cadence is very agreeable to the ear. It is a language well adapted to poetry; but it also inclines to exaggeration, and its vehemence easily degenerates into bombast. Though naturally grave, it easily admits of pleasantry. In the mouth of well educated men it is noble and expressive; lively and pointed in that of the common people; sweet, seductive, and persuasive, when uttered by a female. Amongst the orators it is touching and imposing, though rather diffuse; at the bar and in the schools it is barbarous, and is spoken about the court in a concise and agreeable manner.

The literature of Spain is highly reputable, though little known to the other countries of Europe since the decline of Spanish power. The Bibliotheca Hispanica of Antonio will completely satisfy the curious reader on this subject. Among the fathers of literature in this country must be named Isidore of Seville, many of whose works are extant, and inferior in merit to few of that epoch. Lives of saints, and chronicles, are also found among the earliest productions; and successive writers may be traced to the 11th century, when they become numerous; but before mentioning some Spanish authorities posterior to that period, it will be proper to recollect that Arabian learning flourished under the caliphs of Cordova, and produced many illustrious names well known to the oriental scholar, as Aben Roe, or Averroes, Aben Zoar, Rhazes, &c. nor must it be forgotten that Aben Nazan wrote a book on the learning and authors of Spain. On this subject the inquisitive are referred to the work of Casiri.

In the 11th century, the Spanish authors began to increase in number, and the native language begins to appear. This was the epoch of the famous *Cid*, Roderic Didac de Bivar, whose actions against the Moors were celebrated in contemporary songs, and by a long poem written in the following century. After the 13th century, it would be idle to attempt enumerating all the Spanish authors, among whom are Alphonso the Wise, who wrote the Libro del Teroso, a treatise on the Three Parts of Philosophy; and at whose command were compiled the famous Alphonsine Tables of Astronomy. Raymond Lully is said to have written not fewer than 319 books, full of metaphysical froth. In the 15th century appeared Juan de Mena, a poet of surprising powers, since which time a department of literature can scarcely be mentioned in which the Spaniards have not excelled. It would be unnecessary to repeat the well-known names of Cervantes, Quevedo, Lopez de Vega, and others, whose works are known to all Europe. The history of Mexico has been celebrated as a composition; but in fact it is defective and erroneous. The name of Bayer in learning, and of Feyjos in general knowledge, have recently attracted deserved respect; nor has the line of royal authors failed, an elegant translation of Sallust having been published by the heir apparent to the monarchy, the present Ferdinand VII*.

* *Pinkerton's Geography*, vol. i.

214 Education.

As the rudiments of education are in Spain generally imparted by the monks, it can scarcely be expected that useful knowledge should be common in that country. The accounts given on this subject by travellers, have thrown so little light on the state of education in Spain, that it can be generally understood only by comparison with other Catholic countries. In this comparison Spain will be found inferior to France and Italy, but in many respects superior to Austria and the German states.

215 Universities

The number of universities in Spain was formerly 24, but only the following 17 now remain, viz. that of Pampeluna, in Navarre; of Oviedo, in the Asturias; of San Jago, in Gallicia; of Seville, and of Granada, in the provinces of the same name; of Huesca and Zaragoza, in Aragon; of Avila, Osma, and Valladolid, in Old Castile; of Toledo, Siguenza, and Alcala de Hamarez, in New Castile; of Cervera, in Catalonia; of Orihuela and Valencia, in Valencia; and of Salamanca, in the province of Leon. Of these the most celebrated, are the universities of Zaragoza, Toledo, Alcala, Cervera, and Salamanca.

The university of Zaragoza has 22 professors, and that of Toledo has 24; about 900 students attend the classes of the former, and nearly 3000 those of the latter; yet neither of these establishments is known in Europe, or regarded as of high reputation even in Spain.

The university of Alcala, established at a prodigious expence by Cardinal Ximenes, answered for nearly a century the views of its illustrious founder. This splendid institution consists of 31 general professors, and 13 colleges, each of which has its particular establishment of masters and professors, and of students, who receive gratuitous support and instruction. At present, however, this university is gone so entirely to decay, that scarcely a vestige of its ancient splendour remains, and the whole number of students scarcely amounts to 500.

The university of Cervera, founded at the commencement of the 18th century, with a magnificence truly royal, possesses 43 professors, five colleges, about 900 students; but it partakes of the radical fault of all the Spanish universities; the course of study is incomplete and antiquated, and the very name of the institution is scarcely known beyond the boundaries of Catalonia.

Spain.

The university of Salamanca, the most ancient of any in Spain, has enjoyed a degree of celebrity which entitles it to a particular description.

It was founded by Alphonso IX. between the years 1230 and 1244, and was considerably enlarged by Ferdinand III. his grandson. But its most magnificent patron was Alphonso X. surnamed the Wise, son and successor of the last-mentioned sovereign. This prince richly endowed it, and drew up a set of statutes for its government. He established a professorship of civil law, with a salary of 500 maravedies; a professorship of canon law, with a salary of 300 maravedies; two professorships of decretals with salaries of 500 maravedies; two professors of natural philosophy, and as many of logic, with salaries of 200 maravedies each; and two masters of grammar, with salaries of 300 maravedies. It experienced also the liberality of many succeeding sovereigns, and received from the popes a vast extent of privileges.

For many years this university enjoyed a high reputation; its fame extended over all Europe; it was consulted by kings and by popes, and its deputies were received into the general councils, where they well sustained the character of the body which they represented. Students flocked to it not only from all the provinces of Spain and Portugal, and from the islands of Majorca and the Canaries, but also from the West Indies and New Spain, and even from France, Flanders, and England. The number of students who attended the classes amounted nearly to 15,000. The whole of this vast establishment consisted of 25 colleges, a library, and an hospital, called *Del Estudio*, intended for the amelioration of poor scholars.

The celebrity of Salamanca continued in full vigour during many ages; but, at length, as rival institutions sprang up, declined by slow degrees, so that by the year 1595, the number of students did not exceed 7000*.

* *De Laborde.*

216 State of the Spanish stage.

After the evacuation of Spain by the Romans, theatrical representations were discontinued till they were restored by the Moors, and from them adopted by the Gothic Spaniards, who soon became passionately fond of the stage, a taste which they have ever since preserved.

They had at first neither theatres nor a stage, their dramas were acted in a court, a garden, or the open fields; the actors and spectators were mingled, and were equally exposed to the injuries of the weather.

At a subsequent period the stage was marked out by a kind of boarded platform, and was surrounded by old clothes, drawn back, on occasion, by means of cords, which formed the only decorations, and behind which the actors dressed. Their properties consisted only of crooks, some wigs and false beards, and a few white skins, trimmed with gold fringe.

Theatrical exhibitions became more regular and decent towards the end of the 16th century, when a new form was given to them by the exertions of Bartholemew Naharro, a middling dramatic poet. Theatres were then erected, but the greatest part were upon tressels, and two parallel pieces of canvas formed their scenes, which were sometimes checquered with various colours, sometimes covered with miserable paintings, or adorned with foliage, trees, or flowers.

During all these periods, the prompter, with a candle in his hand, stationed himself on the stage by the side of the performers who were speaking, and jumped from side to side whenever the actors changed their places. This custom prevailed at the end of the 17th century, and even still prevails among the strolling companies of small towns.

Theatres have at length, however, assumed a handsomer appearance in this country, and customs more conformable to the rest of Europe. Handsome theatres have been multiplied, and their stages are now well arranged and decorated; all the great cities are well provided with them, and many of the smaller towns may boast of elegant and not ill furnished playhouses.

The prompter no longer runs from one side of the stage to the other; he is placed in the middle before the scenes, in a kind of well, where he no longer offends the sight and taste of the spectator: but an old custom which is still observed, greatly injures the interest and effect of the representation. The prompter, who has the piece before him, does not wait till the actor is at a loss to prompt him, but recites the whole drama aloud, so that the actor appears to follow him in his declamation. By this means two voices are heard in the theatre pronouncing the same words, which are confounded, and often produce a discord, and the spectator who has first heard the piece recited, no longer takes an equal interest in the same verses, phrases, and words, which the actor afterwards declaims.

The Spanish theatres are divided into a *patio*, or area, and boxes called *balco* and *aposentos*. The orchestra, where the musicians are stationed, adjoins the stage; an inclosure between it and the pit is set round with arm chairs, and destined for the reception of the higher class: the *patio*, or pit, is placed behind, and filled with benches, and the *gradas* consist of two rows of benches disposed amphitheatrically on each side below the boxes, and sometimes also across the lower end of the theatre. This last division is found only in a few theatres; in the others, the space beneath the boxes is empty, and persons stand in it. The *patio* and the *gradas* contain the common people, the most numerous, most noisy, and most imperious part of the public.

There are commonly only two tiers of boxes, sometimes three; they extend on each side from the stage to the end of the theatre. The form is the usual one, but they are divided from each other by partitions, which completely shut them up on each side, a circumstance which greatly injures the beauty of the general effect.

There is commonly at the end of the theatre fronting the stage, a large box with seats placed semicircularly behind one another, which is called the *cazuela*. No man is allowed to enter it, and only women muffled up in their *mantelas* are admitted.

There are several things very singular and amusing in this cazuela. Women of every age and condition are there united; the married are confounded with the single; the wives of the common people with those of tradesmen and the ladies of the court; the poor woman with the rich one who would not be at the trouble of dressing to appear in her box. Their appearance is most curious; they are all covered with their *mantelas*, a kind of white or black veil, and give the idea of a choir of nuns. It is the place for chattering, and between the acts there proceeds from the cazuela a confused noise like the hum of bees, which astonishes and diverts all who hear it for the first time. Scarcely is the performance ended, when the door of this box, its galleries, passages, and the staircase leading to it, are all

all besieged by a great crowd of men of every condition; some attracted by curiosity; others coming to wait upon the women who are in it.

Notwithstanding all that has been done for its improvement, the Spanish stage is still far from the celebrity which it once possessed; and the people do not second the efforts of their best writers. The acting is in a still lower state. The performers possess neither that dignity which characterizes great personages, and ennobles a subject without injuring its interest; nor that sweet expression of voice and gesture which goes to the heart, and awakens the sentiments it expresses. In their acting every thing is violent or inanimate; every thing departs from nature. Their recitation is a feat of strength, and is performed at the sole expence of the lungs. Cries and shrieks are its most impressive part, and the most applauded by the majority of the audience. They put nothing in its proper place: all their action is exaggerated; when they threaten they roar; when they command they thunder; when they sigh, it is with an effort which completely exhausts the breath. They substitute anger for dignity, violence for spirit, insipidity for gallantry. Their gestures rarely correspond with the sentiments they ought to express; but resemble their recitation; and are usually monotonous, capricious, ignoble, and almost always violent. The women, in their bursts of passion, become furies; warriors become villains; generals robbers; and heroes bravos. Nothing, as they manage it, is pathetic; nothing makes any impression on the audience. The spectators, equally unmoved at the end of the piece, as at the beginning, see it, without having experienced a single moment of interest or emotion *.

* Laborde.

217 Produce and agriculture.

As labour and culture are reckoned derogatory to the Spanish character, a sufficient quantity of grain for the support of the inhabitants is not raised, though societies for the encouragement of agriculture have been established in different parts of the kingdom. The principal products are wine, delicious fruits, oil, silk, honey, and wax. A considerable proportion of the mountains and valleys is pastured by immense flocks of sheep, whose wool is extremely fine and valuable. Estremadura is noted for its excellent pastures; and the wool in Old Castile is reputed the finest in the kingdom. In Catalonia the hills are covered with forest and fruit trees. Valencia is celebrated for its silk, and for the exquisite flavour of its melons. Murcia abounds in mulberry trees; and the southern provinces yield the most delicious wines and fruits. Upon the whole, it has been observed of Spain, that few countries owe more to nature, and less to industry.

The soil in general reposes on beds of gypsum, which is an excellent manure. The common course of husbandry about Barcelona begins with wheat; which being ripe in June, is immediately succeeded by Indian corn, hemp, millet, cabbage, kidney beans, or lettuce. The second year these same crops succeed each other as before. The next year they take barley, beans, or vetches; which coming off the ground before midsummer, are followed, as in the former years, by other crops, only changing them acording to the season, so as to have on the same spot the greatest possible variety. Near Carthagena the course is wheat, barley, and fallow. For wheat they plough thrice, and sow from the middle of November to the beginning of December; in July they reap from 10 to 100 for one, as the season happens to be humid. The rich vale of Alicant yields a perpetual succession of crops. Barley is sown in September, reaped in April; succeeded by maize, reaped in September; and by a mixed crop of esculents which follow. Wheat is sown in November, and reaped in June; flax in September, pulled in May. In the vale of Valencia wheat yields from 20 to 40; barley from 18 to 24; oats from 20 to 30; maize 100; rice 40. The Spanish plough is generally light; and is drawn by oxen with the yoke over the horns; the most proper and natural mode, as the chief strength of the animal centres in the head. For a very minute account of agriculture in Spain, see De Laborde's View, vol. iv. chap. 2.

That prejudice which regards the mechanic arts as 218 State of the arts.
base, is not yet extinguished in Spain: hence it happens that these arts are either neglected, or abandoned to such unskilful hands, as in general to render the Spaniards much behind their neighbours in the useful arts of life. The influence of this prejudice is least in the province of Catalonia, where the laws, customs, and opinions are favourable to artizans; and it is accordingly in this province that the mechanic arts have made the greatest progress. Foreign artists experience great difficulties in this country. They are not allowed to practice without gaining admission into some incorporation or company, and this has almost always been refused them.

Some arts have, however, made considerable progress in Spain, especially those of gilding leather, and printing, which has lately acquired a great degree of perfection.

The fabrication of articles of gold and silver might become an important object in a country where these metals abound; but it is neglected, and the demand is almost entirely supplied from foreign markets. What little they perform in this way at home is usually very ill executed, and exorbitantly dear. Madrid, however, begins to possess some good workmen in this way; encouragement would increase their number, and facilitate the means of improvement; but manual labour is there excessively dear. Hence the Spaniards prefer foreign articles of this kind, which, notwithstanding the expence of carriage, the enormous duties which are paid on these articles, and the profits of the merchants, are still cheaper than those made at home.

The liberal arts are cultivated in this country with 219 Architecture.
more assiduity and success. The 16th century was the most brilliant period of the arts in Spain, as well as of the sciences, of literature, and of the power and grandeur of the monarchy. A crowd of able architects appeared at once under Charles V. and Philip II. They erected numerous edifices, which will immortalize the reigns of these princes and the names of the artists. John de Herrera and Cepedes displayed the highest talents; Pedro de Uria constructed the magnificent bridge of Almaraz, in Estremadura; John-Baptist-Monegro of Toledo, assisted in the building of the Escurial, and of the church of St Peter at Rome.

The structures of that age are the finest in Spain, and perhaps the only ones in the country which deserve to fix the attention of the skilful spectator. There are some among them which, in regularity, solidity, and magnificence, deserve to be compared with the fine buildings of the Romans. The bridges of Badajoz over the Guadiana, and of Toledo, over the Manzanares, are of this period; as are also the grand house or palace, now the council-

Spain. council-house at Madrid, and the beautiful edifices which adorn Toledo; the palace of Los Vargas; the hospital of St John the Baptist, and that of the Holy Cross. During the same time, the *alcazar* of this city built under Alphonso X. was restored with the grandeur and magnificence which it still displays; and the noble palace was erected, known under the name of the House of Pilate, at Madrid.

That magnificent building the Escurial, which the Spaniards called the eighth wonder of the world, which used to lodge at once the king and his court, and 200 monks; this famous palace, which astonishes us by its mass and extent, by the strength of its structure, the regularity of its proportions, and the splendour of its decorations, as much as by the repulsive appearance of its site and neighbourhood, also belongs to the same period, having been erected in the reign of Philip II.

The decline of architecture became as complete in the 17th century as its state had been flourishing in the preceding age. From this period no architect occurs worthy of remembrance; and the buildings are monstrous masses, destitute of order, taste, and regularity. One only deserves notice, the prison of Madrid, called Carcel de Conte, the work of a happy genius, who knew how to profit by the bright examples of the preceding period.

About the middle of the 18th century, however, architecture began again to be cultivated with success. The academy of San-Fernando, at Madrid, has already produced several able men in this branch, who pursue their art with credit. The handsome bridge built over the Xarama, between Aranjuez and Madrid, in the reign of Charles III. displays the talents of Mark de Vierna, his architect; the custom-house of Valencia, and the temple-church of the same city, constructed on the plan of Michael Fernandez; the exchange of Barcelona; the triumphal arch which forms the gate of Alcala at Madrid, and the snuff manufactory at Seville, do honour to the Spanish architecture of the present day.

220 Painting. Spain justly boasts of many eminent sculptors; but of all the liberal arts, painting is that which has been most cultivated in Spain, and in which its natives have best succeeded. The Spanish school is much less known than it deserves; it holds a middle place between the Italian and Flemish schools; it is more natural than the former, more noble than the latter, and partakes of the beauties of both. It has particularly excelled in sacred subjects; and we recognise in the Spanish pictures the feelings usually experienced by the people of the mysteries of religion. By none have devout ecstasy, fervour, and genuine piety, been so well expressed, or the mystic passion given with so much truth. It is not in correctness of design, or nobleness of form, that the Spanish artists usually excel, but in the pure imitation of nature, in grace, truth, effect, and the expression of feelings.

The Spaniards have at length opened their eyes to the utility of the arts; they acknowledge them to be advantageous and deserving of respect, and have begun to give them such encouragement as is likely to promote a taste for them, and to insure their advancement. Government has done something by affording protection and countenance to the new establishments; but the strongest impulse has been given by individuals, or private associations.

Spain now possesses an academy of painting, at Seville, and two academies of the fine arts, one at Madrid, and the other at Valencia. The first owes its origin to an association of the painters of Seville formed by themselves, about the year 1660; Charles III. revived it, and established there a school of the fine arts. That of Madrid was founded by Philip V. The last was established by the exertions of some private persons, assisted by the benefaction of Andrew Majoral, archbishop of Valencia, and the protection of the municipal body. Charles III. came to its assistance 26 years after its establishment, with an annual gift of nearly 700l. These academies have for their object the study and improvement of painting, sculpture, and architecture; they give public lessons on these three arts, and distribute annual prizes among their pupils. That of Madrid, or San-Fernando, sends its pupils to Rome at the expence of government, to complete their studies.

Public and gratuitous schools for drawing have been established within the last 20 years in different places; at Madrid, Cordova, Valencia, Seville, Zaragoza, Barcelona, &c. The last of these is supported by the merchants; that of Vergara was founded by the patriotic society of Biscay; and those of Zaragoza and Cordova owe their birth to the zeal and generosity of two individuals; the first to Don Martin Noy Cochear, the last to Don Antonio Cavallero, the present bishop of Cordova. Those of Madrid, Seville, and Valencia, depend on the academies of these cities.

221 Manufactures. The manufactures of Spain were more flourishing during the government of the Moors in that country, than they have been at any subsequent period. So completely had the kingdom declined in this respect at the end of the 16th century, when Philip V. ascended the throne, that it is said by De Laborde to have been absolutely destitute of trade. The intestine wars which ravaged the kingdom during the first 14 years of that reign, and the low state to which the national finances were reduced, prevented the government from paying attention to manufactures; and it was not till after tranquillity had been restored, and regulations adopted with respect to the public revenue, that the natives were induced to wear articles of their own manufacture. Since the reigns of Ferdinand VI. and Charles III. this part of the internal trade of the kingdom has greatly improved, and the manufactures of Spain are now once more on a respectable footing.

The Spanish manufactures enumerated by De Laborde, in his View of Spain, are those of cloth and other woollen goods; silks; brocaded stuffs in gold and silver; linens and other articles formed from flax or hemp; cottons; leather and other articles manufactured from skins and hides; paper; china and delft ware; brandies; beer; aquafortis; salt of lead; shears for the woollen trade; copper, iron, and brass goods; glass and mirrors; soap; hats; articles for the marine; military implements; arms and ammunition; tobacco and snuff. Of these, the most important are, the woollen and silk manufactures; leather; brandy; military weapons; soap and tobacco.

The principal places for the woollen manufactures are, Aulot, Arens, Vich, and the convent of Gironne in Catalonia; Jaca, and the district of Cincavilla in Aragon, and Burgos in Old Castile, for woollen stockings; Barcelona, Zaragoza, and Burgos, for blankets; Junquera, Segovia, Burgos, and many others, for baizes and

Spain.

and flannels; Estella in Navarre, Escoray in Biscay, Grazolerna in Seville, Toledo, &c. for coarse cloths, which last article is manufactured in large quantities throughout the kingdom. The woollen stuffs fabricated in Spain, are in general of a very inferior quality, the wool being imperfectly scoured, and the dyeing so ill executed, that the colours are never permanent.

The chief manufactures for silken articles are those for blonde lace throughout Catalonia, and at Almagro in La Mancha; for silk stockings, at Malaga, Zaragoza, Valencia, Talavera, and Barcelona; and for silk taffeties, serges, damasks, and velvets, at Jaen, Granada, Murcia, Valencia, Malaga, Zaragoza, Toledo, Talavera, and Barcelona. The articles of this manufacture are in general stout and excellent; but they do not possess that brilliancy of appearance so remarkable in the French silks.

Tanning, currying, and dressing hides, skins, and all kinds of leather, are very general throughout Spain; but the skins and hides prepared at Arevaea and Pozuelo, are in greatest repute. The greatest quantity of sole leather is manufactured in the provinces of Aragon and Catalonia; and in the latter province are made and exported a prodigious number of shoes.

The making of brandy is confined chiefly to the states belonging to the crown of Aragon, especially at Torres in Aragon; at Selva, Mataro, &c. in Catalonia; and in Valencia.

Spain.

Spain has long been famous for its manufacture of military weapons; and it is well known that the swords, sabres, hangers, and bayonets, made at Toledo and Barcelona, are of a very superior temper. Large manufactories for fire-arms occur in the district of Guipuscoa, and two royal founderies for brass cannon, are established at Barcelona and Seville.

There is only one manufactory for tobacco and snuff in Spain, viz. at Seville; but this is on a most extensive scale, and is supposed to yield of annual profits about 800,000l. sterling. Here are employed 202 mills, turned by 300 horses or mules; and the various operations call for the daily labour of above 1400 persons.

222 Commerce.

Considering the extent of sea coast belonging to the kingdom of Spain, its commerce is but inconsiderable, and principally takes place between the mother-country and the American colonies. Spain, indeed, carries on a foreign trade with every country in Europe; but its principal transactions are, with England, Holland, Italy, and France. Its exports to these countries consist almost entirely of raw produce, as, if we except oil, wine, brandy, shoes, salt, and a few coarse cloths and silken articles, the trade in manufactured goods is almost wholly confined to the interior of the country. Its chief exports, and the amount yielded by each for the several provinces, as well as the whole amount of the export trade of Spain, to the rest of Europe, will be seen in the following table.

Value of Exports from each Province in Pounds Sterling.

Goods exported.	*Catalonia.*	*Valencia.*	*Andalusia.*	*Murcia.*	*Aragon.*	*Other Provinces.*	*Total.*

Spain.

The above table is confined almost entirely to the European exports. To these must be added the amount of Spanish exports to the American colonies, in order to acquire a just view of the total amount of the export commerce. The following table will show the amount of the exports, both of home and foreign produce, from Spain to America in 1784, as estimated by Mr Townsend in pounds sterling.

Ports.	Home produce.	Foreign produce.	Total.
Cadiz	1,438,912	2,182,531	3,621,443
Malaga	196,379	14,301	210,680
Seville	62,713	30,543	93,256
Barcelona	122,631	21,240	143,871
Corunna	64,575	39,962	104,537
Santander	36,715	90,173	126,888
Canaries	24,974		24,974
Tortosa	7,669	289	7,958
Gijon	4,281	10,190	14,471
Total	L.1,958,849	L.2,389,229	L.4,384,878

Of these exports we are to regard chiefly those of Spanish produce, and these Mr Townsend has probably estimated too high. M. de Laborde, on whose authority we are more disposed to rely, states the value of Spanish domestic merchandise exported to America in the year 1788, as amounting to 1,635,658l. sterling, while in 1792, it amounted to 2,812,500l. sterling, and on an average of five years, from 1788 to 1792, it amounted to 1,833,333l. sterling. The amount of foreign merchandise exported in 1788, was 1,484,315l. sterling. Adding the average to this last sum, we have 3,317,648l. sterling for the whole export trade to America. This added to 4,908,304l. sterling, makes a grand total of 8,225,952l. sterling for the whole export trade of Spain.

The Spanish imports are much more considerable than the exports. Before the present troubles, Spain imported from Holland, tapes, linen drapery, common lace, cutlery goods and paper; from Silesia linen drapery; from Germany, more particularly from Hamburgh, quantities of haberdashery; from England, calicoes, iron and steel goods, fine cloth, quantities of cod fish and ling; the value of the last articles is estimated at three millions of duros, five millions livres tournois, (208,333l. 13s. 4d.); from France, calicoes, linen drapery, silk stockings, silks, camlets, and other kinds of worsted stuffs, fine cloths, gilded articles, jewellery, iron goods, haberdashery, steel goods, and perfumery.

We have not satisfactory documents sufficient to ascertain the amount of these imports, but it was certainly much less than that of the imports from the American colonies. These latter, according to Mr Townsend's statement, amounted in 1784 to 12,635,173l. sterling; to which, if we add nearly half a million for duty, we shall have a total of above thirteen millions sterling for American imports alone. De Laborde estimates the total amount of American imports for the year 1788 at 8,382,330l. sterling, of which Cadiz alone imported 6,617,873l. sterling. If to the above amount we add 577,679l. for the duty at the same period, we shall have a total of 8,960,009l. sterling against the mother country, deducting from this 3,317,648l. for the average exports, we have 5,642,361l. as the balance of trade in favour of the Spanish colonies.

Spain.

223 Inland navigation.

Though there are in Spain many navigable rivers, few canals of communication have been constructed to improve the internal navigation of the country. The canal of Aragon, completed during the reign of Charles IV. must be highly beneficial to that province. Two canals, viz. that of Tueustre, and the imperial canal, both of which begin at Navarre, run in various windings through Aragon, by turns receding from or approaching the river Ebro, where at length they terminate. Besides the dykes, banks, sluices, and bridges necessary in the course of these canals, an aqueduct has been constructed in the valley of Riozalen, 710 fathoms in length, and 17 feet thick at the base, in which the canal runs.

The canal of Castile, projected and begun in the last reign, has been almost abandoned. It was to commence at Segovia, sixteen leagues north of Madrid, to follow the course of the Eresma, that falls into the Douro, and to be continued as far north as Reynosa; which is twenty leagues from St Ander, a sea port. At Reynosa is the communication with the canal of Aragon, that unites the Mediterranean to the bay of Biscay. Above Palencia, a branch goes westward through Rio-Seco and Benevento to Zamora; making the canal of Castile, in its whole extent 140 leagues; where it is completed, viz. between Reynosa and Rio-Seco, its width at top is 56 feet, at bottom 20, and nine in depth.

In 1784, a canal was planned, which, from the foot of the mountains of Guadarama near the Escurial, should proceed southward to the Tagus; afterwards to the Guadiana, and terminate at the Guadalquivir above Andaxar. Some other attempts to improve the inland navigation of the country have been unsuccessful.

224 General character of the Spaniards.

There is no nation in Europe which displays such a variety of national character as Spain. In no two provinces are the manners and characters exactly alike. It is therefore difficult to collect traits on which to found the national character of the Spaniards; and this character has been variously represented by different writers. From the transactions which have lately taken place between that people and the British nation, we confess ourselves prejudiced against them; and we shall therefore, instead of sketching their character according to our own preconceived notions, endeavour to delineate it as concisely as possible from De Laborde, who is probably a sufficiently competent judge.

The national pride, says this author, is everywhere the same. The Spaniard has the highest opinion of his nation and himself, and this he expresses with energy, in his gestures, words, and actions. This opinion is discovered among all ranks in life, and all classes of society. Its result is a kind of haughtiness, sometimes repulsive to him who is its object, but useful in giving to the mind a sentiment of nobleness and self-esteem which fortifies it against all meanness.

In later times the Spaniards have not degenerated from the valour of their ancestors. The Spanish soldier is still one of the best in Europe, when placed under an experienced general, and brave and intelligent officers. He possesses a cool and steady valour; he long endures fatigue and hunger, and easily inures himself to labour.

The Spaniards are very reserved, and rather wait for, than

than court the advances of a stranger. Yet in spite of their apparent gravity, they possess an inward gaiety, which frequently shines out when proper occasions call it forth.

The Spaniard is very slow in all his operations; he often deliberates when he ought to act, and spoils affairs as much by temporising as the natives of other countries do by precipitation. This tardiness would be but a slight defect, did it not proceed from a serious radical want, from the invincible indolence and hatred of labour which prevails among all ranks of society.

That jealousy which was formerly proverbial among the Spaniards, is now greatly diminished; husbands are much less suspicious, and women much more accessible. Lattices have disappeared; duennas exist only in romances; veils are exchanged for mantelas; houses are thrown open, and the women have recovered a liberty by which they are less tempted to go astray than when their virtue was entrusted to locks and grates, and to the superintendance of guards often faithless and easily corrupted.

In fine, the Spaniards are sober, discreet, adroit, frank, patient in adversity, slow in decision, but wise in deliberation; ardent in enterprise, and constant in pursuit. They are attached to their religion, faithful to their king, hospitable, charitable, noble in their dealings, generous, liberal, magnificent; good friends, and full of honour. They are grave in carriage, serious in discourse, gentle and agreeable in conversation, and enemies to falsehood and evil speaking.

225
Diversities of character in the several provinces.

Such is the Spanish character as drawn by De Laborde. Its varieties in the several provinces are thus stated by the same author. The Old Castilians are silent, gloomy, and indolent, and are the most severely grave of all the Spaniards; but they possess a steady prudence, an admirable constancy under adversity, an elevation of soul, and an unalterable probity and uprightness. The character of the natives of New Castile is nearly the same, but more open, and less grave and taciturn. Indocility and conceit make part of the character of the people of Navarre; they are distinguished by lightness and adroitness. The Biscayans are proud, impetuous, and irritable; abrupt in discourse and in action; haughty and independent, but industrious, diligent, faithful, hospitable, and sociable. The Gallicians are gloomy, and live very little in society; but they are bold, courageous, laborious, very sober, and distinguished for their fidelity. The Asturians partake of the character of the Gallicians and Biscayans; but they are less industrious than the former, less civilized, less sociable, less amiable, and more haughty than the latter. The people of Estremadura are proud, haughty, vain, serious, indolent; but remarkably sober, honourable, and much attached to their own province, which they seldom quit. The Murcians are lazy, listless, plotting, and suspicious; attached neither to sciences, arts, commerce, navigation, nor a military life. The Valencians are light, inconstant, and indecisive; gay, fond of pleasure, little attached to each other, and still less to strangers, but affable, agreeable, and diligent. The Catalans are proud, haughty, violent in their passions, rude in discourse and in action, turbulent, untractable, and passionately fond of independence; they are not particularly liberal, but active, industrious, and indefatigable; they are sailors, husbandmen, and builders, and resort to all corners of the world to seek their fortunes. They are brave, intrepid, sometimes rash, obstinate in adhering to their schemes, and often successful in vanquishing, by their steady perseverance, obstacles which would appear insurmountable to others.

226
Manners and customs.

The natives of almost every province have some distinguishing peculiarity in their dress, manners, and pursuits. Before the accession of the house of Bourbon to the throne, the usual dress of a Spanish nobleman consisted of a slouched hat, a long black or brown cloak, short jerkin, and strait breeches, with a long Toledo sword; but French dresses are now introduced at court. The higher classes wear their hats under their arm. The common people wrap themselves up to the eyes in a brown cloak, called *aleapo*, that reaches to the ground; and conceal their hair beneath a cotton cap, and a broad hat called a *sombrero*. When a lady walks abroad, her head and upper part of her body are covered with a mantela; that is, a white or black veil, so that it is impossible she should be known. At home, the dress is a jacket and a petticoat of silk or cotton. The hair is generally a fine black; and powder is rare.

In romance, the ladies are celebrated for beauty, and some of them deserve that character; yet beauty is not their general character. They are of a slender make, but with great art they supply the defects of nature. By an indiscriminate use of paint, they disfigure their complexion and shrivel their skin.

Several of the Spanish customs and habits, which seem ridiculous to foreigners, are gradually wearing out, and in process of time will no doubt be corrected. The higher classes at breakfast use chocolate, and seldom tea. Dinner generally consists of beef, veal, pork, mutton, and beans, boiled together. They are fond of garlic; and it is proverbial that olives, salad, and radishes, are food for gentlemen. The men drink little wine, and the women use water or chocolate. Both sexes sleep after dinner, and air themselves in the cool of the evening. Their repasts are composed of sweatmeats, biscuit, coffee and fruit, which servants distribute to the company; who keep their seats, and have little conversation.

Dancing and cards are favourite amusements. Theatrical exhibitions are generally insipid or ridiculous bombast, low wit, absurdity, and buffoonery. The combats of the cavalleros, and bull fights, are almost peculiar to this country. On these occasions young gentlemen were used to show their courage to their mistresses; and were honoured and rewarded according to their success. But these exhibitions were lately conducted with greater economy and parsimony; and mercenary champions studied in the most secure and graceful manner to destroy the devoted animal. See *Bull-Fighting*.

The chief defect in all ranks is an aversion to labour and industry. The higher orders bestow no attention on agriculture and commerce; they reside for the most part at court and in the metropolis, reckoning it beneath their dignity to live in villas on their estates among their tenants. In their estimation, a labouring man quits the dignity of the Spanish character, and renders himself an object of contempt. Hence a listless indolence prevails. Thousands waste their time in total want of every incitement to action. Their intellectual powers lie dormant, and their views and exertions are confined within the narrow sphere of mere existence. The common people have no encouragement to industry; and must feel little concern

Spain.

concern for the welfare of a country where a few overgrown families engross every thing valuable, and never think of the condition of their vassals. The indigent Spaniard does not bestir himself unless impelled by want, because he perceives no advantage to be derived from industry. A stranger to intemperance and excess, his scanty fare is easily procured; and under a climate so propitious, few clothes are required. The hovel which he occupies, together with all its contents, has a mean, filthy, despicable appearance; and all that relates to him bears the impression of wretchedness and misery ‡.

‡ Playfair's *Geography*, vol. i. p. 68.

There are certain customs which may be regarded as peculiar to the Spaniards, or which at least are scarcely found in any other European country. The number of servants retained in the families of the higher ranks is prodigious; and even a tradesman's wife, in narrow circumstances, will frequently have four maid servants, though she cannot, with propriety, employ more than two. The houses of gentlemen, and especially of grandees, swarm with them; and, not unfrequently, all the principal servants will have their wives and children lodged with them, and supported by their master. We have heard of one nobleman who was at the daily expence of 120l. merely for the maintenance of his numerous retainers.

The Spaniards are fond of meeting in the evening in parties, which are often very numerous. On these occasions, the ladies as they arrive place themselves in one room, and the gentlemen in another; or else the ladies range themselves in a line along the side of the room, the lady of the house always taking the lowest place next to the door, whilst the men remain standing, or seat themselves on the opposite side. They remain separated in this manner till the card parties are introduced. They play at loo, loto, and other games of a similar kind. Those who do not play, either look on, or embrace the opportunity of chatting with the person most interesting to them. Others form little circles, where the conversation is usually very animated. These parties very much resemble the French evening, and the English rout.

A *refresco* sometimes makes part of these entertainments, but only on particular occasions, when the company is more than usually numerous. But orgeat, lemonade, orangeade, ices of different kinds, sweetmeats, and biscuits, are distributed with uncommon profusion; and chocolate ends the *funcion*, as all these entertainments are called.

Many precautions are taken in Spain against the heat. The rooms are watered several times a-day, and the windows are shaded on the outside with awnings of cloth or ticking, or on the inside by large and full curtains. In some places, as at Valencia, the glass is taken out of the windows at the approach of summer, and the doors of the apartments are all set open.

The beds in Spain are hard, being made of mattresses, laid on paillasses, resting on a wooden bottom. The furniture of the houses is usually very simple, and the floors are covered with matting or printed cloth. The chairs have rush bottoms, and are usually of different heights, those for the ladies being one-third lower than those for the gentlemen.

227 Amusements.

Among the principal amusements of the Spaniards must be reckoned music and dancing. Though the Spaniards have a taste for music, they are by no means proficients in that accomplishment. Their principal instrument is the guitar, which is in the hands of every body. Different provinces have also their peculiar instruments. Thus the Gallicians use a dull and heavy bagpipe; the Catalonians a large flageolet, and a little drum or tabor; and the Biscayans a short flute, with four holes. Castanettes are also extremely common, and are employed with great dexterity and address in the national dances.

The Spaniards are passionately fond of dancing, and they have certain dances which are peculiar to Spain. Of these the fandango is the most celebrated, and appears to be the most ancient. It is a very extraordinary dance, in which the whole body is thrown into a regular and harmonious convulsion, expressive of the most lascivious ideas.

The passion of the Spaniards for these dances is carried to a height which can scarcely be imagined. No sooner are the guitar and the singing to which they are danced heard in a ball room or theatre, than a murmur of delight arises on all sides; all faces become animated; the feet, hands, and eyes of all present are put in motion: it is impossible to describe the effect produced. Mr Townsend, an English traveller, affirms, that if a person were to come suddenly into a church or a court of justice playing the *fandango*, or the *colero*, priests, judges, lawyers, criminals, audience, one and all, grave and gay, young or old, would quit their functions, forget all distinctions, and all set themselves a dancing.

The Spanish balls are directed by two persons chosen among the visitors, who are called *bastoneras*, and with the hat under the arm, and the cane in the hand, perform the office of masters of the ceremonies. One is for the gentlemen, the other for the ladies. It is their business to appoint who is to dance, whether minuets or country dances: they are in general very attentive to the observance of precedence and etiquette, and have usually the complaisance to contrive that those shall dance together to whom it is peculiarly agreeable to meet.

A singular custom is observed at these balls, which appears new and strange to a foreigner. The lady chosen to dance rises, crosses the room alone, and places herself where she is to begin dancing, without waiting for her partner to lead her out; and after the dance is over, her partner makes his bow to her again in the middle of the room without taking any further concern about her, or handing her back to her place. But this custom prevails only in the provinces.

The bull-fights noticed above were once not only a favourite but a fashionable spectacle in Spain. Every city, and almost every small town, had a place set apart for these darling combats; and hither all ranks and ages resorted with the greatest avidity, and witnessed the prowess of the combatants, and the torture of the wretched animals, whom they were hired to butcher, with the most savage expressions of delight. These fights made a part of every festival, and, as soon as they were announced, the housewife left her family, the tradesman forsook his shop, the artist his work-room, the labourer his field, and joy and expectation were painted on every countenance. To the honour of the nation, these cruel sports are at length abolished, and Spain has thus set an example of humanity, which Britain, with all her civilization and refinement, need not blush to copy.

New-SPAIN.

New-Spain || Spallanzani.

New-Spain. See Mexico.

SPALATRO, or Spalatto, a rich, populous, and strong town, capital of Venetian Dalmatia, now belonging to Austria, with a good harbour and an archbishop's see. Here are the ruins of the palace of Diocletian, of which the late Mr Robert Adam published in 1764 a splendid account, enriched with 71 folio plates. In 1784, Spalatro was nearly depopulated by the plague. It is strong by situation, being built on a peninsula, which is joined to terra firma by a neck of land half a mile over. It is seated on the gulf of Venice, 35 miles south-east of Sebenico, and 102 north-west of Ragusa. E. Long. 17. 31. N. Lat. 44. 4.

SPALLANZANI, Lazarus, a celebrated naturalist, was born at Scandiano, in the duchy of Modena, in January 1729. He began his studies in his native country, and went to Reggio de Modena at 15 years of age, to prosecute them further. He was instructed in the *belles lettres* by the Jesuits, who contended with the Dominicans in order to secure his attachment; but his thirst for knowledge determined him to go to Bologna, where his relative Laura Bassi, a woman highly celebrated for her genius, eloquence, and skill in natural philosophy and mathematics, was one of the most distinguished professors of the Institute and of Italy. Under this enlightened guide, he was taught to prefer the study of nature to that of her commentators, judging of the real value of the commentary by its resemblance to the original. He availed himself of the wisdom of that lady's counsels, the happy effects of which he very soon experienced. Spallanzani's taste for philosophy was not exclusive, for he carefully studied his own language, became a proficient in the Latin tongue, and attached himself above every other to the Greek and French. By the advice of a father whom he ardently loved, he applied himself to jurisprudence; but being urged by Anthony Vallisnieri to renounce his vocation, by procuring the consent of his father, he gave himself up to the study of mathematics with more zeal than ever, at the same time devoting himself to the study of languages, both living and dead.

It was not long before he was known all over Italy, and, what is seldom the case, his own country first put that value on his talents which they justly merited. He was chosen professor of logic, metaphysics, and Greek, in the university of Reggio, in the year 1745, where he taught during ten years, devoting every moment of his leisure time to the study and contemplation of the works of nature. The attention of Haller and Bonnet was fixed by his observations on the animalculæ of infusions, the latter assisting him in his laudable career, and ever after distinguishing him as one of the learned interpreters of nature.

Spallanzani was invited to the university of Modena in the year 1760, and some years after he declined to accept of the offers made to him by the academy of Petersburgh, as well as similar ones from Coimbra, Parma, and Cesena, though extremely advantageous. He preferred his native spot, and therefore continued at Modena till the year 1768, and saw raised up by his care a generation of men constituting at that time the glory of Italy, among whom we find Venturi, Belloni, Lucchesini, and Angelo Mazzo.

While Spallanzani remained at Modena, he published his *Saggio di Osservazioni Microscopiche concernente il Systema di Needham e Buffon*, in 1765, in which he establishes, by a number of the most ingenious and solid experiments, the *animality of microscopic animalculæ*. This work was sent by the author to Bonnet, who drew from it a prediction respecting the future celebrity of Spallanzani, which he lived to see accomplished. This circumstance gave birth to the most intimate friendship, which lasted to the close of life, and constituted their chief happiness. During the same year he published a truly original work, entitled *De Lapidibus ab aqua resilientibus*, in which he proves, in opposition to the commonly received opinion, by the most satisfactory experiments, that what are called *ducks* and *drakes*, are not produced by the elasticity of the water, but by the effect naturally resulting from the change of direction experienced by the stone in its movement, after it has struck the water, and that it has been carried over the hollow of the cup formed by the concussion.

When the university of Padua was re-established upon a larger scale, the Count de Firmian was directed by the empress Maria Theresa, to invite Spallanzani to be professor of natural history, to which his great reputation made him competent, although it was solicited by many celebrated characters; and he merited it by his success, as immense crowds of students thronged to his lectures. He had a fine genius, and his knowledge was of vast extent; his method was simple, but rigorous in its nature, and what he knew he connected with principles firmly established. He acquired the valuable art of interpreting nature by herself, which diffused such a light over his lectures, that every thing became perspicuous, which could be said to afford any instruction. His discourses were plain and animated, and the elegance and purity of his style charmed every hearer. He prepared his lectures a year before-hand, and it was his chief aim to render them useful in an eminent degree. His new observations made them always new and engaging. Many learned persons who attended his lectures were not above becoming his scholars, in order to acquire a more extensive knowledge of what they knew before, and to learn that which otherwise they might probably never have known. The *Contemplation de la Nature* of Bonnet was his text book, the vacancies of which he ably filled up, fully explained the ideas, and established the theories by his own experiments. This work was translated by him into the Italian language, and he added much to its value by notes of his own, the first volume of which he published in 1769, and the second the following year.

His connection with Bonnet tended, in a great measure, to influence his genius, which yielded to the severe method of investigation adopted by the philosopher of Geneva. He was proud of being the pupil of such an illustrious character, upon whose writings he incessantly bestowed every leisure moment, and thus became anxious to learn from Nature herself the proofs of Bonnet's sentiments respecting the generation of organized bodies, the pleasing nature of which research captivated his attention for a considerable time.

The first two volumes of this work, entitled *Opusculi di Fisica Animale e Vegetabile*, were published in the year 1776, containing the explanation of part of the microscopic observations which were previously given to the world.

If it must be admitted that the art of accurate observation

Spallanzani.

tion is by far the most difficult, it cannot be denied that it is at the same time the most necessary, and requires the most brilliant talents and abilities, which were possessed by Spallanzani in a remarkable degree, as is fully evinced by all his researches and all his admirable writings.

The polite manner in which he conducted his dispute with Needham respecting the phenomena of generation, secured for him a high degree of applause. On this occasion he treated of the influence of cold upon animals, and proved that the torpidity of some during winter, does not depend on the impression the blood may receive from it, since a frog deprived of blood, becomes torpid when reduced to the same cold state by being immersed in ice, and swims as formerly when restored to a proper degree of warmth.

Spallanzani travelled through Switzerland and the Grisons in the year 1779, after which he went to Geneva, spending a month with his friends, by whom his conversation was as much admired as his masterly writings. From this place he returned to Pavia, and in 1780 published two more volumes of his *Dissertazione di Fisica Animale e Vegetabile*, wherein he unfolded the secrets of the interpretation of two very intricate phenomena, concerning the economy of animals and vegetables. He was led to this study from some experiments made by him upon *digestion*, for his lectures; and he repeated the experiments of Reaumur on gallinaceous birds, remarking that the trituration which in this case is favourable to digestion, could not be a very powerful means. He perceived that the gizzard of those birds, by which the stones of fruit are pulverized, did not digest the powder thus formed, it being necessary that it should undergo a new operation in the stomach, previous to its becoming chyle for the production of the blood and other humours.

This subject may be regarded as one of the most difficult in physiology, because the observer is always under the necessity of acting and looking in the midst of darkness; the animal must be managed with care, that the derangement of the operations may be avoided; and when the experiments are completed with great labour, it is requisite that the consequences be well distinguished. Spallanzani in this work is truly enchanting, analysing facts with scrupulosity, in order to ascertain their causes with certainty; comparing Nature with his experiments, in order to form a correct judgment respecting them; laying hold of every thing essential to them in his observations, and measuring their solidity by the increase or diminution of supposed causes.

Mr John Hunter appears to have been greatly hurt by this work, which led him to publish, in the year 1785, *Some Observations upon Digestion*, in which he threw out some bitter sarcasms against the Italian naturalist, who took ample revenge by publishing this work in the Italian language, and addressing to Caldani in 1788, *Una Lettera Apologetica in Risposta alle Osservazione del Signor Giovanni Hunter*. In this he exposed with great moderation, but at the same time with logic which nothing could resist, the mistakes and errors of the British physiologist, leaving the power of a reply altogether hopeless.

The generation of animals and plants is treated of in the second volume of this last-mentioned work, in which he proves the pre-existence of germs to fecundation, by experiments as satisfactory as surprising; shewing also the existence of tadpoles in the females of five different species of frogs, in salamanders, and toads, before their fecundation. He likewise recounts the success of some artificial fecundations upon the tadpoles of those five species, and even upon a quadruped.

In the year 1781, he took the advantage of the academical vacation, for the purpose of making a journey, in order to add to the cabinet of Pavia. He set out for Marseilles in the month of July that year, where he began a new history of the sea, which presented him with many new and curious facts on numerous genera of the natives of the ocean. He went also to Finale, Genoa, Massa, and Carrara, to make observations on the quarries of marble, held by statuaries in such estimation. He then returned to Spezzia, and brought from thence to Pavia a vast number of fishes, which he deposited in the cabinet of that city, wholly collected by himself. With the same view and success he visited the coasts of Istria in 1782, and the Apennine mountains the subsequent year, taking notice of the dreadful hurricanes, and the astonishing vapours by which that year became so noted in meteorology. The emperor Joseph, on examining this cabinet, presented Spallanzani with a gold medal. In 1785, he was offered the chair of natural history by the university of Padua, vacant by the death of Anthony Vallisnieri; but in order to prevent his acceptance of it, his salary was doubled by the archduke, and he went to Constantinople with Chevalier Zuliani, who had been appointed ambassador from the Venetian republic. He set out on the 21st of August, and reached the Turkish metropolis on the 11th of October, where he remained during eleven months. His attention was fixed by the physical and moral phenomena of this country, which were new even to Spallanzani. He strayed along the borders of the two seas, and ascended the mountains in the vicinity; he paid a visit to the island of Chalki, discovering to the Turks a copper mine, the existence of which they had never once conjectured. He discovered an iron mine not far from Constantinople, in the island of Principi, of which the Turks were equally ignorant, and prepared to return for Italy on the 16th of August 1786.

A voyage by sea was undoubtedly the safest, but the dangers to which he would be exposed by land were regarded as nothing when contrasted with the idea of being beneficial to science and to man. Having reached Bucharest, Mauroceni the friend of science, received Spallanzani with marks of distinction, presented him with many rarities which the country produced, and gave him horses for travelling, with an escort of 30 troopers, to the utmost confines of his own dominions. Our philosopher passed by Hermanstadt in Transylvania, and reached Vienna on the 7th of December, where he remained during five days, and had two long conferences with the emperor Joseph II. was much esteemed by the nobility of that city, and respectfully visited by many literary characters. When he arrived at Pavia, the students went out of the city gates to meet him, and testified their joy at his return by repeated acclamations. He was almost instantly drawn to the auditory, and compelled to ascend the chair from which he had been accustomed to deliver his fascinating lectures; but their demonstrations of joy and shouts of applause made him request of them to give over, and indulge him with that

that repose in his own house which was now so absolutely necessary. His students this year exceeded 500.

So extensive was the fame of Spallanzani become by this time, that envy was determined, if possible, to wound his reputation. If his discoveries were too new, solid, and original, to be successfully disputed, that vile passion, or rather *fiend*, began to question his integrity and uprightness respecting the administration of the cabinet of Pavia; but this iniquitous attempt to tarnish his honour, only made it shine forth with redoubled splendour. The juridical examination of the tribunals made his integrity appear even purer than before; and it must be mentioned to his honour, that he had the fortitude to forget this event; his enemies in general confessed their mistake, renounced their unprovoked animosity, and still hoped to regain a friendship of which they had proved themselves so unworthy.

In the voyage of Spallanzani we meet with what may be denominated a new volcanology. We are there instructed how to measure the intensity of volcanic fires, and in his analysis of the lava, almost to touch the particular gas which tears those torrents of stone in fusion from the bowels of the earth, and raises them to the top of Mount Etna. This delightful work is closed by some important enquiries into the nature of swallows, the mildness of their dispositions, the rapidity of their flight; discussing the celebrated problem respecting their remaining torpid during the winter season; proving that artificial cold, much more intense than what is ever naturally experienced in our climates, does not reduce these birds to the torpid state.

Things apparently impossible were often discovered by Spallanzani. In the year 1795 he made one of this description, which he gave to the world in his *Lettere sopra il sopetto d'un nuovo senso nei Pippistrelli*. In that work we are informed that bats, if deprived of sight, act with the same precision in every instance as those which have their eyes; that they shun in the same manner the most trivial obstacles, and also know where to fix themselves when their flight is terminated. Several philosophers confirmed these astonishing experiments, from which a suspicion arose, that these animals must have a new sense, as it appeared to Spallanzani that the other known senses could not compensate for the want of sight; but he was afterwards inclined to think, in consequence of Professor Jurine's experiments on the organ of hearing in bats, that in this particular instance the sense of hearing might possibly supply the want of sight.

The literary career of this celebrated naturalist was terminated by a letter to Giobert, entitled *Sopra la piante chiuse ne vasi dentro l'aqua e l'aria, esposte a l'immediata lume solare e a l'ombra*. These numerous works, which met with the highest approbation, do not comprehend the whole of his multifarious labours; for the phenomena of respiration had occupied his attention a considerable time; their points of resemblance and dissimilitude in many species of animals; and he had nearly finished his voyage to Constantinople, as well as collected many valuable materials for a history of the sea, when his life and labours were unfortunately terminated.

He was seized with a retention of urine on the 4th of February 1799, and next morning was deprived of the regular use of his faculties, only enjoying a sound mind during very short intervals. Tourdes and Professor Scarpa did every thing to save him, which could be produced by the joint exertions of genius, experience, and friendship, but in vain. He died on the 17th; but we know not what credit is due to the assertion, that he edified those around him during his last moments by his *piety*. Be that as it may, while his works exist to speak for themselves, impartial posterity will regard him as a very extraordinary man. These works have been translated into almost every European language, and he was admitted a member of the academies and learned societies of London, Stockholm, Gottingen, Holland, Lyons, Bologna, Turin, Padua, Mantua, and Geneva, and he received from Frederick the Great the diploma of member of the academy of Berlin.

SPAN, a measure taken from the space between the thumb and the tip of the little finger when both are stretched out. The span is estimated at three handsbreadths or nine inches.

SPANDRELL, the solid work on each haunch of an arch, to keep it from spreading.

SPANHEIM, Ezekiel, a learned writer in the 17th century, was born at Geneva in 1629; and in 1642 went to Leyden to study. Here he distinguished himself to great advantage; and his reputation spreading, Charles Louis elector palatine sent for him to be tutor to his only son. This task our author discharged to the entire satisfaction of the elector; by whom he was also employed in divers negotiations at foreign courts. He afterwards entered into the service of the elector of Brandenburg, who in 1680 sent him envoy extraordinary to the court of France, and soon after made him a minister of state. After the peace of Ryswic, he was again sent on an embassy to France, where he continued from the year 1697 to 1702. The elector of Brandenburg having during that interval assumed the title of *King of Prussia*, conferred on him the title and dignity of a baron. In 1702 he left France; and went ambassador to England, where he had been several times. Here he died in 1710, aged 81 years. It is surprising, that in discharging the duties of a public minister with so much exactness, and amidst so many different journeys, he could find time enough to write the several books published by him. It may be said of him, that he acquitted himself in his negotiations like a person who had nothing else in his thoughts; and that he wrote like a man who had spent his whole time in his study. The principal of his works are, 1. *De præstantia et usu numismatum antiquorum*; the best edition of which is in two volumes folio. 2. Several letters or dissertations on scarce and curious medals. 3. A preface and notes to the edition of the emperor Julian's works, printed at Leipsic in 1696, folio.

SPANIEL, in *Zoology*. See Canis, Mammalia *Index*.

SPAR, in *Mineralogy*, a name given chiefly to some of the crystallized combinations of lime, as the carbonate and the fluate; the former being called simply *lime spar*, the latter fluor spar, or Derbyshire spar, from the name of the place where it is found in greatest abundance. See Mineralogy.

SPARTA, or LACEDÆMON, the capital of the country of Laconia in Greece, an ancient and most renowned state, the inhabitants of which have been in all ages celebrated for the singularity of their laws and character.—The history of Sparta for many ages is entirely fabulous; and the authentic accounts commence only with the celebrated lawgiver Lycurgus, who flourished about 870 B. C. See the article LYCURGUS.

1 The history of Sparta mostly fabulous till the time of Lycurgus.

After his death, the first important transaction which we find mentioned in the Spartan history is the Messenian war, which commenced in the year 752 B. C. and ended in the total reduction of the Messenian territory, as related under the article MESSENIA. During this period, according to some authors, a great change took place in the government of Sparta. This was the creation of the ephori, which is ascribed to one of the kings named *Theopompus*. This man perceiving that there was a necessity for leaving magistrates to execute the laws, when the kings were obliged to be in the field, appointed the magistrates above mentioned, who afterwards made so great a figure in the state (see EPHORI). One great privilege of the ephori was, that they did not rise up at the presence of the kings, as all other magistrates did: another was, that if the kings offended against the laws, the ephori took cognizance of the offence, and inflicted a suitable punishment. From the first election of the ephori, the year was denominated, as at Athens from the first election of the archons.

The conquest of Messenia gave Sparta the superiority over the rest of the states, excepting only that of Athens, which for a long time continued to be a very troublesome rival: but the contests between these two rival states have been so fully related under the article ATTICA, that nothing more is requisite to be added in this place.—In the time of the Persian war, Leonidas the Spartan king, distinguished himself in such a manner as to become the admiration not only of that but of every succeeding age. It being resolved in a general council to defend the straits of Thermopylæ against the Persians, 7000 * foot were put under the command of Leonidas: of whom, however, only 300 were Spartans. Leonidas did not think it practicable to defend the pass against such multitudes as the Persian king commanded; and therefore privately told his friends, that his design was to devote himself to death for his country.

2 Leonidas undertakes to defend the straits of Thermopylæ against the Persians.

* See *Anacharsis's Travels*, vol. i. p. 468.

Xerxes advancing near the straits, was strangely surprised to find that the Greeks were resolved to dispute his passage; for he had always flattered himself, that on his approach they would betake themselves to flight, and not attempt to oppose his innumerable forces. However, Xerxes still entertaining some hopes of their flight, waited four days without undertaking any thing, on purpose to give them time to retreat. During this time, he used his utmost endeavours to gain and corrupt Leonidas, promising to make him master of all Greece if he would come over to his interest. His offers being rejected with contempt and indignation, the king ordered him by a herald to deliver up his arms. Leonidas, in a style and with a spirit truly laconical, answered, "Come thyself, and take them." Xerxes, at this reply, transported with rage, commanded the Medes and Cissians to march against them, take them all alive, and bring them to him in fetters. The Medes, not able to stand the shock of the Greeks, soon betook themselves to flight: and in their room Hydarnes was ordered to advance with that body which was called *Immortal*, and consisted of 10,000 chosen men; but when these came to close with the Greeks, they succeeded no better than the Medes and Cissians, being obliged to retire with great slaughter. The next day the Persians, reflecting on the small number of their enemies, and supposing so many of them to be wounded that they could not possibly maintain a second fight, resolved to make another attempt; but could not by any efforts make the Greeks give way: on the contrary, they were themselves put to a shameful flight. The valour of the Greeks exerted itself on this occasion in a manner so extraordinary, that Xerxes is said to have three times leaped from his throne, apprehending the entire destruction of his army.

Sparta. 3 The Persians repulsed with great slaughter.

Xerxes having lost all hopes of forcing his way through troops that were determined to conquer or die, was extremely perplexed and doubtful what measures he should take in this posture of affairs; when one Epialtes, in expectation of a great reward, came to him, and discovered a secret passage to the top of the hill which overlooked and commanded the Spartan forces. The king immediately ordered Hydarnes thither with his select body of 10,000 Persians; who marching all night, arrived at break of day, and possessed themselves of that advantageous post. The Phocæans, who defended this pass, being overpowered by the enemy's numbers, retired with precipitation to the very top of the mountain, prepared to die gallantly. But Hydarnes, neglecting to pursue them, marched down the mountain with all possible expedition, in order to attack those who defended the straits in the rear. Leonidas being now apprised that it was impossible to bear up against the enemy, obliged the rest of his allies to retire: but he staid himself, with the Thespians, Thebans, and 300 Lacedæmonians, all resolved to die with their leader; who being told by the oracle, that either Sparta should be destroyed or the king lose his life, determined without the least hesitation to sacrifice himself for his country. The Thebans indeed remained against their inclination, being detained by Leonidas as hostages; for they were suspected to favour the Persians. The Thespians, with their leader Demophilus, could not by any means be prevailed upon to abandon Leonidas and the Spartans. The augur Megistias, who had foretold the event of this enterprise, being pressed by Leonidas to retire, sent home his only son; but remained himself, and died by Leonidas. Those who staid did not feed themselves with any hopes of conquering or escaping, but looked upon Thermopylæ as their graves; and when Leonidas, exhorting them to take some nourishment, said, that they should

4 They are shown a way over the hill to surround the Greeks.

Sparta.

should all sup together with Pluto, with one accord they set up a shout of joy, as if they had been invited to a banquet.

5
Leonidas killed with all his men.

Xerxes, after pouring out a libation at the rising of the sun, began to move with the whole body of his army, as he had been advised by Epialtes. Upon their approach, Leonidas advanced to the broadest part of the passage, and fell upon the enemy with such undaunted courage and resolution, that the Persian officers were obliged to stand behind the divisions they commanded, in order to prevent the flight of their men. Great numbers of the enemy falling into the sea, were drowned; others were trampled under foot by their own men, and a great many killed by the Greeks; who knowing they could not avoid death upon the arrival of those who were advancing to fall upon their rear, exerted their utmost efforts. In this action fell the brave Leonidas; which Abrocomes and Hyperanthes, two of the brothers of Xerxes, observing, advanced with great resolution to seize his body, and carry it in triumph to Xerxes. But the Lacedæmonians, more eager to defend it than their own lives, repulsed the enemy four times, killed both the brothers of Xerxes, with many other commanders of distinction, and rescued the body of their beloved general out of the enemy's hands. But in the mean time, the army that was led by the treacherous Epialtes, advancing to attack their rear, they retired to the narrowest place of the passage, and drawing altogether, except the Thebans, posted themselves on a rising ground. In this place they made head against the Persians, who poured in upon them on all sides, till at length, not vanquished, but oppressed and overwhelmed by numbers, they all fell, except one who escaped to Sparta, where he was treated as a coward and traitor to his country; but afterwards made a glorious reparation in the battle of Platæa, where he distinguished himself in an extraordinary manner. Some time after, a magnificent monument was erected at Thermopylæ, in honour of those brave defenders of Greece, with two inscriptions; the one general, and relating to all those who died on this occasion, importing, that the Greeks of Peloponnesus to the number only of 4000, made head against the Persian army, consisting of 3,000,000. The other related to the Spartans in particular, and was composed by the poet Simonides, to this purport: "Go, passenger, and acquaint the Spartans that we died here in obedience to their just commands." At those tombs a funeral oration was yearly pronounced in honour of the dead heroes, and public games performed with great solemnity, wherein none but the Lacedæmonians and Thespians had any share, to show that they alone were concerned in the glorious defence of Thermopylæ.

6
A dreadful earthquake in Sparta.

At the end of the 77th Olympiad, a most dreadful earthquake happened at Sparta, in which, according to Diodorus, 20,000 persons lost their lives; and Plutarch tells us, that only five houses were left standing in the whole city. On this occasion the Helotes or slaves, whom the Spartans had all along treated with the utmost cruelty, attempted to revenge themselves, by taking up arms, and marching directly to the ruins of the city, in hopes of cutting off at once those who had escaped from the earthquake. But in this they were prevented by the prudence of the Spartan king Archidamus; for he, observing that the citizens were more desirous of preserving their effects than taking care of their own lives, caused an alarm to be sounded, as if he had known that an enemy was at hand. On this the citizens armed themselves in haste with such weapons as they could come at; and having marched a little way from the city, met the Helotes, whom they soon compelled to retire. The latter, however, knowing that they had now no mercy to expect from those who had already treated them with such cruelty, resolved to defend themselves to the last. Having therefore seized a sea-port town in Messenia, they from thence made such incursions into the Spartan territories, that they compelled those imperious masters to ask assistance from the Athenians. This was immediately granted; but when the Spartans saw that the skill of the Athenians in besieging towns was much greater than their own, they became jealous, and dismissed their allies, telling them that they had now no farther occasion for their services. On this the Athenians left them in disgust; and as the Helotes and Messenians did not choose to come to an engagement with a Spartan army in the field, but took shelter in their fortified places, the war was protracted for ten years and upwards. At last the Helotes were reduced to their former misery; and the Messenians were obliged to leave Peloponnesus, on pain of being made slaves also. These poor people were then received by the Athenians, who granted them Naupactus for their residence, and afterwards brought them back to a part of their own country, from whence in the course of the Peloponnesian war they had driven the Spartans.

7
War with the Helotes.

8
With the Athenians and Persians.

In the year 431 B. C. the Peloponnesian war commenced; of which a full account has been given under the article ATTICA, N° 116—165. It ended most unfortunately for the Athenians; their city being taken and dismantled, as related in the article above mentioned. Thus were the Spartans raised to the highest pitch of glory; and in the reign of Agesilaus, they seemed to be on the point of subverting the Persian empire, as related under the article PERSIA, N° 34. But here their good fortune and their views of empire were suddenly checked. Agesilaus had carried on the war in Asia with the greatest success; and as he would hearken to no terms of accommodation, a Persian governor named *Tithraustes*, having first attempted in vain to bribe the king, dispatched Timocrates the Rhodian with 50 talents into Greece, in order to try whether he could there meet with any persons less incorruptible than the Spartan monarch. This agent found many who inclined to accept his offers; particularly in Thebes, Corinth, and Argos. By distributing the money in a proper manner, he inflamed the inhabitants of these three cities against the Spartans; and of all others the Thebans came into his terms with the greatest readiness. They saw that their antagonists would not of their own accord break with any of the states of Greece, and did not choose to begin the war themselves, because the chiefs of the Persian faction were unwilling to be accountable for the event. For this reason they persuaded the Locrians to invade a small district which lay in dispute betwixt the Phocians and themselves. On this the Phocians invaded Locris; the Locrians applied to the Thebans, and the Phocians to the Spartans. The latter were glad of an opportunity of breaking with the Thebans; but met with a much warmer reception than they expected. Their old general Lysander, who had reduced

9
A general combination against Sparta.

reduced Athens, was defeated and killed, with the loss of 1000 men: on which disaster Agesilaus was recalled, and obliged to relinquish all hopes of conquering the Persians. His return changed the fortune of the war so much, that all the states began to grow weary of a contest from which nobody derived any advantage except the king of Persia. In a short time a treaty was concluded, known in history by the name of the *peace of Antalcidas*. The terms of this treaty were highly disadvantageous and dishonourable to the Greeks*; for even the Spartans, though successful in Greece, had lost a great battle at sea with the Persian fleet under Conon the Athenian, which entirely broke their power in Asia.

10
Peace of Antalcidas.

* See Persia, N° 37.

By the peace of Antalcidas, the government of Bœotia was taken from the Thebans, which they had for a long time enjoyed; and by this they were so much provoked, that at first they absolutely refused to accede to the treaty; but as Agesilaus made great preparations to invade them, they thought proper at last to comply. However, it was not long before a new war commenced, which threatened the total subversion of the Spartan state. As, by the peace of Antalcidas, the king of Persia had in a manner guaranteed the sovereignty of Greece to Sparta, this republic very soon began to exercise its power to the utmost extent. The Mantineans were the first who felt the weight of their resentment, although they had been their allies and confederates. In order to have a pretence for making war against them, they commanded them to quit their city, and to retire into five old villages which, they said, had served their forefathers, and where they would live in peace themselves, and give no umbrage to their neighbours. This being refused, an army was sent against them to besiege their city. The siege was continued through the summer with very little success on the part of the Spartans; but having during the winter season dammed up the river on which the city stood, the water rose to such a height, as either to overflow or throw down the houses; which compelled the Mantineans to submit to the terms prescribed to them, and to retire into the old villages. The Spartan vengeance fell next on the Phliasians and Olynthians, whom they forced to come into such measures as they thought proper. After this they fell on the Thebans, and, by attempting to seize on the Piræum, drew the Athenians also into the quarrel. But here their career was stopped: the Thebans had been taught the art of war by Chabrias the Athenian; so that even Agesilaus himself took the command of the Spartan army in vain. At sea they were defeated by Timotheus the son of Conon; and by land the battle of Leuctra put an end to the superiority which Sparta had held over Greece for near 500 years. See Leuctra.

11
Hostilities recommenced.

12
The power of Sparta entirely broken.

After this dreadful defeat, the Spartans had occasion to exert all their courage and resolution. The women and nearest relations of those who were killed in battle, instead of spending their time in lamentations, shook each other by the hand, while the relations of those who had escaped from the battle hid themselves among the women; or if they were obliged to go abroad, they appeared in tattered clothes, with their arms folded, and their eyes fixed on the ground. It was a law among the Spartans, that such as fled from battle should be degraded from their honours, should he constrained to appear in garments patched with divers colours, to wear their beards half-shaved, and to suffer any to beat them who pleased, without resistance. At present, however, this law was dispensed with; and Agesilaus by his prudent conduct kept up the spirits of the people, at the same time that by his skill in military affairs he checked the progress of the enemy. Yet, during the lifetime of Epaminondas the Theban general, the war went on greatly to the disadvantage of the Spartans; but he being killed at the battle of Mantinea, all parties became quickly desirous of peace. Agesilaus did not long survive; and with him, we may say, perished the glory of Sparta. Soon after this all the states of Greece fell under the power of Alexander the Great; and the Spartans, as well as the rest, having become corrupt, and lost their martial spirit, became a prey to domestic tyrants, and to foreign invaders. They maintained their ground, however, with great resolution against the celebrated Pyrrhus king of Epirus; whom they repulsed for three days successively, though not without assistance from one of the captains of Antigonus. Soon after this, one of the kings of Sparta named *Agis*, perceiving the universal degeneracy that had taken place, made an attempt to restore the laws and discipline of Lycurgus, by which he supposed the state would be restored to its former glory. But though at first he met with some appearance of success, he was in a short time tried and condemned by the ephori as a traitor to his country. Cleomenes, however, who ascended the throne in 216 B. C. accomplished the reformation which Agis had attempted in vain. He suppressed the ephori; cancelled all debts; divided the lands equally, as they had been in the time of Lycurgus; and put an end to the luxury which prevailed among the citizens. But at last he was overborne by the number of enemies which surrounded him; and being defeated in battle by Antigonus, he fled to Egypt, where he put an end to his own life. With him perished every hope of retrieving the affairs of Sparta: the city for the present fell into the hands of Antigonus; after which a succession of tyrants took place; till at last all disturbances were ended by the Romans, who reduced Macedon and Greece to provinces of their empire, as has been related under these articles.

13
Agis and Cleomenes attempt in vain to restore it.

It remains now only to say something concerning the character, manners, and customs of the Spartans, which, as they were founded on the laws of Lycurgus, may best be learned from a view of these laws.

14
Institutions of Lycurgus.

The institutions of Lycurgus were divided into 12 tables. The first comprehended such of the Spartan laws as regarded religion. The statues of all the gods and goddesses were represented in armour, even to Venus herself; the reason of which was, that the people might conceive a military life the most noble and honourable, and not attribute, as other nations did, sloth and luxury to the gods. As to sacrifices, they consisted of things of very small value; for which Lycurgus himself gave this reason, That want might never hinder them from worshipping the gods. They were forbidden to make long or rash prayers to the heavenly powers, and were enjoined to ask no more than that they might live honestly and discharge their duty. Graves were permitted to be made within the bounds of the city, contrary to the custom of most of the Greek nations; nay, they buried close by their temples, that all degrees of

15
His laws concerning religion.

Sparta. of people might be made familiar with death, and not conceive it such a dreadful thing as it was generally esteemed elsewhere: on the same account, the touching dead bodies, or assisting at funerals, made none unclean, but were held to be as innocent and honourable duties as any other. There was nothing thrown into the grave with the dead body; magnificent sepulchres were forbidden; neither was there so much as an inscription, however plain or modest, permitted. Tears, sighs, outcries, were not allowed in public, because they were thought dishonourable in Spartans, whom their lawgiver would have to bear all things with equanimity. Mourning was limited to 11 days; on the 12th the mourner sacrificed to Ceres, and threw aside his weeds. In favour of such as were slain in the wars, however, and of women who devoted themselves to a religious life, there was an exception allowed as to the rules before mentioned; for such had a short and decent inscription on their tombs. When a number of Spartans fell in battle, at a distance from their country, many of them were buried together under one common tomb; but if they fell on the frontiers of their own state, then their bodies were carefully carried back to Sparta, and interred in their family sepulchres.

16 Concerning the division of land.

II. Lycurgus divided all the country of Laconia into 30,000 equal shares: the city of Sparta he divided into 9000 as some say; into 6000, as others say; and as a third party will have it, into 4500. The intent of the legislator was, that property should be equally divided among his citizens, so that none might be powerful enough to oppress his fellows, or any be in such necessity, as to be therefrom in danger of corruption. With the same view he forbade the buying or selling these possessions. If a stranger acquired a right to any of these shares, he might quietly enjoy it, provided he submitted to the laws of the republic. The city of Sparta was unwalled; Lycurgus trusting it rather to the virtue of its citizens than to the art of masons. As to the houses, they were very plain; for their ceilings could only be wrought by the axe, and their gates and doors only by the saw; and their utensils were to be of a like stamp, that luxury might have no instruments among them.

Of the citizens, children, &c.

III. The citizens were to be neither more nor less than the number of city lots; and if at any time there happened to be more, they were to be led out in colonies. As to children, their laws were equally harsh and unreasonable; for a father was directed to carry his new-born infant to a certain place, where the gravest men of his tribe looked upon the infant; and if they perceived its limbs straight, and thought it had a wholesome look, they then returned it to its parents to be educated; otherwise it was thrown into a deep cavern at the foot of the mountain Taygetus. This law seems to have had one very good effect, viz. making women very careful, when they were with child, of either eating, drinking or exercising, to excess; it made them also excellent nurses; for which they were in mighty request throughout Greece. Strangers were not allowed to reside long in the city, that they might not corrupt the Spartans by teaching them new customs. Citizens were also forbidden to travel, for the same reason, unless the good of the state required it. Such as were not bred up in their youth according to the law, were not allowed the liberty of the city, because they held it unreasonable, that one who had not submitted to the laws in his youth should receive the benefit of them when a man. They never preferred any stranger to a public office; but if at any time they had occasion for a person not born a Spartan, they first made him a citizen, and then preferred him.

18 Of celibacy and marriage.

IV. Celibacy in men was infamous, and punished in a most extraordinary manner; for the old bachelor was constrained to walk naked, in the depth of winter, through the market-place: while he did this, he was obliged to sing a song in disparagement of himself; and he had none of the honours paid him which otherwise belonged to old age, it being held unreasonable, that the youth should venerate him who was resolved to leave none of his progeny behind him, to revere them when they grew old in their turn. The time of marriage was also fixed; and if a man did not marry when he was of full age, he was liable to an action; as were such also as married above or below themselves. Such as had three children had great immunities; such as had four were free from all taxes whatsoever. Virgins were married without portions; because neither want should hinder a man, nor riches induce him, to marry contrary to his inclinations. When a marriage was agreed on, the husband committed a kind of rape upon his bride. Husbands went for a long time, secretly and by stealth, to the beds of their wives, that their love might not be quickly and easily extinguished. Husbands were allowed to lend their wives; but the kings were forbidden to take this liberty. Some other laws of the like nature there were, which as they were evidently against modesty, so they were far from producing the end for which Lycurgus designed them; since, though the men of Sparta were generally remarkable for their virtue, the Spartan women were as generally decried for their boldness and contempt of decency.

19 Education of their children.

V. It was the care of Lycurgus, that, from their very birth, the Lacedæmonians should be inured to conquer their appetites: for this reason he directed, that nurses should accustom their children to spare meals, and now and then to fasting; that they should carry them, when 12 or 13 years old, to those who should examine their education, and who should carefully observe whether they were able to be in the dark alone, and whether they had got over all other follies and weaknesses incident to children. He directed, that children of all ranks should be brought up in the same way; and that none should be more favoured in food than another, that they might not, even in their infancy, perceive any difference between poverty and riches, but consider each other as equals, and even as brethren, to whom the same portions were assigned, and who, through the course of their lives, were to fare alike: the youths alone were allowed to eat flesh: older men ate their black broth and pulse; the lads slept together in chambers, and after a manner somewhat resembling that still in use in Turkey for the Janizaries: their beds, in the summer, were very hard, being composed of the reeds plucked by the hand from the banks of the Eurotas: in winter their beds were softer, but by no means downy, or fit to indulge immoderate sleep. They ate altogether in public; and in case any abstained from coming to the tables, they were fined. It was likewise strictly forbidden for any to eat or drink at home before they came to the common meal; even then each

Sparta.

each had his proper portion, that every thing might be done there with gravity and decency. The black broth was the great rarity of the Spartans, which was composed of salt, vinegar, blood, &c. so that in our times, it would be esteemed a very unsavoury soup. If they were moderate in their eating, they were so in their drinking also; thirst was the sole measure thereof; and never any Lacedæmonian thought of drinking for pleasure: as for drunkenness, it was both infamous and severely punished; and, that young men might perceive the reason, slaves were compelled to drink to excess, that the beastliness of the vice might appear. When they retired from the public meal, they were not allowed any torches or lights, because it was expected, that men who were perfectly sober should be able to find their way in the dark: and besides, it gave them a facility of marching without light; a thing wonderfully useful to them in time of war.

20 Of their diet, clothing, &c.

VI. As the poor ate as well as the rich, so the rich could wear nothing better than the poor: they neither changed their fashion nor the materials of their garments; they were made for warmth and strength, not for gallantry and show: and to this custom even their kings conformed, who wore nothing gaudy in right of their dignity, but were contented that their virtue should distinguish them rather than their clothes. The youths wore a tunic till they were twelve years old; afterwards they had a cloak given them, which was to serve them a year; and their clothing was, in general, so thin, that a Lacedæmonian vest became proverbial. Boys were always used to go without shoes; but when they grew up, they were indulged with them, if the manner of life they led required it; but they were always inured to run without them, as also to climb up and slip down steep places with bare feet: nay, the very shoe they used was of a particular form, plain and strong. Boys were not permitted to wear their hair; but when they arrived at the age of twenty, they suffered their hair and beard to grow. Baths and anointing were not much in use among the Lacedæmonians; the river Eurotas supplied the former, and exercise the latter. In the field, however, their sumptuary laws did not take place so strictly as in the city; for when they went to war, they wore purple habits; they put on crowns when they were about to engage the enemy; they had also rings, but they were of iron; which metal was most esteemed by this nation. Young women wore their vests or jerkins only to their knees, or, as some think, not quite so low; a custom which both Greek and Roman authors censure as indecent. Gold, precious stones, and other costly ornaments, were permitted only to common women; which permission was the strongest prohibition to women of virtue, or who affected to be thought virtuous. Virgins went abroad without veils, with which married women, on the contrary were always covered. In certain public exercises, in which girls were admitted as well as boys, they were both obliged to perform naked. Plutarch apologises for this custom, urging, that there could be no danger from nakedness to the morals of youth whose minds were fortified and habituated to virtue One of Lycurgus's principal views in his institutions, was to eradicate the very seeds of civil dissension in his republic. Hence proceeded the equal division of estates enjoined by him; hence the contempt of wealth, and the neglect of other distinctions, as particularly birth, he considering the people of his whole state as one great family; distinctions which, in other commonwealths, frequently produce tumults and confusions that shake their very foundation.

21 Obedience to their superiors.

VII. Though the Spartans were always free, yet it was with this restriction, that they were subservient to their own laws, which bound them as strictly in the city, as soldiers, in other states, were bound by the rules of war in the camp. In the first place, strict obedience to their superiors was the great thing required in Sparta. This they looked upon as the very basis of government; without which neither laws nor magistrates availed much. Old age was an indubitable title to honour in Sparta: to the old men the youth rose up whenever they came into any public place; they gave way to them when they met them in the streets, and were silent whenever their elders spoke. As all children were looked upon as the children of the state, so all the old men had the authority of parents: they reprehended whatever they saw amiss, not only in their own, but in other people's children: and by this method Lycurgus provided, that as youth are everywhere apt to offend, they might be nowhere without a monitor. The laws went still farther: if an old man was present where a young one committed a fault, and did not reprove him, he was punished equally with the delinquent. Amongst the youths there was one of their own body, or at most two years older than the rest, who was styled *iren:* he had authority to question all their actions, to look strictly to their behaviour, and to punish them if they did amiss; neither were their punishments light, but, on the contrary, very severe; whereby the youth were made hardy, and accustomed to bear stripes and rough usage. Silence was a thing highly commended at Sparta, where modesty was held to be a most becoming virtue in young people; nor was it restrained only to their words and actions, but to their very looks and gestures; Lycurgus having particularly directed, that they should look forward, or on the ground, and that they should always keep their hands within their robes. A stupid inconsiderate person, one who would not listen to instruction, but was careless of whatever the world might say of him, the Lacedæmonians treated as a scandal to human nature; with such a one they would not converse, but threw him off as a rotten branch and worthless member of society.

22 Learning.

VIII. The plainness of their manners, and their being so very much addicted to war, made the Lacedæmonians less fond of the sciences than the rest of the Greeks. A soldier was the only reputable profession in Sparta; a mechanic or husbandman was thought a low fellow. The reason of this was, that they imagined professions which required much labour, some constant posture, being continually in the house, or always about a fire, weakened the body and depressed the mind: whereas a man brought up hardily, was equally fit to attend the service of the republic in time of peace, and to fight its battles when engaged in war. Such occupations as were necessary to be followed for the benefit of the whole, as husbandry, agriculture, and the like, were left to their slaves the Helotes; but for curious arts, and such as served only to luxury, they would not so much as suffer them to be introduced in their city; in consequence of which, rhetoricians, augurs,

Sparta.

gurs, bankers, and dealers in money, were shut out. The Spartans admitted not any of the theatrical diversions among them; they would not bear the representation of evil even to produce good; but other kinds of poetry were admitted, provided the magistrates had the perusal of pieces before they were handed to the public.

Above all things, they affected brevity of speech, and accustomed their children, from their very infancy, never to express themselves in more words than were strictly necessary; whence a concise and sententious oratory is to this day styled *Laconic*. In writing they used the some conciseness; of which we have a signal instance in a letter of Archidamus to the Eleans, when he understood that they had some thoughts of assisting the Arcadians. It ran thus: "Archidamus to the Eleans: It is good to be quiet." And therefore Epaminondas thought that he had reason to glory in having forced the Spartans to abandon their monosyllables, and to lengthen their discourses.

The greatest part of their education consisted in giving their youth right ideas of men and things: the iren or master proposed questions, and either commended the answers that were made him, or reproved such as answered weakly. In these questions, all matters, either of a trivial or abstruse nature, were equally avoided; and they were confined to such points as were of the highest importance in civil life; such as, Who was the best man in the city? wherein lay the merit of such an action? and, Whether this or that hero's fame was well-founded? Harmless raillery was greatly encouraged; and this, joined to their short manner of speaking, rendered laconic replies universally admired.

Music was much encouraged; but in this, as in other things, they adhered to that which had been in favour with their ancestors; nay, they were so strict therein, that they would not permit their slaves to learn either the tune or the words of their most admired odes; or, which is all one, they would not permit them to sing them if they had learned them. Though the youth of the male sex were much cherished and beloved, as those that were to build up and continue the future glory of the state, yet in Sparta it was a virtuous and modest affection, untinged with that sensuality which was so scandalous at Athens. The good effects of this part of Lycurgus's institutions were seen in the union that reigned among his citizens; and which was so extraordinary, that even in cases of competition, it was hardly known that rivals bore ill-will to each other; but, on the contrary, their love to the same person begat a secondary friendship among themselves, and united them in all things which might be for the benefit of the person beloved.

Some authors have accused this great lawgiver of encouraging theft in his institutions; which, they say, was not held scandalous among the Spartans, if it were so dexterously managed as that the person was not detected in it. But this is certain, and seems to be a strong contradiction of the heinous charge, that when a theft was discovered, it was punished with the utmost severity: a person even suspected of it would endure the heaviest punishments rather than acknowledge it, and be branded with so base a crime.

23 Exercises.

IX. The exercises instituted by law fall under the ninth table. In these all the Greeks were extremely careful, but the Lacedæmonians in a degree beyond the rest; for if a youth, by his corpulence, or any other means, became unfit for these exercises, he underwent public contempt at least, if not banishment.—Hunting was the usual diversion of their children; nay, it was made a part of their education, because it had a tendency to strengthen their limbs, and to render those who practised it supple and fleet: they likewise bred up dogs for hunting with great care. They had a kind of public dances, in which they exceedingly delighted, and which were common alike to virgins and young men: indeed, in all their sports, girls were allowed to divert themselves with the youths: insomuch, that, at darting, throwing the quoit, pitching the bar, and such like robust diversions, the women were as dexterous as the men. For the manifest oddity of this proceeding, Lycurgus assigned no other reason, than that he sought to render women, as well as men, strong and healthy, that the children they brought forth might be so too. Violent exercises, and a laborious kind of life, were only enjoined the youth; for when they were grown up to men's estate, that is, were upwards of 30 years old, they were exempted from all kinds of labour, and employed themselves wholly either in affairs of state or in war. They had a method of whipping, at a certain time, young men in the temple of Diana, and about her altar; which, however palliated, was certainly unnatural and cruel. It was esteemed a great honour to sustain these flagellations without weeping, groaning, or showing any sense of pain; and the thirst of glory was so strong in these young minds, that they very frequently suffered death without shedding a tear or breathing a sigh. A desire of overcoming all the weaknesses of human nature, and thereby rendering his Spartans not only superior to their neighbours, but to their species, runs through many of the institutions of Lycurgus; which principle, if well attended to, thoroughly explains them, and without attending to which it is impossible to give any account of them at all.

X. Gold and silver were, by the constitutions of Lycurgus, made of no value in Sparta. He was so well apprized of the danger of riches, that he made the very possession of them venal; but as there was no living without some sort of money, that is, some common measure or standard of the worth of things, he directed an iron coinage, whereby the Spartans were supplied with the useful money, and at the same time had no temptation to covetousness afforded them; for a very small sum was sufficient to load a couple of horses, and a great one must have been kept in a barn or warehouse. The introduction of all foreign money was also prohibited, that corruption might not enter under the name of commerce. The most ancient method of dealing, viz. by barter, or exchange of one commodity for another, was preserved by law in Sparta long after it had gone into disuse everywhere else. Interest was a thing forbidden in the Spartan commonwealth; where they had also a law against alienation of lands, accepting presents from foreigners, even without the limits of their own country, and when their authority and character might well seem to excuse them. 24 Money, &c.

XI. Such of the laws of Sparta as related to courts of justice may be brought under the 11th table. Thirty years must have passed over the head of him who had a right to concern himself in juridical proceedings. 25 Courts of justice.

Young

Young men were thought unfit for them; and it was even held indecent, and of ill report, for a man to have any fondness for law-suits, or to be busying himself at the tribunals, when he had no affairs there of his own. By these rules Lycurgus thought to shut out litigiousness, and to prevent that multiplicity of suits which is always scandalous in a state. As young people were not permitted to inquire about the laws of other countries, and as they were hindered from hearing judicial proceedings in their courts, so they were likewise forbidden to ask any questions about, or to endeavour to discover, the reasons of the laws by which themselves were governed. Obedience was their duty; and to that alone they would have them kept. Men of abandoned characters, or who were notoriously of ill fame, lost all right of giving their votes in respect of public affairs, or of speaking in public assemblies; for they would not believe that an ill man in private life could mean his country better than he did his neighbour.

26 Military service.

XII. Till a man was 30 years old, he was not capable of serving in the army, as the best authors agree: though some think that the military age is not well ascertained by ancient writers. They were forbidden to march at any time before the full-moon; the reason of which law is very hard to be discovered, if indeed it had any reason at all, or was not rather founded on some superstitious opinion, that this was a more lucky conjuncture than any other. They were likewise forbidden to fight often against the same enemy; which was one of the wisest maxims in the political system of Lycurgus: and Agesilaus, by offending against it, destroyed the power of his country, and lost her that authority which for many ages she maintained over the rest of Greece; for, by continually warring against the Thebans, to whom he had an inveterate hatred, he at last beat them into the knowledge of the art of war, and enabled them, under the command of Epaminondas, to maintain for a time the principality of Greece. Maritime affairs they were forbidden to meddle with, though the necessity of things compelled them, in process of time, to transgress this institution, and by degrees to transfer to themselves the dominion of the sea as well as of the land: but, after the Peloponnesian war, they again neglected naval affairs, from a persuasion that sailors and strangers corrupted those with whom they conversed. As they never fortified Sparta, they were not ready to undertake sieges: fighting in the field was their proper province, and, while they could overcome their enemies there, they rightly conceived that nothing could hurt them at home. In time of war they relaxed somewhat of their strict manner of living, in which they were singular. The true reason for this was, in all probability, that war might be less burdensome to them; for, as we have more than once observed, a strong desire to render them bold and warlike was the reigning passion of their legislator. They were forbidden to remain long encamped in the same place, as well to hinder their being surprised, as that they might be more troublesome to their enemies, by wasting every corner of their country. They slept all night in their armour; but their outguards were not allowed their shields, that, being unprovided of defence, they might not dare to sleep. In all expeditions they were careful in the performance of religious rites; and, after their evening meal was over, the soldiers sung together hymns to their gods. When they were about to engage, the king sacrificed to the muses, that, by their assistance, they might be enabled to perform deeds worthy of being recorded to latest times. Then the army advanced in order to the sound of flutes, which played the hymn of Castor. The king himself sung the pæan, which was the signal to charge. This was done with all the solemnity imaginable; and the soldiers were sure either to conquer or die: indeed they had no other choice; for if they fled they were infamous, and in danger of being slain, even by their own mothers, for disgracing their families. In this consisted all the excellency of the Spartan women, who, if possible, exceeded in bravery the men, never lamenting over husbands or sons, if they died honourably in the field; but deploring the shame brought on their house, if either the one or the other escaped by flight. The throwing away a shield also induced infamy; and, with respect to this, mothers, when they embraced their departing sons, were wont to caution them, that they should either return armed as they were, or be brought back so when they were dead; for, as we have observed, such as were slain in battle were nevertheless buried in their own country. When they made their enemies fly, they pursued no longer than till victory was certain; because they would seem to fight rather for the honour of conquering, than of putting their enemies to death. According to their excellent rules of war, they were bound not to spoil the dead bodies of their enemies; but in process of time, this, and indeed many other of their most excellent regulations, fell into desuetude. He who overcame by stratagem, offered up an ox to Mars; whereas he who conquered by force, offered up only a cock; the former being esteemed more manly than the latter. After 40 years service, a man was, by law, no longer required to go into the field; and consequently, if the military age was 30, the Spartans were not held invalids till they were 70.

SPARTIANUS, Ælius, a Latin historian, who wrote the lives of Adrian, Caracalla, and four other Roman emperors. He lived under the reign of Dioclesian, about the year 290.

SPARTIUM, Broom, a genus of plants belonging to the class of diadelphia, and order of decandria; and in the natural system arranged under the 32d order, *Papilionaceæ*. See Botany *Index*.

The flower buds are in some countries pickled, and eaten as capers; and the seeds have been used as a bad substitute for coffee. The branches are used for making besoms, and tanning leather. They are also used instead of thatch to cover houses. The old wood furnishes the cabinet-maker with beautiful materials for vaneering. The tender branches are in some places mixed with hops for brewing, and the macerated bark may be manufactured into cloth.

The *junceum*, or Spanish broom, grows naturally in the southern provinces of France, as well as in other parts of the south of Europe. It grows in the poorest soils, on the steepest declivities of the hills, in a stony soil, where hardly any other plant could vegetate. In a few years it makes a vigorous shrub; insinuating its roots between the interstices of the stones, it binds the soil, and retains the small portion of vegetable earth scattered over these hills, which the autumnal rains would otherwise

Journal de Physique.

wise wash away. It is most easily raised from seed, which is usually sown in January, after the ground has received a slight dressing.

The shrub serves two useful purposes. Its branches yield a thread of which linen is made, and in winter support sheep and goats.

In manufacturing thread from broom, the youngest plants are cut in the month of August, or after harvest, and gathered together in bundles, which at first are laid in the sun to dry; they are then beaten with a piece of wood, washed in a river or pond, and left to steep in the water for about four hours. The bundles thus prepared are taken to a little distance from the water, and laid in a hollow place made for them, where they are covered with fern or straw, and remain thus to steep for eight or nine days; during which time, all that is necessary, is to throw a little water once a-day on the heap, without uncovering the broom. After this, the bundles are well washed, the green rind of the plant or epidermis comes off, and the fibrous part remains; each bundle is then beaten with a wooden hammer upon a stone, to detach all the threads, which are at the same time carefully drawn to the extremity of the branches. After this operation, the faggots are untied, and spread upon stones or rocks till they are dry. The twigs must not be peeled till they are perfectly dry; they are then dressed with the comb, and the threads are separated according to the fineness, and spun upon a wheel.

The linen made of this thread serves various purposes in rural economy. The coarsest is employed in making sacks and other strong cloths for carrying grain or seeds. Of the finest is made bed, table, and body linen. The peasants in several places use no other, for they are unacquainted with the culture of hemp or flax, their soil being too dry and too barren for raising them. The cloth made with the thread of the broom is very useful; it is as soft as that made of hemp; and it would perhaps look as well as that made of flax if it was more carefully spun. It becomes white in proportion as it is steeped. The price of the finest thread, when it is sold, which seldom happens, is generally about a shilling a pound.

The other use to which this broom is applied, is to maintain sheep and goats during winter. In the mountains of Lower Languedoc these animals have no other food from November to April, except the leaves of trees preserved. The branches of this broom therefore are a resource the more precious, that it is the only fresh nourishment which at that season the flocks can procure, and they prefer it at all times to every other plant. In fine weather the sheep are led out to feed on the broom where it grows; but in bad weather the shepherds cut the branches, and bring them to the sheep folds. There is, however, an inconvenience attending the continued use of this food. It generally produces inflammation in the urinary passages. But this inconvenience is easily removed by cooling drink, or a change of food, or by mixing the broom with something else.

It is perhaps needless to add, that it differs much from the broom that is common everywhere in the north of Europe, though this too, in many places, is used for food to cattle. Both of them produce flowers that are very much resorted to by bees, as they contain a great quantity of honey juice. And this should be another inducement to the cultivation of the Spanish broom.

SPARUS, Gilthead, a genus of fishes belonging to the order of *thoracici*. See Ichthyology *Index*. The sparus auratus, or gilthead, was well known to the Romans, who did not esteem them unless they were fed with Lucrine oysters, as Martial informs us,

Non omnis laudem pretiumque Aurata *meretur,*
Sed qui solus erit concha Lucrina cibus.
Lib. xiii. Ep. 90.

SPASM, a convulsion. See Medicine, N° 278.

SPATHA, in *Botany*, a sheath; a species of calyx which bursts lengthwise, and protrudes a stalk supporting one or more flowers, which commonly have no perianthium or flower-cup.

SPATHACEÆ (from *spatha*, "a sheath"), the name of the ninth order in Linnæus's Fragments of a Natural Method, consisting of plants whose flowers are protruded from a spatha or sheath. See Botany *Index*.

SPATHELIA, a genus of plants belonging to the class of pentandria, and to the order of trigynia. See Botany *Index*.

SPAW. See Spa.

SPAWN, in *Natural History*, the eggs of fishes or frogs.

SPAVENTO. See Scanto.

SPAVIN, in the manege, a disease in horses, being a swelling or stiffness, usually in the ham, occasioning a lameness. See Farriery *Index*.

SPAYING, or Spading, the operation of castrating the females of several kinds of animals, as sows, bitches, &c. to prevent any further conception, and promote their fattening. It is performed by cutting them in the mid flank, on the left side, with a sharp knife or lancet, taking out the ovaries, and cutting them off, and so stitching up the wound, anointing the part with tar, and keeping the animal warm for two or three days. The usual way is to make the incision a-slope, two inches and half long; that the fore-finger may be put in towards the back, to feel for the ovaries, which are two kernels as big as acorns on both sides of the uterus, one of which is drawn to the wound, and thus both taken out.

SPEAKER *of the House of Commons*, a member of the house elected by a majority of votes thereof to act as chairman or president in putting questions, reading briefs, or bills, keeping order, reprimanding the refractory, adjourning the house, &c. See Parliament.

SPEAKING, the art or act of expressing one's thoughts in articulate sounds or words. See Grammar, Language, Reading, and Oratory, Part iv.

Speaking-Trumpet. See Trumpet.

SPEAR-Mint. See Mentha, Botany *Index*.

Spear-Wort. See Ranunculus, Botany *Index*.

SPECIAL, something that is particular, or has a particular designation; from the Latin *species*, in opposition to the *general*, from *genus*.

SPECIES, in *Logic*, a relative term, expressing an idea which is comprised under some general one called a *genus*. See Logic, N° 68.

Species, in *Commerce*, the several pieces of gold, silver, copper, &c. which having passed their full

 preparation

preparation and coinage, are current in public. See MONEY.

SPECIES, in *Algebra*, are the letters, symbols, marks, or characters, which represent the quantities in any operation or equation. This short and advantageous way of notation was chiefly introduced by Vieta, about the year 1590; and by means of it be made many discoveries in algebra, not before taken notice of.

SPECIES, in *Optics*, the image painted on the retina by the rays of light reflected from the several points of the surface of an object, received by the pupil, and collected in their passage through the crystalline, &c.

It has been a matter of dispute among philosophers, whether the species of objects which give the soul an occasion of seeing, be an effusion of the substance of the body; a mere impression which they make on all bodies under certain circumstances; or whether they are not some more subtile body, such as light. The moderns have decided this point by the invention of artificial eyes, in which the species of objects are received on paper, in the same manner as in the natural eye.

SPECIFIC, in *Philosophy*, that which is peculiar to any thing, and distinguishes it from all others.

SPECIFICS, in *Medicine*. By specifics is not meant such as infallibly and in all patients produce salutary effects. Such medicines are not to be expected, because the operations and effects of remedies are not formally inherent in them, but depend upon the mutual action and reaction of the body and medicine upon each other; hence the various effects of the same medicine in the same kind of disorders in different patients, and in the same patient at different times. By specific medicines we understand such medicines as are found to be more uniform in their effects than others in any particular disorder.

SPECIFIC Gravity, is a term much employed in the discussions of modern physics. It expresses the weight of any particular kind of matter, as compared with the weight of the same bulk of some other body of which the weight is supposed to be familiarly known, and is therefore taken for the standard of comparison. The body generally made use of for this purpose is pure water.

The specific gravity of bodies is a very interesting question both to the philosopher and to the man of business. The philosopher considers the weights of bodies as measures of the number of material atoms, or the quantity of matter which they contain. This he does on the supposition that every atom of matter is of the same weight, whatever may be its sensible form. This supposition, however, is made by him with caution, and he has recourse to specific gravity for ascertaining its truth in various ways. This shall be considered by and by. The man of business entertains no doubt of the matter, and proceeds on it as a sure guide in his most interesting transactions. We measure commodities of various kinds by tons, pounds, and ounces, in the same manner as we measure them by yards, feet, and inches, or by bushels, gallons, and pints; nay, we do this with much greater confidence, and prefer this measurement to all others, whenever we are much interested to know the exact proportions of matter that bodies contain. The weight of a quantity of grain is allowed to inform us much more exactly of its real quantity of useful matter than the most accurate measure of its bulk. We see many circumstances which can vary the bulk of a quantity of matter, and these are frequently such as we cannot regulate or prevent; but we know very few indeed that can make any sensible change in this weight without the addition or abstraction of other matter. Even taking it to the summit of a high mountain, or from the equator to the polar region, will make no change in its weight as it is ascertained by the balance, because there is the same real diminution of weight in the pounds and ounces used in the examination.

Notwithstanding the unavoidable change which heat and cold make in the bulk of bodies, and the permanent varieties of the same kind of matter which are caused by different circumstances of growth, texture, &c. most kinds of matter have a certain constancy in the density of their particles, and therefore in the weight of a given bulk. Thus the purity of gold, and its degree of adulteration, may be inferred from its weight, it being purer in proportion as it is more dense. The density, therefore, of different kinds of tangible matter becomes characteristic of the kind, and a test of its purity; it marks a particular appearance in which matter exists, and may therefore be called, with propriety, SPECIFIC.

But this density cannot be directly observed. It is not by comparing the distances between the atoms of matter in gold and in water that we say the first is 19 times denser than the last, and that an inch of gold contains 19 times as many material atoms as an inch of water; we reckon on the equal gravitation of every atom of matter whether of gold or of water; therefore the weight of any body becomes the indication of its material density, and the weight of a given bulk becomes specific of that kind of matter, marking its kind, and even ascertaining its purity in this form.

It is evident that, in order to make this comparison of general use, the standard must be familiarly known, and must be very uniform in its density, and the comparison of bulk and density must be easy and accurate. The most obvious method would be to form, with all nicety, a piece of the standard matter of some convenient bulk, and to weigh it very exactly, and keep a note of its weight: then, to make the comparison of any other substance, it must be made into a mass of the same precise bulk, and weighed with equal care; and the most convenient way of expressing the specific gravity would be to consider the weight of the standard as unity, and then the number expressing the specific gravity is the number of times that the weight of the standard is contained in that of the other substance. This comparison is most easily and accurately made in fluids. We have only to make a vessel of known dimensions equal to that of the standard which we employ, and to weigh it when empty, and then when filled with the fluid. Nay, the most difficult part of the process, the making a vessel of the precise dimensions of the standard, may be avoided, by using some fluid substance for a standard. Any vessel will then do; and we may ensure very great accuracy by using a vessel with a slender neck, such as a phial or matrass; for when this is filled to a certain mark in the neck, any error in the estimation by the eye will bear a very small proportion to the whole. The weight of the standard fluid which fills it to this mark being carefully ascertained, is kept in remembrance. The specific gravity of any other fluid is had by weighing the contents of this vessel when filled with it, and dividing

Specific Gravity.

dividing the weight by the weight of the standard. The quotient is the specific gravity of the fluid. But in all other cases this is a very difficult problem: it requires very nice hands, and an accurate eye, to make two bodies of the same bulk. An error of one hundredth part in the linear dimensions of a solid body makes an error of a 30th part in its bulk; and bodies of irregular shapes and friable substance, such as the ores of metals, cannot be brought into convenient and exact dimensions for measurement.

From all these inconveniences and difficulties we are freed by the celebrated Archimedes, who, from the principles of hydrostatics discovered or established by him, deduced the accurate and easy method which is now universally practised for discovering the specific gravity and density of bodies. (See ARCHIMEDES and HYDRODYNAMICS). Instead of measuring the bulk of the body by that of the displaced fluid (which would have been impossible for Archimedes to do with any thing like the necessary precision), we have only to observe the loss of weight sustained by the solid. This can be done with great ease and exactness. Whatever may be the bulk of the body, this loss of weight is the weight of an equal bulk of the fluid; and we obtain the specific gravity of the body by simply dividing its whole weight by the weight lost: the quotient is the specific gravity when this fluid is taken for the standard, even though we should not know the absolute weight of any given bulk of this standard. It also gives us an easy and accurate method of ascertaining even this fundamental point. We have only to form any solid body into an exact cube, sphere, or prism, of known dimensions, and observe what weight it loses when immersed in this standard fluid. This is the weight of the same bulk of the standard to be kept in remembrance; and thus we obtain, by the bye, a most easy and accurate method for measuring the bulk or solid contents of any body, however irregular its shape may be. We have only to see how much weight it loses in the standard fluid; we can compute what quantity of the standard fluid will have this weight. Thus should we find that a quantity of sand, or a furze bush, loses 250 ounces when immersed in pure water, we learn by this that the solid measure of every grain of the sand, or of every twig and prickle of the furze, when added into one sum, amounts to the fourth part of a cubic foot, or to 432 cubic inches.

To all these advantages of the Archimedean method of ascertaining the specific gravity of bodies, derived from his hydrostatical doctrines and discoveries, we may add, that the immediate standard of comparison, namely, water, is, of all the substances that we know, the fittest for the purpose of an universal standard of reference. In its ordinary natural state it is sufficiently constant and uniform in its weight for every examination where the utmost mathematical accuracy is not wanted; all its variations arise from impurities, from which it may at at times be separated by the simple process of distillation: and we have every reason to think that when pure, its density, when of the same temperature, is invariable.

Water is therefore universally taken for the unit of that scale on which we measure the specific gravity of bodies, and its weight is called 1. The specific gravity of any other body is the real weight in pounds and ounces, when of the bulk of one pound or one ounce of water. It is therefore of the first importance, in all discussions respecting the specific gravity of bodies, to have the precise weight of some known bulk of pure water. We have taken some pains to examine and compare the experiments on this subject, and shall endeavour to ascertain this point with the precision which it deserves. We shall reduce all to the English cubic foot and avoirdupois ounce of the Exchequer standard, on account of a very convenient circumstance peculiar to this unit, viz. that a cubic foot contains almost precisely a thousand ounces of pure water, so that the specific gravity of bodies expresses the number of such ounces contained in a cubic foot.

We begin with a trial made before the house of commons in 1696 by Mr Everard. He weighed 2145.6 cubic inches of water by a balance, which turned sensibly with 6 grains, when there were 30 pounds in each scale. The weights employed were the troy weights, in the deposit of the Court of Exchequer, which are still preserved, and have been most scrupulously examined and compared with each other. The weight was 1131 ounces 14 pennyweights. This wants just 11 grains of a thousand avoirdupois ounces for 1728 cubic inches, or a cubic foot; and it would have amounted to that weight had it been a degree or two colder. The temperature indeed is not mentioned; but as the trial was made in a comfortable room, we may presume the temperature to have been about 55° of Fahrenheit's thermometer. The dimensions of the vessel were as accurate as the nice hand of Mr Abraham Sharp, Mr Flamstead's assistant at Greenwich, could execute, and it was made by the Exchequer standard of length.

This is confided in by the naturalists of Europe as a very accurate standard experiment, and it is confirmed by many others both private and public. The standards of weight and capacity employed in the experiment are still in existence, and publicly known, by the report of the Royal Society to parliament in 1742, and by the report of a committee of the house of commons in 1758. This gives it a superiority over all the measures which have come to our knowledge.

The first experiment, made with proper attention, that we meet with, is by the celebrated Snellius, about the year 1615, and related in his *Eratosthenes Batavus.* He weighed a Rhinland cubic foot of distilled water, and found it 62.79 Amsterdam pounds. If this was the ordinary weight of the shops, containing 7626 English troy grains, the English cubic foot must be 62 pounds 9 ounces, only one ounce more than by Everard's experiment. If it was the Mint pound, the weight was 62 pounds 6 ounces. The only other trials which can come into competition with Mr Everard's are some made by the Academy of Sciences at Paris. Picart, in 1691, found the Paris cubic foot of water of the fountain d'Arcueil to weigh 69.588 pounds, *poids de Paris.* Du Hamel obtained the very same result; but Mr Monge, in 1783, says that filtered rain-water of the temperature 12° (Reaumur) weighs 69.3792. Both these measures are considerably below Mr Everard's, which is 62.5, the former giving 62.053, and the latter 61.868. M. Lavoisier states the Paris cubic foot at 70 pounds, which makes the English foot 62.47. But there is an inconsistency

Specific Gravity.

sistency among them which makes the comparison impossible. Some changes were made in 1688, by royal authority, in the national standards, both of weight and length; and the academicians are exceedingly puzzled to this day in reconciling the differences, and cannot even ascertain with perfect assurance the lineal measures which were employed in their most boasted geodetical operations.

Such variations in the measurements made by persons of reputation for judgment and accuracy engaged the writer of this article some years ago to attempt another. A vessel was made of a cylindrical form, as being more easily executed with accuracy, whose height and diameter were 6 inches, taken from a most accurate copy of the Exchequer standard. It was weighed in distilled water of the temperature 55° several times without varying 2 grains, and it lost 42895 grains. This gives for the cubic foot 998.74 ounces, deficient from Mr Everard's an ounce and a quarter; a difference which may be expected, since Mr Everard used the New River water without distillation.

We hope that these observations will not be thought superfluous in a matter of such continual reference, in the most interesting questions both to the philosopher and the man of business; and that the determination which we have given will be considered as sufficiently authenticated.

Let us, therefore, for the future take water for the standard, and suppose that, when of the ordinary temperature of summer, and in its state of greatest natural purity, viz. in clean rain or snow, an English cubic foot of it weighs a thousand avoirdupois ounces of 437.5 troy grains each. Divide the weight of any body by the weight of an equal bulk of water, the quotient is the specific gravity of that body; and if the three first figures of the decimal be accounted integers, the quotient is the number of avoirdupois ounces in a cubic foot of the body. Thus the specific gravity of the very finest gold which the refiner can produce is 19.365, and a cubic foot of it weighs 19365 ounces.

But an important remark must be made here. All bodies of homogeneous or unorganised texture expand by heat, and contract by cooling. The expansion and contraction by the same change of temperature is very different in different bodies. Thus water, when heated from 60° to 100°, increases its volume nearly $\frac{1}{167}$ of its bulk, and mercury only $\frac{1}{243}$, and many substances much less. Hence it follows, that an experiment determines the specific gravity only in that very temperature in which the bodies are examined. It will therefore be proper always to note this temperature; and it will be convenient to adopt some very useful temperature for such trials in general: perhaps about 60° of Fahrenheit's thermometer is as convenient as any. It may always be procured in these climates without inconvenience. A temperature near to freezing would have some advantages, because water changes its bulk very little between the temperature 32° and 45°. But this temperature cannot always be obtained. It will much conduce to the facility of the comparison to know the variation which heat produces on pure water. The following table, taken from the observations of Dr Blagden and Mr Gilpin (Phil. Trans. 1792) will answer this purpose.

Temperature of Water.	Bulk of Water.	Specific Gravity
30		
35	99910	1.00090
40	99070	1.00094
45	99914	1.00086
50	99932	1.00068
55	99962	1.00038
60	100000	1.00000
65	100050	0.99950
70	100106	0.99894
75	100171	0.99830
80	100242	0.99759
85	100320	0.99681
90	100404	0.99598
95	100501	0.99502
100	100602	0.99402

Those gentlemen observed the expansion of water to be very anomalous between 32° and 45°. This is distinctly seen during the gradual cooling of water to the point of freezing. It contracts for a while, and then suddenly expands. But we seldom have occasion to measure specific gravities in such temperature.

The reader is now sufficiently acquainted with the principles of this hydrostatical method of determining the specific gravity of bodies, and can judge of the propriety of the forms which may be proposed for the experiment.

The specific gravity of a fluid may be determined either by filling with it a vessel with a narrow neck, or by weighing a solid body that is immersed in it. It is hard to say which is the best way. The last is not subject to any error in filling, because we may suspend the solid by a fine wire, which will not displace any sensible quantity of the fluid; and if the solid is but a little heavier than the fluid, the balance being loaded only with the excess, will be very sensible to the smallest want of equilibrium. But this advantage is perhaps compensated by an obstruction to the motion of the solid up or down in the fluid, arising from viscidity. When the weight in the opposite scale is yet too small, we slowly add more, and at last grain by grain, which gradually brings the beam to the level. When it is exactly level, the weight in the scale is somewhat too great; for it not only balances the preponderance of the solid, but also the viscidity of the fluid. But we may get rid of this error. Add a small quantity more; this will bring the beam over to the other side. Now put as much into the scale on the same side with the solid; this will not restore the beam to its level. We must add more till this be accomplished; and this addition is the measure of the viscidity of the fluid, and must be subtracted from the weight that was in the other scale when the beam came *first* to a level. This effect of viscidity is not insensible, with nice apparatus, even in the purest water, and in many fluids it is very considerable—and, what is worse, it is very changeable. It is greatly diminished by heat; and this is an additional reason for making

making those trials in pretty warm temperatures. But for fluids of which the viscidity is considerable, this method is by no means proper; and we must take the other, and weigh them in a vessel with a narrow neck. Mercury must also be treated in this way, because we have no solid that will sink in it but gold and platina.

It is not so easy as one would imagine to fill a vessel precisely to the same degree upon every trial. But if we do not operate on too small quantities, the unavoidable error may be made altogether insignificant, by having the neck of the vessel very small. If the vessel hold a pound of water, and the neck do not exceed a quarter of an inch (and it will not greatly retard the operation to have it half this size), the examinator must be very careless indeed to err one part in two thousand; and this is perhaps as near as we can come with a balance. We must always recollect that the capacity of the vessel changes by heat, and we must know this variation, and take it into the account. But it is affectation to regard (as Mr Homberg would make us believe that he did) the distension of the vessel by the pressure of the fluid. His experiments of this kind have by no means the consistency with each other that should convince us that he did not commit much greater errors than what arose from distension.

In examining either solids or fluids, we must be careful to free their surface, or that of the vessel in which the fluid is to be weighed, from air, which frequently adheres to it in a peculiar manner, and, by forming a bubble, increases the apparent bulk of the solid, or diminishes the capacity of the vessel. The greatest part of what appears on those occasions seems to have existed in the fluid in a state of chemical union, and to be set at liberty by the superior attraction of the fluid for the contiguous solid body. These air bubbles must be carefully brushed off by hand. All greasy matters must be cleared off for the same reason: they prevent the fluid from coming into contact.

We must be no less careful that no water is imbibed by the solid, which would increase its weight without increasing its bulk. In some cases, however, a very long maceration and imbibition is necessary. Thus, in examining the specific gravity of the fibrous part of vegetables, we should err exceedingly if we imagined it as small as appears at first. We believe that in most plants it is at least as great as water, for after long maceration they sink in it.

It is almost needless to say that the nicest and most sensible balances are necessary for this examination. Balances are even constructed on purpose, and fitted with several pieces of apparatus, which make the examination easy and neat. We have described (see BALANCE) Mr Gravesande's as one of the most convenient of any. His contrivance for observing the fractions of a grain is extremely ingenious and expeditious, especially for detecting the effect of viscidity.

The hydrometer, or areometer, is another instrument for ascertaining the specific gravity of fluids. This very pretty instrument is the invention of a lady, as eminent for intellectual accomplishments as she was admired for her beauty. Hypatia, the learned daughter of the celebrated mathematician Theon of Alexandria, became so eminent for her mathematical knowledge, that she was made public professor of the science in the first school in the world. She wrote a commentary on the works of Apollonius and of Diophantus, and composed Astronomical Tables; all of which are lost. These rare accomplishments, however, could not save her from the fury of the fanatics of Alexandria, who cut her in pieces for having taken an offensive part in a dispute between the governor and patriarch.—We have described some of the most approved of these instruments in the article HYDROMETER, and shall in this place make a few observations on the principles of their construction, not as they are usually made, accommodated to the examination of particular liquors, but as indicators of pure specific gravity. And we must premise, that this would, for many reasons, be the best way of constructing them. The very ingenious contrivances for accommodating them to particular purposes are unavoidably attended with many sources of error, both in their adjustment by the maker and in their use; and all that is gained by a very expensive instrument is the saving the trouble of inspecting a table. A simple scale of specific gravity would expose to no error in construction, because all the weights but one, or all the points of the scale but one, are to be obtained by calculation, which is incomparably more exact than any manual operation, and the table can always be more exact than any complex observation. But a still greater advantage is, that the instruments would by this means be fitted for examining all liquors whatever, whereas at present they are almost useless for any but the one for which they are constructed.

Hydrometers are of two kinds. The most simple and the most delicate are just a substitute for the hydrostatical balance. They consist of a ball (or rather an egg or pear-shaped vessel, which moves more easily through the fluid) A (fig. 1.) having a foot projecting down from it, terminated by another ball B, and a slender stalk or wire above, carrying a little dish C. The whole is made so light as to float in the lightest fluid we are acquainted with; such as vitriolic or muriatic ether, whose specific gravity is only 0.73. This number should be marked on the dish, indicating that this is the specific gravity of the fluid in which the instrument floats, sinking to the point D of the stem. The ball B is made heavy, and the foot is of some length, that the instrument may have stability, and swim erect, even if considerably loaded above; and, for the same reason, it must be made very round, otherwise it will lean to a side. When put into a heavier liquor, its buoyancy will cause it to float with a part of the ball above the surface. Weights are now put into the scale C, till the instrument sink to D. The weight put into the scale, added to the weight of the instrument, is the weight of the displaced fluid. This, compared with the weight of the whole when the instrument is swimming in pure water, gives the specific gravity of the fluid. All trouble of calculation may be avoided by marking the weights with such numbers as shall indicate the specific gravity at once. Thus having loaded the instrument so as to sink it to D in pure water, call the whole weight 1000; then weigh the instrument itself, and say, "as the weight when swimming in water is to its present weight, so is 1000 to a 4th proportional." This is the specific gravity of the liquor which would float the unloaded instrument. Suppose this to be 730. The hydrometer would just float in muriatic ether, and this should be marked on the side. Now make a set of small weights,

Plate cccxcix. fig. 1.

weights, and mark them, not by their weights in grains, but in such units that 270 of them shall be equal to the weight which fits the instrument for pure water.

Suppose that, in order to float this instrument in a certain brandy, there are required 186 in these small weights. This added to 730 gives 916 for the specific gravity, and shows it to be precisely excise proof spirit. Nine weights, viz. 256, 128, 64, 32, 16, 8, 4, 2, 1, will suffice for all liquors from ether to the strongest worts. And that the trouble in changing the weights may be greatly lessened, let a few circles *a*, *b*, *c*, *d*, *e*, be marked on the top of the ball. When we see it float unloaded at the circle C for instance, we know it will require at least 128 to sink it to D on the stem.

If the weights to be added above are considerable, it raises the centre of gravity so much, that a small want of equilibrium, by laying the weights on one side, will produce a great inclination of the instrument, which is unsightly. Instead therefore of making them loose weights, it is proper to make them round plates, with a small hole in the middle, to go on a pin in the middle of the scale. This will keep the instrument always upright. But unless the hydrometer is of a considerable size, it can hardly be made so as to extend from the lightest to the heaviest fluid which we may have occasion to examine, even though we except mercury. Some of the mineral acids are considerably more than twice the weight of ether. When there is such a load at top, the hydrometer is very apt to overset, and inclines with the smallest want of equilibrium. Great size is inconvenient even to the philosopher, because it is not always in his power to operate on a quantity of fluid sufficient to float the instrument. Therefore two, or perhaps three, are necessary for general examination. One may reach from ether to water; another may serve for all liquors of a specific gravity between one and one and a half; and the third, for the mineral acids, may reach from this to two. If each of these be about two solid inches in capacity, we may easily and expeditiously determine the specific gravity within one ten thousandth part of the truth: and this is precision enough for most purposes of science or business.

The chief questions are, 1. To ascertain the specific gravity of an unknown fluid. This needs no farther explanation. 2. To ascertain the proportion of two fluids which are known to be in a mixture. This is done by discovering the specific gravity of the mixture by means of the hydrometer, and then deducing the proportion from a comparison of this with the specific gravities of the ingredients.

In this mode of examination the bulk is always the same; for the hydrometer is immersed in the different fluids to the same depth. Now if an inch, for example, of this bulk is made up of the heaviest fluid, there is an inch wanting of the lightest; and the change made in the weight of the mixture is the difference between the weight of an inch of the heaviest, and of an inch of the lightest ingredients. The number of inches therefore of the heaviest fluid is proportional to the addition made to the weight of the mixture. Therefore let B and b be the bulks of the heaviest and lightest fluids in the bulk β of the mixture; and let D, d, and δ be the densities, or the weights, or the specific gravities (for they are in one ratio) of the heavy fluid, the light fluid, and the mixture (their bulk being that of the hydrometer). We have $\beta = B + b$. The addition which would have been made to the bulk β, if the lightest fluid were changed entirely for the heaviest, would be $D - d$; and the change which is really made is $\delta - d$. Therefore $\beta : b = D - d : \delta - d$. For similar reasons we should have $\beta : B = D - d : D - \delta$; or, in words, "*the difference between the specific gravities of the two fluids, is to the difference between the specific gravities of the mixture and of the lightest fluid, as the bulk of the whole to the bulk of the heaviest contained in the mixture;*" and "*the difference of the specific gravities of the two fluids, is to the difference of the specific gravities of the mixture and of the heaviest fluids, as the bulk of the whole to that of the lightest contained in the mixture.*" This is the form in which the ordinary business of life requires the answer to be expressed, because we generally reckon the quantity of liquors by bulk, in gallons, pints, quarts. But it would have been equally easy to have obtained the answer in pounds and ounces; or it may be had from their bulk, since we know their specific gravities.

The hydrometer more commonly used is the ancient one of Hypatia, consisting of a ball A (fig. 2.) made steady by an addition B, below it like the former, but having a long stem CF above. It is so loaded that it sinks to the top F of the stem in the lightest of all the fluids which we propose to measure with it, and to sink only to C in the heaviest. In a fluid of intermediate specific gravity it will sink to some point between C and F.

In this form of the hydrometer the weight is always the same, and the immediate information given by the instrument is that of different bulks with equal weight. Because the instrument sinks till the bulk of the displaced fluid equals it in weight, and the additions to the displaced fluid are all made by the stem, it is evident that equal bulks of the stem indicate equal additions of volume. Thus the stem becomes a scale of bulks to the same weight.

The only form in which the stem can be made with sufficient accuracy is cylindrical or prismatical. Such a stem may be made in the most accurate manner by wire-drawing, that is, passing it through a hole made in a hardened steel plate. If such a stem be divided into equal parts, it becomes a scale of bulks in arithmetical progression. This is the easiest and most natural division of the scale; but it will not indicate densities, specific gravities, or weights of the same bulk in arithmetical progression. The specific gravity is as the weight divided by the bulk. Now as series of divisors (the bulks), in arithmetical progression, applied to the same dividend (the bulk and weight of the hydrometer as it floats in water), will not give a series of quotients (the specific gravities) in arithmetical progression: they will be in what is called *harmonic progression*, their differences continually diminishing. This will appear even when physically considered. When the hydrometer sinks a tenth of an inch near the top of the stem, it displaces one tenth of an inch of a light fluid, compared with that displaced by it when it is floating with all the stem above the surface. In order therefore that the divisions of the stem may indicate equal changes of specific gravity, they must be in a series of harmonic progressionals increasing. The point at which the instrument floats in pure water should be marked 1000, and those above it 999, 998, 997, &c.; and those

SPECIFIC GRAVITY.

Specific Gravity.

those below the water mark must be numbered 1001, 1002, 1003, &c. Such a scale will be a very apposite picture of the densities of fluids, for the density or vicinity of the divisions will be precisely similar to the density of the fluids. Each interval is a bulk of fluid of the same weight. If the whole instrument were drawn out into wire of the size of the stem, the length from the water mark would be 1000.

Such are the rules by which the scale must be divided. But there must be some points of it determined by experiment, and it will be proper to take them as remote from each other as possible. For this purpose let the instrument be accurately marked at the point where it stands, in two fluids, differing as much in specific gravity as the instrument will admit. Let it also be marked where it stands in water. Then determine with the utmost precision the specific gravities of these fluids, and put their values at the corresponding points of the scale. Then the intermediate points of the scale must be computed for the different intervening specific gravities, or it must be divided from a pattern scale of harmonic progressionals in a way well known to the mathematical instrument-makers. If the specific gravities have been accurately determined, the value 1000 will be found to fall precisely in the water mark. If we attempt the division entirely by experiment, by making a number of fluids of different specific gravities, and marking the stem as it stands in them, we shall find the divisions turn out very anomalous. This is however the way usually practised; and there are few hydrometers, even from the best maker, that hold true to a single division or two. Yet the method by computation is not more troublesome; and one scale of harmonic progressionals will serve to divide every stem that offers. We may make use of a scale of equal parts for the stem, with the assistance of two little tables. One of these contains the specific gravities in harmonic progression, corresponding to the arithmetical scale of bulks on the stem of the hydrometer; the other contains the divisions and fractions of a division of the scale of bulks, which correspond to an arithmetical scale of specific gravities. We believe this to be the best method of all. The scale of equal parts on the stem is so easily made, and the little table is so easily inspected, that it has every advantage of accuracy and dispatch, and it gives, by the way, an amusing view of the relation of the bulks and densities.

We have hitherto supposed a scale extending from the lightest to the heaviest fluid. But unless it be of a very inconvenient length, the divisions must be very minute. Moreover, when the bulk of the stem bears a great proportion to that of the body, the instrument does not swim steady; it is therefore proper to limit the range of the instrument in the same manner as those of the first kind. A range from the density of ether to that of water may be very well executed in an instrument of very moderate size, and two others will do for all the heavier liquors; or an equal range in any other densities as may suit the usual occupations of the experimenter.

To avoid the inconveniences of a hydrometer with a very long and slender stem, or the necessity of having a series of them, a third sort has been contrived, in which the principles of both are combined. Suppose a hydrometer with a stem, whose bulk is $\frac{1}{10}$th of that of the ball, and that it sinks in ether to the top of the stem; it is evident that in a fluid which is $\frac{1}{10}$th heavier, the whole stem will emerge; for the bulk of the displaced fluid is now $\frac{1}{10}$th of the whole less, and the weight is the same as before, and therefore the specific gravity is $\frac{1}{10}$th greater.

Thus we have obtained a hydrometer which will indicate, by means of divisions marked on the stem, all specific gravities from 0.73 to 0.803; for 0.803 is $\frac{1}{10}$th greater than 0.73. These divisions must be made in harmonic progression, as before directed for an entire scale, placing 0.73 at the top of the stem and 0.803 at the bottom.

When it floats at the lowest division, a weight may be put to the top of the stem, which will again sink it to the top. This weight must evidently be 0.073, or $\frac{1}{10}$th of the weight of the fluid displaced by the unloaded instrument. The hydrometer, thus loaded, indicates the same specific gravity, by the top of the stem, that the unloaded instrument indicates by the lowest division. Therefore, when loaded, it will indicate another series of specific gravities, from 0.803 to 0.8833 (=0.803+0.0803), and will float in a liquor of the specific gravity 0.8833 with the whole stem above the surface.

In like manner, if we take off this weight, and put on 1=0.080.3, it will sink the hydrometer to the top of the stem; and with this new weight it will indicate another series of specific gravities from 0.8833 to 0.97163 (=0.8833+0.08833). And, in the same manner, a third weight =08833 will again sink it to the top of the stem, and fit it for another series of specific gravities up to 1.068793. And thus, with three weights, we have procured a hydrometer fitted for all liquors from ether to a wort for a malt liquor of two barrels per quarter. Another weight, in the same progression, will extend the instrument to the strongest wort that is brewed.

This is a very commodious form of the instrument, and is now in very general use for examining spirituous liquors, worts, ales, brines, and many such articles of commerce. But the divisions of the scale are generally adapted to the questions which naturally occur in the business. Thus, in the commerec of strong liquors, it is usual to estimate the article by the quantity of spirit of a certain strength which the liquor contains.—This we have been accustomed to call proof spirit, and it is such that a wine gallon weighs 7 pounds 12 ounces; and it is by this strength that the excise duties are levied. Therefore the divisions on the scale, and the weights which connect the successive repetitions of the scale, are made to express at once the number of gallons or parts of a gallon of proof spirits contained in a gallon of the liquor. Such instruments save all trouble of calculation to the exciseman or dealer; but they limit the use of a very delicate and expensive instrument to a very narrow employment. It would be much better to adhere to the expression either of specific gravity or of bulk; and then a very small table, which could be comprised in the smallest case for the instrument, might render it applicable to every kind of fluid.

The reader cannot but have observed that the successive weights, by which the short scale of the instrument is extended to a great range of specific gravities, do not increase by equal quantities. Each difference is the weight of the liquor displaced by the graduated stem of the instrument when it is sunk to the top of the

the scale. It is a determined aliquot part of the whole weight of the instrument so loaded, (in our example it is always $\frac{1}{11}$th of it). It increases therefore in the same proportion with the preceding weight of the loaded instrument. In short, both the successive additions, and the whole weights of the loaded instrument, are quantities in geometrical progressions; and in like manner, the divisions on the scale, if they correspond to equal differences of specific gravity, must also be unequal.—This is not sufficiently attended to by the makers; and they commit an error here, which is very considerable when the whole range of the instrument is great. For the value of one division of the scale, when the largest weight is on, is as much greater than its value when the instrument is not loaded at all, as the full loaded instrument is heavier than the instrument unloaded. No manner whatever of dividing the scale will correspond to equal differences of specific gravity through the whole range with different weights; but if the divisions are made to indicate equal *proportions* of gravity when the instrument is used without a weight, they will indicate equal *proportions* throughout. This is evident from what we have been just now saying; for the proportion of the specific gravities corresponding to any two immediately succeeding weights is always the same.

The best way, therefore, of constructing the instrument, so that the same divisions of the scale may be accurate in all its successive repetitions with the different weights, is to make these divisions in geometrical progression. The corresponding specific gravities will also be in geometric proportion. These being all inserted in a table, we obtain them with no more trouble than by inspecting the scale which usually accompanies the hydrometer. This table is of the most easy construction; for the ratio of the successive bulks and specific gravities being all equal, the differences of the logarithms are equal.

This will be illustrated by applying it to the example already given of a hydrometer extending from 0.73 to 1.068793 with three weights. This gives four repetitions of the scale on the stem. Suppose this scale divided into 10 parts, we have 40 specific gravities.—Let these be indicated by the numbers 0, 1, 2, 3, &c. to 40. The mark 0 is affixed to the top of the stem, and the divisions downward are marked 1, 2, 3, &c. the lowest being 10. These divisions are easily determined. The stem, which we may suppose 5 inches long, was supposed to be $\frac{1}{10}$th of the capacity of the ball. It may therefore be considered as the extremity of a rod of 11 times its length, or 55 inches, and we must find nine mean proportionals between 50 and 55 inches. Subtract each of these from 55 inches, and the remainders are the distances of the points of division from 0, the top of the scale. The smallest weight is marked 10, the next 20, and the third 30. If the instrument loaded with the weight 20 sinks in some liquor to the mark 7, it indicates the specific gravity 27, that is, the 27th of 40 mean proportionals between 0.73 and 1.068793, or 0.944242. To obtain all these intermediate specific gravities, we have only to subtract 9.8633229, the logarithm of 0.73 from that of 1.068793, viz. 9.0288937, and take 0.0041393, the 40th part of the difference. Multiply this by 1, 2, 3, &c. and add the logarithm of 0.73 to each of the products. The sums are the logarithms of the specific gravities required. These will be found to proceed so equably, that they may be interpolated ten times by a simple table of proportional parts, without the smallest sensible error. Therefore the stem may be divided into a hundred parts very sensible to the eye (each being nearly the 20th of an inch), and 406 degrees of specific gravity obtained within the range, which is as near as we can examine this matter by any hydrometer. Thus the specific gravities corresponding to N° 26, 27, 28, 29, are as follow:

		1st Diff.	2d Diff.
26	0.93529	895	
27	0.94424	904	9
28	0.95328	913	9
29	0.96241		

Nay, the trouble of inspecting a table may be avoided, by forming on a scale the logarithms of the numbers between 7300 and 1068.793, and placing along side of it a scale of the same length divided into 400 equal parts, numbered from 0 to 400. Then, looking for the mark shown by the hydrometer on this scale of equal parts, we see opposite to it the specific gravity.

We have been thus particular in the illustration of this mode of construction, because it is really a beautiful and commodious instrument, which may be of great use both to the naturalist and to the man of business.—A table may be comprised in 20 octavo pages, which will contain the specific gravities of every fluid which can interest either, and answer every question relative to their admixture with as much precision as the observations can be made. We therefore recommend it to our readers, and we recommend the very example which we have given as one of the most convenient. The instrument need not exceed eight inches in length, and may be contained in a pocket case of two inches broad and as many deep, which will also contain the scale, a thermometer, and even the table for applying it to all fluids which have been examined.

It is unfortunate that no graduated hydrometer can be made so easily for the examination of the corrosive mineral acids (A). These must be made of glass, and we cannot depend on the accurate cylindric form of any glass stem. But if any such can be procured, the construction is the same. The divided scale may either be on thin paper pasted on the inside of the stem, or it may be printed on the stem itself from a plate, with ink made of a metallic calx, which will attach itself to the glass with a very moderate heat. We would recommend common white enamel, or arsenical glass, as the fittest material for the whole instrument; and the ink used, in taking the impression of the scale, may be the same that is used for the low-priced printing on Delft ware pottery.—First form the scale on the stem. Then, having measured the solid contents of the graduated part as exactly as possible, and determined on the general shape of

(A It would be worth while to try copper enamelled. See note at page 599. of this volume.

Specific Gravity.

of the ball and counterpoise below, calculate its size, so that it may be a little less than ten times that of the stem. The glass-blower can copy this very nearly, and join it to the stem. Then make two brines or other liquors, which shall have specific gravities in the ratio of 10 to 11. Load the instrument so that it may sink to 0 in the lightest. When put into the heaviest, it should rise to 10. If it does not rise so high, the immersed part is too small. Let the glass-blower enlarge the ball of the counterpoise a little. Repeat this trial till it be exact. Nothing now remains but to form the weights: And here we observe, that when the instrument is to have a very great range, as for examining all states of the vitriolic acid, it has a chance of being very tottering when loaded with the greatest weight on the top of so long a scale. To avoid this, Mr Quin and others have added some of their weights below.—But this will not suit the present construction, because it will alter the proportion between the bulks of the stem and immersed part. Therefore let these weights consist of cylinders of metal small enough to go into the stem, and let them be soldered to the end of long wires, which will let them go to the bottom, and leave a small hook or ring at top. These can lie alongside of the instrument in its case. This is indeed the best construction for every hydrometer, because it makes it incomparably more steady. The instrument is poised by small shot or mercury. But it will be much better to do it with Newton's fusible metal (three parts of tin, five parts of lead, and eight parts of bismuth) in coarse filings. When the exact quantity has been put in, the instrument may be set in a vessel of oil, and this kept on the fire till all is completely melted. It soon freezes again, and remains fast. If this metal is not to be had, let a few bits of sealing-wax be added to the mercury or shot, to make up the counterpoise. When heated, it will float a-top, and when it freezes again it will keep all fast. Thus we shall make a very complete and cheap instrument.

There is yet another method of examining the specific gravities of fluids, first proposed by Dr Wilson, late professor of astronomy in the university of Glasgow. This is by a series of small glass bubbles, differing equally, or according to some rule, from each other in specific gravity, and each marked with its proper number. When these are thrown into a fluid which is to be examined, all those which are heavier than the fluid will fall to the bottom. Then holding the vessel in the hand, or near a fire or candle, the fluid expands, and one of the floating bubbles begins to sink. Its specific gravity, therefore, was either equal to, or a little less than, that of the fluid; and the degree of the thermometer, when it began to sink, will inform us how much it was deficient, if we know the law of expansion of the liquor. Sets of these bubbles fitted for the examination of spirituous liquors, with a little treatise showing the manner of using them, and calculating by the thermometer, are made by Mr Brown, an ingenious artist of Glasgow, and are often used by the dealers in spirits, being found both accurate and expeditious.

Also, though a bubble or two should be broken, the strength of spirits may easily be had by means of the remainder, unless two or three in immediate succession be wanting: for a liquor which answers to N° 4. will sink N° 2. by heating it a few degrees, and therefore N° 3. may be spared. This is a great advantage in ordinary business. A nice hydrometer is not only an expensive instrument, but exceedingly delicate, being so very thin. If broken or even bruised, it is useless, and can hardly be repaired except by the very maker.

As the only question here is, to determine how many gallons of excise proof spirits is contained in a quantity of liquor, the artist has constructed this series of bubbles in the simplest manner possible, by previously making 40 or 50 mixtures of spirits and water, and then adjusting the bubbles to these mixtures. In some sets the number on each bubble is the number of gallons of proof spirits contained in 100 gallons of the liquor. In other sets the number on each bubble expresses the gallons of water which will make a liquor of this strength, if added to 14 gallons of alcohol. Thus, if a liquor answers to N° 4, then 4 gallons of water added to 14 gallons of alcohol will make a liquor of this strength. The first is the best method; for we should be mistaken in supposing that 18 gallons, which answer to N° 4, contains exactly 14 gallons of alcohol: it contains more than 14, for a reason to be given by and by.

By examining the specific gravity of bodies, the philosopher has made some very curious discoveries. The most remarkable of these is the change which the density of bodies suffers by mixture. It is a most reasonable expectation, that when a cubic foot of one substance is mixed *any how* with a cubic foot of another, the bulk of the mixture will be two cubic feet; and that 18 gallons of water joined to 18 gallons of oil will fill a vessel of 36 gallons. Accordingly this was never doubted; and even Archimedes, the most scrupulous of mathematicians, proceeded on this supposition in the solution of his famous problem, the discovery of the proportion of silver and gold in a mixture of both. He does not even mention it as a postulate that *may* be granted him, so much did he conceive it to be an axiom. Yet a little reflection seems sufficient to make it doubtful and to require examination. A box filled with musket balls will receive a considerable quantity of small shot, and after this a considerable quantity of fine sand, and after this a considerable quantity of water. Something like this might happen in the admixture of bodies of porous texture. But such substances as metals, glass, and fluids, where no discontinuity of parts can be perceived, or was suspected, seem free from every chance of this kind of introsusception. Lord Bacon, however, without being a naturalist or mathematician *ex professo*, inferred from the mobility of fluids that they consisted of discrete particles, which must have pores interposed, whatever be their figure. And if we ascribe the different densities, or other sensible qualities, to difference in size or figure of those particles, it must frequently happen that the smaller particles will be lodged in the interstices between the larger, and thus contribute to the weight of the sensible mass without increasing its bulk. He therefore suspects that mixtures will be in general less bulky than the sum of their ingredients.

Accordingly, the examination of this question was one of the first employments of the Royal Society of London, and long before its institution had occupied the attention of the gentlemen who afterwards composed it. The register of the Society's early meetings contains many experiments on this subject, with mixtures of gold and silver, of other metals, and of various fluids,

Specific Gravity.

fluids, examined by the hydrostatical balance of Mr Boyle. Dr Hooke made a prodigious number, chiefly on articles of commerce, which were unfortunately lost in the fire of London.

It was soon found, however, that Lord Bacon's conjecture had been well founded, and that bodies changed their density very sensibly in many cases. In general, it was found that bodies which had a strong chemical affinity increased in density, and that their admixture was accompanied with heat.

By this discovery it is manifest that Archimedes had not solved the problem of detecting the quantity of silver mixed with the gold in King Hiero's crown, and that the physical solution of it requires experiments made on all the kinds of matter that are mixed together. We do not find that this has been done to this day, although we may affirm that there are few questions of more importance. It is a very curious fact in chemistry, and it would be most desirable to be able to reduce it to some general laws: For instance, to ascertain what is the proportion of two ingredients which produces the greatest change of density. This is important in the science of physics, because it gives us considerable information as to the mode of action of those natural powers or forces by which the particles of tangible matter are united. If this introsusception, concentration, compenetration, or by whatever name it be called, were a mere reception of the particles of one substance into the interstices of those of another, it is evident that the greatest concentration would be observed when a small quantity of the recipiend is mixed with, or disseminated through, a great quantity of the other. It is thus that a small quantity of fine sand will be received into the interstices of a quantity of small shot, and will increase the weight of the bagful without increasing its bulk. The case is nowise different when a piece of freestone has grown heavier by imbibing or absorbing a quantity of water. If more than a certain quantity of sand has been added to the small shot, it is no longer concealed. In like manner, various quantities of water may combine with a mass of clay, and increase its size and weight alike. All this is very conceivable, occasioning no difficulty.

But this is not the case in any of the mixtures we are now considering. In all these, the first additions of either of the two substances produce but an inconsiderable change of general density; and it is in general most remarkable, whether it be condensation or rarefaction, when the two ingredients are nearly of equal bulks. We can illustrate even this difference, by reflecting on the imbibition of water by vegetable solids, such as timber. Some kinds of wood have their weight much more increased than their bulks: other kinds of wood are more enlarged in bulk than in weight. The like happens in grains. This is curious, and shows in the most unquestionable manner that the particles of bodies are not in contact, but are kept together by forces which act at a distance. For this distance between the centres of the particles is most evidently susceptible of variation; and this variation is occasioned by the introduction of another substance, which, by acting on the particles by attraction or repulsion, diminishes or increases their mutual actions, and makes new distances necessary for bringing all things again into equilibrium. We refer the curious reader to the ingenious theory of the abbé Boscovich for an excellent illustration of this subject (*Theor. Phil. Nat.* § de Solutione Chemica).

This question is no less important to the man of business. Till we know the condensation of those metals by mixture, we cannot tell the quantity of alloy in gold and silver by means of their specific gravity; nor can we tell the quantity of pure alcohol in any spirituous liquor, or that of the valuable salt in any solution of it. For want of this knowledge, the dealers in gold and silver are obliged to have recourse to the tedious and difficult test of the assay, which cannot be made in all places or by all men. It is therefore much to be wished, that some persons would institute a series of experiments in the most interesting cases: for it must be observed, that this change of density is not always a small matter; it is sometimes very considerable and paradoxical. A remarkable instance may be given of it in the mixture of brass and tin for bells, great guns, optical speculums, &c. The specific gravity of cast brass is nearly 8.006, and that of tin is nearly 7.363. If two parts of brass be mixed with one of tin, the specific gravity is 8.917; whereas, if each had retained its former bulk, the sp. grav. would have been only 7.793 $\left(=\frac{2\times 8.006+7.363}{3}\right)$. A mixture of equal parts should have the specific gravity 7.684; but it is 8.441. A mixture of two parts tin with one part brass, instead of being 7.577 is 8.027.

In all these cases there is a great increase of specific gravity, and consequently a great condensation of parts or contraction of bulk. The first mixture of eight cubic inches of brass, for instance, with four cubic inches of tin, does not produce 12 cubic inches of bell-metal, but only $10\frac{1}{2}$ nearly, having shrunk $\frac{1}{8}$. It would appear that the distances of the brass particles are most affected, or perhaps it is the brass that receives the tin into its pores; for we find that the condensations in these mixtures are nearly proportional to the quantities of the brass in the mixtures. It is remarkable that this mixture with the lightest of all metals has made a composition more heavy and dense than brass can be made by any hammering.

The most remarkable instance occurs in mixing iron with platina. If ten cubic inches of iron are mixed with $1\frac{1}{4}$ of platina, the bulk of the compound is only $9\frac{1}{4}$ inches. The iron therefore has not simply received the platina into its pores: its own particles are brought nearer together. There are similar results in the solution of turbith mineral, and of some other salts, in water. The water, instead of rising in the neck of the vessel, when a small quantity of the salt has been added to it, sinks considerably, and the two ingredients occupy less room than the water did alone.

The same thing happens in the mixture of water with other fluids and different fluids with each other: But we are not able to trace any general rule that is observed with absolute precision. In most cases of fluids the greatest condensation happens when the bulks of the ingredients are nearly equal. Thus, in the mixture of alcohol and water, we have the greatest condensation when $16\frac{1}{2}$ ounces of alcohol are mixed with 20 ounces of water, and the condensation is about $\frac{1}{16}$ of the whole bulk of the ingredients. It is extremely various in different substances, and no classification of them can be made in this respect.

A dissertation has been published on this subject by Dr.

ecific avity.

Dr Hahn of Vienna, intitled *De Efficacia Mixtionis in mutandis Corporum Voluminibus*, in which all the remarkable instances of the variation of density have been collected. All that we can do (as we have no directing principle) is to record such instances as are of chief importance, being articles of commerce.

The first that occurs to us is the mixtures of alcohol and water in the composition of spirituous liquors. This has been considered by many with great care. The most scrupulous examination of this, or perhaps of any mixture, has been lately made by Dr Blagden (now Sir Charles Blagden) of the Royal Society, on the requisition of the Board of Excise. He has published an account of the examination in the Philosophical Transactions of London in 1791 and 1792. We shall give an account of it under the article SPIRITUOUS *Liquors*; and at present only select one column, in order to show the condensation. The alcohol was almost the strongest that can be produced, and its specific gravity, when of the temperature 60°, was 0.825. The whole mixtures were of the same temperature.

Column 1. contains the pounds, ounces, or other measures by weight, of alcohol in the mixture. Column 2. contains the pounds or ounces of water. Column 3. is the sum of the bulks of the ingredients, the bulk of a pound or ounce of water being accounted 1. Column 4. is the observed specific gravity of the mixture, taken from Dr Blagden's dissertation. Column 5. is the specific gravity which would have been observed if the ingredients had each retained its own specific gravity. This we calculated by dividing the sum of the two numbers of the first and second columns by the corresponding number of the third. Column 6. is the difference of column 4. and column 5. and exhibits the condensation.

Specific Gravity.

It is to be remarked, that the condensation is greatest when $16\frac{1}{2}$ ounces of alcohol have been added to 20 of water, and the condensation is $\frac{2633}{91835}$, or nearly $\frac{1}{35}$th of the computed density. Since the specific gravity of alcohol is 0.825, it is evident that $16\frac{1}{2}$ ounces of alcohol and 20 ounces of water have equal bulks. So that the condensation is greatest when the substances are mixed in equal volumes; and 18 gallons of alcohol mixed with 18 gallons of water will produce not 36 gallons of spirits, but 35 only.

We may also observe, that this is the mixture to which our revenue laws refer, declaring it to be *one to six* or *one in seven* under proof, and to weigh 7 pounds 13 ounces per gallon. This proportion was probably selected as the most easily composed, viz. by mixing equal measures of water and of the strongest spirit which the known processes of distillation could produce. Its specific gravity is 0.939 very nearly.

We must consider this elaborate examination of the mixture of water and alcohol as a standard series of experiments, to which appeal may always be made, whether for the purposes of science or of trade. The regularity of the progression is so great, that in the column which we have examined, viz. that for temperature 60°, the greatest anomaly does not amount to one part in six thousand. The form of the series is also very judiciously chosen for the purposes of science. It would perhaps have been more directly stereometrical had the proportions of the ingredients been stated in bulks, which are more immediately connected with density. But the author has assigned a very cogent reason for his choice, viz. that the proportion of bulks varies by a change of temperature, because the water and spirits follow different laws in their expansion by heat.

This is a proper opportunity for taking notice of a mistake which is very generally made in the conclusions drawn from experiments of this kind. Equal additions of the spirit or water produce a series of specific gravities, which decrease or increase by differences continually diminishing. Hence it is inferred that there is a contraction of bulk. Even Dr Lewis, one of our most accomplished

Specific Gravity.

complished naturalists, advances this position, in a dissertation on the potash of America; and it considerably affects his method for estimating the strength of the potash leys. But that it is a mistake, appears plainly from this, that although we add for ever equal quantities of the spirits, we shall never produce a *mixture* which has as small a specific gravity as alcohol. Therefore the series of successive gravities must approximate to this without end, like the ordinates of a hyperbolic curve referred to its assymptote.

That this may appear in the most general terms, let w represent the weight of the constant quantity of water in the mixture, and let a be the weight of the small addition of spirits. Also let w represent the bulk of this quantity of water, and b the bulk of the small addition of alcohol. The weight of the mixture is $w+a$, and its bulk is $w+b$, and its specific gravity is $\frac{w+a}{w+b}$. If we now add a second equal quantity of spirits, the weight will be $w+2a$, and if the spirit retains its density unchanged, the bulk will be $w+2b$, and the specific gravity is $\frac{w+2a}{w+2b}$: and after any number m of such equal additions of spirits, the specific gravity will be $\frac{w+ma}{w+mb}$. Divide the numerator of this fraction by its denominator, and the quotient or specific gravity will be $1+\frac{m\times\overline{a-b}}{w+mb}$. This consists of the constant part 1, and the variable part $\frac{m(a-b)}{w+mb}$. We need attend only to this part. If its denominator were constant, it is plain that the successive specific gravities would have equal differences, each being $=\frac{a-b}{w+mb}$, because m increases by the continual addition of an unit, and $a-b$ is a constant quantity. But the denominator $w+mb$ continually increases, and therefore the value of the fraction $\frac{a-b}{w+mb}$ continually diminishes.

Therefore the gradual diminution of the increments or decrements of specific gravity, by equal additions of one ingredient to a constant measure of the other, is not of itself an indication of a change of density of either of the ingredients; nor proves that in every diluted mixtures a greater proportion of one ingredient is absorbed or lodged in the interstices of the other, as is generally imagined. This must be ascertained by comparing each specific gravity with the gravity expressed by $1+\frac{w+m(a-b)}{w+mb}$.

This series of specific gravities resembles such a numerical series as the following, 1; ....; 1.56; 1.163; 1.+69; &c. the terms of which also consist of the constant integer 1, and the decimal fractions 0.156; 0.163; 0.169; &c. The fraction $\frac{m(a-b)}{w+mb}$ expresses this decimal part. Call this d, or make $d=\frac{m(a-b)}{w+mb}$. This will give us $b=\frac{ma-wd}{m(1+d)}$. Now a is the weight of the added ingredient, and d is the variable part of the specific gravity observed; and thus we learn whether b, the bulk of the added ingredient, suffers any change. We shall have occasion by and by to resume the consideration of this question, which is of the first moment in the theory of specific gravities, and has great influence in many transactions of commerce.

This series of specific gravities is not so well fitted for commercial transactions. In these the usual question is, how many gallons of alcohol is there in a cask, or some number of gallons of spirit? and it is more directly answered by means of a table, formed by mixing the ingredients in aliquant parts of one constant bulk. The following table, constructed from the experiments of Mr Brisson of the academy of Paris, and published in the Memoirs for 1769, is therefore inserted.

W.	A.	Density observed.	Density Computed.	Condensation.	Bulk of 10,000 grains.
0	16	0.8371	0.8371		1.0000
1	15	0.8527	0.8473	63	0.9937
2	14	0.8674	0.8575	115	0.9885
3	13	0.8815	0.8677	157	0.9844
4	12	0.8947	0.8778	189	0.9811
5	11	0.9075	0.8880	214	0.9786
6	10	0.9199	0.8982	235	0.9765
7	9	0.9317	0.9084	251	0.9749
8	8	0.9427	0.9186	256	0.9744
9	7	0.9519	0.9287	243	0.9757
10	6	0.9598	0.9389	217	0.9783
11	5	0.9674	0.9491	189	0.9811
12	4	0.9733	0.9593	144	0.9856
13	3	0.9791	0.9695	99	0.9901
14	2	0.9852	0.9796	57	0.9943
15	1	0.9919	0.9898	21	0.9979
16	0	1.0000	1.0000		1.0000

In this table the whole quantity of spirituous liquor is always the same. The first column is the number of measures (gallons, pints, inches, &c.) of water in the mixture: and column 2d gives the measures of alcohol. Column 3d is the specific gravity which was observed by Mr Brisson. Column 4th is the specific gravity which would have been observed if the spirits, or water, or both, had retained their specific density unchanged. And the 5th column marks the augmentation of specific gravity or density in parts of 10,000. A 6th column is added, showing the bulk of the 16 cubic measures of the two ingredients. Each measure may be conceived as the 16th part of 10,000, or 625; and we may suppose them cubic inches, pints, gallons, or any solid measure.

This table scarcely differs from Sir Charles Blagden's; and the very small difference that may be observed, arises from Mr Brisson's having used an alcohol not so completely rectified. Its specific gravity is 9.8371, whereas the other was only 0.8250.

Here it appears more distinctly that the condensation is greatest when the two ingredients are of equal bulk.

Perhaps this series of specific gravities is as declarative as the other, whether or not there is a change of density induced in either of the ingredients. The whole

whole bulk being always the same, it is plain that the successive equal additions to one of the ingredients is a successive equal abstraction of the other. The change produced, therefore, in the weight of the whole, is the difference between the weight of the ingredient which is taken out and the weight of the equal measure of the other which supplies its place. Therefore, if neither ingredient changes its density by mixture, the weights of the mixtures will be in arithmetical progression. If they are not, there is a variation of density in one or both the ingredients.

We see this very clearly in the mixtures of water and alcohol. The first specific gravity differs from the second by 156, and the last differs from the preceding by no more than 81. Had neither of the densities changed, the common difference would have been 102. We observe also that the augmentation of specific gravity, by the successive addition of a measure of water, grows less and less till 12 measures of water is mixed with 4 of alcohol, when the augmentation is only 58, and then it increases again to 81.

It also appears, that the addition of one measure of water to a quantity of alcohol produces a greater change of density than the mixture of one measure of alcohol to a quantity of water. Hence some conclude, that the water disappears by being lodged in the intestines of the spirit. But it is more agreeable to the justest notions which we can form of the internal constitution of tangible bodies, to suppose that the particles of water diminish the distances between the particles of alcohol, by their strong attractions, and that this diminution (exceedingly minute in itself) becomes sensible on account of the great number of particles whose distances are thus diminished. This is merely a probability founded on this, that it would require a much greater diminution of distances if it was the particles of water which had their distances thus diminished. But the greater probability is, that the condensation takes place in both.

We have been so particular in our consideration of this mixture, because the law of variation of density has, in this instance, been ascertained with such precision by the elaborate examination of Sir Charles Blagden, so that it may serve as an example of what happens in almost every mixture of bodies. It merits a still farther discussion, because it is intimately connected with the action of the corpuscular forces; and an exact knowledge of the variations of distance between the particles will go far to ascertain the law of action of these forces. But the limits of a work like this will not permit us to dwell longer on this subject. We proceed therefore to give another useful table.

The vitriolic or sulphuric acid is of extensive use in manufactures under the name of oil of vitriol. Its value depends entirely on the saline ingredient, and the water is merely a vehicle for the acid. This, being much denser than water, affects its specific gravity, and thus gives us a method of ascertaining its strength.

The strongest oil of vitriol that can be easily manufactured contains $612\frac{1}{20}$ grains of dry acid, united with $387\frac{1}{20}$ grains of water, which cannot be separated from it by distillation, making 1000 grains of OIL OF VITRIOL. Its specific gravity in this state is 1.877.

The following table shows its specific gravity at the

temperature of 55° when diluted by the successive addition of parts of water by weight.

Ol. Vit.		Water.	Specific Gravity. Observed.	Calculated.	Cond.
10	×	0	1.877	1.877	.00
		4	1.644	1.501	.143
		8	1.474	1.350	.124
		12	1.381	1.269	.112
		16	1.320	1.219	.101
		20	1.274	1.184	.090
		24	1.243	1.159	.084
		28	1.211	1.140	.071
		32	1.195	1.125	.070
		36	1.183	1.113	.070
		40	1.172	1.103	.070
		50	1.148	1.084	.064
		60	1.128	1.069	.059

Here is observed a much greater condensation than in the mixture of alcohol and water. But we cannot assign the proportion of ingredients, which produces the greatest condensation; because we cannot, in any case, say what is the proportion of the saline and watery ingredients. The strongest oil of vitriol is already a watery solution; and it is by a considerable and uncertain detour that Mr Kirwan has assigned the proportion of 612 and 388 nearly. If this be the true ratio, it is unlike every other solution that we are acquainted with; for in all solutions of salts, the salt occupies less room in its liquid form than it did when solid; and here it would be greatly the reverse.

This solution is remarkable also for the copious emergence of heat, in its dilutions with more water. This has been ascribed to the great superiority of water in its capacity of heat; but there are facts which render this very doubtful. A vessel of water, and another of oil of vitriol, being brought from a cold room into a warm one, they both imbibe heat, and rise in their temperature; and the water employs nearly the same time to attain the temperature of the room.

Aquafortis or nitrous acid is another fluid very much employed in commerce; so that it is of importance to ascertain the relation between its saline strength and its specific gravity. We owe also to Mr Kirwan a table for this purpose.

The most concentrated state into which it can easily be brought is such, that 1000 grains of it consists of 563 grains of water and 437 of dry acid. In this state its specific gravity is 1.557. Let this be called *nitrous acid.*

Nitr. Ac.		Water.			
10	×	0	1.557	1.557	
		1	1.474	1.474	
		6	1.350	1.273	0.077
		11	1.269	1.191	0.078
		16	1.214	1.147	0.067
		21	1.175	1.120	0.055
		26	1.151	1.101	0.050
		31	1.127	1.087	0.040
		36	1.106	1.077	0.029
		41	1.086	1.068	0.018

There is not the same uniformity in the densities of this acid in its different states of dilution. This seems owing

Specific Gravity.

owing to the variable proportion of the deleterious and vital air which compose this acid. It is more dense in proportion as it contains more of the latter ingredient.

The proportions of the aeriform ingredients of the muriatic acid are so very variable, and so little under our command, that we cannot frame tables of its specific gravity which would enable us to judge of its strength.

It is a general property of these acids, that they are more expansible by heat as they are more concentrated.

There is another class of fluids which it would be of great consequence to reduce to some rules with respect to specific gravity, namely, the solutions of salts, gums, and resins. It is interesting to the philosopher to know in what manner salts are contained in these watery solutions, and to discover the relation between their strength and density; and to the man of business it would be a most desirable thing to have a criterion of the quantity of salt in any brine, or of extractable matter in a decoction. It would be equally desirable to those who are to purchase them as to those who manufacture or employ them. Perhaps we might ascertain in this way the value of sugar, depending on the quantity of swectening matter which it contains; a thing which at present rests on the vague determination of the eye or palate. It would therefore be doing a great service to the public, if some intelligent person would undertake a train of experiments with this view. Accuracy alone is required; and it may be left to the philosophers to compare the facts, and draw the consequences respecting the internal arrangement of the particles.

One circumstance in the solution of salts is very general; and we are inclined, for serious reasons, to think it universal: this is a diminution of bulk. This indeed in some salts is inconsiderable. Sedative salt, for instance, hardly shows any diminution, and might be considered as an exception, were it not the single instance. This circumstance, and some considerations connected with our notions of this kind of solution, dispose us to think that this salt differs in contraction from others only in degree, and that there is some, though it was not sensible, in the experiments hitherto made.

These experiments, indeed, have not been numerous. Those of Mr Achard of Berlin, and of Dr Richard Watson of Cambridge, are perhaps the only ones of which we have a descriptive narration, by which we can judge of the validity of the inferences drawn from them. The subject is not susceptible of much accuracy; for salts in their solid form are seldom free from cavities and shivery interstices, which do not admit the water on their first immersion, and thereby appear of greater bulk when we attempt to measure their specific gravity by weighing them in fluids which do not dissolve them, such as spirits of turpentine. They also attach to themselves, with considerable tenacity, a quantity of atmospheric air, which merely adheres, but makes no part of their composition. This escapes in the act of solution, being set at liberty by the stronger affinity of the water. Sal gem, however, and a few others, may be very accurately measured; and in these instances the degree of contraction is very constant.

The following experiments of Dr Watson appear to us the most instructive as to this circumstance. A glass vessel was used, having a slender cylindrical neck, and holding 67 ounces of pure water when filled to a certain mark. The neck above this mark had a scale of equal parts pasted on it. It was filled to the mark with water. Twenty-four pennyweights of salt were thrown into it as speedily as possible, and the bulk of the salt was measured by the elevation of the water. Every thing was attended to which could retard the immediate solution, that the error arising from the solution of the first particles, before the rest could be put in, might be as small as possible; and in order that both the absolute bulk and its variations might be obtained by some known scale, 24 pennyweights of water were put in. This raised the surface 58 parts of the scale. Now we know exactly the bulk of 24 pennyweights of pure water. It it 2.275 cubic inches; and thus we obtain every thing in absolute measures: And by comparing the bulk of each salt, both at its first immersion and after its complete solution, we obtain its specific gravity, and the change made on it in passing from a solid to a fluid form. The following table is an abstract of these experiments. The first column of numbers is the elevation of the surface immediately after immersion; the second gives the elevation when the salt is completely dissolved; and the third and fourth columns are the specific gravities of the salts in these two states.

Twenty-four Pennyweights.	I.	II.	III.	IV.

The inspection of this list naturally suggests two states of the case as particularly interesting to the philosopher studying the theory of solution. The first state is when the lixivium approaches to saturation. In the very point of saturation any addition of salt retains its bulk unchanged. In diluted brines, we shall see that the density

sity of the fluid salt is greater, and gradually diminishes as we add more salt. It is an important question, Whether this diminution goes on continually, till the fluid density of the salt is the same with its solid density? or, Whether there is an abrupt passage from some degree of the one to the fixed degree of the other, as we observe in the freezing of iron, the setting of stucco, and some other instances?

The other interesting state is that of extreme dilution, when the differences between the successive density bear a great proportion to the densities themselves, and thus enable the mathematician to ascertain with some precision the variations of corpuscular force, in consequence of a variation of distance between the particles. The sketch of an investigation of this important question given by Boscovich in his Theory of Natural Philosophy, is very promising, and should incite the philosophical chemist to the study. The first thing to be done is to compare the law of specific gravity; that is, the relation between the specific gravity and quantity of salt held in solution.

Wishing to make this work as useful as possible, we have searched for experiments, and trains of experiments, on the density of the many brines which make important articles of commerce; but we were mortified by the scantiness of the information, and disappointed in our hopes of being able to combine the detached observations, suited to the immediate views of their authors, in such a manner as to deduce from them scales (as they may be called) of their strength. We rarely found these detached observations attended with circumstances which would connect them with others; and there was frequently such a discrepancy, nay opposition, in serieses of experiments made for ascertaining the relation between the density and the strength, that we could not obtain general principles which enable us to construct tables of strength *à priori*.

Mr Lambert, one of the first mathematicians and philosophers of Europe, in a dissertation in the Berlin Memoirs (1762), gives a narration of experiments on the brines of common salt, from which he deduces a very great condensation, which he attributes to an absorption in the weak brines of the salt, or a lodgement of its particles in the interstices of the particles of water. Mr Achard of the same academy, in 1785, gives a very great list of experiments on the bulks of various brines, made in a different way, which show no such introsusception; and Dr Watson thinks this confirmed by experiments which he narrates in his Chemical Essays. We see great reason for hesitating our assent to either side, and do not think the experiments decisive. We incline to Mr Lambert's opinion; for this reason, that in the successive dilutions of oil of vitriol and aquafortis there is a most evident and remarkable condensation. Now what are these but brines, of which we have not been able to get the saline ingredient in a separate form? The experiments of Mr Achard and Dr Watson were made in such a way that a single grain in the measurement bore too great a proportion to the whole change of specific gravity. At the same time, some of Dr Watson's are so simple in their nature that it is very difficult to withhold the assent.

In this state of uncertainty, in a subject which seems to us to be of a public importance, we thought it our duty to undertake a train of experiments to which recourse may always be had. Works like this are seldom considered as sources of original information; and it is thought sufficient when the knowledge already diffused is judiciously compiled. But a due respect for the public, and gratitude for the very honourable reception hitherto given to our labours, induced us to exert ourselves with honest zeal to merit the continuance of public favour. We assure our readers that the experiments were made with care, and on quantities sufficiently large to make the unavoidable irregularities in such cases quite insignificant. The law of density was ascertained in each substance in two ways. We dissolved different portions of salt in the same quantity of water, and examined the specific gravity of the brine by weighing it in a vessel with a narrow neck. The portions of salt were each of them one-eighth of what would make a nearly saturated solution of the temperature 55. We did not make the brine stronger, that there might be no risk of a precipitation in form of crystals. We considered the specific gravities as the ordinates of a curve, of which the abscissæ were the numbers of ounces of dry salt contained in a cubic foot of the brine. Having thus obtained eight ordinates corresponding to 1, 2, 3, 4, 5, 6, 7, and 8 portions of salt, the ordinates or specific gravities for every other proportion of salt were had by the usual methods of interposition.

The other method was, by first making a brine nearly saturated, in which the proportion of salt and water was exactly determined. We then took out one eighth of the brine, and filled up the vessel with water, taking care that the mixture should be complete; for which purpose, besides agitation, the diluted brine was allowed to remain 24 hours before weighing. Taking out one-eighth of the brine also takes out one-eighth of the salt; so that the proportion of salt and water in the diluted brine was known. It was now weighed, and thus we determined the specific gravity for a new proportion of salt and water.

We then took out one-seventh of the brine. It is evident that this takes out one-eighth of the original quantity of salt; an abstraction equal to the former. We filled the vessel with water with the same precautions; and in the same manner we proceeded till there remained only one-eighth of the original quantity of salt.

The specific gravities by these two methods agreed extremely well. In the very deliquescent salts the first method exhibited some small irregularities, arising from the unequal quantities of water which they had imbibed from the atmosphere. We therefore confided most in the experiments made with diluted brines.

That the reader may judge of the authority of the tables which we shall insert, we submit to his inspection one series of experiments.

Two thousand one hundred and eighty-eight grains of very pure and dry (but not decrepitated) common salt, prepared in large crystals, were dissolved in 6562 grains of distilled water of the temperature 55°. A small matrass with a narrow neck, which held 4200 grains of distilled water, was filled with this brine. Its contents weighed 5027 grains. Now $6562 + 2188 : 2188 = 5027 : 1256.75$. Therefore the bottle of brine contained 1256.75 grains of salt dissolved in 3770.25 grains of water Its specific gravity is $= \frac{5027}{4200}$, or 1.196905; and a cubic foot of brine weighs

1196.9

Specific Gravity.

1196.9 ounces avoirdupois. Also 5027 : 1256.75 = 1196.9 : 299.28. Therefore a cubic foot of this brine contains 299.28 ounces of perfectly dry salt.

The subsequent steps of the process are represented as follows.

Salt.	Brine.	Water.	Wt. of Cub. Ft.	Salt in Cub. Ft.
8)1256.75	8)5027	3770.25	1196.9	299.28
157.1	628.4	$=\frac{1}{8}$ of brine.		$37.41\frac{1}{8}$
	4398.6	Remains.		
	527.4	Water to fill it again.		
7)1099.6	7)4926.0	2d Brine.	1172.7	261.87
157.1	703.7	$\frac{1}{7}$ taken out.		37.41
	4222.3			
	604.7	Water added		
942.5	6)4827.0	3d Brine.	1149.3	224.46
157.1	804.5	Taken out.		
	4022.5	Remains.		
	706.5	Water added		
785.4	5)4729.0	4th Brine.	1125.9	187.05
157.1	946	Taken out.		
	3783	Remains.		
	847	Water added		
628.3	4)4630	5th Brine.	1102.3	149.64
157.1	1157.5	Taken out.		
	3472.5	Remains.		
	1054.5	Water added		
471.2	3)4527	6th Brine.	1077.9	112.23
157.1	1509	Taken out.		
	3018	Remains.		
	1405	Water added		
314.1	2)4423	7th Brine.	1053.3	74.82
157.1	2212	Taken out.		
	2211	Remains.		
	2102	Water added		
157.0	4313	8th Brine.	1027.9	37.41

Thus, by repeated abstraction of brine, so as always to take out $\frac{1}{8}$th of the salt contained in one constant bulk, we have obtained a brine consisting of 157 grains of salt united with 4313—157, or 4156 grains of water. Its specific gravity is $\frac{4313}{4200}$, =1,0279, and a cubic foot of it weighs 1028 ounces, and contains $37\frac{4}{10}$ ounces of dry salt. In like manner may the specific gravity, the weight of a cubic foot, and the salt it contains, be estimated for the intermediate brines.

When these eight quantities of salt contained in a cubic foot are made the abscissæ, and the weights of the cubic foot of brine are the corresponding ordinates, the curve will be found to be extremely regular, resembling a hyperbolic arch whose assymptote makes an angle of 30° with the axis. Ordinates were then interpolated analytically for every 10 ounces of contained salt, and thus the table was constructed. We did not, however, rest it on one series alone; but made others, in which one-fourth of the salt was repeatedly abstracted. They agreed, in the case of common salt, with great exactness, and in some others there were some very inconsiderable irregularities.

To show the authority of the tables of strength was by no means our only motive for giving an example of the process. It may be of use as a pattern for similar experiments. But, besides, it is very instructive. We see, in the first place, that there is a very sensible change of density in one or both of the ingredients. For the series is of that nature (as we have formerly explained), that if the ingredients retained their densities in every proportion of commixture, the specific gravities would have been in arithmetical progression; whereas we see that their differences continually diminish as the brines grow more dense. We can form some notion of this by comparing the different brines. Thus in the first brine, weighing 5027 grains, there are 3770 grains of of water in a vessel holding 4200. If the density of the water remains the same, there is left for the salt only as much space as would hold 430 grains of water. In this space are lodged 1257 grains of salt, and its specific gravity, in its liquid form, is $\frac{1257}{430}$, = 2.8907 very nearly. But in the 8th brine the quantity of water is 4156, the space left for 157 grains of salt is only the bulk of 44 grains of water, and the density of the salt is $\frac{157}{44}$ = 3.568, considerably greater than before. This induced us to continue the dilution of the brine as follows, beginning with the 8th brine.

157	2)4313	8th brine
78.5	2156.5	
	2156.5	
	2105.5	
78.5	2)4262.0	9th brine
39.7	2131	
	2102	
39.7	2)4233	10th brine
	2116.5	
	2116.5	
	2102	
19.8	4218	11th brine.

This last brine contains 4198.2 grains of water, leaving only the bulk of 1.8 grains of water to contain 19.8 of salt, so that the salt is ten times denser than water. This will make the strength 243 instead of 210 indicated by the specific gravity. But we do not pretend to measure the densities with accuracy in these diluted brines. It is evident from the process that a single

single grain of excess or defect in taking out the brine and replacing it with water has a sensible proportion to the whole variation. But we see with sufficient evidence, that from the strong to the weak brines the space left for the portion of salt is continually diminishing. In the first dilution $527\frac{1}{2}$ grains of water were added to fill up the vessel; but one-eighth of its contents of pure water is only 525: so that here is a diminution of two grains and a half in the space occupied by the remaining salt. The subsequent additions are 604.7; 706.5; 847; 1054.5; 1405; 2102; 2105.5; 2102; 2102; instead of 600; 700; 840; 1050; 1400; 2100; 2100; 2100; 2100. Nothing can more plainly show the condensation in general, though we do not learn whether it happens in one or both of the ingredients; nor do the experiments show with sufficient accuracy the progression of this diminution. The excesses of the added water being only six or seven grains, we cannot expect a nice repartition. When the brine is taken out, the upper part of the vessel remains lined with a briny film containing a portion of salt and water, perhaps equal or superior to the differences. Had our time permitted, we should have examined this matter with scrupulous attention, using a vessel with a still narrower neck, and in each dilution abstracting one half of the brine. The curve, whose abscissæ and ordinates represent the weight of the contained salt and the weight of a constant bulk of the brine, exhibits the best and most synoptical view of the law of condensation, because the position of the tangent in any point, or the value of the symbol $\frac{x}{y}$, always shows the rate at which the specific gravity increases or diminishes. We are inclined to think that the curve in all cases is of the hyperbolic kind, and complete; that is, having the tangent perpendicular to the axis at the beginning of the curve. The mathematical reader will easily guess the physical notions which incline us to this opinion; and will also see that it is hardly possible to discover this experimentally, because the mistake of a single grain in the very small ordinates will change the position of the tangent many degrees. It was for this reason that we thought it useless to prosecute the dilution any farther. But we think that it may be prosecuted much farther in Dr Watson's or Mr Achard's method, viz. by dissolving equal weights of salt in two vessels, of very different capacities, having tubular necks, in which the change of bulk may be very accurately observed. We can only conclude, that the condensation is greatest in the strongest brines, and probably attains its maximum when the quantities of true saline matter and water are nearly equal, as in the case of vitriolic acid, &c.

We consider these experiments as abundantly sufficient for deciding the question, "Whether the salt can be received into the pores of the water, or the water into the pores of the salt, so as to increase its weight without increasing its bulk? and we must grant that it may. We do not mean that it is simply lodged in the pores as sand is lodged in the interstices of small shot; but the two together occupy less room than when separate. The experiments of Mr Achard were insufficient for a decision, because made on so small a quantity as 600 grains of water. Dr Watson's experiments have, for the most part the same defect. Some of them, however, are of great value in this question, and are very fit for ascertaining the specific gravity of dissolved salts. In one of them (not particularly narrated) he found that a quantity of dissolved salt occupied the same bulk in two very different states of dilution. We cannot pretend to reconcile this with our experiments. We have given these as they stood; and we think them conclusive, because they were so numerous and so perfectly consistent with each other; and their result is so general, that we have not found an exception. Common salt is by no means the most remarkable instance of condensation. Vegetable alkali, sal ammoniac, and some others, exhibit much condensation.

We thought this a proper opportunity of considering this question, which is intimately connected with the principles of chemical solution, and was not perhaps considered in sufficient detail under the article CHEMISTRY. We learn from it in general, that the quantities of salt in brines increase at somewhat a greater rate than their specific gravities. This difference is in many cases of sensible importance in a commercial view. Thus an alkaline lixivium for the purposes of bleaching or soap-making, whose specific gravity is 1.234, or exceeds that of water by 234, contains 361 ounces of salt in a cubic foot; a ley which exceeds the weight of water twice as much, or 468 ounces per cubic foot, contains 777 ounces of salt, which exceeds the double of 361 by 55 ounces, more than seven per cent. Hence we learn, that hydrometers for discovering the strength of brines, having equal divisions on a cylindrical stem, are very erroneous; for even if the increments of specific gravity were proportional to the quantities of salt in a gallon of brine, the divisions at the bottom of the stem ought to be smaller than those above.

The construction of the following table of strengths from the above narrated series of brines is sufficiently obvious. Column first is the specific gravity as discovered by the balance or hydrometer, and also is the number of ounces in a cubic foot of the brine. Col. 2d is the ounces of the dry salt contained in it.

TABLE of Brines of Common Salt.

Weight Cub. Ft. Brine.	Salt in Cub. Ft.	Weight Cub. Ft. Brine.	Salt in Cub. Ft.
1.000	0	1.115	170
1.008	10	1.122	180
1.015	20	1.128	190
1.022	30	1.134	200
1.029	40	1.140	210
1.036	50	1.147	220
1.043	60	1.153	230

1.070	100	1.178	270
1.077	110	1.184	280
1.083	120	1.190	290
1.090	130	1.197	300
1.096	140	1.203	310
1.103	150	1.206	316
1.109	160	1.208	320

The

Specific Gravity.

The table differs considerably from Mr Lambert's. The quantities of salt corresponding to any specific gravity are about $\frac{1}{18}$th less than in his table. But the reader will see that they correspond with the series of experiments above narrated; and these were but a few of many which all corresponded within an hundredth part. The cause of the difference seems to be, that most kinds of common salt contain magnesian salts, which contain a very great proportion of water necessary for their crystallization. The salt which we used was of the purest kind, but such as may be had from every salt work, by Lord Dundonald's very easy process, viz. by passing through it a saturated solution boiling hot, which carries off with it about four-fifths of all the bitter salts. Our aim being to ascertain the quantities of pure sea-salt, and to learn by the bye its relation to water in respect of density, we thought it necessary to use the purest salt. We also dried it for several days in a stove, so that it contained no water not absolutely necessary for its crystallization. An ounce of such salt will communicate a greater specific gravity to water than an ounce of a salt that is less pure, or that contains extraneous water.

The specific gravity 1.090 is that of ordinary pickles, which are estimated as to strength by floating an egg.

We cannot raise the specific gravity higher than 1.206 by simply dissolving salt in cold water. But it will become much denser, and will even attain the specific gravity 1.240 by boiling, then holding about 366 ounces in the cubic foot of hot brine. But it will deposit by cooling, and when of the temperature 55° or 60°, hardly exceeds 1.206. We obtained a brine by boiling till the salt grained very rapidly. When it cooled to 60°, its specific gravity was 1.2063; for a vessel which held 3506 grains of distilled water held 4229 of this brine. This was evaporated to dryness, and there were obtained 1344 grains of salt. By this was computed the number interposed between 310 and 320 in the table. We have, however, raised the specific gravity to 1.217, by putting in no more salt than was necessary for this density, and using heat. It then cooled down to 60° without quitting any salt; but if a few grains of salt be thrown into this brine, it will quickly deposit a great deal more, and its density will decrease to 1.206. We find this to hold in all salts; and it is a very instructive fact in the theory of crystallization; it resembles the effect which a magnet produces upon iron filings in its neighbourhood. It makes them temporary magnets, and causes them to arrange themselves as if they had been really made permanent magnets. Just so a crystal already formed disposes the rest to crystallize. We imagine that this analogy is complete, and that the forces are similar in both cases.

The above table is computed for the temperature 55°; but in other temperatures the strength will be different on two accounts, viz. the expansion of the brine and the dissolving power of the water. Water expands about 40 parts in 1000 when heated from 60° to 212°. Saturated brine expands about 48 parts, or one-fifth more than water; and this excess of expansion is nearly proportional to the quantity of salt in the brine. If therefore any circumstance should oblige us to examine a brine in a temperature much above 60°, allowance should be made for this. Thus, should the specific gravity of brine of the temperature 130 (which is nearly half way between 60 and 212) be 1.140, we must increase it by 20 (half of 40); and having found the strength 240 corresponding to this corrected specific gravity, we must correct it again by adding 1 to the specific gravity for every 45 ounces of salt.

But a much greater and more uncertain correction is necessary on account of the variation of the dissolving power of water by heat. This indeed is very small in the case of sea-salt in comparison with other salts. We presume that our readers are apprised of this peculiarity of sea-salt, that it dissolves nearly in equal quantities in hot or in cold water. But although water of the temperature 60 will not dissolve more than 320 or 325 ounces of the purest and dryest sea-salt, it will take up above 20 ounces more by boiling on it. When thus saturated to the utmost, and allowed to cool, it does not quit any of it till it is far cooled, viz. near to 60°. It then deposits this redundant salt, and holds the rest till it is just going to freeze, when it lets it go in the instant of freezing. If evaporated in the state in which it continues to hold the salt, it will yield above 400 ounces per cubic foot of brine, in good crystals, but rather overcharged with water. And since in this state the cubic foot of brine weighs about 1220 ounces it follows, that 820 ounces of water will, by boiling, dissolve 400 of crystallized salt.

The table shows how much any brine must be boiled down in order to grain. Having observed its specific gravity, find in the table the quantity of salt corresponding. Call this x. Then, since a boiling hot graining or saturated solution contains 340 ounces in the cubic foot of brine, say $340 : 1000 = x : \frac{1000}{340}x$. This is the bulk to which every cubic foot (valued at 1000) must be boiled down. Thus suppose the brine has the specific gravity 1109. It holds 160 ounces per foot, and we must boil it down to $\frac{1000 \times 160}{340}$ or 471; that is, we must boil off $\frac{529}{1000}$ of every cubic foot or gallon.

These remarks are of importance in the manufacture of common salt; they enable us to appreciate the value of salt springs, and to know how far it may be prudent to engage in the manufacture. For the doctrine of latent heat assures us, that in order to boil off a certain quantity of water, a certain quantity of heat is indispensably necessary. After the most judicious application of this heat, the consumption of fuel may be too expensive.

The specific gravity of sea-water in these climates does not exceed 1.03, or the cubic foot weighs 1030 ounces, and it contains about 41 ounces of salt. The brine pits in England are vastly richer; but in many parts of the world brines are boiled for salt which do not contain above 10 or 20 ounces in the cubic foot.

In buying salt by weight, it is of importance to know the degree of humidity. A salt will appear pretty dry (if free from magnesian salts) though moistened with one per cent. of water; and it is found that incipient humidity exposes it much to farther deliquescence. A much smaller degree of humidity may be discovered by the specific gravity of a brine made with a few ounces of the salt. And the inspection of the table informs us, that

that the brine should be weak; for the differences of specific gravity go on diminishing in the stronger brines; 300 ounces of dry salt dissolved in 897 ounces of water should give the specific gravity 1197. Suppose it be but 1190, the quantity of salt corresponding is only 290; but when mixed with 897 ounces of water, the weight is 1197, although the weight of the cubic foot is only 1190. There is therefore more than a cubic foot of the brine, and there is as much salt as will make more than a cubic foot of the weight 1190. There is $290 \times \frac{1197}{1190}$, or $291\frac{2}{3}$ ounces, and there is $8\frac{1}{3}$ ounces of water attached to the salt.

The various informations which we have pointed out as deducible from a knowledge of the specific gravity of the brines of common salt, will serve to suggest several advantages of the knowledge of this circumstance in other lixivia. We shall not therefore resume them, but simply give another table or two of such as are most interesting. Of those, alkaline leys are the chief, being of extensive use in bleaching, soap-making, glass making, &c.

We therefore made a very strong ley of the purest vegetable alkali that is ever used in the manufactories, not thinking it necessary, or even proper, to take it in its state of utmost purity, as obtained from cubic nitre and the like. We took salt of tartar from the apothecary, perfectly dry, of which 3983 grains were dissolved in 3540 grains of distilled water; and after agitation for several days, and then standing to deposit sediment, the clear ley was decanted. It was again agitated; because, when of this strength, it becomes, in a very short time, rarer above and denser at the bottom. A flask containing 4200 grains of water held 6165 of this ley when of the temperature 55°. Its specific gravity was therefore 1.4678, and the 6165 grains of ley contained 3264 grains of salt. We examined its specific gravity in different states of dilution, till we came to a brine containing 51 grains of salt, and 4189 grains of water, and the contents of the flask weighed 4240 grains: its specific gravity was therefore 1.0095. In this train of experiments the progression was most regular and satisfactory; so that when we constructed the curve of specific gravities geometrically, none of the points deviated from a most regular curve. It was considerably more incurvated near its commencement than the curve for sea-salt, indicating a much greater condensation in the diluted brines. We think that the following table, constructed in the same manner as that for common salt, may be depended on as very exact.

Weight of Cub. foot oz.	Salt cont. oz.	Weight of Cub. Foot oz.	Salt cont oz.	Weight of Cub. Foot. oz.	Salt. cont. oz.	Weight of Cub. Foot oz.	Salt. cont. oz.
1000	0	1174	260	1329	520	1471	780
1016	20	1187	280	1340	540	1482	800
1031	40	1200	300	1351	560	1493	820
1045	60	1212	320	1362	580	1504	840
1085	80	1224	340	1372	600	1515	860

1162	240	1317	500	1460	760		

We see the same augmentation of the density of the salt in the diluted brines here as in the case of common salt. Thus a brine, of which the cubic foot weighs 1482 ounces, or which has the specific gravity 1.482, contains 800 ounces of dry alkali and 682 of water. Therefore, if we suppose the density of the water unchanged, there remains the bulk of 318 ounces of water to receive 840 ounces of salt: its density is therefore $\frac{800}{318}$, $= 2.512$ nearly. But in the brine whose weight per foot is only 1016 there are 20 ounces of salt, and therefore 996 of water; and there is only four ounce-measures of water, that is, the bulk of four ounces of water, to receive 20 ounces of salt. Its specific gravity therefore is $\frac{20}{4}, = 5$, almost twice as great as in the strong brine. Accordingly Mr Achard is disposed to admit the absorption (as it is carelessly termed) in the case of sal tart. But it is a general (we think an universal) fact in the solution of salts. It must be carefully distinguished from the first contraction of bulk which salts undergo in passing from a solid to a fluid form. The contraction now under consideration is analogous to the contraction of oil of vitriol when diluted with water; for oil of vitriol must be considered as a very strong brine which we cannot dephlegmate by distillation, and therefore cannot obtain the dry saline ingredient in a separate form, so as to observe its solid density, and say how much it contracts in first becoming fluid. The way of conceiving the first contraction in the act of solution as a lodging of the particles of the one ingredient on the interstices of the other, "*qu'ils se nichent, en augmentant le poids sans affecter le volume de la saumure*," as Euler and Lambert express themselves, is impossible here, when both are fluids. Indeed it is but a slovenly way of thinking

Specific Gravity.

thinking in either case, and should be avoided, because inadvertent persons are apt to use as a physical principle what is merely a mode of speech.

We learn from the table, that a hydrometer with equidistant divisions on a cylindrical or prismatical stem is still more erroneous than in the brines of common salt.

We learn from the experiments of Kirwan, Lavoisier, and others, that dry salt of tartar contains about one-fourth of its weight of fixed air. In many applications of this salt to the purposes of manufacture, this ingredient is of no use. In some it is hurtful, and must be abstracted by lime. Soap-maker's ley consists of the pure alkaline salt dissolved in water. It is therefore of importance to ascertain its quantity by means of the specific gravity of the brine. For this purpose we took a ley of sal tart. whose specific gravity was 1.20417, containing 314 ounces of mild alkali in a cubic foot of ley, and we rendered it nearly caustic by lime. The specific gravity was then 1.1897. This is a very unexpected result. Nothing is employed with more success than quicklime for dephlegmating any watery fluid. We should rather have expected an increase of specific gravity by the abstraction of some of the water of the menstruum, and perhaps the water of the crystallization, and the aerial part of the salt. But we must ascribe this to the great density in which the fixed air exists in the mild alkali.

It is unnecessary to give similar tables for all the salts, unless we were writing a dissertation on the theory of their solution. We shall only observe, that we examined with particular attention sal ammoniac, because Mr Achard, who denies what is called the absorption of salts, finds himself obliged to allow something like it in this salt. It does not, however, differ from those of which we have given an account in detail in any other respect than this, that the changes of fluid density are much less than in others (instead of being greater, as Achard's experiments seem to indicate) in all brines of moderate strength. But in the very weak brines there is indeed a remarkable difference; and if we have not committed an error in our examination, the addition of one part of sal ammoniac to 64 of water occupies less room than the water alone. We think that we have met with this as an accidental remark by some author, whose work we do not recollect. But we do not choose to rest so much on our form of the experiment in such weak brines. The following mixtures will abundantly serve for constructing the table of its strength: Sal ammoniac =960 grains was dissolved in 3506 grains of water, making a brine of 4466 grains. A phial which held 1600 grains water held 1698 of this brine. It contained $\frac{1698 \times 960}{4466}$, or 365 grains of salt. The specific gravity was $\frac{1698}{1600}$, =1.061, and the cubic foot weighed 1061 ounces. It also contained $\frac{1061 \times 365}{1698}$, or 288 ounces of salt. By repeated abstraction of brine, and replacing with water, we had the following series:

Series.		Brine.	Sp. Gr.	Oz. Salt in Cub. Ft.
Weight of brine,	*1st*,	1698	1.061	228
After taking out $\frac{1}{4}$,	*2d*,	1676	1.048	171
After taking out $\frac{1}{3}$,	*3d*,	1653	1.033	114
After taking out $\frac{1}{2}$,	*4th*,	1630	1.019	57
After taking out $\frac{1}{2}$,	*5th*,	1616	1.010	$28\frac{1}{2}$
$\frac{1}{2}$,	*6th*,	1610	1.0063	$14\frac{1}{4}$
$\frac{1}{2}$,	*7th*,	1605	1.0038	$7\frac{1}{8}$

This series is extremely regular, and the progress of density may be confidently deduced from it.

From the whole of this disquisition on the relation between the specific gravities of brines and the quantities of salt contained, we see in general that it may be guessed at, with a degree of useful precision, from the density or specific gravity of saturated solutions. We therefore conclude with a list of the specific gravities of several saturated solutions, made with great care by the bishop of Landaff.—The temperature was 42°. The first numerical column is the density of saturated brine, and the next is the density of a brine consisting of 12 parts (by weight) of water and one of salt. From this may be inferred the quantity in the saturated solution, and from this again may be inferred the quantity corresponding to inferior densities.

Spectacles.

SPECTACLES, in *Dioptrics*, a machine consisting of two lenses set in silver, horn, &c. to assist the defects of the organ of sight. Old people, and others who have flat eyes, use convex spectacles, which cause the rays of light to converge so as to meet upon the retina: whereas myopes, or short-sighted people, use concave lenses for spectacles, which cause the rays to diverge, and prevent their meeting ere they reach the retina. See OPTICS.

Some cases of a peculiar nature have been met with where the sight receives no assistance from the use of either convex or concave glasses. To remedy this, the following method was contrived and successfully adopted. A man about sixty years of age having almost entirely lost his sight, could see nothing but a kind of thick mist with little black specks in it which seemed to float in the air. He could neither read, walk the streets, nor distinguish his friends who were most familiar to him. In this deplorable situation he procured some spectacles with large rings; and having taken out the glasses, Spectacles glasses, he substituted for them a conic tube of black Spanish copper. Looking through the large end of the cone he could read the smallest print placed at its other extremity. These tubes were of different lengths, and the openings at the end were also of different sizes; the smaller the aperture the better could he distinguish the smallest letters; the larger the aperture the more words or lines it commanded; and consequently the less occasion was there for moving the head and the hand in reading. Sometimes he used one eye, sometimes the other, alternately relieving each, for the rays of the two eyes could not unite upon the same object when thus separated by two opaque tubes. The thinner these tubes, the less troublesome are they. They must be totally blackened within so as to prevent all shining, and they should be made to lengthen, or contract, and enlarge or reduce the aperture at pleasure.

Spectre.

When he placed convex glasses in these tubes, the letters indeed appeared larger, but not so clear and distinct as through the empty tube; he also found the tubes more convenient when not fixed in the spectacle rings; for when they hung loosely they could be raised or lowered with the hand, and one or both might be used as occasion required. It is almost needless to add that the material of the tubes is of no importance, and that they may be made of iron or tin as well as of copper, provided the insides of them be sufficiently blackened *.

* Monthly Mag. 1799.

OCULAR SPECTRA, images presented to the eye after removing them from a bright object, or closing them. When any one has long and attentively looked at a bright object, as at the setting sun, on closing his eyes, or removing them, an image, which resembles in form the object he was attending to, continues some time to be visible. This appearance in the eye we shall call the ocular spectrum of that object.

Phil. Trans. 1786.

These ocular spectra are of four kinds: 1st, Such as are owing to a less sensibility of a defined part of the retina, or spectra from defect of sensibility. 2d, Such are owing to a greater sensibility of a defined part of the retina, or spectra from excess of sensibility. 3d, Such as resemble their object in its colour as well as form; which may be termed direct ocular spectra. 4th, Such as are of a colour contrary to that of their object, which may be termed reverse ocular spectra.

SPECTRE, an apparition, or something supposed to be preternaturally visible to human sight, whether the ghosts of dead men or beings superior to man.

A belief that supernatural beings sometimes make themselves visible, and that the dead sometimes revisit the living, has prevailed among most nations, especially in the rudest ages of society. It was common among the Jews, among the Greeks, and among the Romans, as we find from the Scriptures, and from the poems of Homer and Virgil. Celestial appearances were indeed so often exhibited to the Jews, that the origin of their belief is not difficult to be explained.—The Divine Being manifested himself to each of the patriarchs by some sensible sign, generally by a flame of fire, as he did to Moses. Under this semblance also did he appear to the Israelites during their abode in the desert, and after they obtained a settlement in the land of Canaan. Nor did they believe that heavenly beings alone assumed a sensible appearance: They believed that deceased men also sometimes revisited this world. When Saul went to consult the witch at Endor, he asked her to bring up the person whom he should name unto her: a proof that he considered his demand as easy to be performed, and therefore that he probably acted under the influence of popular opinion. The same opinions had been generally entertained at a much earlier period; for necromancy and witchcraft, the arts by which the dead were supposed to be raised, had been prohibited while the Israelites were in the wilderness, and yet untainted with the vices of the Canaanites. They must therefore have derived them from Egypt, the cradle of superstition, as well as of the arts and sciences.

Spectre.

Among the Greeks and Romans the apparition of spectres was generally believed. On innumerable occasions the gods are said to have discovered themselves to the eyes of mortals, to have held conferences, and to have interposed their aid. The ghosts of the dead, too, are said to have appeared. When Æneas, amidst the distraction and confusion of his mind in flying from the destruction of Troy, had lost his wife by the way, he returned in search of her. Her shade appeared to him (for she herself had been slain) with the same aspect as before, but her figure was larger. She endeavoured to assuage the grief of her unhappy husband, by ascribing her death to the appointment of the gods, and by foretelling the illustrious honours which yet awaited him. But when Æneas attempted to clasp her in his arms, the phantom immediately vanished into air. From this story we may observe, that the ancients believed that the umbræ or shades, retained nearly the same appearance after death as before; that they had so far the resemblance of a body as to be visible; that they could think and speak as formerly, but could not be touched. This description applies equally well to those shades which had passed the river Styx, and taken up their residence in the infernal regions. Such were the shades of Dido, of Deiphobus, and all those which Æneas met with in his journey through the subterraneous world.

It appears from the writings of modern travellers who have visited rude and savage nations, that the belief of spectres is no less common among them. Mr Bruce tells us, that the priest of the Nile affirmed, that he had more than once seen the spirit of the river in the form of an old man with a white beard. Among the Mahometans the doctrine of spectres seems to be reduced to a regular system, by the accounts which they give of genii. Whoever has read the Arabian Nights Entertainments must have furnished his memory with a thousand instances of this kind. Their opinions concerning genii seem to be a corrupted mixture of the doctrines of the Jews and ancient Persians. In Christian countries, too, notwithstanding the additional light which their religion has spread, and the great improvement in the sciences to which it has been subservient, the belief of ghosts and apparitions is very general, especially among the lower ranks. They believe that evil spirits sometimes make their appearance in order to terrify wicked men, especially those who have committed murder.—They suppose that the spirits of dead men assume a corporeal appearance, hover about church-yards and the houses of the deceased, or haunt the places where murders have been committed. (See GHOST). In some places it is believed that beings have been seen bearing a perfect resemblance to men alive. In the Highlands of Scotland, what is called the second sight is still believed

Spectre.

lieved by many (see *Second Sight*); viz. that future events are foretold by certain individuals by means of spectral representation.

So general has the belief of spectres been, that this circumstance alone may be thought by some sufficient to prove that it must have its foundation in human nature, or must rest upon rational evidence. When any doctrine has been universally received by all nations, by generations living several thousand years from one another, and by people in all the different stages of society, there is certainly the strongest presumption to conclude that such a doctrine has its foundation in reason and in truth. In this way we argue in favour of the existence of a God, concerning moral distinction, and the doctrine of a future state: and certainly so far we argue well. But if the same argument be applied to idolatry, to sacrifices, or to apparitions, we shall find that it is applied improperly. Idolatry was very general among ancient nations; so was the offering of sacrifices, so was polytheism: but they were by no means universal. Should we allow, for the sake of shortening the argument, that all ancient nations were polytheists and idolaters, and presented oblations to their imaginary deities, all that could be concluded from this concession is, that they fell into these mistakes from their ignorance and from the rude state of society, from which their imperfect knowledge of theology and moral philosophy was never able to rescue them. These erroneous notions fled before the brightness of the Christian system; while the doctrines of the existence of God, of moral distinction, and of a future state, have been more thoroughly confirmed and ascertained. The same thing may be said of the belief of spectres. However generally it has been adopted in the first stages of society, or by civilized nations who had made but little progress in the study of divine things, it has been rejected, we may say invariably, wherever theology and philosophy have gone hand in hand.

As all popular and long established opinions are objects of curiosity and research for the philosopher, we think the belief of spectres worthy of some attention even in this light. It will therefore, we hope, give some satisfaction to the philosophical reader to see a short account of the sources or principles from which this belief is derived. But as the belief of spectres is connected with other opinions which appear to us highly injurious to religion; opinions which have been supported by many learned men, and which are still believed by some men of literary education—it will also be proper, in the first place, to consider the evidence on which this belief rests, in which we must consider both their probability and credibility.

In the present investigation we mean to set aside altogether the celestial appearances recorded in Scripture, as being founded on unquestionable evidence, and perfectly agreeable to those rules by which the Deity acts in the usual course of his Providence. The Israelites, during the existence of their state, were immediately under the authority of God, not only as the moral governor of the world, but as the king of Israel. In the infancy of the world, while men were rude and unenlightened, and entirely under the influence of idolatry, many revelations were necessary to preserve in their minds pure ideas of the nature of God, and of the worship due to him. They were necessary also to pave the way for that illustrious dispensation which the Lord Jesus came from Heaven to diffuse over the world. Every celestial appearance recorded in Scripture was exhibited for some wise and important purpose, which must be apparent to every person who considers these appearances with attention. But when the Scriptures were written and published, and the Christian religion fully established, revelation ceased, and miracles and heavenly messages were no longer requisite. What credit then ought we give to those marvellous stories related in ancient authors concerning prodigies in the heavens, and the apparition of angels both good and bad?

It is not pretended that any of these prodigies and appearances were exhibited for purposes equally great and important with those which are described in Scripture: And can we suppose that the all-wise Governor of the world would permit his angels to render themselves visible to the eye of man for no purpose at all, or for a purpose which might have been equally well accomplished without their interposition? Would this be consistent with perfect wisdom, or would it be consistent even with the excellence and superiority of understanding which we are taught to ascribe to these elevated beings? The whole will of God is revealed to us in the Scriptures; what further use for the visible interposition of angels? It may be objected, Are they not all ministering spirits, sent forth to minister for them who shall be heirs of salvation *? We answer, that angels may animate and support good men by an invisible interposition. But the Apostle is not speaking of celestial spirits. The word αγγελος signifies "a messenger;" and in Scripture often refers to men. In the passage which we are now reviewing it certainly is applied with much more propriety to men than to angels: for the Apostle is stating a comparison between *the prophets*, by whom God, at sundry times and in divers manners, spake in time past to the fathers, and *the Son*, by whom he hath spoken in these last days.

* Heb. i. 14.

And if God has given no commission to his angels to deliver to men since the publication of the Christian religion, is there any probability that he would give any commission or any licence to evil spirits? It will be said, that this doctrine is clearly taught in the New Testament, in these words, "The devil goeth about as a roaring lion seeking whom he may devour." We will not avail ourselves of the interpretation of some, who say that the word *devil*, which in the Greek language signifies an *adversary*, or *slanderer*, refers here to some human being, who was a violent enemy of the Christians. All that can be deduced from these words, upon the supposition that they refer to a malignant spirit, is merely that he goeth about seducing men to vice. But it is not by assuming a hideous form, and presenting himself to the midnight traveller, that such a purpose is to be accomplished. A spirit may probably have direct access to our minds without the intervention of any thing corporeal; and by exciting our passions may plunge us into vice, which is the only object such a being is supposed to have in view. None of the marvellous stories which we have heard concerning the apparition of evil spirits lead us to conclude that they appear to entice men to commit crimes. We never heard of any evil spirits that required men to steal, to perpetrate robbery or murder. They only appeared to terrify some crazy timorous individuals, who have whims and fancies enow

Spectre. enow of their own to agitate their minds, though no preternatural vision should ever appear to them. It is not consistent, therefore, with the character of God, and what he has revealed to us of his will, to believe that he would commission good angels, or permit evil angels, to appear to men since the propagation of the gospel, or indeed at any former period of the world, unless some great and mighty purpose was to be fulfilled. It is not consistent with what we know of the nature of good or bad angels to suppose, that though permission were granted them occasionally to show themselves to men, that they would appear in that way which story-tellers describe.

It is equally improbable that the spirits of the dead who have removed from this world should again be permitted to visit it. At death men undergo as great, perhaps a greater change, than when they came first into the light of the sun. Is it not therefore as improbable that a man should return in a visible corporeal form after death, as that, after having arrived at manhood, he should return to the state in which he was before his birth? Such changes as these are evidently made permanent by the invariable laws of nature. But suppose it were possible, for what purpose should they return? To describe to us what is passing in the other world, to animate us to virtue, by informing us of the rewards which there await the good: or to alarm us, by describing the punishment of the wicked. These seem important reasons. But Divine Providence has wisely thrown a veil over futurity. We know every thing of the other world from the scripture which it is proper for us at present to know. And as to incentives to virtue, we are already blessed with a number sufficiently great and powerful for moral beings, who are to act from rational motives, and not from compulsion. "He that will not hear Moses and the prophets, will not be persuaded though one rose from the dead."

There is one strong objection against the probability of spectres, which is sufficient to prove that they are not intelligent creatures; or at least that they possess so small a degree of intelligence, that they are unqualified to act with prudence, to propose any end to themselves, or use the proper means to accomplish that end. Ghosts often appear in order to discover some crime that has been committed: but they never appear to a magistrate, or person in authority, but to some illiterate clown, who happens to live near the place where the crime was perpetrated; to some person who has no connection with the affair at all, and who in general is the most improper in the world for making the discovery. For instance, in Glanville's *Saducismus triumphatus* (a book written in the last century by a chaplain of Charles II. in support of the common opinions respecting witchcraft and apparitions), we have the following story: James Haddock, a farmer, was married to Elenor Welsh, by whom he had a son. After the death of Haddock, his wife married one Davis; and both agreed to defraud the son by the former marriage of a lease bequeathed to him by his father. Upon this the ghost of Haddock appeared to one Francis Taverner the servant of Lord Chichester, and desired him to go to Elenor Welsh, and to inform her that it was the will of her former husband that their son should enjoy the lease. Taverner did not at first execute this commission; but he was continually haunted by the apparition in the most hideous shapes, which even threatened to tear him in pieces, till at last he delivered the message. Now, had this spectre had the least common sense, it would have appeared first to Elenor Welsh and her husband Davis, and frightened them into compliance at once, and not have kept poor Taverner in such constant disquietude, who had no concern in the matter.

Another very odd circumstance respecting apparitions in general must not be omitted, which, is, that they have no power to speak till they are addressed. In the 27th of Glanville's Relations we read of an old woman that appeared often to David Hunter, a neat-herd, at the house of the bishop of Down and Conners. Whenever she appeared, he found himself obliged to follow her; and for three quarters of a year poor David spent the whole of almost every night in scampering up and down through the woods after this old woman. How long this extraordinary employment might have continued, it is impossible to guess, had not David's violent fatigue made him one night exclaim, "Lord bless me! would I were dead!—shall I never be delivered from this misery!" On which the phantom replied, "Lord bless me too! It was happy you spoke first, for till then I had no power to speak, though I have followed you so long." Then she gave him a message to her two sons, though David told her he remembered nothing about her. David, it seems, neglected to deliver the message; at which the old beldam was so much provoked, that she returned and hit him a hearty blow on the shoulder, which made him cry out, and then speak to her. Now if she could not speak till David addressed her, why might she not have applied this oratorial medicine the first time she appeared to him? It would have saved both herself and him many a weary journey; and certainly David would much rather have had even half a dozen of blows from her choppy fists than have wanted so many nights sleep. To complete the story, we must add, that when David's wife found it impossible to keep him from following the troublesome visitor, she trudged after him, but never was gratified with a sight of the enchantress. David's little dog too was a dutiful attendant on his master during his pilgrimage.

It is remarked by Glanville, that ghosts are generally very eager to be gone. Indeed they are often so much so, that they do not stay to tell their errand. One would be induced from this, as well as the circumstances already mentioned, to think that they are the stupidest and dullest of the dead that assume the appearance of ghosts; unless we adopt the ingenious solution of Glanville, "that it is a very bad and painful thing for them to force their thin and tenuious bodies into a visible consistence; that their bodies must needs be exceedingly compressed; and that therefore they must be in haste to be delivered from the unnatural pressure."

With respect to the *evidence* in favour of spectres, if examined ever so slightly, it will be found very defective. They only appear to one person at a time; they are seen only in the night; they are visible only to ignorant, illiterate, and credulous persons, and never present themselves before men of education and learning.

That spectres only appear to one person at a time, even though there are more in company, is an objection against the credibility of their appearance quite insurmountable.

Spectre.

mountable. How is it possible that two men of eye-sight equally good, directing their eyes to the same spot, should not see so large an object as that of a man or woman at a small distance equally well! Some will tell us that a mist is cast over the eyes of the one, while the view of the other is free from obstruction. But how is this to be proved? and besides, what purpose would it serve? Ghosts have seldom any secrets to disclose; they might be proclaimed to a multitude with as much propriety as confined to one person. Shall we be told, that the spectre has the power of becoming visible to some, and of remaining invisible to others? This cannot be allowed without adopting opinions destructive to revealed religion; for it would be a miracle: and we cannot be persuaded, without evidence, that God would empower any inferior being to controul at pleasure the wise laws which he has ordained for governing the world. To him who is of a different opinion, we would recommend Farmer on Miracles; a book in which this question is fully examined.

Spectres appear only in the night. But why should they shun the light of the sun? Those mischievous ghosts that Glanville mentions might indeed have some reason to choose midnight for the execution of their pranks, as they would be more easily detected in open day. Such was the roguish drummer that haunted Mr Mompesson's house, who beat his drum all night, threw the old gentlewoman's clothes about the room, hid her Bible in the ashes, plucked the clothes off the bed, and amused himself with tossing about Mr Mompesson's shoes. But why should a grave serious ghost appear at midnight? Might it not deliver its message with as much ease and more success in the day-time? In the day-time it would not excite much fear; it would be listened to therefore with more attention; and did it choose to exhibit itself before a number of witnesses, its grievances would be more speedily redressed, because more persons would interest themselves in seeing justice done to the injured ghost.

Spectres not only choose the most improper time, but the most improper persons. To render the testimony of any person credible, he must not only be a man of veracity, but he must have sufficient ability to judge of the subject to which he is to bear witness. It is not on the evidence of an ignorant illiterate person, who has more fancy and fear than judgment, that we are to rest our belief of what is supernatural. It is also worthy of remark, that we have never heard of a ghost appearing to any person who did not previously believe their existence. A man must be prejudiced in favour of this opinion, or he will never see a ghost. But sensible men know, that he who has been accustomed to hear frightful stories of ghosts and apparitions gliding through a churchyard, or haunting some particular place, can scarcely pass through a churchyard, or haunted spot without conjuring up in his imagination the hideous phantoms which he has been accustomed to associate with such places. Is it strange, then, that an ignorant man, with a mind uncultivated and uninformed, with all the prejudices of the nursery about him, should imagine he sees ghosts in those places where he believes they hover, especially in the dead hour of midnight, when, with the slightest aid of the imagination, a cow may be turned into a monstrous phantom, and the reflection of the beams of the moon from a little water be converted into a ghost with a winding-sheet? But why should apparitions shun men of understanding and learning? Why should learning be formidable to them (A)? It was not so with the celestial messengers mentioned in the Scriptures: they appeared to the patriarchs and prophets; and the miracles there recorded were performed in the most public places, before the eyes of Rabbies, of Scribes, and Pharisees. Indeed this circumstance is sufficient to destroy the evidence of spectres. They have never been seen by any but men of weak or distempered minds, or by men who have previously believed in them.

Having now considered the evidence on which the belief of spectres rests, we will endeavour to give some account of the foundation of it. To trace an opinion, that has prevailed so generally in the world to its source, is a labour not unworthy of the philosopher, even though the opinion be false. It is always gratifying to detect the causes of error: it is no less useful; for in order to refute error, it is often sufficient to point out the sources from which it has sprung. To reach the origin of the belief of spectres is not more difficult than to account for idolatry or polytheism. In the infant state of the intellectual powers every thing is considered as possessing life and intelligence. The child beats the stool

(A) The celebrated historian De Thou had a very singular adventure at Saumur, in the year 1598. One night, having retired to rest very much fatigued, while he was enjoying a sound sleep, he felt a very extraordinary weight upon his feet, which, having made him turn suddenly, fell down and awakened him. At first he imagined that it had been only a dream, but hearing soon after some noise in his chamber, he drew aside the curtains, and saw, by help of the moon, which at that time shone very bright, a large white figure walking up and down, and at the same time observed upon a chair some rags, which he thought belonged to thieves who had come to rob him. The figure then approaching his bed, he had the courage to ask it what it was. "I am (said it) the Queen of Heaven." Had such a figure appeared to any credulous ignorant man in the dead of night, and made such a speech, would he not have trembled with fear, and have frightened the whole neighbourhood with a marvellous description of it? But De Thou had too much understanding to be so imposed upon. Upon hearing the words which dropped from the figure, he immediately concluded that it was some mad woman, got up, called his servants, and ordered them to turn her out of doors; after which he returned to bed and fell asleep. Next morning he found that he had not been deceived in his conjecture, and that having forgot to shut his door, this female figure had escaped from her keepers, and entered his apartment. The brave Schomberg, to whom De Thou related his adventure some days after, confessed that in such a case he would not have shown so much courage. The king also, who was informed of it by Schomberg, made the same acknowledgement.

stool over which he has fallen with the same passion that he would treat his companion: The young girl talks to her doll as if it understood her: The savages ascribe every change which they observe on the face of nature to the action of some animated being. As knowledge advances, they single out those beings which seem to produce the most striking effects, arrange them into some kind of order, and divide the government of the world among them. Unable, at the same time, to conceive any notion of a pure spirit, they imagine those divinities are corporeal beings. This is the foundation of idolatry. The belief of spectres is but another step. That these animated corporeal beings, to whom they address their prayers, and who preside over the world, should on particular occasions display themselves to the human eye, is what they must be previously disposed to expect. Hence the numberless appearances of the heathen gods, of the Persian and Mahometan genii. The belief of ghosts may be easily deduced from the opinions entertained respecting a future state. These opinions are founded on that essential doctrine of natural religion, that there is another world in which men shall exist when death has removed them hence. This doctrine has been universally received both by savage and civilized nations; but, as might be expected, men have formed very different sentiments concerning the nature of a future state, of the situation and employments of departed spirits, according to the degree of knowledge which they possessed. But the general opinion in ancient and rude nations was, that departed spirits retained the same external appearance, the same passions and principles as before. Nothing therefore was more natural than the opinion, that they might occasionally revisit this world, from an anxious desire to alleviate the sufferings of those beloved friends and relations whom they had left behind them, or to communicate from the unseen world what might be important to their welfare. Upon such an errand did Cerüsa appear to Æneas. The apparition of the ghosts of murderers is easily explained upon the same general principles. The remorse and horror of mind which the murderer feels are supposed to haunt him in the other world, and to render his situation there intolerable (especially if the murder was never detected and punished), till he return and give information against himself. In this way, then, we think it highly probable the belief of spectres has originated. But many other causes concur to confirm and propagate this belief. These are, imperfect vision united with fear, dreams, opium, diseases, drunkenness, and artifice.

1. Indistinct vision is one source of apparitions, especially when the mind is under the influence of fear. It is well known, that the sense of seeing conveys no idea of distance till improved by experience and observation; and how we come at length to distinguish objects at a distance from those that are near, has been explained in another place (see METAPHYSICS, N° 50.).

In the daytime we seldom commit mistakes, because we know the object at which we look; but at night, when we see objects obscurely, and know not what they are, we have no distinct idea either of their distances or of their magnitude. We may mistake a bush that is near us for a tree at a distance; or if the imagination be under the influence of fear, it will easily convert it into a gigantic figure. "It is generally asserted (says Buffon) that these figures exist only in the imagination; yet they may have a real existence in the eye; for whenever we have no other mode of judging of an unknown object but by the angle it forms in the eye, its magnitude will uniformly increase in proportion to its propinquity. If it appears, when at the distance of 20 or 30 paces, to be only a few feet high, its height, when within two or three feet of the eye, will be many fathoms. An object of this kind must naturally excite terror and astonishment in the spectator, till he approaches and recognises it by actual feeling; for the moment a man knows an object, the gigantic appearance it assumed in the eye instantly diminishes, and its apparent magnitude is reduced to its real dimensions. But if, instead of approaching such an object, the spectator flies from it, he can have no other idea of it but from the image which it formed in his eye; and, in this case, he may affirm with truth that he saw an object terrible in its aspect, and enormous in its size. Thus the notions concerning spectres are founded in nature, and depend not, as some philosophers affirm, upon the imagination alone."

In addition to these observations of Buffon, we may take notice, that objects are always magnified in a fog; so that when a fog happens in the night-time, objects may be magnified to an enormous size. But, at any rate, whether there be a fog in the night or not, there is such a great analogy between darkness and a fog, that if the latter deceive us with respect to the size of objects, the former will also deceive us. The writer of this article was passing the Frith of Forth at Queensferry, near Edinburgh, one morning which was extremely foggy. Though the water be only two miles broad, the boat did not get within sight of the southern shore till it approached very near it. He then saw to his great surprise a large perpendicular rock, where he knew the shore was low and almost flat. As the boat advanced a little nearer, the rock seemed to split perpendicularly into portions, which separated at a little distance from one another. He next saw these perpendicular divisions move; and upon approaching a little nearer, found it was a number of people standing on the beach, waiting the arrival of the ferry-boat.

2. Dreams are another fertile source of apparitions. It is well known to every person, that while the mind is under the influence of a dream it considers it as much a reality as it does any particular action while awake. Now if a person of a weak superstitious mind should have a very lively dream, which interests his passions, particularly the passion of fear, it may make so deep an impression, that he may be firmly convinced that he has actually seen with his eyes what has only passed before his imagination (see APPARITION) (B). We shall here tell a story, by way of illustration, which we have

(B) When the thoughts are much troubled, and when a person sleeps without the circumstances of going to bed, or putting off his clothes, as when he nods in his chair, it is very difficult, as Hobbes remarks, to distinguish a dream from a reality. On the contrary, he that composes himself to sleep, in case of any uncouth or absurd fancy, easily suspects it to have been a dream.—*Leviathan*, par. i. c. i.

Spectre. have received on unquestionable authority. An East India captain had an honest faithful servant named *John*, for whom he had a great regard. John died, if we recollect right, on a voyage from England to the East Indies during a French war. As the ship approached the place of its destination the captain had a dream, in which John appeared to him, and earnestly besought him not to sail to the port for which he was bound, as it was in the hands of the French. The captain, though not addicted to superstition, thought it prudent to follow this admonition; and after landing at a different port, he was informed that the place to which he had intended to steer was, according to the information of the dream, captured by the French. On the voyage home, the captain had a second dream, in which John again appeared to him, and gave him notice that he should soon die, and that the ship should be taken in the mouth of the Channel by the French. Next morning the captain called his first mate, told him his dream, which he believed was prophetic, and delivered his papers, that he might take proper care of them after his decease. Every thing happened exactly as the dream had foretold; the captain died, and the vessel was taken by a French man of war in the mouth of the Channel. This dream, wonderful as it appears, is easily explained. In the voyage out to India, nothing was more natural than that the captain should sometimes be thinking, that amidst the various chances of war, the port to which he was bound might be taken; perhaps it was a place of consequence, which the French might be eager to possess. The captain being accustomed to revolve these thoughts in the day-time, they would naturally return at night; the regret which he felt for the loss of a faithful servant might mingle with his apprehensions, and thus produce the dream. Perhaps the advice was such as John would have given had he been alive. It is equally easy to explain the cause of the dream in the passage home. The captain, we are told, was very ill, and thought himself dying, at the very time he had the second dream, and therefore did not expect to reach England. This part of the dream, then, was only his own thoughts, delivered by his servant. As to the other part, that his ship should be taken in the mouth of the Channel, it might be thought unaccountable how the very place should be foreseen. But we must recollect, that the mouth of the Channel, being over against the coast of France, was by far the most dangerous place in the whole passage; and that, therefore, the captain had more reason to be afraid of losing his ship there than in any other place. The use which we mean to make of this story is this: Had the captain been a man of a weak mind, he would certainly have considered the dream as a reality, and believed that, instead of having dreamed of the things on which his imagination had dwelt, he had actually seen his servant return from the dead, and heard him deliver the message. But on the other hand, the captain, though he believed the dream was prophetic, mentioned it without any signs of fear; and no man of courage and reflection ever sees an apparition. This sight is reserved for the weak, the timid, and the superstitious. Of this many instances might be mentioned.

3. Spectres are also sometimes occasioned by opium. Gassendi the philosopher found a number of people going to put a man to death for having intercourse with the devil; a crime which the poor wretch readily acknowledged. Gassendi begged of the people that they would permit him first to examine the wizard before putting him to death. They did so; and Gassendi, upon examination, found that the man firmly believed himself guilty of this impossible crime. He even offered to Gassendi to introduce him to the devil. The philosopher agreed; and when midnight came, the man gave him a pill, which he said it was necessary to swallow before setting off. Gassendi took the pill, but gave it to his dog. The man having swallowed his, fell into a profound sleep; during which he seemed much agitated by dreams. The dog was affected in a similar manner. When the man awoke, he congratulated Gassendi on the favourable reception he had met with from his sable highness. It was with difficulty Gassendi convinced him that the whole was a dream, the effect of soporific medicines, and that he had never stirred from one spot during the whole night.

4. That diseases, especially the night-mare, the hypochondria, hysteric passion, and madness, are another source of spectres, we have the strongest reason to affirm. Persons subject to the night-mare often imagine that they see spectres. This is still more the case with hypochondriac and hysteric persons, and those who are in any degree deranged in their intellects. A fact which fell within the observation of the writer of this article will both prove and illustrate this assertion. In a village in one of the midland counties of Scotland, lived a widow distinguished among her neighbours for decency of manners, integrity, and respect for religion. She affirmed, that for several nights together she had heard a supernatural voice exclaiming aloud, *Murder! murder!* This was immediately reported through the neighbourhood; all were alarmed, and looked around them with solicitude for the detection of the murder which they supposed to have been committed; and it was not long till a discovery seemed actually to be made. It was reported, that a gentleman, who had relations at no great distance, and had been residing in the West Indies, had lately arrived with a considerable fortune; that he had lodged in an inn about three miles off; and that he had afterwards been seen entering a house in the village where the widow lived, from which he had never returned. It was next affirmed, that a tradesman passing the churchyard about twelve at midnight had seen four men carry a dead corpse into that cemetery. These three facts being joined together seemed perfectly to agree and to confirm one another, and all believed some horrible murder had been committed. The relations of the gentleman thought they were called upon to make inquiry into the truth of these allegations: they accordingly came first to the churchyard, where, in company with the sexton, they examined all the graves with great care, in order to discover whether any of them had been lately dug, or had the appearance of containing more than one coffin. But this search was to no purpose, for no alteration had been made upon the graves. It was next reported that the murdered man had been buried in a plantation about a mile distant from the village. As the alarm was now very general, a number of the inhabitants proposed of their own accord to explore it. They accordingly spread themselves over the wood, and searched it with care, but no grave nor new dug earth was found. The writer of this article, who was then a boy at school, was along with them. The matter

Spectre.

ter did not rest here: The person who was said to have seen four men carry a dead corpse into the churchyard at midnight was summoned to appear before a meeting of the justices of the peace. Upon examination he denied any knowledge of the affair, but referred the court to another person from whom he had received his information. This person was examined, and the result was the same as the former. In short, one person had heard it from another, who had received it from a third, who had heard it from a fourth; but it had received a little embellishment from every person who repeated it. It turned out to be the same with Smollet's story of the three black crows, which some body was said to have vomited.

Upon inquiry at the inn where the West Indian gentleman had lodged, no such gentleman had been seen there. It was found afterwards he had never left the West Indies. Still, however, the veracity of the widow was not disputed; and some dark and secret transaction was suspected. But the whole affair was at length explained by discovering that she was somewhat deranged by melancholy. And the cries which she had at first imagined she had heard were afterwards imitated by some roguish person, who was highly amused with spreading terror among the credulous.

5. Drunkenness also has the power of creating spectres. Its natural effect in most cases is to derange the understanding, to throw it off its guard, and to give full scope to that passion which has a natural disposition to gain an ascendancy; and sometimes it excites passions which scarcely seem to exist at any other time. It makes some men licentious, some furious, some all benevolence and kindness, some from being cowards it renders undaunted heroes. It seldom, if ever, excites fear; and therefore it may be thought strange that men should imagine they see ghosts when intoxicated. But it must be remarked, that the ghosts which the drunkard sees, he sees not with the same alarm and terror as men who are sober. He is not afraid of them. He has the courage to converse with them, and even to fight with them, if they give him provocation. A man returning home intoxicated, affirmed that he had met with the devil; and that after a severe encounter he had vanquished him and brought him to the ground, to which he had nailed him fast by driving his staff through his body. Next morning the staff was found stuck with great violence into a heap of turfs!

6. Many apparitions of spectres have no other origin than the artifices of the waggish or self-interested. Dr Plot, in his Natural History of Oxfordshire, relates a marvellous story, which will illustrate this assertion. Soon after the murder of King Charles I. a commission was appointed to survey the king's house at Woodstock, with the manor, park, woods, and other demesnes to that manor belonging; and one Collins, under a feigned name, hired himself as secretary to the commissioners, who, upon the 13th of October 1649, met, and took up their residence in the king's own rooms. His majesty's bed-chamber they made their kitchen, the council hall their pantry, and the presence-chamber was the place where they sat for the dispatch of business. His majesty's dining-room they made their wood yard, and stored it with the wood of the famous royal-oak from the High Park, which, that nothing might be left with the name of king about it, they had dug up by the roots, and split and bundled up into faggots for their firing. Things being thus prepared, they sat on the 16th of the same month for the dispatch of business; and in the midst of their first debate there entered a large black dog (as they thought), which made a dreadful howling, overturned two or three of their chairs, and then crept under a bed and vanished. This gave them the greater surprise, as the doors were kept constantly locked, so that no real dog could get in or out. The next day their surprise was increased, when sitting at dinner in a lower room, they heard plainly the noise of persons walking over their heads, though they well knew the doors were all locked, and there could be no body there. Presently after they heard also all the wood of the king's oak brought by parcels from the dining-room, and thrown with great violence into the presence chamber; as also all the chairs, stools, tables, and other furniture, forcibly hurried about the room; their papers, containing the minutes of their transactions were torn, and the ink-glass broken. When all this noise had ceased, Giles Sharp, their secretary, proposed to enter first into these rooms; and in presence of the commissioners, from whom he received the key, he opened the doors, and found the wood spread about the room, the chairs tossed about and broken, the papers torn, the ink-glass broken (as has been said, but not the least track of any human creature, nor the least reason to suspect one, as the doors were all fast, and the keys in the custody of the commissioners. It was therefore unanimously agreed, that the power who did this mischief must have entered the room at the key-hole. The night following, Sharp the secretary, with two of the commissioners servants, as they were in bed in the same room, which room was contiguous to that where the commissioners lay, had their bed's feet lifted up so much higher than their heads, that they expected to have their necks broken, and then they were let fall at once with so much violence as shook the whole house, and more than ever terrified the commissioners. On the night of the 19th, as all were in bed in the same room for greater safety, and lights burning by them, the candles in an instant went out with a sulphureous smell, and that moment many trenchers of wood were hurled about the room, which next morning were found to be the same their honours had eaten on the day before, which were all removed from the pantry, though not a lock was found opened in the whole house. The next night they fared still worse; the candles went out as before, the curtains of their honours beds were rattled to and fro with great violence; their honours received many cruel blows and bruises, by eight great pewter-dishes and a number of wooden trenchers being thrown on their beds, which being heaved off, were heard rolling about the room, though in the morning none of these were to be seen. This night likewise they were alarmed with the tumbling down of oaken billets about their beds, and other frightful noises; but all was clear in the morning, as if no such thing happened. The next night the keeper of the king's house and his dog lay in the commissioners room, and then they had no disturbance. But on the night of the 22d, though the dog lay in the room as before, yet the candles went out, a number of brick-bats fell from the chimney into the room, the dog howled piteously, their bed-clothes were all stripped off, and their terror increased. On the

24th

Spectre.

24th they thought all the wood of the king's oak was violently thrown down by their bed sides; they counted 64 billets that fell, and some hit and shook the beds in which they lay; but in the morning none were found there, nor had the door been opened where the billet wood was kept. The next night the candles were put out, the curtains rattled, and a dreadful crack like thunder was heard; and one of the servants running in haste, thinking his master was killed, found three dozen of trenchers laid smoothly under the quilt by him. But all this was nothing to what succeeded afterwards: The 29th, about midnight, the candles went out, something walked majestically through the room, and opened and shut the windows; great stones were thrown violently into the room, some of which fell on the beds, others on the floor; and at about a quarter after one a noise was heard as of forty cannon discharged together, and again repeated at about eight minutes distance. This alarmed and raised all the neighbourhood, who coming into their honours room, gathered up the great stones, fourscore in number, and laid them by in the corner of a field, where, in Dr Plot's time, who reports this story, they were to be seen. This noise, like the discharge of cannon, was heard through all the country for 16 miles round. During these noises, which were heard in both rooms together, the commissioners and their servants gave one another over for lost, and cried out for help; and Giles Sharp, snatching up a sword, had well nigh killed one of their honours, mistaking him for the spirit, as he came in his shirt from his own room to theirs. While they were together, the noise was continued, and part of the tiling of the house was stript off, and all the windows of an upper room were taken away with it. On the 30th at midnight something walked into the chamber treading like a bear; it walked many times about, then threw the warming-pan violently on the floor; at the same time a large quantity of broken glass, accompanied with great stones and horses bones, came pouring into the room with uncommon force. These were all found in the morning to the astonishment and terror of the commissioners, who were yet determined to go on with their business. But on the first of November the most dreadful scene of all ensued: Candles in every part of the room were lighted up, and a great fire made; at midnight, the candles all yet burning, a noise like the bursting of a cannon was heard in the room, and the burning billets were tossed about by it even into their honours beds; who called Giles and his companions to their relief, otherwise the house had been burnt to the ground; about an hour after the candles went out as usual, the crack as if many cannon was heard, and many pailfuls of green stinking water were thrown upon their honours beds; great stones were also thrown in as before, the bed curtains and bedsteads torn and broken, the windows shattered, and the whole neighbourhood alarmed with the most dreadful noises; nay, the very rabbit-stealers that were abroad that night in the warren were so terrified, that they fled for fear and left their ferrets behind them. One of their honours this night spoke, and, *in the name of God, asked what it was, and why it disturbed them so?* No answer was given to this; but the noise ceased for a while, when the spirit came again; and, as they all agreed, *brought with it seven devils worse than itself.* One of the servants now lighted a large candle, and set it in the door-way between the two chambers, to see what passed; and as he watched it, he plainly saw a hoof striking the candle and candlestick into the middle of the room, and afterwards making three scrapes over the stuff, scraped it out. Upon this the same person was so bold as to draw a sword; but he had scarce got it out when he felt another invisible hand holding it too, and pulling it from him; and at length prevailing, struck him so violently on the head with the pummel, that he fell down for dead with the blow. At this instant was heard another burst like the discharge of the broadside of a ship of war, and at about a minute or two's distance each no less than 19 more such: these shook the house so violently, that they expected every moment it would fall upon their heads. The neighbours, on this, as has been said, being all alarmed, flocked to the house in great numbers, and all joined in prayer and psalm singing; during which the noise still continued in the other rooms, and the discharge of cannons was heard as from without, though no visible agent was seen to discharge them. But what was the most alarming of all, and put an end to their proceedings effectually, happened the next day as they were all at dinner, when a paper, in which they had signed a mutual agreement to reserve a part of the premises out of the general survey, and afterwards to share it equally amongst themselves, (which paper they had hid for the present under the earth in a pot in one corner of the room, and in which an orange-tree grew), was consumed in a wonderful manner, by the earth's taking fire with which the pot was filled, and burning violently with a blue fume, and an intolerable stench; so that they were all driven out of the house, to which they could never again be prevailed upon to return.

This wonderful contrivance was all the invention of the memorable Joseph Collins of Oxford, otherwise called *Funny Joe*, who having hired himself as secretary, under the name of *Giles Sharp*, by knowing the private traps belonging to the house, and the help of *pulvis fulminans* and other chemical preparations, and letting his fellow-servants into the scheme, carried on the deceit without discovery to the very last; insomuch that the Dr Plot, in his Natural History, relates the whole for fact, and concludes in this grave manner, "That though tricks have been often played in affairs of this kind, many of the things above related are not reconcileable with juggling; such as the loud noises, beyond the power of man to make without such instruments as were not there; the tearing and breaking the beds; the throwing about the fire; the hoof treading out the candle; and the striving for the sword, and the blow the man received from the pummel of it."

Spectre of the *Broken*, a singular phenomenon observed on the top of the *Broken*, one of the Hartz mountains in Hanover, of which M. Haue has given the following account. "After having been here (says he) for the thirtieth time, and having procured information respecting the above-mentioned atmospheric phenomenon, I was at length, on the 23d of May 1797, so fortunate as to have the pleasure of seeing it; and perhaps my description may afford satisfaction to others who visit the Broken through curiosity. The sun rose about four o'clock, and, the atmosphere being quite serene towards the east, his rays could pass without any obstruction over the Heinrichshöhe. In the south-west, however, Spectre ever, towards Achtermannshöhe, a brisk west wind carried before it thin transparent vapours, which were not yet condensed into thick heavy clouds.

"About a quarter past four I went towards the inn, and looked round to see whether the atmosphere would permit me to have a free prospect to the south-west; when I observed, at a very great distance towards Achtermannshöhe, a human figure of a monstrous size. A violent gust of wind having almost carried away my hat, I clapped my hand to it by moving my arm towards my head, and the colossal figure did the same.

"The pleasure which I felt on this discovery can hardly be described; for I had already walked many a weary step in the hopes of seeing this shadowy image, without being able to gratify my curiosity. I immediately made another movement by bending my body, and the colossal figure before me repeated it. I was desirous of doing the same thing once more—but my colossus had vanished. I remained in the same position, waiting to see whether it would return; and in a few minutes it again made its appearance on the Achtermannshöhe. I paid my respects to it a second time, and it did the same to me. I then called the landlord of the Broken; and having both taken the same position which I had taken alone, we looked towards the Achtermannshohe, but saw nothing. We had not, however, stood long, when two such colossal figures were formed over the above eminence, which repeated our compliments by bending their bodies as we did; after which they vanished. We retained our position; kept our eyes fixed on the same spot, and in a little the two figures again stood before us, and were joined by a third. Every movement that we made by bending our bodies these figures imitated—but with this difference, that the phenomenon was sometimes weak and faint, sometimes strong and well defined. Having thus had an opportunity of discovering the whole secret of this phenomenon, I can give the following information to such of my readers as may be desirous of seeing it themselves. When the rising sun, and according to analogy the case will be the same at the setting sun, throws his rays over the Broken upon the body of a man standing opposite to fine light clouds floating around or hovering past him, he needs only fix his eyes stedfastly upon them, and, in all probability, he will see the singular spectacle of his own shadow extending to the length of five or six hundred feet, at the distance of about two miles before him."

SPECULARIS LAPIS, composed of large plates of extreme thinness. (See TALC, MINERALOGY *Index*). The white variety with large and broad leaves, commonly called *isinglass and Muscovy glass*, is imported in great quantities; the miniature-painters cover their pictures with it; the lantern-makers sometimes use it instead of horn; and minute objects are usually preserved between two plates of it, for examination by the microscope.

SPECULATIVE, something relating to the theory of some art or science, in contradistinction to practical.

SPECULUM for reflecting telescopes, is made of a kind of white copper consisting of 32 parts fine red copper, one of brass, 15 of grain-tin, and three of white arsenic. The process given by the late J. Edwards, who was rewarded by the Board of Longitude for disclosing it to the public, was published in the Nautical Almanack for 1787, and is as follows: Melt the copper in a large crucible, employing some black flux, composed of two parts of tartar and one of nitre: when melted, add to it the brass and the silver. Let the pure tin be melted in another crucible, also with some black flux. Take them both from the fire, and pour the melted tin into the fused mass in the large crucible. Stir the whole well with a dry spatula of birch, and pour off the fused metal immediately into a large quantity of cold water. The sudden chill of the water will cause the fluid metal to divide into an infinite number of small particles, which will cool instantly.

Speculum. Cronstedt's Mineralogy, vol. ii. p. 712.

If the copper be completely saturated, the fracture of one piece of this mixed metal will appear bright, and of a glossy look, resembling the face of pure quicksilver. But if it is of a brown reddish colour, it wants a little more tin. To ascertain the required proportion, melt a small quantity, known by weight, of the mixed metal, with a known very small part of tin; and, if necessary, repeat the trial with different doses, till the fracture of the new mixture looks as already described. Having now ascertained the necessary addition of tin that is required, proceed to the last melting of the whole metal, together with the additional proportional dose of tin; fuse the whole, observing the same cautions as before; and you will find that the mixture will melt with a much less heat than that for the first fusion. Have ready as many ounces of white arsenic in coarse powder as there are pounds in the weight of the metal; wrap up the arsenic in a small paper, and put it, with a pair of tongs, into the crucible; stir it well with the spatula, retaining the breath to avoid the arsenical fumes or vapours (which however are not found to be hurtful to the lungs) till they disappear; take the crucible off the fire, clear away the dross from the top of the metal, pour in about one ounce of powdered rosin, with as much nitre, in order to give the metal a clean surface, and pour out the metal into the moulded flasks.

The speculum should be moulded with the concave surface downwards, and many small holes should be made through the sand upwards, to discharge the air. The moulding sand from Highgate near London, used by the founders, is as good as any for casting these metallic mirrors. The cast metal should be taken out from the sand of the flasks whilst it is hot, or else it may happen to crack if left to cool within. See TELESCOPE.

But in addition to what has now been said, we must notice some other information relative to the grinding, polishing, and other important circumstances connected with the method of preparing the most perfect speculum for telescopes. The metal being taken out of the flask, as already noticed, and this should be done as soon as it has become solid, and while it is yet red hot, care must be taken to keep the face downwards to prevent it from sinking. Holding it in that position by the git, force out the sand from the hole in the middle of the mirror with a piece of wood or iron, and place the speculum in an iron pot, with a large quantity of hot ashes or small coals, so as to bury the speculum in them a sufficient depth. If the sand is not forced out of the hole in the manner above directed, the metal, by sinking as it cools, will

Speculum. will embrace the sand in the middle of the speculum so tight, as to cause it to crack before it becomes entirely cold. And if the metal be not taken out of the sand, and put in a pot with hot ashes or coals to anneal it, the moisture from the sand will always break the metal. Let the speculum remain in the ashes till the whole is become quite cold. The git may be easily taken off by marking it round with a common fine half round file, and giving it then a gentle blow. The metal is then to be rough ground and figured.

But before we proceed to describe that process, it may be proper to give an account of another composition for the speculum of a reflecting telescope, which has been employed with great success, by Rochon director of the marine observatory at Brest. Of this composition the principal ingredient is platina; which, in grains, must be purified in a strong fire by means of nitre and the salt of glass, or that flux which in the English glass-houses is called by the workmen *sandifer*. To the platina, when purified, add the eighth part of the metal employed in the composition of common specula; for tin without red copper would not produce a good effect. This mixture is then to be exposed to the most violent heat, which must be still excited by the oxygen gas that disengages itself from nitre when thrown into the fire. One melting would be insufficient: five or six are requisite to bring the mixture to perfection. It is necessary that the metal should be in a state of complete fusion at the moment when it is poured into the mould. By this process I have been enabled (says the author) to construct a telescope with platina, which magnifies the diameters of objects five hundred times, with a degree of clearness and distinctness requisite for the nicest observations. The large speculum of platina weighs fourteen pounds: it is eight inches in diameter, and its focus is six feet. Though the high price of platina will, in all probability, for ever prevent it from coming into general use for the speculums of telescopes, we thought it proper to notice this discovery, and shall now proceed to the grinding of the speculum.

For accomplishing this object, a very complicated process is recommended in Smith's Optics, and one not much more simple, by Mr Mudge in the 67th volume of the *Philosophical Transactions*; but according to Mr Edwards, whose speculums are confessedly the best, neither of these is necessary. Besides a common grindstone, all the tools that he made use of are a rough grinder, which serves also as a polisher, and a bed of hones. When the speculum was cold, he ground its surface bright on a common grindstone, previously brought to the form of the gage; and then took it to the rough grinder.

The tool is composed of a mixture of lead and tin, or of pewter, and is made of an elliptical form, of such dimensions, that the shortest diameter of the ellipse is equal to the diameter of the mirror or speculum, and the longest diameter is to the shortest in the proportion of ten to nine. This rough grinder may be fixed upon a block of wood, in order to raise it higher from the bench; and as the metal is ground upon it with fine emery, Mr Mudge, with whom, in this particular, Mr Edwards agrees, directs a hole or pit to be made in the middle of it as a lodgement for the emery, and deep grooves to be cut out across its surface with a graver for the same purpose. By means of a handle fixed on the back of the metal with soft cement, the speculum can be whirled round upon this grinder so rapidly, that a common labourer has been known to give a piece of metal, four inches in diameter, so good a face and figure as to fit it for the hones in the space of two hours. The emery, however fine, will break up the metal very much; but that is remedied by the subsequent process of honing and polishing. Speculum.

When the metal is brought to a true figure, it must be taken to a convex tool, formed of some stones from a place called Edgedon in Shropshire, situated between Ludlow and Bishop's Castle. The common blue hones, used by many opticians for this purpose, will scarcely touch the metal of Mr Edwards's speculums; but where they must be employed for want of the others, as little water should be used as possible when the metal is put upon them; because it is found by experience that they cut better when but barely wet, than when drenched with water. The stones, however, from Edgedon are greatly preferable; for they cut the metal more easily, and having a very fine grain, they bring it to a smooth face. These stones are directed by Mr Mudge to be cemented in small pieces upon a thick round piece of marble, or of metal made of tin and lead like the former composition, in such a manner, that the lines between the stones may run straight from one side to the other; so that placing the teeth of a very fine saw in each of these divisions, they may be cleared from one end to the other of the cement which rises between the stones. As soon as the hones are cemented down, this tool must be fixed in the lathe, and turned as exactly true to the gage as possible. It should be of a circular figure, and but very little larger than the metal intended to be figured upon it. If it be made considerably larger, it will grind the metal into a larger sphere and a bad figure; and if it be made exactly of the same size, it will work the metal indeed into a figure truly spherical, but will be apt to shorten its focus, unless the metal and tool be worked alternately upwards. On these accounts Mr Edwards recommends it to be made about one twentieth part longer in diameter than the speculum, because he has found that it does not then alter its focus; and he earnestly dissuades the use of much water on the hone pavement at the time of using it, otherwise, he says, that the metal in different parts of it will be of different degrees of brightness.

The metal being brought to a very fine face and figure by the bed of stones, is ready to receive a polish, which is given to it by the elliptical rough grinder covered with pitch. With respect to the consistency of this pitch, Mr Mudge and Mr Edwards give very different directions. Whilst the former says that it should be neither too hard nor too soft, the latter affirms that the harder the pitch is, the better figure it will give to the metal. Pitch may be easily made of a sufficient hardness by adding a proper quantity of rosin; and when it is hardened in this way, it is not so brittle as pitch alone, which is hardened by boiling. Mr Edwards advises to make the mixture just so hard as to receive, when cold, an impression from a moderate pressure of the nail of one's finger. When the elliptical tool is to be covered with this mixture, it must be made pretty warm, and in that state have the mixture poured upon it when beginning to cool in the crucible. Our author

Speculum.

author recommends this coating to be made everywhere of about the thickness of half a crown; and to give it the proper form, it must, when somewhat cool, be pressed upon the face of the mirror, which has first been dipped in cold water, or covered over with very fine writing paper. If it be not found to have taken the exact figure from the first pressure, the surface of the pitch must be gently warmed, and the operation repeated as before. All the superfluous pitch is now to be taken away from the edge of the polisher with a pen knife, and a hole to be made in the middle, accurately round, with a conical piece of wood. This hole should go quite through the tool, and should be made of the same size, or somewhat less than the hole in the middle of the speculum. Mr Edwards says, that he has always found that small mirrors, though without any hole in the middle, polish much better, and take a more correct figure, for the polisher's having a hole in the middle of it.

The polisher being thus formed, it must be very gently warmed at the fire, and divided into several squares by the edge of a knife. These, by receiving the small portion of metal that works off in polishing, will cause the figure of the speculum to be more correct than if no such squares had been made. Mr Mudge directs the polisher to be strewed over with very fine *putty*; but Mr Edwards prefers COLCOTHAR of vitriol. Putty (says he) gives to metals a white lustre, or, as workmen call it, a silver hue; but good colcothar of vitriol will polish with a very fine and high black lustre, so as to give the metal finished with it the complexion of polished steel. To know if the colcothar of vitriol is good, put some of it into your mouth, and if you find it dissolves away it is good; but if you find it hard, and crunch between your teeth, then it is bad, and not well burned. Good colcothar of vitriol is of a deep red, or of a deep purple colour, and is soft and oily when rubbed between the fingers; bad colcothar of vitriol is of a light red colour, and feels harsh and gritty. The colcothar of vitriol should be levigated between two surfaces of polished steel, and wrought with a little water; when it is worked dry, you may add a little more water, to carry it lower down to what degree you please. When the colcothar of vitriol has been wrought dry three or four times, it will acquire a black colour, and will be low enough, or sufficiently fine, to give an exquisite lustre. This levigated colcothar of vitriol must be put into a small phial, and kept with some water upon it. When it is to be used, every part of the pitch-polisher must be first brushed over with a fine camel's hair brush, which has been dipped in pure water, and rubbed gently over a piece of dry clean soap. The washed colcothar of vitriol is then to be put upon the polisher; and Mr Edwards directs a large quantity of it to be put on at once, so as to saturate the pitch, and form a fine coating. If a second or third application of this powder be found necessary, it must be used very sparingly, or the polish will be destroyed which has been already attained. When the metal is nearly polished, there will always appear some black mud upon its surface, as well as upon the tool. Part of this must be wiped away with some very soft wash leather; but if the whole of it be taken away, the polishing will not be so well completed.

With respect to the *parabolic figure* to be given to the mirror, Mr Edwards assures us, that a very little experience in these matters will enable any one to give it with certainty, by polishing the speculum in the common manner, only with cross strokes in every direction, upon an elliptical tool of the proper dimensions.

Speculum || Spell.

SPECULUM, a looking-glass or mirror, capable of reflecting the rays of the sun.

SPECULUM, in *Surgery*, an instrument for dilating a wound, or the like, in order to examine it attentively. See SURGERY.

SPEECH, in general, the art or act of expressing a person's thoughts by means of articulate sounds, which we call words. See LANGUAGE, GRAMMAR, READING, and ORATORY, Part IV.

SPEED, JOHN, an English historian, was born at Farington, in Cheshire, in the year 1542. He was by profession a taylor, and freeman of the company of merchant taylors in the city of London. In 1606, he published his Theatre of Great Britain, which was afterwards reprinted in folio, under the title of the *Theatre of the Empire of Great Britain*. His genealogies of Scripture were first bound up with the Bible in 1611, when the first edition of the present translation was printed. In 1614 appeared his *History of Great Britain*, which has been translated into Latin; and in 1616 he published his *Cloud of Witnesses*, in octavo. He lived in marriage 57 years with his wife, by whom he had twelve sons and six daughters; and died in 1629. He was interred in the church of St Giles's, Cripplegate, London, where a monument was erected to his memory.

SPEEDWELL. See VERONICA, BOTANY *Index*.

SPELL, a charm consisting of some words of occult power, generally attended with some ceremony.—In order to explain it, we will produce a few examples. On St Agnes's night, 21st of January, take a row of pins, and pull out every one, one after another, saying a Pater-noster on sticking a pin in your sleeve, and you will dream of him or her you shall marry.

Another method to see a future spouse in a dream. The party inquiring must lie in a different county from that in which he commonly resides, and on going to bed must knit the left garter about the right-legged stocking, letting the other garter and stocking alone; and as he rehearses the following verses, at every comma, knit a knot: *Grose's Provincial Glossary.*

This knot I knit,
To know the thing I know not yet;
That I may see
The man (woman) that shall my husband (wife) be;
How he goes, and what he wears,
And what he does all days and years.

Accordingly, in a dream, he will appear with the insignia of his trade or profession.

Another, performed by charming the moon, thus: At the first appearance of the new moon, immediately after the new year's day, (though some say any other new moon is as good), go out in the evening, and stand over the spars of a gate or stile, and, looking on the moon, repeat the following lines:

All hail to the moon! all hail to thee!
I prithee, good moon, reveal to me
This night who my husband (wife) must be.

Immediately after you must go to bed, when you will dream of the person destined for your future husband or wife.

SPELLING, in *Grammar*, that part of orthography which teaches the true manner of resolving words into their syllables.

All words are either simple or compound, as *use*, *disuse*; *done*, *undone*; and the rules for dividing each must be such as are derived from the analogy of language in general, or from the established custom of speaking; which, for the English language, are reduced to the following rules: 1. A consonant between two vowels must be joined with the latter in spelling, as *na-ture*, *ve-ri-ly*, *ge-ne-rous*; except, however, the letter *x*, which is joined to the first, as in *flax-en*, *ox-en*, &c. and compound words, as in *up-on*, *un-used*, &c. 2. A double consonant must be divided, as in *let-ter*, *man-ner*, &c. 3. Those consonants which can begin a word, must not be parted in spelling, as in *de-fraud*, *re-prove*, *di-stinct*; however, this rule is found sometimes to fail; for though *gn* begins a word, as *gnaw*, *gnat*, &c. yet it must be divided in spelling, as in *cog-ni-zance*, *ma-lig-ni-ty*, &c. 4. Those consonants which cannot begin a word must be divided, as *ld* in *seldom*, *lt* in *mul-ti-tude*, *mp* in *temper*, *rd* in *ar-dent*; but in final syllables there are exceptions, as *tl* in *ti-tle*, *dl* in *han-dle*, &c. 5. When two vowels come together, and are both of them distinctly sounded, they must be separated in spelling, as in *co-e-val*, *mu-tu-al*, &c. 6. The grammatical terminations or endings must be separated in spelling, as *ed* in *wing-ed*, *edst* in *de-li-ver-edst*, *ing* in *hear-ing*, *ance* in *de-li-ver-ance*, &c. 7. Compound words must be resolved into their simple or component words, as *up-on*, *in-to*, *ne-ver-the-less*, *not-with-stand-ing*, &c.

SPELMAN, Sir Henry, an eminent English antiquarian, was descended from an ancient family, and born at Cengnam, near Lynn in Norfolk, about the year 1561. He was knighted by King James I. who had a particular esteem for him on account of his known capacity for business; and he employed him several times in Ireland on public affairs. When he was about 50 years of age, he went to reside in London; where falling into a study to which his own genius had always inclined him, he collected all such books and MSS. as concerned the subject of antiquities, either foreign or domestic. In 1626, he published the first part of his well-known Glossary, which he never carried beyond the letter L; because, as some have suggested, he had said things under "Magna charta," and "Maximum consilium," that could not then have appeared without giving offence. Upon his death all his papers came into the hands of his son Sir John Spelman, a gentleman who had abilities to have completed his father's design, if death had not prevented him. The second part was afterwards published by Sir William Dugdale; but with all the marks of a scanty unfinished performance. The next work he entered upon was an edition of the English Councils, of which he published the first volume about two years before his death, leaving the second volume, as well of this as of his Glossary, to be published by Sir William Dugdale. Sir Henry wrote several other things, all relating to ancient laws and customs, and died in 1641. His Posthumous Works were published in folio, 1698, under the inspection of Mr Gibson, afterwards bishop of London.

SPELTER, in *Metallurgy*, the same with Zinc.

SPENCE, Joseph, an eminent writer, was fellow of New College, Oxford, where he took the degree of A.M. in 1727. About that time he became first known as an author, by an *Essay on Pope's Odyssey, in which some particular beauties and blemishes of that work are considered*; a work of great merit, and which for sound criticism and candid disquisition is almost without a parallel. He was elected professor of poetry by the university in 1728, and held that office ten years, which is as long as the statutes will allow. His History of Stephen Duck was first published in 1731; but it was afterwards much altered, and prefixed to an edition of Duck's poems.

About this time he travelled into Italy as tutor to the earl of Lincoln, afterwards duke of Newcastle.—In 1736 he republished Gorboduc, at Mr Pope's desire, with a preface giving an account of the author, the earl of Dorset. He quitted his fellowship in 1742, upon being presented by the Society of New College to the rectory of Great Harwood in Buckinghamshire.—He never resided in his living; but paid it an annual visit, distributing large sums of money among the poor, and providing for many of their children. The same year he was made professor of modern history at Oxford. In 1747 he published *Polymetis*; or an inquiry concerning the agreement between the works of the Roman poets and the remains of ancient artists, being an attempt to illustrate them mutually from each other. This work was treated by Gray with a contempt which it did not deserve. He raises objections because the author did not illustrate his subject from Greek writers; that is, because he failed to execute what he never undertook. He was installed prebendary of the seventh stall at Durham the 24th May 1754. He published the same year, "An Account of the Life, Character, and Poems, of Mr Blacklock, student of philosophy at Edinburgh;" which was afterwards prefixed to his Poems. The prose pieces which he printed in the Museum he collected and published, together with some others, in a pamphlet called *Moralities*, by Sir Harry Beaumont. Under the same name he published "Crito, or a Dialogue on Beauty," and "A particular Account of the emperor of China's Gardens near Pekin, in a letter from F. Attiret, a French missionary now employed by that emperor to paint the apartments in those gardens, to his friend at Paris." Bosh these treatises are printed in Dodsley's fugitive pieces, as is also "A Letter from a Swiss Officer to his friend at Rome;" which Mr Spence first published in the Museum. In 1758 he published "A Parallel, in the Manner of Plutarch, between a most celebrated man of Florence and one scarce ever heard of in England." This was also inserted in the fugitive pieces. The same year he made a journey into Scotland, which he described in an affectionate letter to Mr Shenstone, published in Hall's Collection of Letters, 1778. In 1764 he was very well described by Mr James Ridley, in his admirable Tales of the Genii, under the name of *Phesoi Ecneps* (his name read backwards), dervise of the groves. A letter from Mr Spence to that ingenious moralist, under the same signature, is preserved in the 3d volume of "Letters

ters of Eminent Persons." In 1768 he published "Remarks and Dissertations on Virgil, with some other classical observations, by the late Mr Holdsworth." On the 20th of August the same year he was unfortunately drowned in a canal in his garden at Byfleet in Surrey. He was found flat upon his face at the edge of the canal, where the water was so shallow as not even to cover his head. The accident, it was supposed, for he was quite alone, was owing to a fit.

The duke of Newcastle possesses some manuscript volumes of anecdotes collected by Mr Spence, from which Dr Johnson was permitted to insert many extracts in his Lives of the Poets.

SPENCER, Dr John, an eminent divine, was born in Kent in 1630, and educated at Cambridge. He was chosen fellow of his college, and took a doctor's degree in 1663. In 1667 he was chosen master of Corpus Christi College, and preferred to the deanery of Ely in 1677. He died on the 20th of May 1695. His works are, 1. The Righteous Ruler; a Sermon on Proverbs xxix. 2. preached June 28. 1660. 2. A Discourse concerning Prodigies, wherein the vanity of presages by them is reprehended, and their true and proper ends asserted and vindicated. To this excellent work was afterwards added, A Discourse concerning vulgar prophecies, wherein the vanity of receiving them as the certain indications of any future event is exposed; and some marks of distinction between true and pretended prophets are laid down. 3. A Latin dissertation concerning Urim and Thummim. 4. His famous treatise *De legibus Hebræorum ritualibus et earum rationibus*. The intention of this book, as he informs us himself, was to vindicate the Deity from the imputation of acting from arbitrary and fantastical motives. It has been highly and justly esteemed both for the elegance of style and the uncommon erudition and sound sense which it displays. It has, however, (that part of it particularly which endeavours to deduce some of the Jewish ceremonies from the practices of their heathen neighbours), alarmed many persons, as if such a doctrine, if it could be proved, would derogate from the Divine wisdom, and undermine revelation. But this is so far from being the case, that Dr Spencer's attempt, whether successful or not, deserves the gratitude of Christians, because it has a tendency to throw light on an important and difficult subject.

SPENSER, Edmund, the poet, was born in London in the year 1553, and descended from an ancient family of the Spensers in Northamptonshire. All we know concerning his education is, that he was admitted a sizer of Pembroke-hall in Cambridge, and matriculated in 1569. At this time began his intimacy with Mr Gabriel Harvey, a man of genius and a poet. In 1576, having completed his degrees in arts, he left the university, as is conjectured, for want of subsistence, and retired to the north of England. Here he had the misfortune to become enamoured of his Rosalind, who, after flattering his passion for a time, at length preferred his happier rival. Spenser continued in the country till the year 1578, when at the persuasion of his friend Mr Harvey he removed to London, where that gentleman introduced him to Mr Sidney (afterwards Sir Philip Sidney). Concerning his first introduction to Sir Philip, there is indeed a different story, which was first told by the writer of his life, prefixed to his works in 1670, and transcribed by Hughes, Cibber, and several others; which, nevertheless, is certainly not true. The purport of it is, that Spenser, being unknown to this Mecænas of the age, went to Leicester-house, and sent in the 9th canto of the first book of the Fairy Queen; that, on reading part of it, Sir Philip ordered his steward to give the bearer 50l.; on reading a little farther 50l. more; then 200l.; bidding him to make haste and pay the money, lest he should give the poet his whole estate. The story tells prettily enough; but it is very certain, that the Fairy Queen was begun long after his aquaintance with Sir Philip. By this universal patron of genius, however, he was presented to Queen Elizabeth, who honoured him with the place of poet-laureat. About this time he finished his Shepherd's Calendar, which was first printed in 1579; and in the following year, being recommended by his patron to the earl of Leicester, he went to Ireland as secretary to the lord Grey of Wilton, then appointed lord-lieutenant of that kingdom. Lord Grey was recalled in 1582, and with him Spenser returned to London, where he continued till after the death of Sir Philip Sidney in 1586; a loss which he bewailed to the end of his life. The following year, our poet, having obtained a royal grant of 3000 acres of forfeited lands in the county of Cork in Ireland, set out for that kingdom, took possession of his estate, and fixed his residence in the castle of Kilcolman, which had belonged to the earl of Desmond. In this retirement he resumed his great work of the Fairy Queen; and continued in Ireland till, being visited by his old friend Sir Walter Raleigh in 1589, he came over with him to England, but returned to Ireland the year following, where he fell in love with a country girl, and married her. Soon after his marriage, he paid another visit to his native country, where we also find him in 1596. In the following year he returned once more to Kilcolman; but on the rebellion of Lord Tyrone, who ravaged the whole county of Cork, he was obliged to fly for safety with his family to England, where, in the year 1599, he died in extreme poverty (A). He was buried in Westminster Abbey, according to his request, near Chaucer. A monument was erected to his memory by Ann countess of Dorset. We know but little of his character as a man; as a poet, considering the age in which he lived, he deserves our utmost veneration. He wrote various pieces besides those above mentioned. His whole works, with his life by Hughes, were published in six volumes 12mo, in 1715 and 1750.

SPERGULA, Spurrey, a genus of plants belonging to the class of decandria; and in the natural system arranged

(A) This is Camden's account, and it has been generally believed; but Mr Malone, the last editor of Shakespeare's works, by examining the patent roll, 33 Eliz. p. 3. has discovered, that in February 1690-1 Spenser obtained from Queen Elizabeth an annuity or pension of 50l. during his life; a sum equivalent to 200l. at present.

arranged under the 22d order, *Caryophylleæ*. See Botany *Index*.

SPERM, the seed whereof an animal is formed. See Physiology.

SPERMACETI, a whitish, unctuous, flaky substance, prepared from oil, but chiefly from the brains of a species of whale called *physeter macrocephalus*.

The method of preparing spermaceti is kept a secret; but the process is said to be this: The brains being taken out of the animal, are then, as some say, melted over a gentle fire, poured into moulds, and when cold melted again; and this process is continued till they are purified. Others say, that after being pressed and drained they are more thoroughly purified by steeping them in a ley of alkaline salt and quicklime. The brains are then washed, and cut into thin flakes or slices with wooden knives. One fish is said to afford some tons of brains. Good spermaceti is glossy and semitransparent, in fine white flakes; soft and unctuous to the touch, yet dry and friable; in taste, somewhat like butter, and of a faint smell like that of tallow. Some adulterate it with wax; but the deceit is discovered, either by the smell of the wax or by the dulness of the colour. Some also sell a preparation of oil taken from the tail of the whale instead of that from the brain; but this kind turns yellow as soon as exposed to the air. Indeed it is apt in general to grow yellowish, and to contract a rancid fishy smell if not carefully secured from the air. The more perfectly it has been purified at first, the less susceptible it is of these alterations; and after it has been changed, it may be rendered white and sweet again by steeping it afresh in a ley of alkaline salt and quicklime. It melts in a small degree of heat, and congeals again as it cools.

Spermaceti is of use in medicine. Quincy says it is a noble remedy in the asthma, &c. though chiefly used in bruises, inward hurts, and after delivery. For internal use, it may be dissolved in aqueous liquors into the form of an emulsion, by trituration with almonds, the yoke or white of an egg, and more elegantly by mucilages; or made into a lohoch, by mixing two drams of it with a suitable quantity of yolk of egg, then adding half an ounce of fresh drawn oil of almonds, and an ounce of balsamic syrup. Spermaceti is not capable of being dissolved by caustic alkalies, and of forming soaps, like other oily matters: but it is altogether soluble in oils, and unites by liquefaction with wax and resins; and in these forms is applied externally. But it is certain, its greatest property, and that which makes it so much in vogue in many places, is its softening the skin. Whence it comes to be used by the ladies in pastes, washes, &c.

Spermaceti candles are of modern manufacture: they are made smooth, with a fine gloss, free from rings and scars, superior to the finest wax candles in colour and lustre: and, when genuine, leave no spot or stain on the finest silk, cloth, or linen.

A meth.d has been lately proposed by Dr Smith Gibbes of Bristol, to convert animal muscle into a substance much resembling spermaceti. The process is remarkably simple: Nothing more is necessary than to take a dead carcase and expose it to a stream of running water: it will in a short time be changed to a mass of fatty matter. To remove the offensive smell, a quantity of nitrous acid may then be poured upon it, which uniting with the fetid matter, the fat is separated in a pure state. This acid indeed turns it yellow, but it may be rendered white and pure by the action of the oxygenated muriatic acid. Mr Gibbes brought about the same change in a much shorter time. He took three lean pieces of mutton and poured on them the three mineral acids, and he perceived that at the end of three days each was much altered; that in the nitrous acid was much softened, and on separating the acid from it, he found it to be exactly the same with that which he had before got from the water; that in the muriatic acid was not in that time so much altered; the vitriolic acid had turned the other black.

Phil. Trans. 1794.

SPERMACOCE, Button-wood, a genus of plants belonging to the class of tetrandria; and in the natural system arranged under the 47th order, *Stellatæ*. See Botany *Index*.

SPERMATIC, in *Anatomy*, something belonging to the sperm or seed.

SPEUSIPPUS, an Athenian philosopher, the nephew and successor of Plato. Contrary to the practice of Plato, Speusippus required from his pupils a stated gratuity. He placed statues of the Graces in the school which Plato had built. On account of his infirm state of health, he was commonly carried to and from the academy in a vehicle. On his way thither he one day met Diogenes, and saluted him; the surly philosopher refused to return the salute, and told him, that such a feeble wretch ought to be ashamed to live; to which Speusippus replied, that he lived not in his limbs, but in his mind. At length, being wholly incapacitated, by a paralytic stroke, for the duties of the chair, he resigned it to Xenocrates. He is said to have been of a violent temper, fond of pleasure, and exceedingly avaricious. Speusippus wrote many philosophical works, which are now lost, but which Aristotle thought sufficiently valuable to purchase at the expence of three talents. From the few fragments which remain of his philosophy, it appears that he adhered very strictly to the doctrine of his master.

SPEY, a river of Scotland, rising from a lake of the same name in Badenoch, and, after a serpentine course of 76 miles, passes by Rothes castle, and falls into the German sea at Garnoch near Elgin. Mr Pennant tells us, that the Spey is a dangerous neighbour to Castle Gordon, overflowing frequently in a dreadful manner, as appears by its ravages far beyond its banks. The bed of the river is wide and full of gravel, and the channel very shifting. In 1746 the duke of Cumberland passed this river at Belly church near Castle Gordon, when the channel was so deep as to take an officer, from whom Mr Pennant had the account, and who was six feet four inches high, up to the breast. The banks are here very high and steep; so that had not the rebels been infatuated in such a manner as to neglect opposition, the passage must have been attended with considerable loss. On this river there is a great salmon-fishery; about 1700 barrels full are caught in the season, and the shore was formerly rented for about 1200l. per annum: now it is probably doubled.

SPHACELUS, in *Surgery* and *Medicine*, an absolute and perfect corruption or death of the parts.

SPHÆRANTHUS, a genus of plants belonging to the

Sphæranthus || Sphinx.

the class of syngenesia, and to the order of polygamia segregata; and in the natural system arranged under the 49th order, *Compositæ*. See BOTANY *Index*.

SPHAGNUM, BOG-MOSS, a genus of plants belonging to the class of cryptogamia and order of musci. See BOTANY *Index*.

Os SPHENOIDES, the seventh bone of the cranium or skull. See ANATOMY, N° 11.

SPHERE, is a solid contained under one uniform round surface, every point of which is equally distant from a certain point in the middle called its *centre;* and is formed by the revolution of a semicircle about its diameter. See GEOMETRY.

Projection of the SPHERE. See PROJECTION.

SPHERE, in *Astronomy*, that concave orb or expanse which invests our globe, and in which the heavenly bodies appear to be fixed, and at an equal distance from the eye.

The better to determine the places of the heavenly bodies in the sphere, several circles are supposed to be described on the surface thereof, hence called the *circles of the sphere:* of these some are called *great circles*, as the equinoctial, ecliptic, meridian, &c. and others *small circles*, as the tropics, parallels, &c. See GEOGRAPHY; and ASTRONOMY, *passim*.

Armillary SPHERE. See GEOGRAPHY.

SPHERE *of Activity of a Body*, is that determinate space or extent to which, and no farther, the effluvia continually emitted from that body reach; and where they operate according to their nature.

SPHERES, in *Optics*, the same with metalline mirrors, for telescopes or other purposes. See MIRROR.

SPHEROID, in *Geometry*, a solid approaching to the figure of a sphere. It is generated by the entire revolution of a semi-ellipsis about its axis. When the revolution is made round the largest axis, the spheroid is called *prolate;* and when round the shortest, *oblate*. This last is the figure of the earth, and probably of all the planets.

SPHEX, ICHNEUMON WASP, or *Savage;* a genus of insects belonging to the order of *hymenopteræ*. See ENTOMOLOGY *Index*.

SPHINCTER, in *Anatomy*, a term applied to a kind of circular muscles, or muscles in form of rings, which serve to close and draw up several orifices of the body, and prevent the excretion of the contents.

SPHINX, in fabulous history, a monster which had the head and breasts of a woman, the body of a dog, the tail of a serpent, the wings of a bird, the paws of a lion, and a human voice. It sprang from the union of Orthos with the Chimæra, or of Typhon with Echidna. The Sphinx had been sent into the neighbourhood of Thebes by Juno, who wished to punish the family of Cadmus, which she persecuted with immortal hatred, and it laid this part of Bœotia under continual alarms, by proposing enigmas, and devouring the inhabitants, if unable to explain them. In the midst of their consternation the Thebans were told by the oracle, that the sphinx would destroy herself as soon as one of the enigmas she proposed was explained. In this enigma she wished to know what animal walked on four legs in the morning, two at noon, and three in the evening. Upon this Creon king of Thebes promised his crown and his sister Jocasta in marriage to him who could deliver his country from the monster by a successful explanation of the enigma. It was at last happily explained by Oedipus, who observed, that man walked on his hands and feet when young, or in the morning of life; at the noon of life he walked erect; and in the evening of his days he supported his infirmities upon a stick. (*Vid. Oedipus*). The sphinx no sooner heard this explanation than she dashed her head against a rock, and immediately expired. Some mythologists wish to unriddle the fabulous traditions about the sphinx by the supposition that one of the daughters of Cadmus, or Laius, infested the country of Thebes by her continual depredations, because she had been refused a part of her father's possessions. The lion's paw expressed, as they observe, her cruelty, the body of the dog her lasciviousness, her enigmas the snares she laid for strangers and travellers, and her wings the dispatch she used in her expeditions.

Lempriere's Bibliotheca Classica.

Sphinx, Spigelia.

Among the Egyptians the sphinx was the symbol of religion, by reason of the obscurity of its mysteries; and on the same account the Romans placed a sphinx in the pronaos or porch of their temples. Sphinxes were used by the Egyptians to show the beginning of the water's rising in the Nile: with this view, as it had the head of a woman and body of a lion, it signified that the Nile began to swell in the months of July and August, when the sun passes through the signs of Leo and Virgo. There are several of these still to be seen; one in particular, near the pyramids, much spoken of by the ancients; being of a prodigious size, and cut out of the rock; the head and neck appear only at present, the rest of the body being hid in the sand. This, according to Thevenot, is 26 feet high, and 15 feet from the ear to the chin: but Pliny assures us, the head was no less than 102 feet in circumference, and 62 feet high from the belly, and that the body was 143 feet long, and was thought to be the sepulchre of King Amasis.

The learned Mr Bryant * observes that the sphinx seems to have been originally a vast rock of different strata; which, from a shapeless mass, the Egyptians fashioned into an object of beauty and veneration. The Egyptians used this figure in their building; from them the Greeks derived it, and afterwards improved it into an elegant ornament. It is also frequently used in modern architecture.

* *Ancient Mythology*, vol. iii. p. 532.

It is proper to observe, that the sphinx of the Egyptians is said in the Asiatic Researches † to have been found in India. Colonel Pearse was told by Murari Pandit, a man of learning among the Hindoos, that the sphinx, there called *singh*, is to appear at the end of the world, and as soon as he is born will prey on an elephant: he is therefore figured seizing an elephant in his claws; and the elephant is made small, to show that the *singh*, even a moment after his birth, will be very large in proportion to it. But in opposition to this account given by Múrari Pandit, the late Sir William Jones, the learned and illustrious president of the Asiatic Society, was assured by several Brahmans, that the figure taken for a sphinx was a representation of a lion seizing a young elephant. This point therefore requires farther investigation.

† Vol. ii. p. 334.

SPHINX, *Hawk-Moth*, a genus of insects belonging to the order of *lepidopteræ*. See ENTOMOLOGY *Index*.

SPIGELIA, WORM-GRASS, a genus of plants belonging

longing to the class of pentandria; and in the natural system arranged under the 47th order, *Stellatæ*. See BOTANY and MATERIA MEDICA *Index*.

SPICE, any kind of aromatic drug that has hot and pungent qualities; such are pepper, nutmeg, ginger, cinnamon, cloves, &c.

SPICE-Islands, in the East Indies. See BANDA, *MOLUCCA-Islands*, and CEYLON.

SPIDER. See ARANEA, ENTOMOLOGY *Index*.

SPIDERWORT. See PHALANGIUM, } BOTANY *Index*.

SPIGNEL. See ATHAMANTA, } BOTANY *Index*.

SPIKE, or *Oil of SPIKE*, a name given to an essential oil distilled from lavender, and much used by the varnish-makers and the painters in enamel.

SPIKENARD. See NARDUS, BOTANY *Index*.

SPILANTHUS, a genus of plants belonging to the class of syngenesia. See BOTANY *Index*.

SPINA CERVINA, an old name for rhamnus catharticus. See RHAMNUS, BOTANY *Index*.

SPINA Ventosa, in *Surgery*, that species of corruption of the bones which takes its rise in the internal parts, and by degrees enlarges the bone, and raises it into a tumor. See SURGERY.

SPINACIA, SPINAGE, a genus of plants belonging to the class of diœcia; and in the natural system arranged under the 12th order, *Holoraceæ*. See BOTANY *Index*; and for an account of the method of cultivating spinage in the garden, see GARDENING.

SPINAGE, or SPINACH. See SPINACIA.

SPINÆ, in *Botany*, thorns, rigid prickles: a species of *arma*, growing on various parts of certain plants for their defence; *spinæ ramorum arcent pecora*. On the branches we find examples in the pyrus prunus, citrus, hippophaes, gmelina, rhamnus, lycium, &c.; on the leaves, in the aloe, agave, yucca, ilex, hippomane, theophrasta, carlina, &c.; on the calyx, in the carduus cnicus, centaurea, moluccella, galeopsis, &c.; on the fruit, in the trapa, tribulus, murex, spinacia, agrimonia, datura, &c.

SPINAL MARROW. See ANATOMY *Index*.

SPINALIS, in *Anatomy*, the name of several muscles, &c. of the spine.

SPINDLE, in *Geometry*, a solid body generated by the revolution of some curve line about its base or double ordinate; in opposition to a conoid, which is generated by the rotation of the curve about its axis or absciss, perpendicular to its ordinate. The spindle is denominated circular, elliptic, hyperbolic, or parabolic, according to the figure of its generating curve.

SPINDLE-TREE. See EUONYMUS, BOTANY *Index*.

SPINE, SPINA DORSI. See ANATOMY, N° 30.

SPINE. See SPINÆ.

SPINET, or SPINNET, a musical instrument ranked in the second or third place among harmonious instruments. It consists of a chest or belly made of the most porous and resinous wood to be found, and a table of fir glued on slips of wood called *summers*, which bear on the sides. On the table are raised two little prominences or bridges, wherein are placed so many pins as there are chords or strings to the instrument. It is played on by two ranges of continued keys, the former range being the order of the diatonic scale, and that behind the order of the artificial notes or semitones. The keys are so many flat pieces of wood, which, touched and pressed down at the end, make the other raise a jack which strikes and sounds the strings by means of the end of a crow's quill, wherewith it is armed. The 30 first strings are of brass, the other more delicate ones of steel or iron-wire; they are all stretched over the two bridges already mentioned. The figure of the spinet is a long square or parallelogram; some call it an *harp couched*, and the harp an *inverted spinet*. See the article HARP.

This instrument is generally tuned by the ear, which method of the practical musicians is founded on a supposition that the ear is a perfect judge of an octave and a fifth. The general rule is to begin at a certain note, as C, taken towards the middle of the instrument, and tuning all the octaves up and down, and also the fifths, reckoning seven semitones to each fifth, by which means the whole is tuned. Sometimes to the common or fundamental play of the spinet is added another similar one in unison, and a third in octave to the first, to make the harmony the fuller; they are either played separately or together by means of a stop: these are called *double* or *triple spinets*; sometimes a play of violins is added, by means of a bow, or a few wheels parallel to the keys, which press the strings and make the sounds last as long as the musician pleases, and heighten and soften them more or less, as they are more or less pressed. The harpsichord is a kind of spinet, only with another disposition of the keys (see the article HARPSICHORD). The instrument takes its name from the small quill ends which touch the strings, resembling *spinæ* or thorns.

SPINIFEX, a genus of plants belonging to the class of *polygamia*. See BOTANY *Index*.

SPINNING, in *Commerce*, the act or art of reducing silk, flax, hemp, wool, hair or other matters, into thread. Spinning is either performed on the wheel, or with a distaff and spindle, or with other machines proper for the several kinds of working. Hemp, flax, nettle-thread, and other like vegetable matters, are to be wetted in spinning: silks, wools, &c. are spun dry, and do not need water; yet there is a way of spinning or reeling silk as it comes off the cases or balls, where hot and even boiling water is to be used (see SILK). The vast variety, and the importance of those branches of our manufactures, which are produced from cotton, wool, and flax, spun into yarn, together with the cheapness of provisions, and the low price of labour in many foreign countries, which are our rivals in trade, have occasioned many attempts at home to render spinning more easy, cheap, and expeditious; for which see *COTTON-Spinning* and *COTTON MILLS*.

To give an intelligible and accurate description of a cotton mill would be abundant employment for a volume. Our limits admit of nothing like this; but as we are certain that many of our readers have viewed a cotton mill with wonder, but not with intelligence, or with leisure to trace the steps by which the wool from the bag ultimately assumes the form of a very fine thread. Bewildered by such a complication of machinery, all in rapid motion, very few, we imagine, are able to recollect with distinctness and intelligence the essential part of the progress by which the form of the cotton is so wonderfully changed. Such readers will not think a page or two misemployed, if they are thereby able to understand this particular, to which all the rest of the process is subservient.

We pass over the operation of carding, by which all the

Spinning.

the clots and inequalities of the cotton wool are removed, and the whole is reduced to an uniform thin fleece, about 20 inches broad. This is gradually detached from the finishing card, and, if allowed to hang down from it, would pile up on the floor as long as the mill continues to work; but it is guided off from the card, very tenderly, in a horizontal direction, by laying its detached end over a roller, which is slowly turned round by the machine. Another roller lies above the fleece, pressing it down by its weight. By this pressure, a gentle hold is taken of the fleece, and therefore the slow motion of the rollers draws it gently from the card at the same rate as it is disengaged by the comb; but between the card and the rollers a set of smooth pins are placed in two rows, leading from the card to the rollers, and gradually approaching each other as we approach the rollers. By these pins the broad fleece is hemmed in on both sides, and gradually contracted to a thick roll; and in this state passes between the rollers, and is compressed in a pretty firm flat riband, about two inches broad, which falls off from the rollers, and piles up in deep tinplate cans set below to receive it.

It is upon this stripe or riband of cotton wool that the operation of spinning begins. The general effect of the spinning process is to draw out this massive roll, and to twist it as it is drawn out. But this is not to be done by the fingers, pulling out as many cotton fibres at once as are necessary for composing a thread of the intended fineness, and continuing this manipulation regularly across the whole end of the riband, and thus, as it were, nibbling the whole of it away. The fingers must be directed, for this purpose, by an attentive eye. But in performing this by machinery, the whole riband must be drawn out together, and twisted as it is drawn. This requires great art, and very delicate management. It cannot be done at once; that is, the cotton roll cannot first be stretched or drawn out to the length that is ultimately produced from a tenth of an inch of the roll, and then be twisted. There is not cohesion enough for this purpose; we should only break off a bit of the roll, and could make no farther use of it. The fibres of cotton are very little implicated among each other in the roll, because the operation of carding has laid them almost parallel in the roll; and though compressed a little by its contraction from a fleece of 20 inches to a riband of only two, and afterwards compressed between the discharging rollers of the carding machine, yet they cohere so slightly, that a few fibres may be drawn out without bringing many others along with them. For these reasons, the whole thickness and breadth of two or three inches of the riband is stretched to a very minute quantity, and then a very slight degree of twist is given it, viz. about three turns in the inch; so that it shall now compose an extremely soft and spungy cylinder, which cannot be called a thread or cord, because it has scarcely any firmness, and is merely rounder and much slenderer than before, being stretched to about thrice its former length. It is now called slab, or roove.

Although it be still extremely tender, and will not carry a weight of two ounces, it is much more cohesive than before, because the twist given to it makes all the longitudinal fibres bind each other together, and compress those which lie athwart; therefore it will require more force to pull a fibre from among the rest, but still not nearly enough to break it. In drawing out a single fibre, others are drawn out along with it; and if we take hold of the whole assemblage, in two places, about an inch or two inches asunder, we shall find that we may draw it to near twice its length without any risk of its separating in any intermediate part, or becoming much smaller in one part than another. It seems to yield equably over all.

Such is the state of the slab or roove of the first formation. It is usually called the *preparation;* and the operation of spinning is considered as not yet begun. This preparation is the most tedious, and requires more attendance and hand labour than any subsequent part of the process. For the stripes or ribands from which it is made are so light and bulky, that a few yards only can be piled up in the cans set to receive them. A person must therefore attend each thread of slab, to join fresh stripes as they are expended. It is also the most important in the manufacture: for as every inch of the slab meets with precisely the same drawing and the same twisting in the subsequent parts of the process, therefore every inequality and fault in the slab (indeed in the fleece as it quits the finishing card) will continue through the whole manufacture. The spinning of cotton yarn now divides into two branches. The first, performed by what are called *jennies*, perfectly resembles the ancient spinning with the distaff and spindle; the other, called *spinning of twist*, is an imitation of the spinning with the fly-wheel. They differ in the same manner as the spinning with the old wool or cotton wheel differs from the spinning with the flax-wheel. Mr Arkwright's chief invention, the substitution of machinery for the immediate work of the human finger, is seen only in the manufacture of twist. We shall therefore confine our attention to this.

The rest of the process is little more than a repetition of that gone through in making the first slab or roove. It is formed on bobins. These are set on the back part of the drawing frame; and the end of the slab is brought forwards toward the attending workman. As it comes forward, it is stretched or drawn to about four-thirds of its former length, or lengthened one-third; and is then twisted about twice as much as before, and in this state wound up on another bobin. In some mills two rooves, after having been properly drawn, are brought together through one hole, and twisted into one; but we believe that, in the greater number of mills, this is deferred to the second drawing. It is only after the first drawing that the produce of the operation gets the name of *slab;* before this it is called *preparation*, or *roove*, or by some other name. The slab is still a very feeble, soft, and delicate yarn, and will not carry much more weight than it did before in the form of roove. The perfection of the ultimate thread or yarn depends on this extreme softness; for it is this only which makes it susceptible of an equable stretching; all the fibres yielding and separating alike.

The next operation is the *second drawing*, which no way differs from the first, except in the different proportionings of the lengthening, and the proportion between the lengthening and the subsequent twist. On these points we cannot give any very distinct information. It is different in different mills, and with different species of cotton wool, as may be easily imagined. The immediate mechanism or manipulation must be skilfully accommodated to the nature of that friction which

Spinning.

which the fibres of cotton exert on each other, enabling one of them to pull others along with it. This is greatly aided by the contorted curled form of a cotton fibre, and a considerable degree of elasticity which it possesses. In this respect it greatly resembles woollen fibres, and differs exceedingly from those of flax: and it is for this reason that it is scarcely possible to spin flax in this way: its fibres become lank, and take any shape by the slightest compression, especially when damp in the slightest degree. But besides this, the surface of a cotton fibre has a harshness or roughness, which greatly augments their mutual friction. This is probably the reason why it is so unfit for tents and other dressings for wounds, and is refused by the surgeon even in the meanest hospitals. But this harshness and its elasticity fit it admirably for the manufacture of yarn. Even the shortness of the fibre is favourable; and the manufacture would hardly be possible if the fibre were thrice as long as it generally is. If it be just so long that in the finished thread a fibre will rather break than come out from among the rest, it is plain that no additional length can make the yarn any stronger with the same degree of compression by twining. A longer fibre will indeed give the same firmness of adherence with a smaller compression. This would be an advantage in any other yarn; but in cotton yarn the compression is already as slight as can be allowed; were it less, it would become woolly and rough by the smallest usage, and is already too much disposed to teazle out. It can hardly be used as sewing thread. Now suppose the fibres much longer; some of them may chance to be stretched along the slab through their whole length. If the slab is pulled in opposite directions, by pinching it at each end of such fibres, it is plain that it will not stretch till this fibre be broken or drawn out; and that while it is in its extended state, it is acting on the other fibres in a very unequal manner, according to their positions, and renders the whole apt to separate more irregularly. This is one great obstacle to the spinning of flax by similar machinery; and it has hitherto prevented (we believe) the working up of any thing but the *shorts* or tow, which is separated from the long fine flax in the operation of hatcheling.

A third, and sometimes even a fourth, drawing is given to the slab formed on the bobins of this second operation. The slab produced is now a slender, but still extremely soft cord, susceptible of considerable extension, without risk of separation, and without the smallest chance of breaking a single fibre in the attempt. In one or more of the preparatory drawings now described, two, and sometimes three slabs, of a former drawing, are united before the twist is given them. The practice is different in different mills. It is plain, that unless great care be taken to preserve the slab extremely soft and compressible during the whole process, the subsequent drawing becomes more precarious, and we run a risk of at last making a bad loose thread instead of a uniform and simple yarn. Such a thread will have very little lateral connection, and will not bear much handling without separating into strands. The perfection of the yarn depends on having the last slab as free of all appearance of strands as possible.

The last operation is the spinning this slab. This hardly differs from the foregoing drawings in any thing but the twist that is given it after the last stretching in its length. This is much greater than any of the preceding, being intended to give the yarn hardness and firmness, so that it will now break rather than stretch any more.

The reader, moderately acquainted with mechanics, cannot but perceive that each of the operations now described, by which the roove is changed into the soft slab, and each of these into one slenderer and somewhat firmer, by alternately teazling out and twining the soft cord, is a substitute for a single pull of the finger and thumb of the spinster, which she accommodates precisely to the peculiar condition of the lock of wool which she touches at the moment. She can follow this through all its irregularities; and perhaps no two succeeding plucks are alike. But when we cannot give this momentary attention to every minute portion, we must be careful to introduce the roove in a state of perfect uniformity; and then every inch being treated in the same manner, the final result will be equable—the yarn will be uniform.

We are now to describe the mechanism by which all this is effected. But we do not mean to describe a cotton mill; we only mean to describe what comes into immediate contact with the thread; and in so doing, to confine ourselves to what is necesary for making the reader perceive its ability to perform the required task. We see many cases where individuals can apply this knowledge to useful purposes. More than this would, we think, be improper, in a national point of view.

Let ABC (fig. 1.) represent the section of a roller, whose pivot D does not turn in a pivot hole, but in the bottom of a long narrow notch DE, cut in an iron standard. *a b c* is the section of another iron roller, whose pivot *d* is in the same notches at each end, while the roller itself lies or rests on the roller ABC below it. The surfaces of these rollers are fluted lengthwise like a column: only the flutings are very small and sharp, like deep strokes of engraving very close together. It is plain, that if the roller ABC be made to turn slowly round its axis by machinery, in the direction ABC (as expressed by the dart), the roughness of the flutings will take hold of the similar roughness of the upper roller *a b c*, and carry it round also in the direction of the dart, while its pivots are engaged in the notches DE, which they cannot quit. If therefore we introduce the end F of the cotton string or riband, formed by the carding machine, it will be pulled in by this motion, and will be delivered out on the other side at H, considerably compressed by the weight of the upper roller, which is of iron, and is also pressed down by a lever which rests on its pivots, or other proper places, and is loaded with a weight. There is nothing to hinder this motion of the riband thus compressed between the rollers, and it will therefore be drawn through from the cans. The compressed part at H would hang down, and be piled upon the floor as it is drawn through; but it is not permitted to hang down in this manner, but is brought to another pair of sharp fluted iron rollers K and L. Supposing this pair of rollers to be of the same diameter, and to turn round in the same time, and in the same direction, with the rollers ABC, *a b c*; it is plain that K and L drag in the compressed riband at I, and would deliver it on the other side at M, still more compressed. But the roller K is made (by the wheelwork) to turn round more swiftly than

Plate CCCCXCII. fig. 1.

Spinning. than ABC. The difference of velocity at the surface of the rollers is, however, very small, seldom exceeding one part in 12 or 15. But the consequence of this difference is, that the skein of cotton HI will be lengthened in the same proportion; for the upper rollers pressing on the under ones with a considerable force, their sharp flutings take good hold of the cotton between them; and since K and L take up the cotton faster than ABC and *a b c* deliver it out, it must either be forcibly pulled through between the first rollers, or it must be stretched a little by the fibres slipping among each other, or it must break. When the extension is so very moderate as we have just now said, the only effect of it is merely to begin to draw the fibres (which at present are lying in every possible direction) into a more favourable position for the subsequent extensions.

The fibres being thus drawn together into a more favourable position, the cotton is introduced between a third pair of rollers O, P, constructed in the same way, but so moved by the wheelwork that the surface of O moves nearly or fully twice as fast as the surface of K. The roller P being also well loaded, they take a firm hold of the cotton, and the part between K and O is nearly or fully doubled in its length, and now requires a little twining to make it roundish, and to consolidate it a little.

It is therefore led sloping downwards into a hole or eye in the upper pivot of the first fly, called a *jack*. This turns round an upright axis or spindle; the lower end of which has a pully on it to give it motion by means of a band or belt, which passes round a drum that is turned by the machinery. This jack is of a very ingenious and complicated construction. It is a substitute for the fly of the common spinning wheel. If made precisely in the form of that fly, the thread, being so very bulky and spongy, and unable to bear close packing on the bobin, would swag out by the whirling of the fly, and would never coil up. The bobin therefore is made to lie horizontally; and this occasions the complication, by the difficulty of giving it a motion round a horizontal axis, in order to coil up the twisted roove. Mr Arkwright has accomplished this in a very ingenious manner; the essential circumstances of which we shall here briefly describe. A is a roller of hard wood, having its surface cut into sharp flutes longitudinally. On the axis, which projects through the side of the general frame, there is a pulley P, connected by a band with another pulley Q, turning with the horizontal axis QR. This axis is made to turn by a contrivance which is different in every different cotton mill. The simplest of all is to place above the pulley C (which is turned by the great band of the machinery, and thus gives motion to the jack), a thin circular disc D, loose upon the axis, so as to turn round on it without obstruction. If this disc exceed the pulley in breadth about $\frac{1}{10}$th of an inch, the broad belt which turns the pulley will also turn it; but as its diameter is greater than that of the pulley, it will turn somewhat slower, and will therefore have a relative motion with respect to the axis QR. This can be employed in order to give that axis a very slow motion, such as one turn of it for 20 or 30 of the jack. This we leave to the ingenuity of the reader. The bobin B, on which the roove is to be coiled up, lies on this roller, its pivots passing through upright slits in the sides of the general frame. It lies on A, and is moved round by it, in the same manner as the uppermost of a pair of drawing rollers lies on the under one, and receives motion from it. It is evident that the fluted surface of A, by turning slowly round, and carrying the weight of the bobin, compresses a little the cotton that is between them; and its flutings, being sharp, take a slight hold of it, and cause it to turn round also, and thus coil up the roove, pulling it in through the hole E in the upper pivot (which resembles the fore pivot or eye of a spinning wheel fly) in so gentle a manner as to yield whenever the motion of the bobin is too great for the speed with which the cotton skein is discharged by the rollers O and P.—N. B. The axis QR below, also gives motion to a guide within the jack, which leads the roove gradually from one end of the bobin to the other, and back again, so as to coil it with regularity till the bobin is full. The whole of this internal mechanism of the jack is commonly shut up in a tin cylinder. This is particularly necessary when the whirling motion must be rapid, as in the second and third drawings. If open, the jacks would meet with much resistance from the air, which would load the mill with a great deal of useless work.

The reader is desired now to return to the beginning of the process, and to consider it attentively in its different stages. We apprehend that the description is sufficiently perspicuous to make him perceive the efficacy of the mechanism to execute all that is wanted, and prepare a slab that is uniform, soft, and still very extensible; in short, fit for undergoing the last treatment, by which it is made a fine and firm yarn.

As this part of the process differs from each of the former, merely by the degree of twist that is given to the yarn, and as this is given by means of a fly, not materially different from that of the spinning wheel for flax, we do not think it at all necessary to say any thing more about it.

The intelligent reader is surely sensible that the yarn produced in this way must be exceedingly uniform. The uniformity really produced even exceeds all expectation; for even although there be some small inequalities in the carded fleece, yet if these are not matted clots, which the card could not equalise, and only consist of a little more thickness of cotton in some places than in others, when such a piece of the stripe comes to the first roller, it will be rather more stretched by the second, and again by the bobin, after the first very slight twining. That this may be done with greater certainty, the weights of the first rooving rollers are made very small, so that the middle part of the skein can be drawn through, while the outer parts remain fast held.

It is said that a pound of the finest Bourbon cotton has been spun into a yarn extending a few yards beyond 119 miles!

These contrivances have in some parts of Scotland been applied to the spinning of flax.

Transactions of the Society for the Encouragement of Arts.

SPINNING Wheel. A very considerable improvement has been made by Mr Antis of Fulneck near Leeds of the common spinning wheel. It is well known, that hitherto much time has been lost by stopping the wheel in order to shift the thread from one staple on the flyer to another; but in Mr Antis's wheel the bobin is made to move backwards and forwards, so as to prevent the necessity of this perpetual interruption, as well as to obviate

Plate ccccxcix. fig. 2.

viate the danger of breaking the thread and losing the end. This is effected by the axis of the great wheel being extended through the pillar next the spinner, and formed into a pinion of one leaf A (fig. 2.), which takes into a wheel B, seven inches diameter, having on its periphery 97 teeth; so that 97 revolutions of the great wheel cause one of the lesser wheel. On this lesser wheel is fixed a ring of wire *c c c;* which, being supported on six legs, stands obliquely to the wheel itself, touching it at one part, and projecting nearly three quarters of an inch at the opposite one: near the side of this wheel is an upright lever C, about 15 inches long, moving on a centre, three inches from its lower extremity, and connected at the top to a sliding bar D; from which rises an upright piece of brass E, which working in the notch of a pulley drives the bobin F backward and forward, according as the oblique wire forces a pin G in or out, as the wheel moves round. To regulate and assist the alternate motion, a weight H hangs by a line to the sliding bar, and passing over a pulley I rises and falls as the bobin advances or recedes, and tends constantly to keep the pin in contact with the wire. It is evident, from this description, that one staple only is wanted to the flyer; which, being placed near the extremity K, the thread passing through it is by the motion of the bobin laid regularly thereon. For this invention the Society instituted at London for the Encouragement of Arts, &c. gave the author a premium of 20 guineas.

SPINOSUS CAULIS, in *Botany*, a stem covered with strong woody prickles, whose roots are not superficial, but proceeding from the body of the stem. When applied to a leaf, *spinosum folium*, it indicates the margin running out into rigid points or prickles, *quod margine exit in acumina duriora, rigida, pungentia.*

SPINOUS, in *Botany*. See SPINOSUS.

SPINOUS Fishes, such as have some of the rays of the back fins running out into thorns or prickles, as the perch, &c.

SPINOZA, BENEDICT, was born at Amsterdam the 24th November 1632. His father was a Jew of Portugal, by profession a merchant. After being taught Latin by a physician, he applied himself for many years to the study of theology, and afterwards devoted himself entirely to philosophy. He began very early to be dissatisfied with the Jewish religion; and as his temper was open, he did not conceal his doubts from the synagogue. The Jews, it is said, offered to tolerate his infidelity, and even promised him a pension of a thousand dollars per annum, if he would remain in their society, and continue outwardly to practise their ceremonies. But if this offer was really made, he rejected it, perhaps from his aversion to hypocrisy, or rather because he could not endure the restraint which it would have imposed. He also refused being constituted heir to an independent fortune, to the prejudice of the natural claimants; and he learned the art of polishing glass for spectacles, that he might subsist independently of every one.

He would probably have continued in the synagogue for some time longer, had it not been for an accident. As he was returning home one evening from the theatre he was stabbed by a Jew: the wound was slight; but the attempt naturally led Spinosa to conclude that the Jews had formed the design of assassinating him. After leaving the synagogue he became a Christian, and frequented the churches of the Lutherans and Calvinists. He now devoted himself more than ever to his favourite philosophical speculations; and finding himself frequently interrupted by the visits of his friends, he left Amsterdam, and settled at the Hague, where he often continued for three months together without ever stirring from his lodging. During his residence in that city, his hostess, who was a Lutheran, asked him one day if she could be saved while she continued in her religion? "Yes (replied Spinoza) provided you join to your religion a peaceable and virtuous life." From this answer it has been concluded that he was a Christian in appearance only, while in reality he regarded all religions as indifferent. But this conclusion would be too severe, even if the woman had been a Mahometan. His *Tractatus Theologico-politicus*, which was published about that time, is a better proof of his insincerity than a thousand such conclusions; for this book contains all those doctrines in embryo which were afterwards unfolded in his *Opera Posthuma*, and which are generally considered as a system of atheism.

His fame, which had now spread far and wide, obliged him sometimes to interrupt his philosophical reveries. Learned men visited him from all quarters. While the prince of Conde commanded the French army in Utrecht, he intreated Spinoza to visit him; and though he was absent when the philosopher arrived, he returned immediately, and spent a considerable time with him in conversation. The elector Palatine offered to make Spinoza professor of philosophy at Heidelberg; which, however, he declined.

He died of a consumption at the Hague on the 21st February 1677, at the age of 45. His life was a perpetual contradiction to his opinions. He was temperate, liberal, and remarkably disinterested; he was sociable, affable, and friendly. His conversation was agreeable and instructive, and never deviated from the strictest propriety.

The only edition of the works of Spinoza that we have seen is in two volumes small 4to; the former of which was printed at Hamburgh in the year 1670, and the latter we know not where, in 1677, a few months after his death. In the *Tractatus Theologico-politicus*, already mentioned, he treats of *prophecy* and *prophets;* and of the *call of the Hebrews*, whom he affirms to have been distinguished from other nations only by the admirable form of their government, and the fitness of their laws for long preserving their political state. He is likewise of opinion, or at least pretends to be so, that God may, in what we call a *supernatural way*, have given political institutes to other nations as well as to the Hebrews, who were, he says, at no time a peculiar people to the Supreme Lord of heaven and earth; for, according to him, all history, sacred and profane, testifies that every nation was blessed with the light of prophecy. That light, indeed, if his notions of it be just, was of very little value. He labours to prove, that the prophets were distinguished from other men only by their piety and virtue; that their revelations depended wholly on their imaginations and the dispositions of their minds; that they were often grossly ignorant and highly prejudiced; that the speculative opinions of one prophet are seldom in unison with those of another; and that their writings are valuable to us only for the excellent rules which he acknowledges they contain respecting the practice

Spinoza.

tice of piety and virtue. He then proceeds to treat of the divine law and of miracles; and endeavours to prove that no miracle, in the proper sense of the word, can have been at any time performed; because every thing happens by a necessity of nature, the result of the divine decrees, which are from all eternity necessary themselves. He acknowledges, that in the Scriptures, which he professes to admit as true history, miracles are often mentioned; but he says that they were only singular events which the sacred historians *imagined* to be miraculous: and he then gives some very extraordinary rules for interpreting the books of the Old and New Testaments where they treat of miracles, or appear to foretel future events. See our articles MIRACLE and PROPHECY.

Having thus divested the Scriptures of every thing characteristic of a revelation from heaven, he next calls in question their authenticity. He affirms, in contradiction to the clearest internal evidence, that the Pentateuch and all the other historical books must have been written by one man; and that man, he thinks, could not have flourished at a period earlier than that of Ezra. The grounds of this opinion are unworthy of the talents of Spinoza; for that he had talents is incontrovertible. His principal objection to the authenticity of the Pentateuch is, that Moses is made to speak of himself, in the third person, and to talk of the Cannanites being then in the land; and because he finds in his writings, as well as in the books of Joshua, Judges, Ruth, Samuel, &c. places designed by names which he supposes they had not in the early ages of which these books contain the history, he concludes that these writings must be one compilation from ancient records made at a very late period; more especially as the author often speaks of things of great antiquity remaining to this day. The books of Esther, Ezra, Nehemiah, and Chronicles, must have been compiled, he thinks, under the Maccabees; and he seems to consider as of equal value with them the story of Tobit, and the other two apocryphal treatises intitled the Wisdom of Solomon and Ecclesiasticus.

These senseless cavils, worthy only of one of those modern freethinkers whose learning, in the opinion of Bishop Warburton, is not sufficient to carry them even to the confines of rational doubt, we have sufficiently obviated in another place (see SCRIPTURE, N° 8—31.). Spinoza urges them against the other books of the Old Testament. The prophecies of Isaiah, Jeremiah, Ezekiel, Daniel, Hosea, and Jonah, are, as we have them, only fragments, he says, of the writings of those men compiled by the Pharisees under the second temple from ancient and voluminous records.

In the midst of this dogmatical scepticism, if we may use such a phrase, he bears such a testimony to the last chapters of the book of Daniel, as we should not have looked for in the writings either of a Jew or of a Deist. After detailing the various hypotheses which in his time were held respecting the author and the intention of the book of *Job*; in which, he says, MOMUS is called SATAN, he proceeds in these words: Transeo ad Danielis librum; hic sine dubio ex cap. 8. ipsius Danielis scripta continet. Undenam autem priora septem capita descripta fuerint, nescio *;" thus admitting the famous prophecy of the seventy weeks. The canon of the Old Testament, he says, was finally settled by rabbins of the Pharisaical sect, who wished to exclude from it the books of *Proverbs*, *Ecclesiastes*, and *Ezekiel*, as they had actually excluded others of equal value; but the three books in question were inserted by the influence of two of the rabbis of greater wisdom and integrity than the rest.

* Tractus, cap. x. p. 130.

That so paradoxical a writer, who had been originally a Jew, and was now almost a Deist, should have treated the New Testament with as little ceremony as the Old, will not surprise the intelligent reader. He begins his remarks, however, with affirming, that no man can peruse the Christian Scriptures, and not acknowledge the apostles to have been prophets; but he thinks that their mode of prophesying was altogether different from that which prevailed under the Mosaic dispensation; and that the gift, whatever it was, forsook them the instant that they left off *preaching*, as their *writings* have to him every appearance of human compositions. This distinction between Christian and Jewish prophecy is the more wonderful, that he founds it principally on the dissimilarity of *style* visible in the writings of the Old and New Testaments; though, in his second chapter, which treats of the works of the Jewish prophets, he says expressly, "Stylus deinde prophetiæ pro eloquentia cujusque prophetæ variabat, prophetiæ enim Ezekielis et Amosis non sunt, ut illæ Esaiæ, Nachumi, eleganti, sed rudiore stylo scriptæ." That the Hebrew scholar may be convinced of the truth of this remark, he recommends to him to study diligently the writings of these prophets, and to consider the occasions on which their prophecies were uttered: "Quæ si omnia rectè perpendentur (says he) facilè ostendant, Deum nullum habere stylum peculiarem dicendi, sed tantum pro eruditione, et capacitate prophetæ eatenus esse elegantem, compendiosum, severum, rudem, prolixum, et obscurum." Another objection brought by Spinoza against the prophecies of the New Testament arises from the authors of them having been at all times masters of themselves. This, says he, was peculiarly the case of St Paul, who often confirms his doctrine by *reasoning*, which the Jewish prophets never condescended to do, as it would have submitted their dogmas to the examination of *private judgment*. Yet, with singular inconsistency, he affirms, that the Jewish prophets could not know that the impressions made on their imaginations proceeded from God, but by a sign given them, which by their own *reason* or *judgment* they knew would never be vouchsafed to an impious or a wicked man.

After these very free remarks on the Scriptures of the Old and New Testaments, he naturally enough expresses a suspicion, that by those who consider the Bible as the epistle of God sent from heaven to men, he will be thought to have sinned against the Holy Ghost by vilifying his dictates. This leads him to inquire in what sense the Scriptures are the word of God; and he gravely determines them to be so only as they *actually* contribute to make men more virtuous and holy. It is not enough that they are *calculated* to improve virtue and holiness: for should the words of the languages in which they are written acquire in process of time a signification different from what they had originally; should mankind lose all knowledge of these languages; or even should they agree to neglect the books, whether from ignorance or from wilfulness—those books would cease

to

Spinoza.

to be the word of God, and become nothing better than waste paper and ink; just as the two tables, which Moses broke on observing the idolatry of his countrymen, were not the covenant between Jehovah and the Israelites, but merely two pieces of stone! The Scriptures, however, are the work of God, because they teach the true religion of which God is the author; and they have taught it in such a manner, he says, that it can never be lost or corrupted whatever become of the books of the Old and New Testaments, or of the languages in which they are written. The whole of religion, as the Scriptures themselves testify, consists in the love of God above all things, and of our neighbours as ourselves: whence it follows, that we must believe that God exists, and watcheth over all things by his providence; that he is omnipotent, and has decreed the pious to be ultimately happy, and the impious miserable; and that our final salvation depends solely on His grace or favour. These truths, with their necessary consequences, are the word of God: they are clearly taught in the Scriptures, and can never be corrupted; but every thing else in these volumes is vain, he says, and of no greater importance to us than facts related in any other ancient and authentic history.

Such are the opinions which were entertained of revelation by a man, whom a critic, writing in a Christian country, and professing to be a zealous Christian himself, has lately pronounced to have been a *chosen vessel.* For what purpose he was *chosen* it is not easy to conceive. His religion, as it appears in the *Tractatus*, is the worst kind of Deism, and his politics are such as our monthly critics are not wont to teach, and such as we trust shall never be seriously taught by any British subject. By the law of nature, he says, every man before the formation of civil government has an unquestionable right to whatever appears eligible either to his reason or to his appetites; and may get possession of it by *intreaty*, by *violence*, by *fraud*, or by *any other means* attended with less trouble to himself (*sive vi, sive dolo, sive precibus, sive quocunque demum modo facilius poterit*); and may treat as an enemy every person who shall attempt to obstruct his purpose. But when men agree to devolve this right upon others, and to constitute a political state, which both reason and appetite must persuade them to do, then are they in duty bound to obey every mandate of the government, however absurd it may be (*omnia mandata tametsi absurdissima*), as long as that government can enforce its edicts, and no longer; for according to him, right and power are so inseparably united, that when a government loses its power, it has no longer the smallest claim to obedience. This doctrine, he says, is most *obviously* just when taught of democratical governments; but it is in fact equally true of monarchies and aristocracies: "Nam quisquis summam habet potestatem, sive unus sit, sive pauci, sive denique omnes, certum est ei summum jus *quicquid velit imperandi*, competere: et præterea quisquis potestatem se defendendi, sive sponte, sive *vi coactus*, in alium transtulit, eum suo jure naturali planè cessisse, et consequenter eidem ad omnia absolutè parere decrevisse quod omnia præstare tenetur, quamdiu rex, sive nobiles, sive populus summam, quam acceperunt, potestatem, quæ juris transferendi fundamentum fuit, conservant; nec his plura addere opus est*." We heartily agree with him, that to this precious conclusion it is needless to add a single word.

* *Tractatus*, cap. XVI. p. 181.

Taking our leave therefore of his *Tractatus Theologico-politicus*, we shall now give our readers a short account of his *Opera Posthuma*. These consist of, 1. ETHICA, *more geometrico demonstrata*; 2. POLITICA; 3. DE EMENDATIONE INTELLECTUS; 4. EPISTOLÆ, *et ad eas* RESPONSIONES; 5. COMPENDIUM GRAMMATICES LINGUÆ HEBRÆÆ.

The ETHICA are divided into five parts, which treat in order, *de* DEO; *de natura et origine* MENTIS; *de origine et natura* AFFECTUUM; *de* SERVITUTE *humana, seu de* AFFECTUUM VIRIBUS; *de* POTENTIA INTELLECTUS, *seu de* LIBERTATE *humana*. As the author professes to tread in the footsteps of the geometers, and to deduce all his conclusions by rigid demonstration from a few self-evident truths, he introduces his work, after the manner of Euclid, with a collection of *definitions* and *axioms*. These are couched in terms generally ambiguous; and therefore the reader will do well to consider attentively in what sense, if in any, they can be admitted; for it will not be found easy to grant his premises, and at the same time refuse his conclusions. His definition of substance, for instance, is so expressed as to admit of two senses; in one of which it is just, whilst in the other it is the parent of the most impious absurdity. We shall give it in his own words: "Per substantiam intelligo id, quod in se est, et per se concipitur: hoc est id, cujus conceptus non indiget conceptu alterius rei, à quo formari debeat." If by this be meant, that a substance is that which we can conceive by itself without *attending* to any thing else, or *thinking* of its formation, the definition, we believe, will be admitted by every reflecting mind as sufficiently distinguishing the thing defined from an attribute, which, he says, is that which we perceive *of* a substance, and which we certainly cannot conceive as existing by itself. Thus the writer of this article can shut his eyes and contemplate in idea the small 4to volume now before him, without attending to any thing else, or thinking of its paradoxical author, or even of the Great Being who created the matter both of him and it; but he cannot for an instant contemplate the yellow colour of its vellum boards without thinking of triple extension, or, in other words, of body. The book therefore is a *substance*, because conceivable by itself; the colour is an *attribute* or *quality*, because it cannot be conceived by itself, but necessarily leads to the conception of something else. But if Spinoza's meaning be, that nothing is a substance but what is conceived as existing from eternity, independent of every thing as a cause, his definition cannot be admitted; for every man conceives that which in himself thinks, and wills, and is conscious, as a substance; at the same time that he has the best evidence possible that he existed not as a conscious, thinking, and active being, from eternity.

His fourth axiom is thus expressed: "Effectus cognitio à cognitione causæ dependet, et eandem involvit;" and his fifth, "Quæ nihil commune cum se invicem habent, etiam per se invicem intelligi non possunt, sive conceptus unius alterius conceptum non involvit." The former of these propositions, so far from being self-evident, is not even true; and the latter is capable of two senses very different from each other. That every effect

Spinoza.

fect proceeds from *a cause*, is indeed an axiom; but surely we may know the effect accurately, though we be ignorant of the *particular* cause from which it proceeds (see PHILOSOPHY, N° 36; and PHYSICS, N° 91, &c.); nor does the knowledge of the one by any means involve the knowledge of the other. If different things have nothing in common, it is indeed true that the knowledge of one of them will not give us an *adequate conception* of the other; but it will in many cases compel us to believe, that the other *exists* or has existed. A parcel of gunpowder lying at rest has nothing in common with the velocity of a cannon-ball; yet when we know that a ball has been driven with velocity from a cannon, we infer with certainty that there has been a parcel of powder at rest in the chamber of that cannon.

It is upon such ambiguous definitions and axioms as these that Spinoza has raised his pretended demonstrations, that one substance cannot produce another; that every substance must necessarily be infinite; that no substance exists or can be conceived besides God; and that extended substance or body is one of the infinite *attributes* of God. We shall not waste our own time or the reader's with a formal confutation of these impious absurdities. We trust they are sufficiently confuted in other articles of this work (see METAPHYSICS, Part III. PROVIDENCE, and THEOLOGY, Part I.); and whoever wishes for a more particular examination of the author's principles, may find it in Dr Clarke's Demonstration of the Being and Attributes of God. The truth, however, is, that no man will need the assistance of that eminent metaphysician to discover the fallacy of the reasoning by which they are attempted to be proved, if he affix *any one precise meaning* to the definitions and axioms, and adhere to that meaning steadily through the whole process of the pretended demonstrations.

By way of apology for this jargon, it has been lately said, that "Spinoza takes the word *substance* in its most simple and perfect sense; which is necessary, as he writes mathematically, and proposes a simple idea as the foundation of his theory. What is the proper signification of a substance? It is not that which stands alone, which has the cause of its existence within itself? I wish that this simple meaning of the word could be universally admitted in philosophy. Strictly speaking, no worldly thing is a substance; since all mutually depend on each other, and finally on God, who, in this exalted sense, is the only *substance*. The word *modification* sounds harsh and improper, and therefore it cannot be expected to gain a place in philosophy; but if the school of Leibnitz may term matter the *appearance of substances*, why may not Spinoza be allowed a bolder term? Worldly substances are kept in union by divine power, as it was by divine power that they had existence. They represent also, if you please, *modified* appearances of divine power; each according to the station, the time, and the organs, in and with which it appears. The phrase used by Spinoza is concise, and it gives an unity and simplicity to his whole system, however strange it may sound in our ears."

Herder's Dialogues concerning God.

Spinoza.

From this account of Spinozism, one who had never looked into the works of the author would be led to suppose that his system is the same with that of Berkeley; which, denying the existence of material substance, attributes all our perceptions of what we call the qualities of body to the immediate agency of the Deity on our minds (see METAPHYSICS, Part II. chap. 3.). But Spinoza's doctrine is very different. According to him, bodies are either attributes or affections of God; and as he says there is but one extended substance, he affirms that substance to be indivisible, and employs a long scholium † to prove that those are mistaken who suppose it finite and not *essential to the Deity*. That we do not misrepresent his sentiments, the learned reader will be convinced by the two following definitions, with which he introduces that part of his ethics which treats of the nature and origin of mind. 1. "Per corpus intelligo modum, qui Dei essentiam, quatenus, ut res extensa consideratur, certo et determinato modo exprimit." 2. "Ad essentiam alicujus rei id pertinere dico, quo dato res necessario ponitur, et quo sublato res necessario tollitur; vel id, sine quo res, et vice versa quod sine re nec esse nec concipi potest." In conformity with these definitions, he attempts to prove that God is an extended as well as a thinking substance; that as a thinking substance he is the cause of the *idea* of a circle, and as an extended substance of the *circle* itself; and that the minds of men are not substances, but certain modifications of the divine attributes; or, as he sometimes expresses it, "Quod humanæ mentis actuale constituit, est idea rei singularis actu existentis." Hence, he says, it follows that the human mind is a part of the intellect of the infinite God; so that when we speak of the human mind perceiving this or that, we can only mean that God, not as he is infinite, but as he appears in the human mind or constitutes its essence, has this or that idea; and when we speak of God's having this or that idea, we must conceive of Him not only as constituting the human mind, but as, together with it, having the idea of something else (A). In another place he tells us, that the human mind is nothing but the *idea* which God has of the human body as actually existing; that this *idea* of the body, and the *body* itself, are one and the same thing; and that thinking and extended substances are in reality but one and the same substance, which is sometimes comprehended under one attribute of the Deity, and sometimes under another *.

† See his Prop. xv. &c.

Prop. vii. xi. Part ii.

If this impious jargon be not Atheism, or as it has been sometimes called Pantheism, we know not what it is (see PANTHEISM). According to Spinoza, there is but one substance, which is extended, infinite, and indivisible. That substance indeed he calls God; but he labours to prove that it is corporeal; that there is no difference between mind and matter; that both are attributes

* Prop. vii. xiii. xxi. Part ii.

(A) Hinc sequitur mentem humanam partem esse infiniti intellectus Dei; ac proinde cum dicimus, mentem humanam hoc vel illud percipere, nihil aliud dicimus quam quod Deus, non quatenus infinitus est, sed quatenus per naturam humanæ mentis explicatur, sive quatenus humanæ mentis essentiam constituit, hanc vel illam habet ideam: et cum dicimus Deum hanc vel illam ideam habere, non tantum, quatenus naturam humanæ mentis constituit; sed quatenus simul cum mente humana alterius rei etiam habet ideam. *Corol.* prop. xi. part 2.

tributes of the Deity variously considered; that the human soul is a part of the intellect of God; that the same soul is nothing but the idea of the human body; that this idea of the body, and the body itself, are one and the same thing; that God could not exist, or be conceived, were the visible universe annihilated; and therefore that the visible universe is either the one substance, or at least an essential attribute or modification of that substance. He sometimes indeed speaks of the *power* of this substance; but when he comes to explain himself we find that by power he means nothing but blind necessity*; and though he frequently talks of the *wisdom* of God, he seems to make use of the word without meaning. This we think evident from the long appendix to his 36th proposition; in which he labours to prove that the notion of final causes is an idle figment of the imagination, since, according to him, nothing but the prejudices of education could have led men to fancy that there is any real distinction between *good* and *evil*, *merit* and *demerit*, *praise* and *reproach*, *order* and *confusion*; that *eyes* were given them that they might be enabled to *see*; *teeth* for the purpose of chewing their *food*; *herbs* and *animals* for the *matter* of that *food*; that the *sun* was formed to give light, or the *ocean* to nourish *fishes*. If this be true, it is impossible to discover wisdom in the operations of his *one substance*; since, in common apprehension, it is the very characteristic of folly to act without any end in view.

* Prop. xxxiii. Part I.

Such are the reveries of that writer, whose works a German philosopher of some name has lately recommended to the public, as calculated to convey to the mind more just and sublime conceptions of God than are to be found in most other systems. The recommendation has had its effect. A literary journalist of our own, reviewing the volume in which it is given, feels a peculiar satisfaction from the discovery, that Spinoza, instead of a formidable enemy to the cause of virtue and religion, was indeed their warmest friend; and piously hopes that we shall become more cautious not to suffer ourselves to be deceived by empty names, which those who *cannot* reason (Sir Isaac Newton and Dr Clarke perhaps) give to those who can (Hobbes, we suppose, and Spinoza). But though we have the honour to think on this question with our illustrious countrymen, we have no desire to depict Spinoza as a *reprobate*, which the critic says has often been done by ignorance and enthusiasm. We admit that his conduct in active life was irreproachable; and for his speculative opinions, he must stand or fall to his own Master. His Ethics appear to us indeed a system shockingly impious; and in the tract intitled POLITICA, *power* and *right* are confounded as in the former volume; but in the treatise DE INTELLECTUS EMENDATIONE, are scattered many precepts of practical wisdom, as well as some judicious rules for conducting philosophical investigation; and we only regret, that the reader must wade to them through pages of fatalism, scepticism, and palpable contradictions. His *Compendium Grammatices Linguæ Hebrææ*, though left imperfect, appears to have so much merit, that it is to be wished he had fulfilled his intention of writing a philosophical grammar of that language, instead of wasting his time on abstruse speculations, which though they seem not to have been injurious to his own virtue, are certainly not calculated to promote the virtue of others, or to increase the sum of human happiness.

SPIRÆA, a genus of plants belonging to the class of icosandria, and to the order of pentagynia; and in the natural system arranged under the 26th order, *Pomaceæ*. See BOTANY *Index*.

SPIRAL, in *Geometry*, a curve line of the circular kind, which in its progress recedes from its centre.

SPIRE, in *Architecture*, was used by the ancients for the base of a column, and sometimes for the astragal or tore; but among the moderns it denotes a steeple that continually diminishes as it ascends, whether conically or pyramidally.

SPIRIT, in *Metaphysics*, an incorporeal being or intelligence; in which sense God is said to be a spirit, as are angels and the human soul. See METAPHYSICS, Part III.

SPIRIT, in *Chemistry* and *Pharmacy*, a name applied to every volatile liquid which is not inspid like phlegm or water; and hence the distinction into acid, alkaline, and vinous spirits.

Spirit of Wine. See ALCOHOL, CHEMISTRY *Index*; DISTILLATION, and MATERIA MEDICA *Index*.

SPIRITS, or ANIMAL SPIRITS. See ANATOMY, Part V. N° 136.

SPIRITUAL, in general something belonging to or partaking of the nature of spirit. See SPIRIT.

SPIRITUOUS LIQUORS have in all nations been considered as a proper subject of heavy taxation for the support of the state. This has naturally occasioned a nice examination of their strength. It having been at last found that this was intimately connected with the specific gravity, this has been examined with the most scrupulous attention to every circumstance which could affect it, so that the duties might be exactly proportioned to the quantity of spirit in any strong liquor, independent on every other circumstance of flavour or taste, or other valued quality. The chemist at last found that the basis of all strong liquors is the same, produced by the vinous fermentation of pure saccharine matter dissolved in water. He also found, that whether this vegetable salt be taken as it is spontaneously formed in the juices of plants and fruits, or as it may be formed or extricated from farinaceous fruits and roots by a certain part of the process of vegetation, it produces the same ardent spirit, which has always the same density in every mixture with water. The minute portions of aromatic oils, which are in some degree inseparable from it, and give it a different flavour according to the substance from which it was obtained, are not found to have any sensible effect on its density or specific gravity. This seems very completely established in consequence of the unwearied attempts of the manufacturers to lessen the duties payable on their goods by mixtures of other substances, which would increase their density without making them less palatable. The vigilance of the revenue officers was no less employed to detect every such contrivance. In short, it is now an acknowledged point, that the specific gravity is an accurate test of the strength.

But though this is true in general, we cannot derive much benefit from it, unless we know the precise relation between the strength and the density of a spirituous liquor. Do they increase *pari passu*, or by what law

Spirituous Liquors.

law are they connected? It was natural to expect that equal additions of ardent spirits or alcohol to a given quantity of water would produce equal diminutions of density. Areometers were accordingly made on this principle above 200 years ago, as may be seen in the works of Gaspar Schottus, Sturmius, Agricola, and other old authors. But when mathematical physics became more generally known, this was easily discovered to be erroneous; and it was shown (we think first by Mr Boyle) that equal additions to the specific gravity would be produced by successively taking out of any vessel a certain measure of alcohol and replacing it with an equal measure of water. This was the most convenient discovery for all parties, because then the duties payable on a cask of spirits would be in the exact proportion of the diminution of its density. But it was soon found by those who were appointed guardians of the revenue that this conclusion was erroneous, and that a mixture which appeared by this rule to contain 35 gallons of alcohol, did really contain $35\frac{1}{2}$. This they found by actually making such a mixture: 18 gallons of alcohol mixed with 18 of water produced only 35 gallons of spirits. The revenue officers, finding that this condensation was most remarkable in mixtures of equal parts of water and the strongest spirits which could then be procured, determined to levy the duties by this mixture; because, whether the spirituous liquor was stronger or weaker than this, it would appear, by its specific gravity, rather stronger than it really was. This sagacious observation, and the simplicity of the composition, which could at all times be made for comparison, seem to be the reasons for our excise offices selecting this mode of estimating the strength and levying the duties. A mixture of nearly equal measures of water and alcohol is called PROOF SPIRIT, and pays a certain duty per gallon; and the strength of a spirituous liquor is estimated by the gallons, not of alcohol, but of proof spirit, which the cask contains. But because it might be difficult to procure at all times this proof spirit for comparison, such a mixture was made by order of the board of excise: and it was found, that when six gallons of it was mixed with one gallon of water, a wine gallon of the mixture weighed 7 pounds 13 ounces avoirdupois. The board therefore declared, that the spirituous liquor of which the gallon weighed 7 pounds 13 ounces should be reckoned 1 to 6 or 1 in 7 under proof. This is but an awkward and complex formula; it was in order to suit matters to a mode of examination which had by time obtained the sanction of the board. Mr Clarke, an ingenious artist of that time, had made a hydrometer incomparably more exact than any other, and constructed on mathematical principles fit for computation. This had a set of weights corresponding to the additions of water or proof spirit, and the mixture 1 to 6 or 1 in 7 was the only one which weighed an exact number of ounces per gallon without a fraction.

Thus stands the excise law; and Clarke's hydrometer is still the instrument of authority, although others have been since constructed by DICAS, QUIN, and others, which are much more ingenious and convenient. The mathematician who examines Dicas's hydrometer, with its sliding scale, by which it is adjusted to the different temperatures, and points out the condensations, will perceive a beautiful and sagacious combination of quantities, which he will find it difficult to bring under any analytical formula. Perhaps Quin's may have some preference in respect of conveniency; but *facile inventis addere*. Mr Dicas's was original (A).

As naturalists became more accustomed to exact observations in every topic of inquiry, the condensation which obtains in the mixture of different substances became more familiarly known. This evidently affects the present question; and both the excise and the distillers are interested in its accurate decision. This occasioned an application to the Royal Society; and a most scrupulous examination of the strength of spirituous liquors was made by Sir Charles Blagden and Mr Gilpin, of which they have given a very particular account in the Philosophical Transactions for 1790 and 1792.

We have taken notice of this in the article SPECIFIC GRAVITY, mentioning such circumstances of the results as suited our purposes of physical discussion. At present

(A) Among the various contrivances which have been thought of, among manufacturers and dealers, as well as for the purposes of revenue, for ascertaining the specific gravity, and consequently the real strength and value of high-priced and high-taxed liquids, we are persuaded there is none equal, in point of accuracy, simplicity, and facility of application, to the areometrical beads lately announced to the public by Mrs Lovi of Edinburgh, under the privilege of a patent; and with this persuasion we have no hesitation in recommending them to those to whom the use of a simple and accurate instrument is of great importance in determining the value of high-priced spirituous liquors. Our recommendation rests not solely on our own opinion, but is supported by that of others who are well acquainted with such subjects. We know, too, that the beads have been examined and compared by several intelligent manufacturers and dealers with some of the most accurate hydrometrical instruments, and after a fair trial, a decided preference has been given to the beads. The whole apparatus consists of 100 beads, a sliding rule, a thermometer, a glass jar and brass hook, which are packed in a neat small box; and it is accompanied with directions, which point out, 1. In what manner the real strength of spirits may be ascertained at any given temperature between 40° and 80°. 2. How much per cent. the spirit to be tried is over or under proof according to the practice of spirit-dealers; and, 3. The proportion of water and the strongest spirits or alcohol, according to the views and language of excisemen. The advantages of these beads are, that being made of a substance which is little acted on by chemical agents, they are less liable to be injured by use, than instruments composed of metal; and when a bead happens to be broken, it can be easily replaced. They possess this farther advantage, that with the application of the thermometer, and the calculation of the sliding-rule, the real strength of the spirits may be taken at all temperatures. It has been suggested, that these beads, from their being less liable to change than other instruments, might be usefully employed in checking the errors and variations of other hydrometers. Beads are prepared by Mrs Lovi on the same principle for ascertaining the strength of worts, acids, &c.

Spirituous Liquors.

sent we give the general result in the table of specific gravity, as peculiarly belonging to spirituous liquors, affording the most exact account of their density in every state of dilution of alcohol with water. And as the relation between the proportion of ingredients and the density is peculiar to every substance, so that scarcely any inference can be made from one to another, the reader will consider the tables here given as characteristic with respect to alcohol. In all solutions of salts we found that the condensation increases continually with the dilution, whereas it is greatest when equal bulks of water and alcohol are mixed; yet we do not consider this as an exception; for it is certain, that in the strongest brine the saline ingredient bears but a small proportion to the water—and when we mix two solutions, the condensation is greatest when they are nearly equal in bulk. But we think ourselves entitled to infer, that alcohol is not a dilution of a substance in a quantity of water; but that water, in a certain proportion, not very distant from what we can produce by slow distillation, is an ingredient of alcohol, or is one of its component parts, and not merely a vehicle or menstruum. We therefore imagine that proof spirit contains nearly equal bulks of water and ardent spirits.

The great difficulty in this examination arose from the very dissimilar expansions of water and alcohol by heat. This determined Sir Charles Blagden to estimate the proportions of ingredients by weight, and made it absolutely necessary to give a scale of specific gravity and strength for every temperature. For it must be remarked, that the question (whether in commerce or philosophy) always is, "How many gallons of alcohol and of water, taken just now and mixed together, will produce a hundred gallons of the spirit we are examining?" The proportion of these two will be different according to the temperature of both. As many mixtures therefore must have been made in each proportion as there were temperatures considered; but by taking the ingredients by weight, and examining the density of the compound in one temperature, it is then heated and cooled, and its change of density observed. Calculation then can tell us the change in the proportion of the bulks or numbers of gallons in the mixture, by means of a previous table showing the expansions of water and of alcohol.

The alcohol selected for this examination had the specific gravity 0.825. This is not the purest that can be procured; some was produced of 0.816, of 0.814, and 0.813, both obtained from rum, from brandy, and from malt spirit. We are informed that Dr Black has obtained it of the specific gravity 0.8 by digesting alcohol with fixed ammoniac (muriatic acid united with lime) made very dry. It dephlegmates alcohol very powerfully without decomposing it, which always happens when we use caustic alkali. Alcohol of 0.825 was chosen because expressed by a number of easy management in computation.

The examination commenced by ascertaining the expansions of water and alcohol. The temperature 60° of Fahrenheit's scale was selected for the general temperature of comparison, being easily attainable even in cold weather, and allowing the examinator to operate at ease. The first and last compartments of the tables contain the weights and specific gravities of alcohol and water for every fifth degree of heat from 30° to 100°. From these we have constructed the two following little tables of expansion. The bulk of 1000 ounces, pounds, or other weight of water and of alcohol of the temperature 60°, occupies the bulks expressed in the tables for every other temperature. Water could not be easily or usefully examined when of the temperature 30°, because it is with great difficulty kept fluid in that temperature. It is very remarkable, that when it can be so kept, it expands instead of contracting; while cooling down from 35° or thereabouts, and as it approaches to 32°, it expands rapidly. We observe the same thing in the crystallization of Glauber salt, martial vitriol, and some others, which contain much water in their crystals. We observe, on the other hand, a remarkable contraction in the zeolite just before its beginning to swell into bubbles by a red heat.

Heat.	Bulk of 100,060 ounces.

95	100500	96	123773	380
100	100608	108	124157	384

This being premised, the examination was conducted in the following manner. It was determined to mix 100 parts by weight of pure alcohol with five, ten, fifteen, twenty, parts of distilled water, till they were compounded in equal quantities, and then to mix 100 parts of distilled water with, 95, 90, 85, 80, &c. parts of alcohol, till they were mixed in the proportion of 100 to 5. Thus a series of mixtures would be obtained, extending from pure alcohol to pure water. This series would be such, that the examinations would be most frequent in the cases most usual in the commerce of strong liquors. A set of phials, fitted with ground stoppers, were provided, of sizes fit to hold the intended mixtures. These mixtures were made by suspending the phial to the arm of a very nice balance, in the opposite scale of which (besides the counterpoise of the phial) there was placed the weight 100. Spirit was then poured into the phial till it exactly balanced the weight 100. The weight for the water to be added was then put into the opposite scale, and water was poured into the phial by means of a slender glass funnel, by small quantities at a time, and the phial frequently agitated to promote the mixture. When the additional weight was exactly balanced, the phial was taken off, its stopper put in, and leather tied over it, and it was set by, for at least a month, that the mixture and the whole process of condensation might be completed. The same method

method was followed in the mixtures where the water was predominant.

When the ingredients of these mixtures were judged to have completely incorporated, their specific gravity was examined by weighing with the most scrupulous precision the contents of a vessel which held 2925 troy grains of water, of the temperature 60°. The balance was so exceedingly sensible, that the 50th part of a grain greatly deranged its position when loaded with the scales and their contents. It was constructed by Mr Ramsden, and some account of its exquisite sensibility may be seen in the *Journal de Physique*, vol. xxxiii. This quantity of materials was therefore thought abundantly sufficient for ascertaining the density of the liquor. It is needless to detail the precautions which were taken for having the contents of the weighing bottle brought to the precise temperature proper for the experiment. They were such as every person conversant with such things is accustomed to take.—The bottle had a slender neck, and being put on a lathe, a mark was made round it with a diamond. The bottle was filled till the bottom of the hollow surface of the fluid was in the plane of this mark; and to judge of the accuracy attainable in filling the bottle, the operation was several times repeated and the contents weighed, without the difference of $\frac{1}{30}$th of a grain in 2925. The only source of error which was to be guarded against was air-bubbles adhering to the inside of the bottle, or moisture condensing (in the experiments with low temperatures) on the outside. Both of these were attended to as much as possible.

This method of determining the specific gravity was preferred to the usual method, observing the weight lost by a lump of glass when suspended in water; for Mr Gilpin had been enabled, by means of this nice balance, to discover, even in pure water and in alcohol, a want of perfect fluidity. Something like viscidity rendered the motion of a lump of glass through the liquor sensibly sluggish, so that when the balance was brought to a level, there was not a perfect equilibrium of weight: (See what we have said of this matter in SPECIFIC GRAVITY). Mr Gilpin also tried the ingenious instrument proposed for such experiments by Mr Ramsden, and described by him in a pamphlet on this very subject; and he found the anomalies of experiment much greater than in this method by weighing.—Indeed the regular progression of weights to be seen in the annexed tables is an unquestionable proof of the sufficiency of the method; and it has the evident advantage of all other methods in point of simplicity and practicability without any uncommon apparatus. Any person possessed of a good ordinary balance and a set of exact weights may examine all questions of this kind, by weighing pure water and the liquor which he may have occasion to examine in a common 6 or 8 ounce phial. For this reason, it is recommended (in preference to all hydrometers) to the board of excise to provide this simple apparatus in every principal office.

Every experiment was made at least three times; and the mean result (which never differed one grain from the extreme) was taken.

From these experiments the annexed tables were constructed. The first is the simple abstract of the experiments, containing the weights of the contents of the bottle of every mixture. The second contains the specific gravities deduced from them.

We have said that the experiments appear surprisingly accurate. This we said on the authority of the regular progression of the specific gravity in any of the horizontal rows. In the series, for instance, for the temperature 60°, the greatest anomaly is in the mixture of 50 parts of spirit with 100 of water. The specific gravity is 95804, wanting 3 or 4 of the regular progression. This does not amount to 1 in 18000.

TABLE

TABLE I. Weights at the different Degrees of Temperature.

Heat.	The pure Spirit.	100 grains of spirit to 5 grains of water.	100 grains of spirit to 10 grains of water.	100 grains of spirit to 15 grains of water.	100 grains of spirit to 20 grains of water.	100 grains of spirit to 25 grains of water.	100 grains of spirit to 30 grains of water.	100 grains of spirit to 35 grains of water.	100 grains of spirit to 40 grains of water.	100 grains of spirit to 45 grains of water.	100 grains of spirit to 50 grains of water.	100 grains of spirit to 55 grains o water.	100 grains of spirit to 60 grains of water.	100 grains of spirit to 65 grains of water.

Spirituous Liquors.

We formerly observed, that the series of mixtures chosen by Sir Charles Blagden, for the advantages attending it in making the experiment, was not suited for solving the questions which commonly occur in the spirit business. He accordingly suggests the propriety of forming tables in a convenient series from the data furnished by these experiments, indicating the proportion of ingredients contained in some constant weight or bulk.

To facilitate the construction of such tables, it is necessary to consider the subject in the most general manner. Therefore let a represent the constant number 100. Let w and s represent the quantities of water and spirit by weight in any mixture; that is, the pounds, ounces, or grains of each. Let x represent the quantity per cent. of spirits also by weight; that is, the number of pounds of spirits contained in 100 pounds of the mixture; and let y be its quantity per cent. in gallons, or the number of gallons contained in 100 gallons of the unmixed ingredients. Let m be the bulk of a pound of spirit of any given temperature, the bulk of a pound of water *of the same temperature* being accounted 1.

Then $w+s$ is the weight of any mixture, and $w+ms$ is its bulk.

We have the following proportions: 1. $w+s : s = a : x$, and $x = \frac{a\,s}{w+s}$ (Equation 1st); and hence s may be found when x the per centage in weight is given, for $s = \frac{w\,x}{a-x}$ (Equation 2d).

2. $w+ms : ms = a : y$, and $y = a\frac{m\,s}{w+m\,s}$ (Equation 3d); and s may be found when y, the per centage in gallons, is given; for $s = \frac{m\,y}{a-y}$ (Equation 4th).

The usual questions which can be solved from these experiments are,

1. To ascertain the quantity of spirits per cent. in bulk from observation of the specific gravity, or to tell how many gallons of spirit are in 100 gallons of mixture.

Look for the specific gravity in the table, and at the head of the column will be found the w and s corresponding. If the precise specific gravity observed is not in the tables, the s must be found by interpolation. And here it is proper to remark, that taking the simple proportional parts of specific gravity will not be sufficiently exact, especially near the beginning or the end of the table, because the densities corresponding to the series of mixtures does not change uniformly. We must have recourse to the general rules of interpolation, by means of first and second differences, or be provided with a subsidiary table of differences. A good deal of practice in computations of this kind suggested the following method of making such interpolations with great dispatch and abundant accuracy. On a plate of wood or metal, or stiff card-paper, draw a line EF (fig. 1.), as a scale of equal parts, representing the leading or equable arithmetical series of any table. (In the present case EF is the scale on which s is computed).—Through every point of division draw the perpendiculars BA, EC, FD, &c. Make one of them AB more conspicuous than the rest, and distinguish the others also in such sort, that the eye shall readily catch their distance from the principal line AB. Let GPL be a thin slip of whalebone, of uniform breadth and thickness, also divided into equal parts properly distinguishable. Lastly, let there be a pin P fixed near the middle of the principal line AB.

Plate cccccxcix. fig. 1.

Now suppose that a value of s is to be interpolated by means of an observed specific gravity not in the table. Look for the nearest to it, and not its distance from the preceding and the following. Let these be PH and PK on the flexible scale. Also take notice of the lines K 10 and H 10, whose distances from AB are equal to the constant difference between the successive values of S, or to any easily estimated multiple of it (as in the present case we have taken 10 and 10, instead of 5 and 5, the running difference of Sir Charles Blagden's table). Then, leaning the middle point P of the whalebone on the pin P in the board, bend it, and place it slantwise till the points K and H fall somewhere on the two parallels K 10 and H 10. No matter how oblique the position of the whalebone is. It will bend in such a manner that its different points of division (representing different specific gravities) will fall on the parallels which represent the corresponding values of s. We can say that all this may be done in less than half a minute, and less time than is necessary for inspecting a table of proportional parts, and not the tenth part of that necessary for interpolating by second differences. Yet it is exact enough (if of the size of a duodecimo page) for interpolating three decimal places. This is ten times more exact than the present case requires. To return from this digression.

Having thus found s in the table, we get x or y by the equations $\frac{a\,s}{w+s} = x$, and $a\frac{m\,s}{w+ms} = y$.

But here a material circumstance occurs. The weight of alcohol s, and its per centage x, was rightly determined by the specific gravity, because it was interpolated between two values, which were experimentally connected with this specific gravity. But in making the transition from x to y, we only give the per centage in gallons before mixture, but not the number of gallons of alcohol contained in an hundred gallons of mixed liquor. For when we have taken $\overline{a-y}$ and y instead of w and s; they will indeed make a similar compound when mixed, because the proportion of their ingredients is the same. But they will not make 100 gallons of this compound, because there is a shrinking or condensation by mixture, and the specific gravity by which we interpolated s is the physical or real specific gravity corresponding to w and s; while $\frac{w+s}{w \times ms}$, the specific gravity implied in the value of y, is the mathematical density independent on this condensation. Since therefore y, together with $\overline{a-y}$, make less than 100 gallons of the compound, there must in 100 gallons of it be more alcohol than is expressed by y.

Let G be the mathematical specific gravity ($= \frac{w+s}{w+ms}$), and g the physical or real observed specific gravity (which we cannot express algebraically); and let z be the gallons of alcohol really contained in 100 gallons of the compound. The bulk being inversely as the density or specific gravity, it is evident that the bulk of the compound must be to 100 gallons as g to

Spirituous Liquors.

to G. And since we want to make it still up to 100 gallons, we must increase it in the proportion of G to g. And because this augmentation must be of the same strength with this contracted liquor, both ingredients must be increased in the proportion of G to g, and we must have $G : g = y : z$, and $z = g \times \frac{y}{G}$. Now, instead of y, write $a \frac{m s}{w + m s}$, and instead of $\frac{1}{G}$ write $\frac{w + m s}{w + s}$, which are respectively equal to them. This gives us $z = g\, a \times \frac{w + m s}{w + s} \times \frac{m s}{w + s}, = g\, a \times \frac{m s}{w + s}$.

All this will be illustrated by an example.

Suppose that we have observed the specific gravity of a spirituous liquor of the temperature 60° to be 0.94128. Looking into Sir Charles Blagden's table, we find the gravities 0.94018 and 0.94296, and the s corresponding to them is 80 and 75, the water in each mixture being 100. By interpolation we obtain the s corresponding to 0.94128, viz. 78. At this temperature $m = \frac{1}{0.825}, = 1.21212$, and $m s = 94.54545$. Therefore $z = 0.94128 \times 100 \times \frac{94.54545}{194.54545}, = 49{,}997$, or very nearly 50.

We have seen even persons not unacquainted with subjects of this kind puzzled by this sort of paradox. z is said to be the per centage of spirit in the compound. The compound has the same proportion of ingredients when made up to 100 gallons as before, when y was said to be its per centage, and yet y and z are not the same. The fact is, that although z is the number of gallons of alcohol really contained in 100 gallons of the compound, and this alcohol is in the same proportion as before to the water, this proportion is not that of 50 to 50: for if the ingredients were separated again, there would be 50 gallons of alcohol and 52,876 of water.

The proportion of the ingredients in their separate state is had by the 3d equation $y = a \frac{m s}{w + m s}$, which is equivalent to $G\, a \frac{m s}{w + s}$. For the present example y will be found 48.599, and $a - y$, or the water per cent. 51.401, making 100 gallons of unmixed ingredients. We see then that there has been added 1.398 gallons of alcohol; and since both ingredients are augmented in the proportion of G to g, there have also been added 1.478 of water, and the whole addition for making up the 100 gallons of compound is 2.876 gallons; and if the ingredients of the compound were separate, they would amount to 102,876 gallons. This might have been found at the first, by the proportion, $G : g - G = 100$: *(The addition)*.

The next question which usually occurs in business is to find what density will result from any proposed mixture per gallon. This question is solved by means of the equation $\frac{w y}{m (a - y)} = s$. In this examination it will be most convenient to make $w = a$. If the value of s found in this manner falls on a value in the tables, we have the specific gravity by inspection. If not, we must interpolate.

N. B. The value of m, which is employed in these reductions, varies with the temperature. It is always obtained by dividing the specific gravity of alcohol of that temperature by the specific gravity of water of the same temperature. The quotient is the real specific gravity of alcohol for that temperature. Both of these are to be had in the first and last compartments of Sir Charles Blagden's table.

These operations for particular cases give the answers to particular occasional questions. By applying them to all the numbers in the table, tables may be constructed for solving every question by inspection.

There is another question which occurs most frequently in the excise transactions, and also in all compositions of spirituous liquors, viz. What strength will result from a mixture of two compounds of known strength, or mixing any compound with water? To solve questions of this kind by the table so often quoted, we must add into one sum the water per gallon of the different liquors. In like manner, take the sum of the spirits, and say, as the sum of the waters is to that of the alcohols, so is a to s; and operate with a and s as before.

Analogous to this is the question of the duties. These are levied on proof spirit; that is, a certain duty is charged on a gallon of proof spirit; and the gauger's business is to discover how many gallons of proof spirit there is in any compound. The specification of proof spirit in our excise laws is exceedingly obscure and complex. A gallon weighing 7 pounds 13 ounces (at 55°) is accounted 1 to 6 under proof. The gallon of water contains 58476 grains, and this spirit is 54688. Its density therefore is 0.93523 at 55°, or (as may be inferred from the table) 0.9335 at 60°. This density corresponds to a mixture of 100 grains of water with 93.457 of alcohol. If this be supposed to result from the mixture of 6 gallons of alcohol with 1 of water (as is supposed by the designation of 1 to 6 under proof), the gallon of proof spirits consists of 100 parts of spirits by weight, mixed with 75 parts of water. Such a spirit will have the density 0.9162 nearly.

This being premised, in order to find the gallons of proof spirits in any mixture, find the quantity of alcohol by weight, and then say, as 100 to 175, so is the alcohol in the compound to the proof spirit that may be made of it, and for which the duties must be paid.

We have considered this subject at some length, because it is of great importance to the spirit-trade to have these circumstances ascertained with precision; and because the specific gravity is the only sure criterion that can be had of the strength. Firing of gunpowder, or producing a certain bubble by shaking, are very vague tests; whereas, by the specific gravity, we can very securely ascertain the strength within one part in 500, as will presently appear.

Sir Charles Blagden, or Mr Gilpin, has published * a most copious set of tables, calculated from these valuable experiments. In these, computations are made for every unit of the hundred, and for every degree of the thermometer. But these tables are still not in the most commodious form for business. Mr John Wilson, an ingenious gentleman residing at Dundee, has just published

* *Philos. Transac.* 1794.

Spirituous Liquors.

lished at Edinburgh tables somewhat similar, founded on the same experiments. Both of these tables show the quantities by measure corresponding to every unit by weight of Sir Charles Blagden's experiments, and for every degree of temperature. They also show the per centage of alcohol, and the condensation or the quantity lost by mixture. But as they both retain the original series of parts by weight, which is very unusual, the spirit traders will find considerable difficulty in making use of them. Retaining this series also causes all the per centage numbers (which are the only interesting ones to the trader) to be fractional, and no answer can be had without a double interpolation.

We have therefore calculated a table in the form in which it must be most useful and acceptable to those who are engaged in the spirit trade, showing at once the specific gravity which results from any proportion of admixture in hundredth parts of the whole. This answers immediately the chief questions in the terms in which they are usually conceived and proposed. The two first or leading columns show the proportion in gallons, pints, or other cubic measures, of the mixture, the whole quantity being always 100. The second column shows the corresponding specific gravity: so that we can either find the proportion of the ingredients by the observed specific gravity, or find the gravity resulting from any proportion of the ingredients. A third column shows how much the hundred measures of the two ingredients fall short of making an hundred measures of the compound. A simple proportion, which can be done without the pen, will determine what part of this deficiency must be made up by spirit. The use of this table must now be so familiar to the reader's mind, that we need not give further instructions about it.

This is followed by another similar table, giving an immediate answer to the most usual question, "How many measures of alcohol are there really contained in 100 measures? This is also accompanied by a column of condensation. It would have been somewhat more elegant, had the specific gravities in this table made the equable series and leading column. But we did not advert to this till we had computed the table, and the labour was too great to be repeated for slight reasons. The tables are only for the temperature 60°. To this the spirituous liquors can always be brought in these climates; and in cases where we cannot, a moment's inspection of Sir Charles Blagden's table will point out very nearly (or exactly, by a short computation) the necessary corrections.

"In the first table, of which the sole intention is to point out the proportion of ingredients, the specific gravities are computed only to four places, which will always give the answer true to $\frac{1}{8000}$th part. In the last, which is more immediately interesting to the merchant in his transactions with the excise office, the computation is carried one place further."

The consideration of the first of these two tables will furnish some useful information to the reader who is interested in the philosophy of chemical mixture, and who endeavours to investigate the nature of those forces which connect the particles of tangible matter. These vary with the distance of the particle; and therefore the law of their action, like that of universal gravitation, is to be discovered by measuring their sensible effects at their various distances. Their change of distance is seen in the change of density or specific gravity.

Did the individual densities of the water and spirit remain unchanged by mixture, the specific gravity would change by equal differences in the series of mixtures on which this table is constructed; for the bulk being always the same, the change of specific gravity must be the difference between the weight of the gallon of water which is added and that of the gallon of spirit which is taken out. The whole difference of the specific gravities of spirits and water being 1.750 parts in 10.000, the augmentation by each successive change of a measure of spirit for a measure of water would be the 100dth part of this, or 17.5. But, by taking the successive differences of density as they occur in the table, we see that they are vastly greater in the first additions of water, being then about 10; after which they gradually diminish to the medium quantity 17½. when water and spirits are mixed in nearly equal bulks. The differences of specific gravity still diminish, and are reduced to 9, when about 75 parts of water are mixed with 25 of spirit. The differences now increase again; and the last, when 99 parts of water are mixed with one part of spirit, the difference from the specific gravity of pure water is above 14.

The mechanical effect, therefore, of the addition of a measure of water to a great quantity of spirit is greater than the similar effect of the addition of a measure of spirits to a great quantity of water. What we call mechanical effect is the local motion, the change of distance of the particles, that the corpuscular forces may again be in equilibrio. Observe, too, that this change is greater than in the proportion of the distance of the particles;

Spirituous Liquors.

particles; for the density of water is to that of spirits nearly as 6 to 5, and the changes of specific gravity are nearly as 6 to 3.

We also see that the changing cause, which produces the absolute condensation of each ingredient, ceases to operate when 75 parts of water have been mixed with 25 of alcohol: for the variation of specific gravity, from diminishing comes now to increase; and therefore, in this particular state of composition, is equable. Things are now in the same state as if we were mixing two fluids which did not act on each other, but were mutually disseminated, and whose specific gravities are nearly as 9 to 10; for the variation 9 of specific gravity may be considered as the 100th part of the whole difference, in the same manner as 17.7 would have been had water and alcohol sustained no contraction.

The imagination is greatly assisted in the contemplation of geometrical quantity by exhibiting it in its own form. Specific gravity, being an expression of density (a notion purely geometrical), admits of this illustration.

Plate CCCCXCIX. fig. 2.

Therefore let AB (fig. 2.) represent the bulk of any mixture of water and alcohol. The specific gravity of water may be represented by a line of such a length, that AB shall be the difference between the gravities of alcohol and water. Suppose it extended upwards, towards *a*, till B *a* is to A *a* as 10,000 to 8250. It will suit our purpose better to represent it by a parallelogram *a* BF *e*, of any breadth BF. In this case the difference of the specific gravities of alcohol and water will be expressed by the parallelogram ABFE. If there were no change produced in the density of one or both ingredients, the specific gravity of the compound would increase as this parallelogram does, and AGHE would be the augmentation corresponding to the mixture of the quantity AG of alcohol with the quantity GB of water, and so of other mixtures. But, to express the augmentation of density as it really obtains, we must do it by some curvilinear area DABCHD, which varies at the rate determined by Sir Charles Blagden's experiments. This area must be precisely equal to the rectangle ABFE. It must therefore fall without it in some places, and be deficient in others. Let DMHKC be the curve which corresponds with these experiments. It is evident to the mathematical reader, that the ordinates LM, GH, IK, &c. of this curve are in the ultimate ratio of the differences of the observed specific gravities. If A α, $\omega\beta$, &c. are each = 5, the little spaces A $\omega\delta$ D, $\omega\beta b\delta$, &c. will be precisely equal to the differences of the specific gravities 0.8250; 0.8387; 0.8516; &c. corresponding to the different mixtures of water and alcohol. The curve cuts the side of the parallelogram in K, where the ordinate GK expresses the mean variation of density 0.0017.5. IK is the smallest variation. The condensation may be expressed by drawing a curve *d m* G *f k* parallel to DMGKF, making D *d*=AE. The condensation is now represented by the spaces comprehended between this last curve and the abscissa AGB, reckoning those negative which lie on the other side of it. This shows, not only that the condensation is greatest in the mixture AG × GB, but also that in mixing such a compound with another AI × IB, there is a rarefaction. Another curve ANOPB may be drawn, of which the ordinates LN, GP, IO, &c. are proportional to the areas AL*md*, AG *m* D, AI*k* G*md* (=AG*md*—GI*k*), &c. This curve shows the whole condensation.

This manner of representing the specific gravities of mixtures will suggest many curious inferences to such as will consider them in the manner of Boscovich, with a view to ascertain the nature of the forces of cohesion and chemical affinities: And this manner of viewing the subject becomes every day more promising, in consequence of our improvements in chemical knowledge; for we now see, that mechanism, or motive forces, are the causes of chemical action. We see in almost every case, that chemical affinities are comparable with mechanical pressures; because the conversion of a liquid into a vapour or gas is prevented by atmospheric pressure, and produced by the great chemical agent heat. The action of heat, therefore, or of the cause of heat, is a mechanical action, and the forces are common mechanical forces, with which we are familiarly acquainted.

"It may be also remarked in the column of contractions, that in the beginning the contractions augment nearly in the proportion of the quantity of spirits (but more slowly); whereas, in the end, the contractions are nearly in the duplicate proportion of the quantity of water. This circumstance deserves the consideration of the philosopher. We have represented it to the eye by the curve α *g h d*."

Attempts are made to elude some part of the duties, by adding some ingredient to the spirits. But it would be doing no service to the trader to put fraud more in his power. There are some salts which make a very great augmentation of density, but they render the liquor unpalatable. Sugar is frequently used with this view; 16 grains of refined sugar dissolved in 1000 grains of proof spirits gave it no suspicious taste, and increased its specific gravity from 0.920 to 0.925, which is a very great change, equivalent to the addition of 9 grains of water to a mixture of 100 grains of alcohol and 80 of water. For an account of the process of manufacturing spirits, see DISTILLATION, SUPPLEMENT.

Spirituous Liquors ‖ Spoils.

SPIRLING, a species of fish. See SALMO, ICHTHYOLOGY, p. 99.

SPITHEAD, a road between Portsmouth and the isle of Wight, where the royal navy of Great Britain frequently rendezvous.

SPITTLE, in *Physiology*. See SALIVA.

SPITZBERGEN. See GREENLAND, N° 10.

SPLACHNUM, a genus of plants belonging to the class of cryptogamia, and order of musci. See BOTANY *Index*.

SPLEEN. See ANATOMY *Index*.

SPLEEN-Wort. See ASPLENIUM, BOTANY *Index*.

SPLENETIC, a person afflicted with an obstruction of the spleen.

SPLENT, or SPLINT, among farriers, a callous insensible excrescence, breeding on the shank-bone of horses. See FARRIERY.

SPLICING, in the sea-language, is the untwisting the ends of two cables or ropes, and working the several strands into one another by a fidd, so that they become as strong as if they were but one rope.

SPOILS, whatever is taken from the enemy in time of war. Among the ancient Greeks, the spoils were divided among the whole army; only the general's share was

was largest; but among the Romans, the spoils belonged to the republic.

SPOLETTO, a duchy of Italy, bounded on the north by the marquisate of Ancona and duchy of Urbino, on the east by Farther Abruzzo, on the south by Sabina and the patrimony of St Peter, and on the west by Orvieto and Perugino. It is about 55 miles in length and 40 in breadth. It was anciently a part of Umbria, and now belongs to the pope.—The name of the capital city is also *Spoletto*. It was formerly a large place, but in 1703 was ruined by an earthquake; from whence it has never recovered itself.

SPOLIATION, in ecclesiastical law, is an injury done by one clerk or incumbent to another, in taking the fruits of his benefice without any right thereunto, but under a pretended title. It is remedied by a decree to account for the profits so taken. This injury, when the *jus patronatus*, or right of advowson, doth not come in debate, is cognizable in the spiritual court: as if a patron first presents A to a benefice, who is instituted and inducted thereto; and then, upon pretence of a vacancy, the same patron presents B to the same living, and he also obtains institution and induction. Now if A disputes the fact of the vacancy, then that clerk who is kept out of the profits of the living, whichever it be, may sue the other in the spiritual court for the spoliation, or taking the profits of his benefice. And it shall there be tried, whether the living were or were not vacant; upon which the validity of the second clerk's pretensions must depend. But if the right of patronage comes at all into dispute, as if one patron presented A, and another patron presented B, there the ecclesiastical court hath no cognizance, provided the tithes sued for amount to a fourth part of the value of the living, but may be prohibited at the instance of the patron by the king's writ of *indicavit*. So also if a clerk, without any colour of title, ejects another from his parsonage, this injury must be redressed in the temporal courts: for it depends upon no question determinable by the spiritual law (as plurality of benefices or no plurality, vacancy or no vacancy), but is merely a civil injury.

SPONDEE, in ancient poetry, a foot consisting of two long syllables, as *omnes*.

SPONDIAS, Brasilian or Jamaica Plum, a genus of plants belonging to the class of decandria. See Botany *Index*.

SPONGIA, Sponge; a genus of animals belonging to the class of vermes, and order of zoophyta. It is fixed, flexible, and very torpid, growing in a variety of forms, composed either of reticulated fibres, or masses of small spines interwoven together, and clothed with a living gelatinous flesh, full of small mouths or holes on its surface, by which it sucks in and throws out the water. Fifty species have already been discovered, of which 10 belong to the British coasts. See Helminthology *Index*.

So early as the days of Aristotle sponges were supposed to possess animal life; the persons employed in collecting them having observed them shrink when torn from the rocks, thus exhibiting symptoms of sensation. The same opinion prevailed in the time of Pliny: But no attention was paid to this subject till Count Marsigli examined them, and declared them vegetables. Dr Peysonell, in a paper which he sent to the Royal Society in the year 1752, and in a second in 1757, affirmed they were not vegetables, but the production of animals; and has accordingly described the animals, and the process which they performed in making the sponges. Mr Ellis, in the year 1762, was at great pains to discover these animals. For this purpose he dissected the spongia urens, and was surprised to find a great number of small worms of the genus of nereïs or sea scolopendra, which had pierced their way through the soft substance of the sponge in quest of a safe retreat. That this was really the case, he was fully assured of, by inspecting a number of specimens of the same sort of sponge, just fresh from the sea. He put them into a glass filled with sea-water; and then, instead of seeing any of the little animals which Dr Peysonell described, he observed the papillæ or small holes with which the papillæ are surrounded contract and dilate themselves. He examined another variety of the same species of sponge, and plainly perceived the small tubes inspire and expire the water. He therefore concluded that the sponge is an animal, and that the ends or openings of the branched tubes are the mouths by which it receives its nourishment, and discharges its excrements.

SPONSORS, among Christians, are those persons who, in the office of baptism, answer or are sureties for the persons baptized.

SPONTANEOUS, a term applied to such motions of the body and operations of the mind as we perform of ourselves without any constraint.

SPOON-bill. See Platalea, Ornithology *Index*

SPOONING, in the sea-language, is said of a ship, which being under sail in a storm at sea, is unable to bear it, and consequently forced to go right before the wind.

SPORADES, among ancient astronomers, a name given to such stars as were not included in any constellation.

SPORADIC diseases, among physicians, are such as seize particular persons at any time or season, and in any place; in which sense they are distinguished from epidemical and endemical diseases.

SPOTS, in *Astronomy*, certain places of the sun's or moon's disk, observed to be either more bright or dark than the rest; and accordingly called *faculæ et maculæ*. See Astronomy *Index*.

SPOTSWOOD, John, archbishop of St Andrew's in Scotland, was descended from the lairds of Spotswood in the Merse, and was born in the year 1565. He was educated in the university of Glasgow, and succeeded his father in the parsonage of Calder when but 18 years of age. In 1601 he attended Lodowick duke of Lennox as his chaplain, in an embassy to the court of France for confirming the ancient amity between the two nations, and returned in the ambassador's retinue through England. When he entered into the archbishopric of Glasgow, he found there was not 100l. sterling of yearly revenue left; yet such was his care for his successors, that he greatly improved it, and much to the satisfaction of his diocese. After having filled this see 11 years, he was raised to that of St Andrew's in 1615, and made primate and metropolitan of all Scotland. He presided in several assemblies for restoring the ancient discipline, and bringing the church of Scotland to some degree of uniformity with that of England. He continued in high esteem with King James I. nor was he less valued by King

King Charles I. who was crowned by him in 1633, in the abbey-church of Holyroodhouse. In 1635, upon the death of the earl of Kinnoul chancellor of Scotland, our primate was advanced to that post; but had scarcely held it four years, when the confusions beginning in Scotland, he was obliged to retire into England; and being broken with age, grief, and sickness, died at London in 1639, and was interred in Westminster-abbey. He wrote A History of the Church of Scotland from the year 203 to the reign of King James VI. in folio.

SPOUT, or *Water-Spout*. See *Water-Spout*.

Spout-Fish. See Solen, Conchology *Index*.

SPRAT, Dr Thomas, bishop of Rochester, was born in 1636. He had his education at Oxford, and after the Restoration entered into holy orders. He became fellow of the Royal Society, chaplain to George duke of Buckingham, and chaplain in ordinary to King Charles II. In 1667 he published the History of the Royal Society, and a Life of Mr Cowley; who, by his last will, left to his care his printed works and MSS. which were accordingly published by him. In 1668 he was installed prebendary of Westminster; in 1680, was appointed canon of Windsor; in 1683, dean of Westminster; and in 1684, consecrated to the bishopric of Rochester. He was clerk of the closet to King James II.; in 1685, was made dean of the chapel royal; and the year following, was appointed one of the commissioners for ecclesiastical affairs. In 1692 his lordship, with several other persons, was charged with treason by two men, who drew up an association, in which they whose names were subscribed declared their resolution to restore King James; to seize the princess of Orange, dead or alive; and to be ready with 30,000 men to meet King James when he should land. To this they put the names of Sancroft, Sprat, Marlborough, Salisbury, and others. The bishop was arrested, and kept at a messenger's, under a strict guard, for eleven days. His house was searched, and his papers seized, among which nothing was found of treasonable appearance, except one memorandum, in the following words: *Thorough-paced doctrine*. Being asked at his examination the meaning of the words, he said that, about 20 years before, curiosity had led him to hear Daniel Burgess preach; and that being struck with his account of a certain kind of doctrine, which he said *entered at one ear, and pacing through the head went out at the other*, he had inserted the memorandum in his table-book, that he might not lose the substance of so strange a sermon. His innocence being proved, he was set at liberty, when he published an account of his examination and deliverance; which made such an impression upon him, that he commemorated it through life by an yearly day of thanksgiving. He lived to the 79th year of his age, and died May 20. 1713. His works, besides a few poems of little value, are, "The History of the Royal Society;" "The Life of Cowley;" The Answer to Sorbiere;" "The History of the Rye-house Plot;" "The Relation of his own Examination;" and a volume of "Sermons." Dr Johnson says, "I have heard it observed with great justness, that every book is of a different kind, and that each has its distinct and characteristical excellence."

Sprat. See Clupea, Ichthyology *Index*.

SPRAY, the sprinkling of the sea, which is driven from the top of a wave in stormy weather. It differs from spoon-drift, as being only blown occasionally from the broken surface of a high wave; whereas the latter continues to fly horizontally along the sea, without intermission, during the excess of a tempest or hurricane.

SPRING, in *Natural History*, a fountain or source of water rising out of the ground.

Many have been the conjectures of philosophers concerning the origin of fountains, and great pains have been taken both by the members of the Royal Society and those of the Academy of Sciences at Paris, in order to ascertain the true cause of it. It was Aristotle's opinion, and held by most of the ancient philosophers after him, that the air contained in the caverns of the earth, being condensed by cold near its surface, was thereby changed into water; and that it made its way through, where it could find a passage. But we have no experience of any such transmutation of air into water.
